- The XML attribute `Filter` allows you to include color instructions, picture instructions, or filter instructions written in an Alfabet query or SQL query. For example:

```
<AlfaHtmlElement ApplyTo="@CURRENT_STEP" ShowProps="State">
    <Filter> <![CDATA[COLORASSIGNMENT(EqualTo, "Pending", #c0c000,
    Transparent);]]> </Filter>
    <Filter> <![CDATA[COLORASSIGNMENT(EqualTo, "Confirmed",
    #00c000, Transparent);]]> </Filter>
    <Filter> <![CDATA[COLORASSIGNMENT(EqualTo, "Cancelled",
    #c00000, Transparent);]]> </Filter>
</AlfaHtmlElement>
```

- `AlfaHtmlEvent()` is a function that allows you to specify navigation behavior. The function must be specified in the XML attribute `onclick` of the XML element `AlfabetHTMLElement`. The XML attribute `onclick` allows you to specify where the user will navigate if he/she clicks on the element in the HTML specification. The user must have permissions to therelevant view. For example:

    - To navigate to the object view of the object, use the following parameter:

    ```
    <AlfaHtmlElement ApplyTo="@CURRENT_STEP" ShowProps="State"
        onclick="AlfaHtmlEvent(this,'Navigate_OpenObjectView','@REF'
        , null);" >
    </AlfaHtmlElement>
    ```

    - To navigate to the object cockpit of the object, use the following parameter:

    

    The user must have permissions to the specified object view and the object cockpit. If the user is not permissible for the specified object view and

object cockpit, the object view defined for the class settings of the object class/object class stereotype will be used.

```
<AlfaHtmlElement ApplyTo="@CURRENT_STEP" ShowProps="State"
   onclick="AlfaHtmlEvent(this,'Navigate_OpenObjectView',’@REF'
   ,’<Object View Name:Object Cockpit Name>');" >
</AlfaHtmlElement>
```

- To navigate to a page view, use the following parameter, replacing the `null` with the technical name of the relevant view:

```
<AlfaHtmlElement ApplyTo="@CURRENT_STEP" ShowProps="State"
   onclick="AlfaHtmlEvent(this,'Navigate_OpenGraphicView',’@REF
   ',’WF_Diagram');" >
</AlfaHtmlElement>
```

- To navigate to a configured report, use the following parameter, replacing the `null` with the technical name of the relevant configured report:

```
<AlfaHtmlElement ApplyTo="@CURRENT_STEP" ShowProps="State"
   onclick="AlfaHtmlEvent(this,'Navigate_OpenReportView',’@REF'
   ,’NameOfCustomReport');" >
</AlfaHtmlElement>
```

- To navigate to an `ALFA_IDOCUMENT` object as input and open it for download, use the following parameter:

  For security reasons, a blacklist and whitelist concept is available to restrict the uploading and downloading of files with permissible file extensions. For more information, see the section Configuring the Permissibility of Files and Web Links in Alfabet.

```
<AlfaHtmlElement ApplyTo="@CURRENT_STEP" ShowProps="State"
   onclick="AlfaHtmlEvent(this,'Object_Attachment',’@REF',
   null);" >
</AlfaHtmlElement>
```

- If translation to a secondary language is required for the HTML template, you must provide the translation in the HTML specification. Please note that HTML texts cannot be translated via the **Translation Editor** available in Alfabet Expand. Please consider the following:

- If the HTML description is required in additional languages, each language text must be defined within language elements (For example, `<culture_1031>` for English, `<culture_1033>` for German, etc.)
- The element `<culture_xxx>` must be specified as a child of the root element `<xhtml>`. The element `<html>` must be specified as a child of the element `<culture_xxx>`. The element `<html>` contains the HTML specification in the relevant language. For example, to provide information in English and German:

```
<xhtml>
   <culture_1033>
      <html>
         <body>
            <h3>Glossary: Application</h3>
            <p>An application is a fully-functional integrated IT
            product that provides functionality to end users and/or
            to other applications. As such, an application supports
            the business to accomplish its mission. Applications
            operate on a platform made up of hardware and software
            components necessary to run the application.</p>
         </body>
      </html>
   </culture_1033>
   </culture_1031>
      <html>
         <body>
            <h3>Glossar: Applikation</h3>
            <p>Eine Applikation ist ein voll funktionsfähiges,
            integriertes IT-Produkt, das Funktionalitäten für
            Endanwender und/oder für andere Applikationen bietet.
            Eine Applikation unterstützt das Unternehmen bei der
            Zielerreichung. Applikationen werden auf einer Plattform
            betrieben, die aus den für die Ausführung der
            Applikation erforderlichen Hardware- und Software-
            Komponenten besteht.</p>
         </body>
      </html>
   </culture_1031>
</xhtml>
```

- If only the default language is used in the Alfabet interface, the element `<culture_xxx>` is not required and the `<xhtml>` is immediately followed by its child element `<html>`.

Guidelines for the CSS File

A stylesheet must be defined that can be referenced by one or more HTML templates. A default stylesheet labelled `template_styles.css` is stored in the **Internal Document Selector** of the `Showcase` database in the root folder of the **IDOC** folder. Please note the following in order to implement your own stylesheet:

- The CSS file you specify should contain all necessary styles to display the content of the HTML template as well as the styles required to display the buttons in the toolbar of the **Workflow Activities Explorer** functionality (`WFS_Explorer`). If you configure a new style sheet, you must define the class selectors.`wfButtons`,.`wfButton`, `wfButton td`, and.`wfButtonSeparator` in order to visualize the buttons. The information below displays the class selector, a description of its purpose, and the standard definition in the `template_styles.css` file:

```
.wfButtons{
/* styles for the surrounding table that contains all cells containing
individual button tables */
text-align:center;
    color:#989FA9;
    font-family:Arial;
    font-size:12pt;
    font-weight:bold;
    vertical-align:middle;
    margin-bottom:7px;
    margin-left:7px;
    }
.wfButton{
/* styles for the cell of the table that contains all buttons (td
element) */
    background-color:#efefef;
    cursor:pointer;
    vertical-align:middle;
    }
.wfButton td{
/* styles for the individual td elements inside the table that contain a
button (2 elements if icon and text is used, otherwise one) */
    vertical-align:middle;
    padding:3px;
    padding-right: 5px;
    }
.wfButtonSeparator{
/* styles for the horizontal separator between buttons and the remaining
content of the page. */
    width:100%;
    height:2px;
    background-color:#989FA9;
    overflow:hidden;
```

- The CSS file you specify must be uploaded to the **Internal Document Selector** Stylesheets stored in the **Internal Document Selector** must be located in a document folder that is subordinate to the root folder of the **IDOC** explorer. To upload a file to the **Internal Document Selector**, see the section *Uploading Documents and Managing User Permissions to Document Folders in the Internal Document Selector* in the reference manual *User and Solution Administration*.

  

  Please note that unlike the default CSS file `template_styles.css`, your CSS may not be stored in the root folder of the **IDOC** explorer.

- The CSS file stored in the **Internal Document Selector** available must be referenced in the XML element `<html>` in an XML attribute `<link>`. For example:

```
<xhtml>
    <html>
        <head>
            <meta http-equiv="content-type" content="text/html;charset=utf-
            8" />
            <dscript language="javascript"
            src="alfaembeddedhtml.js"></script>
            <link type="text/css" rel="stylesheet"
            href="IDOC:\CSS\my_style_file.css"></link>
        </head>
        ...
    </html>
</xhtml>
```

Configuring the Maximum Days to Display Finished Workflow Activities

You can specify the maximum number of days that finished, refused, and expired workflow activities shall be displayed in the **Workflow Activities Explorer** functionality. This ensures that obsolete workflows are no longer cluttering the **My Workflow Activities** explorer.

1) Go to the **Presentation** tab and expand the **XML Objects** folder.
2) Right-click the XML object ***SolutionOptions*** and select **Edit XML**. The XML editor is displayed in the center pane. For general information about editing XML objects in Alfabet Expand, see Working with XML Objects.
3) In the XML attribute `ActiveWorkflowHistory`, enter an integer for the maximum number of days that finished, refused, and expired workflow activities shall be displayed in the **Workflow Activities Explorer** functionality..
4) In the toolbar, click the **Save**  button to save the XML definition.

Configuring a Custom Explorer for a Workflow Step

In order to implement a custom explorer for workflows, you must specify the content of the explorer tree as well as the content, layout, and navigation for the reading pane of the view. Unlike the **Workflow Activities Explorer** (`WFS_Explorer`), which only includes workflow activities, you can configure a custom explorer to display nodes with workflows as well nodes with workflow activities. The custom explorer can be simple and display one node with one type of workflow activity such as workflow activities that have been confirmed or may have multiple nodes, each which shows a different type of workflow activity such as workflow activities past their deadline, workflow activities due in a week, workflow activities due in a month, and workflow activities that are not urgent.

The configuration of custom explorers is described in detail in the chapter Configuring Standard Business Functions and Custom Explorers. The information below addresses only particularities about configuring a custom explorer for the workflow context.

The following must be completed in order to implement custom explorer for workflows and/or workflow activities:

1) Configure the workflow template and workflow steps as outlined in this chapter on workflow configuration. All configurations described for workflow templates and workflow steps should be completed before you begin specifying the implementation of the custom explorer. Please note that the following:

- The **Perform**, **Confirm**, **Delegate**, etc. are specified either for the workflow template or for the workflow step via the options (**Perform** button, **Confirm** button, **Delegate** button, etc.) in the **Visualization** section of the attribute grid for the workflow template and/or workflow step. Please note that the workflow step definition will have precedence over the workflow template definition.
- The toolbar buttons specified for the workflow step/workflow template will be displayed above the reading pane in the **Workflow Activities Explorer** functionality.

2) If the custom explorer shall display multiple root-level nodes for the object classes `WorkflowStep`, `Workflow`, or `WorkflowTemplate`, then you must configure object class stereotypes for the object class `GenericReferenceData`. Please note that this is not necessary if the custom explorer includes only one node. For example, to display an explorer with one root-level node with workflow templates and four root-level nodes with different workflow activities such as workflow activities past their deadline, workflow activities due in a week, workflow activities due in a month, and workflow activities that are not urgent, you would specify one object class stereotype for the workflow template node and four other object class stereotypes to represent each type of workflow activity. This must be defined via the **Stereotype** attribute for the object class `GenericReferenceData`. For example:

```
<ClassStereotypes>

    <Stereotype Name="WFExpTemplates" Caption="Workflow Explorer Template"
    CaptionPlural="Workflow Explorer Templates" Comments=""
    HasMandates="false" />

    <Stereotype Name="WFExpExpired" Caption="Workflow Activities Expired"
    CaptionPlural="Workflow Activities Expired" Comments=""
    HasMandates="false" />

    <Stereotype Name="WFExpDueWeek" Caption="Workflow Activities Due in a
    week" CaptionPlural="Workflow Activities Due in a Week" Comments=""
    HasMandates="false" />

    <Stereotype Name="WFExpDueMonth" Caption="Workflow Activities Due in a
    month" CaptionPlural="Workflow Activities Due in a month" Comments=""
    HasMandates="false" />

    <Stereotype Name="WFExpDueAny" Caption="Workflow Activities Not
    Urgent" CaptionPlural="Workflow Activities Not Urgent" Comments=""
    HasMandates="false" />

</ClassStereotypes>
```

3) Specific the custom explorer as described in the chapter Configuring Standard Business Functions and Custom Explorers. Please note the following:

- Each object based on the object class stereotype created for the object class `GenericReferenceData` will be a root node in the custom explorer. The query specified in the **XML Def** attribute of the custom explorer must be specified to search for the objects that are subordinate to each root node. Thus an XML element `ClassEntry` must be created for each object class stereotype with a query that finds the object subordinate to the node. The following example displays the specification for one root-level node:

```
<ExplorerDef
   Name="My Customized Workflow Activities Explorer">
      <Query ClassName="GenericReferenceData:WFExpDueWeek"
      Query="Stereotype ='WFExpDueWeek'" />
         <ClassEntry ClassName="GenericReferenceData:WFExpDueWeek"
         ShowProps="Name" SortProps="Name" >
         <Query ClassName="WorkflowStep"
            Query="SELECT ws.REFSTR, w.CAPTION +'-'
            +ISNULL(dbo.SCF_GetObjectFullName(w.SOURCEARTIFACT),ISNU
            LL(dbo.SCF_GetObjectFullName(ws.ARTIFACT),'No/Unknown
            Artifact'))
            FROM WORKFLOWSTEP ws, WORKFLOWTEMPLATE wt, WORKFLOW w,
            RELATIONS rel, PERSON per
            WHERE ws.WORKFLOW = w.REFSTR
            AND w.TEMPLATE = wt.REFSTR
            AND ws.STATE ='Pending'
            AND rel.FROMREF = ws.REFSTR
            AND rel.TOREF = per.REFSTR
            AND rel.PROPERTY ='SignOnUsers'
            AND per.REFSTR = @CURRENT_USER
            AND DATEDIFF(dd,GETDATE(),ws.DUEDATE) &lt; 8
            AND DATEDIFF(dd,GETDATE(),ws.DUEDATE) &gt; 0
            />
         <Query ClassName="GenericReferenceData:WFExpDueMonth"
         Query="Stereotype ='WFExpDueMonth'" />
      </ClassEntry>
      <ClasEntry...>
      ...
      </ClassEntry>
   <AlfaExplorerNode ClassName="WorkflowStep" UpdateViews=""
   NodeView="GraphicView:CustomExplorerHtmlView" />
</ExplorerDef>
```

- Specify the presentation object that is used for the right pane when a node is clicked. Whereas this is implicit in the configuration of the **Workflow Activities Explorer** (`WFS_Explorer`), you must explicitly specify the graphic view `CustomExplorerHtmlView` in the custom explorer definition in order to ensure that the correct presentation object is available. This ensures that the relevant HTML template configuration is displayed for the workflow activities. If the custom explorer is configured to display

workflow activities. This is specified in the **XML Def** attribute of the custom explorer via the XML element `AlfaExplorerNode`. For example:

```
<AlfaExplorerNode ClassName="WorkflowStep"
UpdateViews=""NodeView="GraphicView:CustomExplorerHtmlView"/>
```

4) Configure the HTML template to display the content, navigation, and layout of the data for the workflow steps. The HTML must be XML-conform HTML, compliant with HTML 5, and use standard HTML tags. For more information about how to specify the HTML template as well as the proprietary HTML elements available for the HTML template, see the section Guidelines for HTML Template Syntax in Workflows.

5) The HTML template must be assigned to the workflow template (if relevant for all or some of the workflow steps) or to the relevant workflow step via the **HTML Template for Step** attribute of either the workflow template or relevant workflow step.

If the **HTML Template for Step** attribute is defined for the workflow template, the HTML template will be applied to all workflow steps unless an HTML template is explicitly defined for a workflow step, in which case the workflow step definition will take precedence over the workflow template definition. All HTML templates listed below the **Visualization Items** node are displayed in the drop-down list for the **HTML Template for Step** attribute.

6) A CSS file must be configured to specify the styles for the HTML template. A reference to the CSS file must be included in the specification of the HTML template. The CSS file that you reference in the HTML template must be stored in the **Internal Document Selector**. For more information about configuring the CSS file, see the section Guidelines for the CSS File.

7) The custom explorer must be assigned as a business function to the user profile or implemented in a guide view to make it accessible to the user community.

Configuring and Visualizing a Workflow in a Diagram

A diagram capability is available for workflow templates that allows you to configure the workflow template in a diagram format. This allows you to visualize the workflow as you configure it, thus simplifying the task of sequencing the workflow steps. You can click any workflow step visualized in the diagram and configure its attributes in the attribute window.

You can carry out the following in the diagram capability:

- Create and define workflow steps for a workflow template.
- Define the sequence of the workflow steps including next workflow steps, expired workflow steps, and refused workflow steps.
- Create pre- and post-conditions as well as actions for a workflow step.
- Graphically design the layout of the workflow steps and the connector items representing their sequence.
- Graphically design the visualization of the workflow by adding a pool with swim lanes, shapes, text, and color.

There is no Undo/Redo function in the workflow diagram capability. If you delete a workflow step, the workflow step, any workflow step sequence definitions, and any pre- or post-conditions as well as pre- or post-actions will be irrevocably deleted from the database.

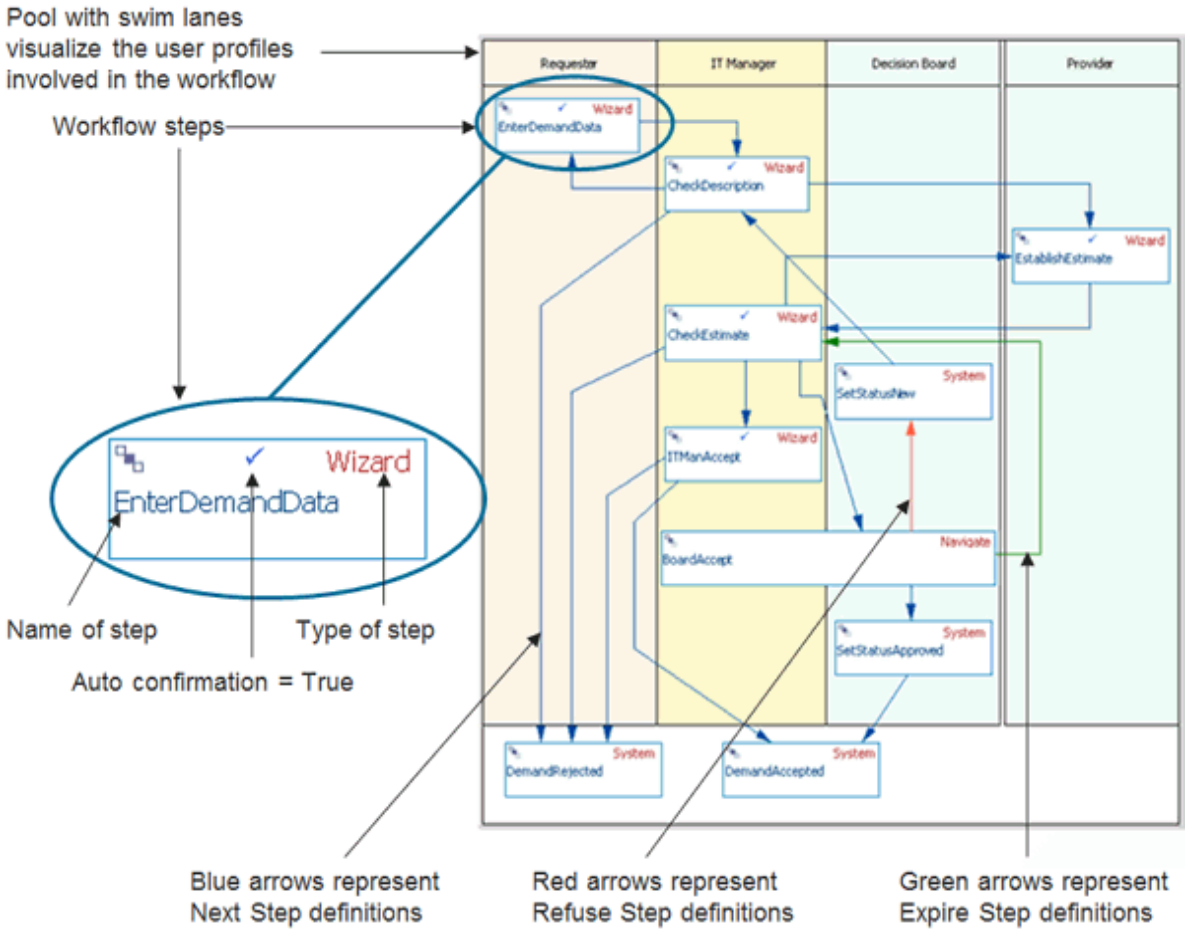

FIGURE: Example of a workflow template configured and visualized in a diagram

The workflow diagram you design in Alfabet Expand can be viewed by the workflow administrator as well as the workflow owners of all workflows associated with the workflow template. Additionally, users processing a workflow step that they are responsible for can also see the workflow diagram in order to understand the workflow step in the context of the entire workflow. Once a workflow step has been performed and confirmed by a user, a timestamp will be displayed on the workflow step in the workflow diagram displayed in the Alfabet interface.

The timestamp on a workflow step in a workflow diagram will display the hour and minutes when the workflow step was confirmed. Users using US culture settings will see AM or PM appended to the timestamp.

If you do not explicitly design a diagram, a rudimentary diagram will be automatically generated. Once the **Workflow State** attribute of the workflow template has been set to `Active`, the diagram will be displayed in the **Workflow Diagram** page view, which is available in the object profile of the respective workflow. The workflow step that is being performed for the selected workflow at the time that the **Workflow Diagram** page view is accessed will be highlighted in the diagram. For more information about using the diagram, see the section *Understand the Course of the Workflow* in the reference manual *User and Solution Administration*.

The following information is available about the configuration and design of workflow diagrams:

- Opening the Workflow Diagram Capability
- Specifying the Diagram Attributes
- Creating a Pool with Swim Lanes for the Diagram
- Adding a Workflow Step to the Diagram
- Deleting a Workflow Step
- Specifying the Sequence of Workflow Steps in the Diagram
- Editing an Existing Workflow Diagram
- General Guidelines for Graphically Refining the Diagram
- Visually Refining the Display of Connection Items
- Adding a Graphic Element to a Diagram
- Deleting a Graphic Element from the Diagram
- Adding a Graphic Image (GIF, BMP, etc.) to a Diagram
- Moving Diagram Elements in a Diagram
- Changing the Size of a Diagram Element
- Simultaneously Changing the Size of Multiple Diagram Elements
- Aligning Diagram Elements in a Diagram
- Changing the Background Color of Graphic Elements

Opening the Workflow Diagram Capability

To work with the diagram capability:

1) In the **Workflow** tab, right-click the **Workflow Templates** icon at the top of the explorer and select **Create New Workflow Template**. The new workflow template is displayed in the explorer.

   Alternatively, you can copy an existing workflow template if the **Workflow State** attribute is set to `Plan` and select **Create New Workflow Template as Copy**. The existing workflow template including workflow steps, pre-conditions, etc. will be copied. The existing diagram will also be copied and can be modified, as needed.

2) Edit the attributes as described in the section Creating a Workflow Template.

3) To open the diagram capability in order to configure the workflow template from scratch or modify an existing workflow template, right-click the workflow template in the explorer and select **Open Diagram**. A tab for the workflow template will open in the workspace area.

   The **Open Diagram** option is only available for workflow templates for which the **Workflow State** attribute is set to `Plan`. You cannot open the diagram capability in Alfabet Expand for a workflow template for which the **Workflow State** attribute is set to `Active` or `Retired`.

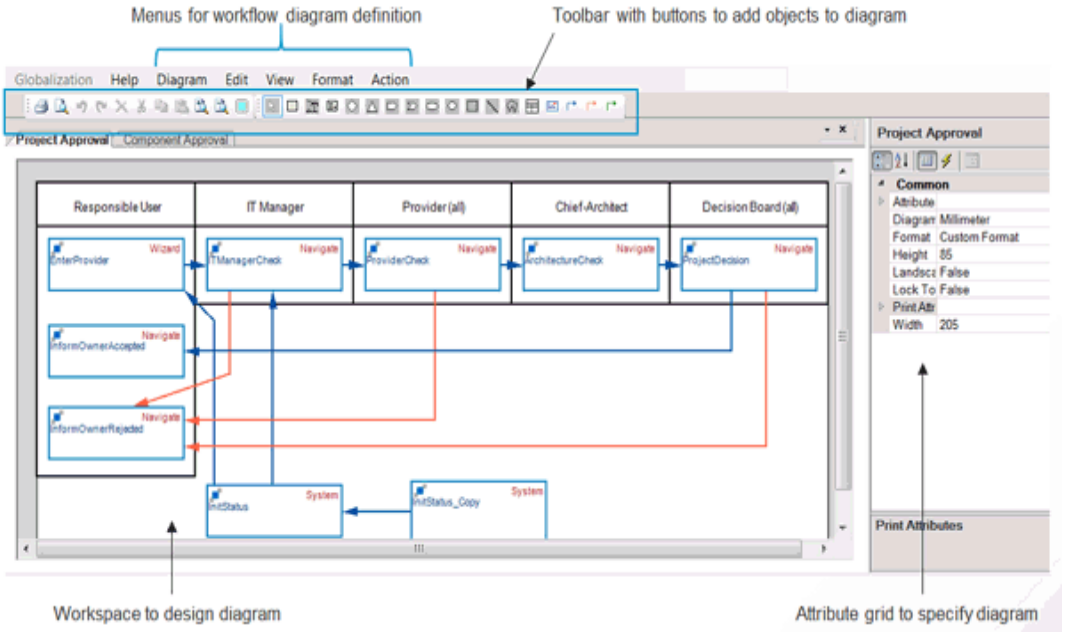

FIGURE: Workflow diagram designed in the workflow diagram capability

4) Click in the diagram workspace. The menus **Diagram**, **Edit**, **View**, **Format**, and **Action** are displayed in the menu bar as well as a toolbar with objects that can be added to the diagram are displayed in the toolbar when the diagram is active. You will also see the attribute window that allows you to define the basic attributes of the diagram. To set up the diagram in order to configure the workflow template, see the section Specifying the Diagram Attributes.

For an overview of the available functionalities in the menus as well as the attributes in the diagram attribute window, see *Workflow Diagram Capability* in the reference manual *Configuring Alfabet with Alfabet Expand - Appendix*.

5) Click the **Save** button to save the diagram.

Specifying the Diagram Attributes

Before you can begin to design a workflow diagram, you must set up the diagram and define the diagram properties including, for example, the format and orientation of the diagram as well as the inclusion of drawing elements such as rulers or a grid. Additionally, you can define print attributes such as margins and print mode.

To display the attribute window for the grid, you must click in the diagram workspace. If a diagram already exists, ensure that you do not click an existing object or shape in the diagram. If the diagram is filled with a pool, for example, you may need to click in the grey area outside of the diagram.

An explanation of all attributes is available in the table *Diagram Property Window* in the section *Workflow Diagram Capability* in the reference manual *Configuring Alfabet with Alfabet Expand - Appendix*.

To specify the diagram attributes:

1) In the diagram attribute window, define the relevant attributes for the diagram. Some of the most important are listed below:

- **Format**: Enter one of the following attributes to determine the paper format to be used as the default for diagrams. Permissible options are:
- `A4 210x297`: Standard A4 paper size
- `A3 297x420`: Standard A3 paper size
- `A2 420x594`: Standard A2 paper size
- `A1 594x840`: Standard A1 paper size
- `A0 840x1186`: Standard A0 paper size
- `Letter`: US Letter paper size (216x279 cm or 8.5x11 in)
- `Legal`: US Legal paper size (216x356 cm or 8.5x14 in)
- `11x17`: US 11x17 paper size (279x432 cm)
- `Custom Format`: If you select this format, you must define the **Height** and **Width** attributes
- **Landscape**: Enter `True` if the diagram should use the specified paper size in landscape mode. Enter `False` if the diagram should use the specified paper size in portrait mode.

2) Click the + symbol next to **Attributes** to expand the table and define diagram options that are useful for designing the diagram. For example, enter values for the following useful options:

- **Center Connection**: Enter `True` if the end points of connection items should be determined by the user via the drag-and-drop action. Enter `False` if the end points of connection items should always be drawn from the center of one diagram object to the center of the other diagram object.
- **Draw Grid**: Enter `True` if a grid should be displayed. Enter `False` if a grid should not be displayed. The grid version can be defined in the attribute **Grid Mode**.
- **Elbowed Connection**: Enter `True` if the connection items (information flows, sequence flows, etc.) should be drawn as an elbow line (with 90° angle). Enter `False` if the connection items should be created as a straight line.
- **Rulers**: Enter `True` if a rulers should be displayed. Enter `False` if rulers should not be displayed.

3) After you have finished defining the necessary object class properties, click in the diagram workspace to reactivate the menu bar and toolbar.

4) Click the **Save** button to save your definitions.

Creating a Pool with Swim Lanes for the Diagram

You can optionally create one or more pools in order to provide additional detail in the diagram such as which user profiles responsible for certain workflow steps. (Pool and swim lanes are derived from Business Process Modeling Notions). The pools can be added to the diagram at any time during the design process, however it is easiest to add the them before workflow steps have been added to the workflow template.

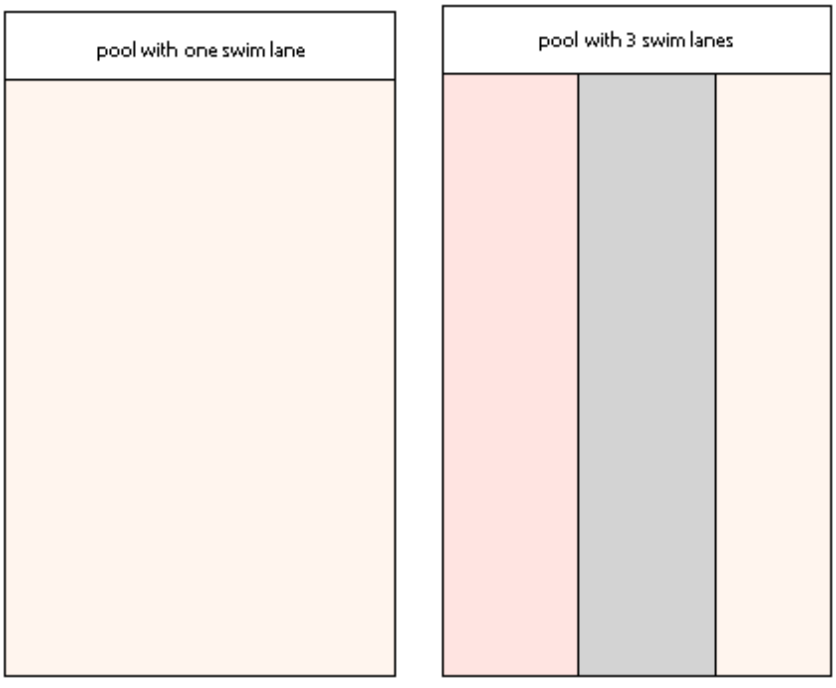

FIGURE: Example of different possibilities of designing a pool for a diagram

A pool can represents major participants in the workflow process and swim lanes could be visualized to depict different categories of the workflow process.

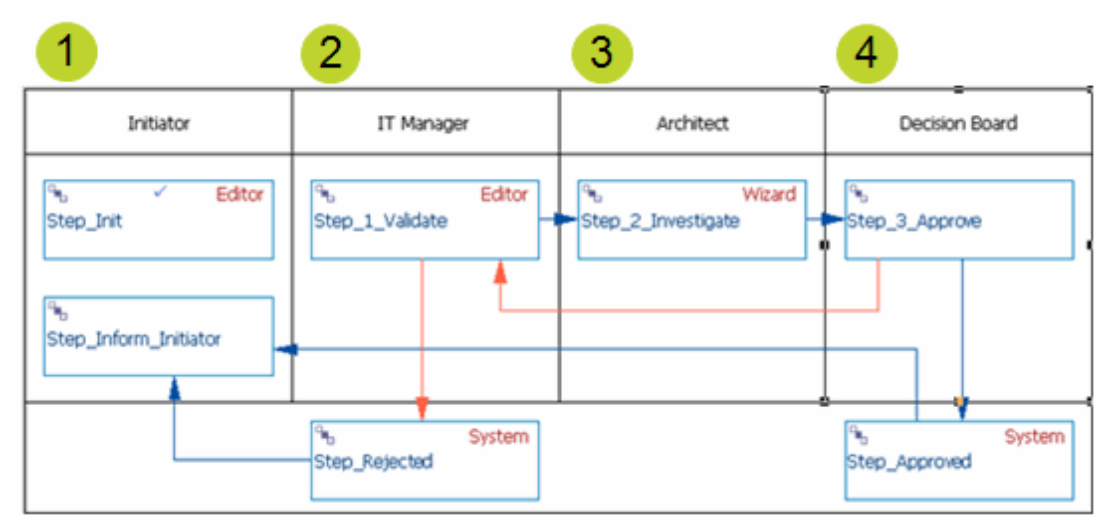

FIGURE: Simple workflow diagram with four pools representing the four user profiles

Although swim lanes can also be added in order to increase the amount of detail, it is advisable to keep the diagrams simple. Typically, however, multiple pools would be added to the diagram for each participant in the workflow. Therefore, their implementation will not be covered in the description below.

To create a pool with swim lanes for the selected workflow template:

1) In the toolbar, click the **Pool** icon and click a blank space in the diagram.
2) In the diagram, drag the pool to the required size.
3) Click in the pool to display the attribute window. Modify the necessary object class properties:

- **Background Color**: Define the background color of the pool
- **Grid Pen Style**: Define the style of the lines for the lanes in the pool.
- **Grid Pen Width**: Define the width of the lines for the lanes in the pool.
- **Pen Attributes**: Define the attributes for the lines of the pool title.
- **Pool Text**: Enter the text that should be displayed for the pool title.
- **Pool Text Attribute**: Define the attributes for the text displayed for the pool title.
- **Pool Text Height**: Define the height of the text displayed for the pool title.
- **Title Color**: Define the color of the pool title.
- **Title Position**: Define the position of the pool title

4) To add swim lanes to the pool, edit the following object class properties:

- **Lanes**: Click the **Browse** button to create swim lanes to display in the pool. In the **Edit Object Collection** dialog box that opens, click the **Add** button. You will see the entry `NewColumn` in the **Members** attribute. Edit the object class properties of this new column in the **Properties** attribute to the right. Continue this procedure until you have the number of swim lanes you want. Click **OK**.
- **Lane Text Attribute**: Define the attributes for the text displayed for the swim lane title(s).
- **Lane Text Height**: Define the height of the text displayed for the swim lane title.

5) To adjust the size of the pool or the size of individual swim lanes, drag the line separating the lanes to the appropriate width.

6) If the pool is covering existing workflow steps, right-click the pool and select **Send to Back**. The pool is moved to the background and any existing workflow steps are on top of the pool and can be dragged to their appropriate position in the diagram.

7) Click the **Save**  button to save your definitions.

Adding a Workflow Step to the Diagram

A workflow step is an activity or task in a workflow that must be performed. The workflow template may have as many workflow steps as needed to complete the relevant task. Standard and custom editors, wizards, page views, configured reports, and object profiles may be implemented in the workflow step so that users can complete the task. A workflow step may entail entering, modifying or reviewing data, or a workflow step may be configured to be automatically executed by the Alfabet system. If the workflow step is not automatically executed by the system, one or more users may be defined as responsible to perform the workflow step. A user may delegate a workflow step to another user or refuse a workflow step. Depending on the configuration of the workflow step, a user may be required to confirm a workflow step before the workflow can advance to the next workflow steps, or the confirmation of the workflow step may occur automatically. A workflow step may also have one or more associated workflow step actions which allow various operations to be performed when the workflow step is entered, exited, refused, or expired. Additionally, each workflow step may have one or more pre-conditions or post-conditions that must be fulfilled in order to enter or exit the workflow step.

You can add a workflow step to the diagram via the workflow step button in the toolbar. After a workflow step is added to the diagram, you can graphically modify it by moving it, changing its size, or adding text. The color of the workflow steps cannot be changed.

To add a workflow step to the diagram:

1) In the toolbar, click the workflow step  icon that you want to add to the diagram and click a blank space in the diagram. A workflow step has been added to the diagram.

2) Edit the attributes as described in the section Creating a Workflow Step. The attributes **Expiration Step**, **Next Steps**, and **Refuse Step** can be ignored in the attribute window. The means to define the sequence of steps within the diagram capability is described in the section Specifying the Sequence of Workflow Steps in the Diagram.

3) Repeat the procedure described above until all workflow steps have been created. You can move the workflow steps to their approximate positions in the diagram or pools by via drag-and-drop.

4) For each workflow step created, you can right-click the workflow step and select either:

- **Add New Pre-Condition**
- **Add New Post-Condition**
- **New Action On Entered Step**
- **New Action On Refused Step**
- **New Action On Expired Step**
- **New Action On Exited Step**

For detailed information about the definition of conditions and actions, see the following sections:

- Configuring Pre- and Post-Conditions for a Workflow Step
- Configuring Automatic Property Updates for a Workflow Step
- Configuring Events to Be Triggered for a Workflow Step
- Configuring a Workflow Step to Trigger a Subordinate Workflow
- Configuring Email Notifications for Workflows

5) Click the **Save** button to save your changes.

Deleting a Workflow Step

You can delete a workflow step from the workflow configuration. The workflow step will be deleted from the database.

There is no Undo/Redo function in the workflow diagram capability. If you delete a workflow step, the workflow step, any workflow step sequence definitions, and any pre- or post-conditions as well as pre- or post-actions will be irrevocably deleted from the database.

Specifying the Sequence of Workflow Steps in the Diagram

You can configure and visualize the sequence of the workflow steps. When you define the sequence of workflow steps, you must define all possible subsequent workflow steps for each workflow step as well as the workflow steps that follow when a workflow step is refused by a user or the deadline to complete the workflow step has expired. The possible next workflow steps will depend on whether pre-conditions that have been defined for any subsequent workflow step are fulfilled for the object that is the target of the workflow step. Therefore, you may opt to define pre-conditions for each workflow step before you define the sequence of workflow steps.

For detailed information relevant to the configuration of workflow steps, see Defining the Sequence of the Workflow Steps.

The diagram capability allows you to define next workflow steps, expired workflow steps, and refused workflow steps by selecting the relative connection item in the toolbar and dragging the connection item from the source workflow step to the target workflow step.

The following connection items are available:

Icon	Purpose
To Next Step	For each workflow step (including the initial workflow step and the first workflow step), define all potential workflow steps that may be executed next for each workflow step. The last workflow step in the workflow should not have a **To Next Step** connection item defined.
To Refuse Step	Define the workflow step that is to be triggered if the current step is refused by the user. A refused workflow step should be configured for each workflow step for which the attribute **Refuse Button** is set to `True`.
To Expire Step	Define the workflow step that is to be triggered if the current step is not performed in the period defined in the **Performance Duration** attribute.

To define the connection items between workflow steps:

1) In the toolbar, click the relevant connection item icon for the workflow step you want to define. The workflow step that you are define will be the source workflow step in the connection item definition.
2) Click the source workflow step in the diagram and drag the connection to the target workflow step.
3) Click the **Save** button to save your definitions.
4) Repeat this procedure as required for all workflow steps.

You can now refine the display of the connection items, as needed. For more information, see Visually Refining the Display of Connection Items.

Editing an Existing Workflow Diagram

You can edit an existing workflow diagram and add or remove workflow steps or connection items between workflow steps. The definitions you make in the workflow diagram will be included in the workflow template definition.

If the workflow diagram is not open, ensure that the **Workflow State** attribute of the workflow template is set to `Plan`. Right-click the workflow template in the explorer and select **Open Diagram**. A tab for the workflow template will open in the workspace area. Edit the diagram as described above.

The **Open Diagram** option is only available for workflow templates for which the **Workflow State** attribute is set to `Plan`. You cannot open the diagram capability in Alfabet Expand for a workflow template that is active or retired. However, if the workflow diagram is already displayed in the workspace area and the **Workflow State** attribute of the workflow template is set to `Active` or `Retired`, you will be able to edit the workflow diagram by adding workflow steps and connection items. In this case, the workflow template does not have to be changed to `Plan`.

General Guidelines for Graphically Refining the Diagram

The following information about how to refine the visualization of the diagram:

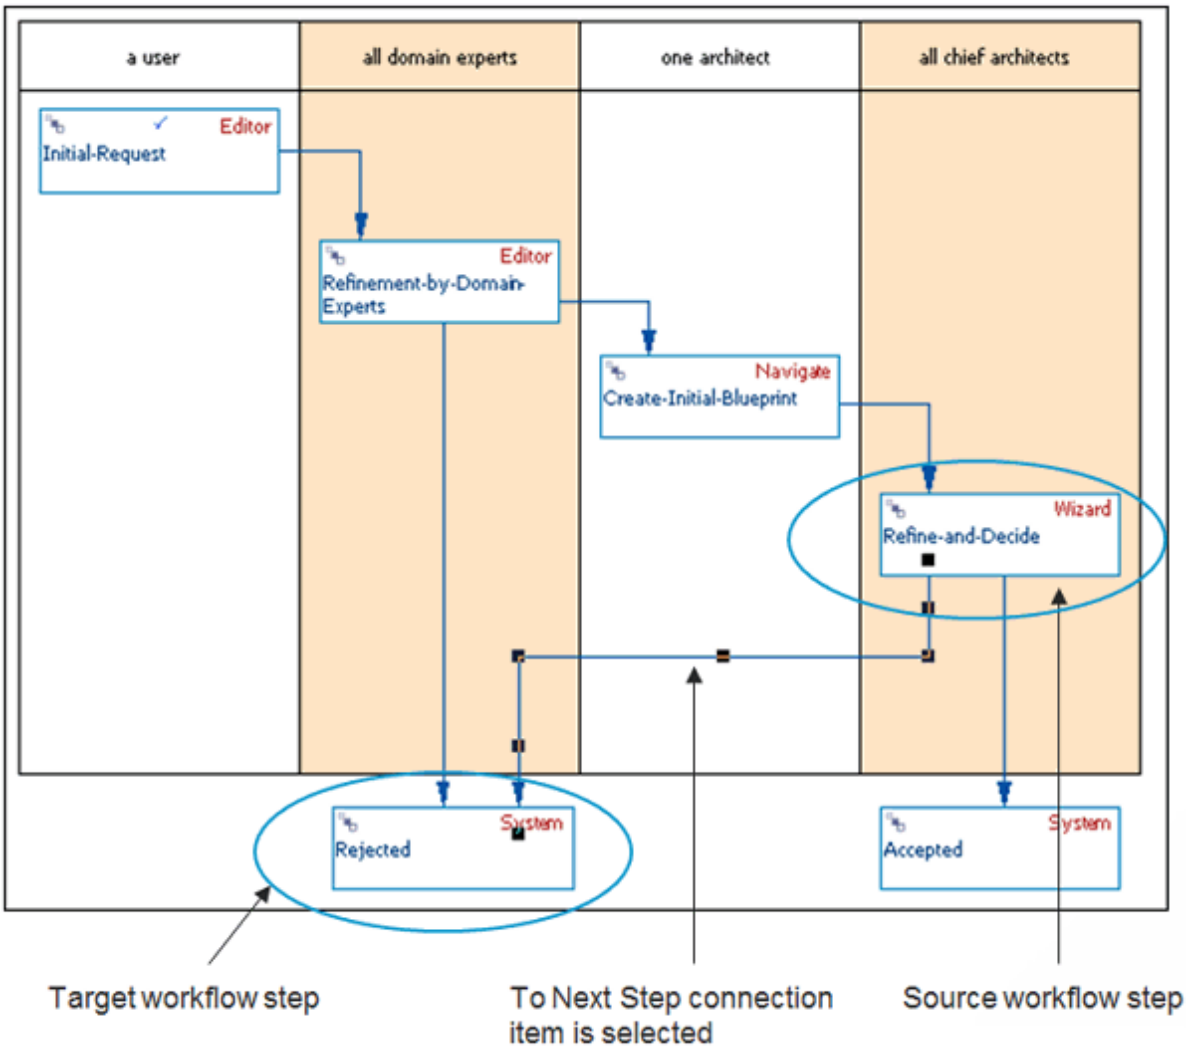
- Visually Refining the Display of Connection Items
- Adding a Graphic Element to a Diagram
- Deleting a Graphic Element from the Diagram
- Adding a Graphic Image (GIF, BMP, etc.) to a Diagram
- Moving Diagram Elements in a Diagram
- Changing the Size of a Diagram Element
- Simultaneously Changing the Size of Multiple Diagram Elements
- Aligning Diagram Elements in a Diagram
- Changing the Background Color of Graphic Elements

Visually Refining the Display of Connection Items

The attributes available in the **Information Flow Attribute** attribute are configured by your solution designer in the XML object ***DiagramInformationFlowDef*** in the configuration tool Alfabet Expand. For more information, see the section Configuring the Visualization of Connection Items and Subordinate Object in Diagrams in the reference manual *Configuring Alfabet with Alfabet Expand*.

Sometimes you may have a confusing network of connection items or you may want to move the connection items so that they are easier to understand graphically. For example, you can define whether the connection items are displayed as elbowed or straight connections.

When you create new connection items, you should first define whether you want elbowed connections or straight connections to be automatically created. To do so, click in the diagram to open the attribute window. In the **Elbowed Connection** attribute, select `True` to create elbowed connections and select `False` to create straight connections. For more information about the attributes in the attribute window, see the table *Diagram Property Window* in *Workflow Diagram Capability* in the reference manual *Configuring Alfabet with Alfabet Expand - Appendix*.



Sometimes connection items may appear entangled or are hard to see. To understand where a connection item starts and ends, click the connection item to see which diagram elements are the source and target objects of the connection item. To move a connection item, grab a center handle and drag the connection to the place you want it to be visualized. Adjust all sections of the connection item until the connection item is correctly positioned. In some cases, you may need to right-click an element in the diagram and select **Move to Front** or **Send to Back** to ensure that a diagram element is adequately visualized. If a connector item becomes mis-shapen by an erroneous drag-and-drop action, you may need to delete the connector item and redefine it.

Adding a Graphic Element to a Diagram

You can add any graphic element that is located in the toolbar in the diagram capability. After a graphic element is placed in the diagram, you can later modify it including moving it in the diagram, changing its size, and adding color, borders, shadow, text, etc. To add a graphic image, see Adding a Graphic Image (GIF, BMP, etc.) to a Diagram.

To add a graphic element to the diagram:

1) In the toolbar, click the graphic element that you want to add to the diagram and click a blank space in the diagram. The graphic element appears on the spot that you click.

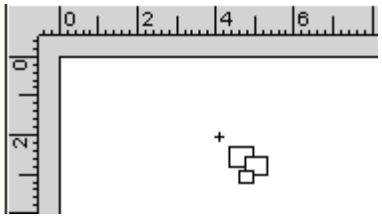


FIGURE: Cursor shows that the toolbar item is selected

To draw a polygon, select the polygon icon. Click in the diagram and drag-and-drop to create a line. Select the CTRL key, click on the line at the point where you want to create an angle, and drag-and-drop to create the desired polygon shape.

2) You can further define the graphic element by changing its color, size, position, or adding text. For more information, see General Guidelines for Graphically Refining the Diagram.

3) Click the **Save** button to save your definitions.

4) Repeat the process in order to add other graphic elements to the diagram, as needed.

Deleting a Graphic Element from the Diagram

There is no Undo/Redo function in the workflow diagram capability. If you delete a workflow step, the workflow step, any workflow step sequence definitions, and any pre- or post-conditions as well as pre- or post-actions will be irrevocably deleted from the database.

There are many different ways to delete one or more graphic elements from the diagram:

You can select several objects at once by holding down the CTRL key while selecting the objects.

To delete one or more graphic elements from the diagram:

- Select the graphic element and click the DELETE key, or
- Select the graphic element and right-click the workspace and select **Delete Selected (Graphics)**, or
- Select the graphic element and click CTRL + G.

Adding a Graphic Image (GIF, BMP, etc.) to a Diagram

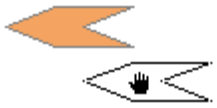
Any graphic files that you want to add to a diagram must first be uploaded to the **Internal Document Selector**. For more information about uploading graphic files to the **Internal Document Selector**, see the section *Uploading Documents and Managing User Permissions to Document Folders in the Internal Document Selector* in the reference manual *User and Solution Administration*. Graphic files are uploaded to the **Internal Document Selector** in the same manner as documents. You can upload a BMP, GIF, JPG, JPE, PNG, DIB, or ICO (icon) file.

To add a graphic image to a diagram:

1) In the toolbar, click the **Bitmap** icon and click a blank space in the diagram. The **Internal Document Selector** will open.
2) Navigate to the directory where the graphic file is located. Click the file and click **OK**. The graphic image is visible in the diagram.
3) To adjust the size of the graphic image, click a corner handle and drag it to the appropriate size.
4) Click the **Save** button to save your changes.

Moving Diagram Elements in a Diagram

You can move any element that is in the diagram.



To move the element to a different spot in the diagram, click the diagram element and drag to the appropriate place.

To move several elements at once, click the diagram elements while holding the CTRL key. Move the group to the appropriate place. After the group has been moved, click each diagram element to deselect it.

Changing the Size of a Diagram Element

You can change the default size of any elements that are in the diagram.

FIGURE: Increasing the size of a rectangle

To increase the size of a diagram object or graphic element, click a corner handle and drag it to the appropriate size.

Simultaneously Changing the Size of Multiple Diagram Elements

You can simultaneously define the size for multiple elements in the diagram.

To define the size of multiple diagram elements:

1) Press the SHIFT key and select all diagram elements in the diagram that should be the same size.
2) In the menu bar, select **Format** > **Size**. The **Size** dialog box opens.
3) Enter values, as needed:

   Width Box:

   - **No change**: The width of the currently selected diagram elements will not be changed.
   - **Shrink to Smallest:** The width of the selected diagram elements is based on the diagram element smallest in width.
   - **Grow to Largest**: The width of the selected diagram elements is based on the item largest in width.
   - **Width**: Enter a size in millimeter to define the width of the selected diagram elements.

   Height Box:

   - **No change**: The height of the currently selected diagram elements will not be changed.
   - **Shrink to Smallest:** The height of the selected diagram elements is based on the diagram element smallest in height.
   - **Grow to Largest**: The height of the selected diagram elements is based on the diagram element largest in height.
   - **Height**: Enter a size in millimeter to define the height of the selected diagram elements.
4) Click **OK**. The size of each selected diagram element adjusts to the size defined.
5) Click the **Save**  button to save your changes.

Aligning Diagram Elements in a Diagram

You can simultaneously define the alignment for multiple elements in the diagram.

To align diagram elements:

1) Press the SHIFT key and select all diagram elements in the diagram you want to align with one another.
2) In the menu bar, select **Format** > **Align**. The **Alignment** dialog box opens.
3) Enter values, as needed:

   Horizontal Box:

   - **No change**: The currently selected diagram elements will not be changed on the horizontal line.
   - **Left sides**: All selected diagram elements are left-aligned according to the selected diagram element closest to the left edge of the diagram.
   - **Centers**: All selected diagram element are left-aligned according to the selected diagram element closest to the left edge of the diagram.
   - **Right sides**: All selected diagram elements are right-aligned according to the selected diagram element closest to the right edge of the diagram.

- **Space Equally**: The distance between the selected diagram elements is equal.
- **Center in diagram**: The selected diagram elements will be placed in the middle of the diagram without changing its horizontal line.

- **Vertical Box:**
  - **No change**: The selected diagram elements will not be changed.
  - **Tops**: All selected diagram elements are top-aligned according to the selected diagram element closest to the top edge of the diagram.
  - **Middles**: All selected diagram elements are center-aligned according to average middle axis.
  - **Bottoms**: All selected diagram elements are bottom-aligned according to the selected diagram element closest to the bottom edge of the diagram.
  - **Space equally**: The distance between the selected diagram elements is equal.
  - **Center in diagram**: The selected diagram element will be placed in the middle of the diagram without changing its vertical line.

4) Click **OK**. The diagram elements are aligned as defined.

5) Click the **Save**  button to save your changes.

Changing the Background Color of Graphic Elements

As you design your diagram, you may want to define color a for various graphic elements in order to make the information more accessible and visually appealing.

The color of workflow steps is preconfigured for Alfabet and cannot be altered.

It is recommended that color assignments are made using explicit color codes or Web colors (and NOT system colors as these will result in differences in display from one client computer to another).

To change the background color of a graphic element in the diagram:

1) Click the graphic element that you want to define a color for to call up its attribute window.
2) Click in the **Background Color** attribute and then click the arrow to open the drop-down box of colors.
3) Click a color in either the `Custom`, `Web`, or `System` tabs. The color fills the selected graphic element in the diagram.

Depending on the kind of graphic element you are currently working with, you can also define other object class properties. For example, for the double arrow rectangle shown above, you can define a double border or choose to point the arrow in the other direction.

4) Click the **Save**  button to save your changes.

Editing an Active Workflow Template

In some cases, you may need to make changes to the configuration of a workflow template after it has been made active and available to the user community. To edit the workflow template, you must return the state of the workflow template to `Plan` in the **Workflow State** attribute. Workflow templates may not be edited if the **Workflow State** attribute of the workflow template is set to either `Active` or `Retired`.

Any modifications made to the workflow template will not impact workflow steps that have already been initiated, performed, or confirmed. It may be necessary to re-initiate all workflows if a workflow template is modified after it has been activated.

If changes are required to a workflow template that is already active in the production environment, see the section Creating a Migration Definition to Update Running Workflows.

To make the workflow template editable, right-click the workflow template and select **Set Workflow State to Plan**. Once the workflow template displays `Plan` in the **Workflow State** attribute, you can edit the workflow template. Any changes you make to the workflow template must be saved by clicking the

Save  button in the toolbar.

Deleting a Workflow Template

Workflow templates may be deleted in Alfabet Expand if the **Workflow State** attribute of the workflow template is set to either `Plan` or `Retired`. A workflow template should not be deleted if there are running workflows. If a workflow is deleted with running workflows, all workflow instances will also be deleted. Before a workflow template is deleted, you should check to see if the workflow template is implemented in other workflow templates. To do so, right-click the workflow template and click **Show Usage**. A window will be displayed showing the configuration objects using the selected workflow template. For more information regarding the **Show Usage** functionality, see the section Using the Show Usage Functionality in the chapter Getting Started with Alfabet Expand.

To delete the workflow template, right-click the workflow template in the explorer and select **Delete**. The deleted workflow template will no longer be displayed in the **Workflows Administration** functionality that can be accessed in the user interface via an administrative user profile.

Validating the Workflow Template

Once you have completed the configuration of the workflow template, it must be validated. You can validate the workflow template at any time by clicking the **Validate** option available for the workflow template. The validation is also automatically executed when you set the workflow template's **Workflow State** attribute to `Active`. When the workflow template is validated, errors will be checked in the workflow template including invalid or missing configurations for wizards, views, and editors specified in the workflow template. Errors in the workflow template definition that may result in failure during execution of the workflow will be reported in a dialog. All errors that are reported must be corrected before the **Workflow State** attribute of the workflow template can be set to `Active`.

A validation will also be executed for running workflows each time a workflow is initiated. If configurations that are relevant to the workflow template are no longer available, an error message

will be displayed to the user stating that the workflow configuration is invalid and that the workflow administrator should be contacted.

To validate all workflow templates in a bulk operation, right-click the **Workflow Templates** explorer root node and select **Validate All**. The validation will review all workflow templates for which the **Workflow State** attribute is set to `Plan` or `Active`. If an error is found in the configuration of a workflow template, an information message will be displayed. If the error was found in a workflow template for which the **Workflow State** attribute was set to `Plan`, a **Set Plan to Workflow State** button will be displayed. An erroneous workflow template must have the **Workflow State** attribute set to `Plan` to be corrected.

To validate a selected workflow template, right-click the workflow template  and select **Validate**.

Changing the Workflow State and Activating/Deactivating the Workflow Template

Workflows can only be initiated for a workflow template for which the **Workflow State** attribute has been set to `Active`. A workflow cannot be initiated for any workflow template that has the **Workflow State** attribute set to `Retired` or `Plan`. Therefore, once the configuration of the workflow template is complete and the workflow template has been validated, you must make it available to the user community.

If you attempt to activate the workflow template and have not yet validated the workflow template, the validation will be performed automatically. If errors exist in the workflow template definition, you will not be able to set the **Workflow State** attribute to `Active`. An error message will be displayed listing the errors that must be corrected before the workflow template can be set to `Active`. For more information about validating workflow templates, see the section Validating the Workflow Template.

To change the workflow state of a selected workflow template:

1) Click the workflow template to open the attribute window.

2) Click the **Save**  button in the toolbar to ensure that all modifications made to the workflow template are saved to the Alfabet database.

3) Right-click the workflow template and select **Validate** to ensure that existing errors will not prevent the workflow template from being activated.

4) Right-click the workflow template and select **Set Workflow State to Active** to activate the workflow template so that workflows can be initiated. The workflow template will now be displayed in the **My Workflows** functionality of all users that have been defined as permitted users of the workflow template.

If you need to modify the workflow template, you must set the **Workflow State** attribute to `Plan`.

To change the workflow state of all workflow templates in a selected workflow group: Right-click the workflow group and click one of the following:

- **Set Workflow State to Active** to activate the workflow templates so that workflows can be initiated.

- **Set Workflow State to Plan** to deactivate the workflow templates so that they can be edited.
- **Set Workflow State to Retired** to deactivate the workflow templates and disable the editing capability.

The state of all workflows directly located in the workflow group and all workflows located in sub-groups of the selected group will be set to the selected state.

Please note that if a workflow template in the workflow group has errors and is invalid, an error message will be displayed for the workflow template. Any workflow templates following the invalid workflow template in the explorer will not be updated.

To activate all workflow templates in all workflow groups. Right-click the **Workflow Templates** node at the top of the explorer and click one of the following:

- **Set Workflow State to Active** to activate the workflow templates so that workflows can be initiated.
- **Set Workflow State to Plan** to deactivate the workflow templates so that they can be edited.
- **Set Workflow State to Retired** to deactivate the workflow templates and disable the editing capability.

Creating a Migration Definition to Update Running Workflows

It may be that a workflow template must be changed even though running workflows based on the workflow template are in progress. For example, if new guidelines have been implemented by the enterprise for cost management, it may be necessary to update the enterprise's workflow templates targeting budgeting processes as well as update any running workflows based on the modified workflow templates. In the context of the workflow migration definition, you can thus edit the workflow template's attributes, add, delete, or modify its workflow steps and/or workflow step actions, etc.

Depending on the extent of changes that need to be made, you can do one of the following:

- For only minor modifications to a workflow template (such as changes to existing pre- or post-conditions, editors/wizards for data capture, etc.) you can modify the existing workflow template without the need to create a new workflow template.
- For major modifications to a workflow template (such as the addition or deletion of a workflow step), you should create a new workflow template based on the existing workflow template and make the necessary changes to the new workflow template.

If the name of a custom editor, class setting, or user profile is changed and that configuration object is implemented in a workflow template, the changed name will be correctly updated in the workflow templates where that configuration object is implemented. A warning message will be generated during the migration process if a configured report, wizard or text template that is used in a workflow template has been renamed. **The modified names of user profiles, configured reports, wizards, or text templates that are referenced in workflow templates must be explicitly retrofitted for running workflow instances by configuring an appropriate workflow migration definition.**

The **Workflow State** attributes of the source workflow template (the workflow template to be changed) and the target workflow template (the updating workflow template), must be set to `Plan`. For the workflow

migration definition, each workflow step in the source workflow template should be mapped to the correct workflow step in the target workflow template. If no mapping is defined for a workflow step, the workflow will continue based on the definition of the source workflow template. Please note the following about the migration process:

- Any running workflows based on the source workflow template will be locked and no further action can be performed for the workflow step. Users will see an error message stating that the current workflow step is blocked.
- The state defined for each workflow prior to the migration will be maintained after the migration to the target workflow template. This is particularly relevant for workflows with the **Workflow State** `Suspended`. Workflows with the **Workflow State** `Finished` will not be updated.
- The state defined for each workflow step prior to the migration will be maintained after the migration. Please note that if the workflow step has the state Error prior to the migration, the workflow owner ow workflow administrator must explicitly redirect the workflow step to another workflow step after the migration. This is explained in the section *Fixing a Workflow with an Error State* in the reference manual *User and Solution Administration*. Please note the following regarding workflow steps:

- **Previous workflow steps**: Workflow steps that have already been completed prior to the migration will be unaffected by the target workflow template.
- **Current workflow steps**:
- Pre-conditions defined for the current workflow step in the target workflow template will not be evaluated.
- Any workflow activity that has already taken place in the current workflow step (such as data capture) of the source workflow template will be ignored. The user must perform the current workflow step anew.
- If the current workflow step has been delegated to another user, the workflow step delegation will be maintained for the current workflow step.
- **Future workflow steps**: The workflow steps that have not yet been completed in the running workflows will be updated to reflect the changes in the target workflow template.

Once the **Workflow State** attribute of the target workflow template is changed to `Active`, users can continue with their workflow activities as well as create new workflows based on the new workflow template. The **Workflow State** attribute of the obsolete workflow template should be set to `Retired` to prevent new workflows from being initiated based on the old workflow template.

Once the target workflow template is activated, the workflow owner can review the migration's consequences to the running workflows and take any necessary action. The **Workflow Event Trace** page view available for each workflow will indicate that the source workflow template of the running workflow has been migrated to the target workflow template. The following information will be available to the workflow owner:

- The **Event** column will show `WorkflowUpdated` and the **Message** column will display a comment indicating that the source workflow template has been updated to the target workflow template.
- The **Event** column will display `GoToStep` and `StepCancelled` for the source workflow steps that were active and blocked when the migration was executed. The **Message** column will display a comment explaining that the source workflow step was updated.

- The **Event** column will display `StepEntered` and `StepPerformed` for all target workflow steps that are subsequently performed after the execution of the workflow template migration.
- All workflow information captured prior to the migration will be unchanged in the **Workflow Event Trace** page view.

.

The following steps are required to migrate workflows to a new workflow template:

- Create a new workflow template based on the source workflow template. This will be the target workflow template. (If you are only making minor modifications, you can edit the existing workflow template. In this case, the source workflow template and the target workflow template will be the same.) The **Workflow State** attribute of the source and target workflow templates must be set to `Plan`.
- Configure the target workflow template as needed. If workflow steps are being added or deleted, be sure to review that the **Next Step** attributes are correctly defined for each workflow step.
- Validate the target workflow template and correct any errors in the configuration.
- Define the migration of the source workflow template to the target workflow template by mapping the source workflow steps to the target workflow steps. Execute the migration.
- Set the **Workflow State** attribute of the target workflow template to `Active` in order to implement the changes to the workflow and allow users to access the workflow step that they are currently working with.
- Set the **Workflow State** attribute of the obsolete workflow template to `Retired` in order to prevent new workflows being created based on the old workflow template.

To create a new target workflow template:

1) Right-click the source workflow template in the explorer and select **Set Workflow State to Plan**.

   If you are only modifying the source workflow template and not creating a new target workflow template, modify the workflow template as needed. Skip steps 2-4. Be sure that the **Workflow State** attribute is set to `Active` before executing the migration definition.

2) Right-click the source workflow template in the explorer and select **Create New Workflow Template as Copy**. The new target workflow template is displayed in the explorer.
3) Define the necessary attributes of the target workflow template. The workflow template should have a different technical name in the **Name** attribute. The **Caption** attribute, however, which is the name that users see in the interface, can stay the same.
4) Make the necessary changes to the target workflow template. If you are adding or deleting workflow steps, review the **Next Step** attribute of all workflow steps to ensure that they are correct.
5) When you have finished defining the target workflow template, right-click the target workflow template and select **Validate**. Review and correct any configuration errors displayed in the dialog.

6) Once the definition of the target workflow template is complete, right-click the target workflow template and select **Set Workflow State to Active** and click the **Save**  button in the toolbar.

7) Right-click source workflow template in the explorer and select **Create Migration Definition**. The **Workflow Template Migration** editor opens.

8) In the **Select Target WorkflowTemplate** attribute, select the new target workflow template that the source template should be migrated to.

9) Now you must map the source workflow steps to the target workflow steps. For each workflow step displayed in the **Source** column, select one workflow step in the **Target** column that it should be mapped to. Select `NONE` if the source workflow step should not be mapped to a target workflow step. In this case, a running workflow that is currently in a source workflow step that is not mapped to a target workflow step will continue with the definition of the source workflow template.

10) Once the mapping of the workflow steps is complete, you can do one of the following:

- Click **Execute** to initiate the migration of the source workflow template to the target workflow template.
- If there are errors in the workflow template definition, the hourglass symbol will be continually displayed. If this is the case, you must click **Close** in the editor, confirm the warning by clicking **Yes**, and review the target workflow template definition to determine where the error lies.
- If there are no errors in the workflow template definition, a message will be displayed describing how many workflows have been successfully migrated. Click **OK** to confirm this message.
- Once the migration has been executed, click the source workflow template and change the **Workflow State** attribute to `Retired` to ensure that new workflows are not initiated for the obsolete workflow template.
- Please note that you can copy an existing migration definition for a selected workflow template and paste it to another workflow template as a basis to plan the workflow migration for that workflow template.
- Click **Save As** to save the configuration to an XML file. This mechanism can be used to define the migration of the workflows in a development or test environment and apply it to the production environment at a later time. To do so, the following procedure should be carried out in the development/test environment:

  1) Create and configure the target workflow template.
  2) Right-click the source workflow template and click **Create Migration Definition**.
  3) Specify the source workflow template and target workflow template.
  4) Map the workflow steps for the migration and click **OK**. The migration definition  is saved below the source workflow template
  5) Right-click the migration definition  and select **Save As** and save the migration definition to an XML file.

The following procedures should be carried out in the production environment:

1) Right-click the source workflow template and select **Read Migration Definition** to import the migration definition.

2) Right-click the migration definition and select **Open Migration Definition**.

3) Ensure that the source workflow template and target workflow template are selected and that the workflow steps are correctly mapped. Click the **Execute** button to update the running workflows for the workflow template.

4) Set the **Workflow State** attribute for the target workflow template to `Active`.

5) Set the **Workflow State** attribute for the obsolete workflow template to `Retired`.

6) Save your changes by clicking the **Save** button.

Translating the Name and Description of Workflows

Captions, descriptions, technical comments, and user messages configured for workflows, workflow steps, workflow step actions, and pre- and post-conditions can be translated to a secondary language for the user community. For more information about translating the terminology to a secondary language, see the chapter Localization and Multi-Language Support for the Alfabet Interface.

Workflow step states (`Confirmed`, `Pending`, `Running`, `Finished`, etc.) cannot be translated.

To update the translated strings for workflows:

- To update the translated strings available in the vocabularies to all running workflows for a selected workflow template for which the **Workflow State** attribute is currently set to `Plan`, right-click the workflow template and select **Update Translation**. A message will be displayed stating that the translated strings available for the selected workflow template and its workflow steps, workflow step actions, and pre- and post-conditions have been updated. If the **Update Translation** option is disabled, ensure that the **Workflow State** attribute is set to `Plan` and that the most recent changes have been saved by clicking the **Save** button.
- To update the translated strings available in the vocabularies for all workflow templates, regardless of the current value of the **Workflow State** attribute. Go to the menu bar and click **Globalization** > **Update Workflow Translation**. A message will be displayed stating that the translated strings available for workflow templates, workflow steps, workflow step actions, and pre- and post-conditions have been updated to all running workflows for all workflow templates

Making the Workflow Template Available to the AlfaBot Capability

Workflow templates can be configured to allow a workflow to be started for new and existing objects via the AlfaBot. Workflows can be started via the AlfaBot for all workflow templates that have been enabled to start via the AlfaBot. In the AlfaBot, a user can ask to start a workflow for an existing object by entering the object class stereotype and object name. If multiple workflows can be started for the object, these will be listed in the AlfaBot and the user can start the relevant workflow. Alternatively, the user can ask to start a workflow by entering the workflow caption. Multiple captions defined to start a workflow with new objects or with existing objects will be taken into account. In this case, the AlfaBot will request information about the object that the workflow shall be started with. The caption of the workflow started via the AlfaBot is a

concatenation of the caption configured for the workflow and the name of the object that the workflow has been started for. For more information about the configuration of the AlfaBot capability, see the section Implementing the AlfaBot for Navigation via a Full-Text Command.

To implement a workflow template in the AlfaBot capability, select the relevant workflow template define the following attributes as needed:

- **Start Base Class**: Please note that if object class stereotypes have been defined for a base class that is the target of the workflow, then the **Start Base Class** attribute should specify <Class:Stereotype>.
- **Allow AlfaBot to Create New Workflows for Existing Objects**: Set to `True` to allow workflows for existing objects to be started via the AlfaBot.
- **Allow AlfaBot to Create New Workflows for New Objects**: Set to `True` to allow workflows for new objects to be started via the AlfaBot.
- **Message for Started Workflow**: Specify a message to be specified when a new workflow is triggered for the workflow template via either the AlfaBot or via the **Workflow** button in an object profile. The message will be displayed in an information dialog after the workflow has been triggered if the workflow template does not define a start step.

Making the Workflow Capability Available to the User Community

Once the workflow template has been configured, validated, and the **Workflow State** attribute set to `Active`, it can be made available for the user community. As with most capabilities in Alfabet, you must ensure that the relevant functionalities are available to the relevant user profiles. Please keep the following in mind:

- Ensure that the users responsible to perform the workflow steps have the relevant functionality available. Assign either the configured **Workflow Activities Explorer** functionality (`WFS_Explorer`), custom explorer, or the relevant standard **My Workflow Activities** functionalities (`WF_UserWorkflowActivities`, `WF_UserWorkflowActivitiesExt`, and `WF_UserWorkflowActivitiesCommon`) to the user profiles of the users who will be responsible for performing the workflow steps. For more information, see the section Making Functionalities Accessible to a User Profile in the chapter Configuring User Profiles for the User Community.
- Users responsible for workflow steps should also have access to a standard or custom object view for the object class `WorkflowStep` via the class setting associated with their user profile. The standard object view is `WFS_ObjectView`. For more information about the configuration of a custom object view, see the chapter Configuring Object Views as well as the section Configuring Class Settings for Object Classes and Object Class Stereotypes in the chapter Configuring User Profiles for the User Community.
- Ensure that potential workflow owners (users who will initiate the workflow or may later have maintenance responsibility for the workflow) have access to the **Initiate Workflows** functionality (`Initiate Workflow` or `Workflows`).
- Users responsible to maintain workflows should also have access to a standard or custom object view for the object classes `Workflow` and `WorkflowTemplate`. The standard object views are `WF_ObjectView` and `WFT_ObjectView`.

- Please note that configured reports, custom object views and object cockpits, and class settings may be configured for the relevant object classes associated with the workflow capability.

Structuring Workflow Templates in Folders

You can structure and organize workflow templates in group folders. The following is possible:

- To create a group for an existing workflow template, enter a name for the group in the **Group** attribute and press ENTER. The group appears as a folder ascendant to the selected workflow template.
- To create a new workflow template for an existing group, right-click the group and select **Create New Workflow Template**.
- To change the group that a workflow template is assigned to, click the **Group** attribute and select the relevant workflow template group.

Any changes you make to the workflow template must be saved by clicking the **Save**  button

Chapter 14: Configuring Alfabet Functionalities Implemented in the Solution Environment

Alfabet Expand provides many options for configuring the solution environment. In some cases, configurations are defined in an XML object whereas in other cases, you configure changes directly in the Alfabet solution that you access from within Alfabet Expand.

The following information is available:

Configuring the Compliance Management Capability

The **Compliance Management** capability in Alfabet provides support for the definition of compliance inquiries, management of compliance projects, evaluation of target objects in the context of a compliance project as well as the auditing of compliance projects. The following business functions constitute the Compliance Management capability:

- **Compliance Configuration** functionality (`ComplianceConfiguration`): Allows compliance control sets, compliance domains, and compliance policies to be defined. Compliance policies require queries to be configured that specify the rules to find target objects and users responsible for answering questions about the target objects.
- **Compliance Projects** functionality (`ComplianceInstances`): Allows compliance projects to be created, activated, and managed.
- **Compliance Evaluation** functionality (`Home_ComplianceObjects`: Allows users to answer questions about the target objects that they are responsible for in the compliance project.

Before the user community can work with this capability, you must first configure the object classes that are the target of the compliance evaluation as well as the color-coding to represent the state of completion of an object's evaluation. These aspects of the configuration are configured in the XML object ***ComplianceManager***.

Furthermore, you must configure queries for the compliance policies that are relevant for a compliance control set. Queries must be defined in order to find the objects that are the target of a compliance project.

Additionally, you may need to define a query in order to find the persons to perform the evaluations of objects, if the persons are not authorized users of the target objects or have a role defined for the target objects.

The following information is available:

- Configuring the Object Classes to Evaluate
- Configuring the Color-Coding for Completion States
- Configuring Queries for Compliance Policies
- Configuring Release Status Definitions for Compliance Projects
- Making the Compliance Management Functionalities Available to the User Community

Configuring the Object Classes to Evaluate

All classes for objects that are to be evaluated in the context of the **Compliance Management** functionalities must be defined in the XML object ***ComplianceManager***.

1) Go to the **Presentations** tab, expand the **XML Objects** folder, and expand the **SolutionManagers** folder.
2) Right-click the XML object ***ComplianceManager*** and select **Edit XML**. The XML editor is displayed in the center pane. For general information about editing XML objects in Alfabet Expand, see Working with XML Objects.
3) In the XML attribute `Classes`, enter the object classes that are to be included in a compliance evaluation. The object classes should be comma-separated. All objects in the defined object classes may be targeted by a compliance policy, which will determine the relevant set of objects that are to be evaluated. The **Affecting Compliance Projects** workspace (`ObjectAffectingCompliancesProjects`) and *Affecting Compliance Projects Page View* (`AffectingCompliancesProjects`) will be added to the object profile for any object class defined.

The following classes may be the target of a compliance project:

- `Application`
- `ApplicationGroup`
- `BusinessData`
- `BusinessFunction`
- `BusinessObject`
- `BusinessProcess`
- `Component`
- `ComponentGroup`
- `Demand`
- `DemandGroup`
- `ICTObjectGroup`
- `Location`
- `MasterPlatform`
- `Peripheral`
- `PeripheralGroup`
- `Project`:<Stereotype>
- `MarketProduct`
- `MarketProductGroup`
- `StandardPlatform`
- `Technology`

- Deployment
- Device
- DeviceGroup
- Domain
- ICTObject
- TechnologyGroup
- Person
- Vendor
- VendorProduct

Please note that names of object class stereotypes may NOT be entered in the `Classes` attribute. You may only enter the names of base object classes in the `Classes` attribute. If object class stereotypes are defined for an object class, you must explicitly add the *Affecting Compliance Projects Page View* (`ObjectAffectingComplianceProjects`) to the custom object view(s) for each object class stereotype that should be included in the compliance evaluation.

4) In the toolbar, click the **Save** button to save the XML definition.

Configuring the Color-Coding for Completion States

The *Manage Objects Page View* (`CMPLI_ObjectsOverview`) displays the objects that are evaluated in a compliance project. The page view displays the objects in a selected class and shows their percentage of completeness. The values displayed in the **Complete** column are color-coded in green, yellow, and red. The threshold values for the colors must be defined in the XML object ***ComplianceManager***.

1) Go to the **Presentation** tab, expand the **XML Objects** folder, and expand the **Solution Managers** folder.
2) Right-click the XML object ***ComplianceManager*** and select **Edit XML**. The XML editor is displayed in the center pane. For general information about editing XML objects in Alfabet Expand, see Working with XML Objects.
3) In the XML attribute `GreenThreshold` and `YellowThreshold` attribute, specify the threshold values for the color. The value entered for the `GreenThreshold` attribute must be larger than the value entered for the `YellowThreshold` attribute. All objects with a value above the `GreenThreshold` value will be highlighted green in the *Manage Objects Page View* (`CMPLI_ObjectsOverview`). All objects with a value below the `GreenThreshold` value will be highlighted yellow. All objects with a value below the `YellowThreshold` attribute will be highlighted red.

   If no values are entered for either attribute in the XML object ***ComplianceManager***, the default value of 66 for the `GreenThreshold` attribute and 33 for the `YellowThreshold` attribute will be applied.

4) In the toolbar, click the **Save** button to save the XML definition.

Configuring Queries for Compliance Policies

Queries may be required in the following contexts in the Compliance Management capability:

- Mandatory: In order to specify which target objects are to be evaluated in the context of a compliance project as well as the persons to perform the evaluation. This is achieved by defining queries to find the objects that are the target of the compliance project. All queries that are relevant to find target objects for a compliance project must be assigned to compliance policies that have been created for the compliance control set.
- Optional: If the users that are responsible for evaluating the target objects are either the authorized user or a user defined via a role for the target object, then queries do not need to be defined to find the responsible users. If however the responsible users are neither the authorized user or user found via a role definition, then queries must also be defined to find these users responsible. All queries that are relevant to find responsible users in a compliance project must be assigned to compliance policies that have been created for the compliance control set.
- Optional: If compliance controls (the questions about target objects) are to be prioritized in terms of the order in which they are executed in a compliance project, then queries must be configured for each rule needed to find the compliance controls that are relevant for the compliance project. For example, you could configure that only compliance controls on with a **Level ID** attribute of 1, 2, and 3 are relevant to a compliance project. Once the first compliance project is completed, you could then initiate the compliance project again and specific that compliance controls with a **Level ID** attribute of 4, 5, and 6 are relevant to a compliance project. The queries must return the relevant compliance controls that should be included in the compliance project. The relevant queries to execute for the compliance project can be selected in the **Compliance Control Prioritization Policy** field in the **Compliance Project** editor.

Please note the following:

- You must create a configured report for each query required for the compliance policies. The **Category** attribute of the configured report must be set to the value defined for the use case `Compliance` in the XML object ***UseCaseCategories***. For more information, see Assigning a Category for Specific Functional Use to a Configured Report.
- Configured reports to be used in the **Compliance Policy** editor must be of the type `Query` and based on an Alfabet query. Configured reports used in the **Compliance Project** editor can be of the type `Query` or `NativeSQL` and define a native SQL query or an Alfabet query. For detailed information about configuring queries, see the chapter Defining Queries. For detailed information about configuring reports, see the chapter Configuring Reports.
- Which objects are found as base objects of the query of the report is relevant for the availability of the report in the editor fields for compliance management:
  - All Alfabet queries specified to find the target objects will be available for selection in the **Object Queries** tab in the **Compliance Policy** editor. Please note the following:
    - The base class of the query should be the object class that shall be evaluated. A base class may be any of the object classes specified in the XML element `Classes` in the XML object ***ComplianceManager***. When a user selects an object class in the **Class** field in the **Compliance Policy** editor, the relevant queries defined for that base class will be displayed in the **Object Queries** tab in the **Compliance Policy** editor.
    - `JOIN` and `WHERE` clauses may be used to define a subset of objects of the base class to be evaluated.

Example of an Alfabet query to find SOX-relevant applications for a compliance project:

```
ALFABET_QUERY_500

FIND DISTINCT

Application

WHERE Application.Sox_Relevant = 1

QUERY_XML

<QueryDef>

    <ShowProperty Type="Property"
    ClassName="Application" Name="Name" />

    <ShowProperty Type="Property"
    ClassName="Application" Name="Version" />

    <ShowProperty Type="Property"
    ClassName="Application" Name="Sox_Relevant" />

    <ShowProperty Type="Property"
    ClassName="Application" Name="Sox_Software_Type" />

</QueryDef>
```

- All Alfabet queries specified for the object class `Person` will be available in the **Permission Rules** tab in the **Compliance Policy** editor:
  - The base class `Person` must be defined in the query. The relevant queries defined for the base class `PERSON` will be displayed in the **Permission Rules** tab in the **Compliance Policy** editor.
  - The relation to the object class of the objects that are to be evaluated must be defined via `JOIN` and `WHERE` clauses.
  - The parameter:`BASE` refers to the current compliance project and not to the artifact that is evaluated.
  - The `REFSTR` property of the base object class `Person` and of the object class of the objects to be evaluated by the person found by the query must be included in the result dataset of the query. You can optionally include other properties in the result data set to test the query.
- All queries will be available in the **Compliance Control Prioritization Policy** field in the **Compliance Project** editor:
  - The query must return objects of the specified for the object class `ComplianceControl`.
  - The property `CompliancePrioritization` is available for the object class `ComplianceControlInstance` in order to allow compliance controls to be prioritized.
  - When the query is executed, all compliance controls found by the query will be displayed in the *Manage Objects Page View* (`CMPLI_ObjectsOverview`) of the compliance project.

For example, a native SQL query to find compliance controls with a **Level ID** attribute of 1, 2, and 3:

```
SELECT REFSTR
FROM COMPLIANCECONTROL
WHERE LEVELIDNUM LIKE '0001%'
   OR LEVELIDNUM LIKE '0002%'
   OR LEVELIDNUM LIKE '0003%'
```

- It is recommended to use a naming convention for the configured reports that clearly mark the configured reports as reports selectable in the **Compliance Project** editor. The **Compliance Control Prioritization Policy** field will display a drop-down list containing also configured reports only selectable in the **Compliance Policy** editor.

To specify the queries relevant for the **Compliance Management** capability:

1) In the **Reports** tab, right-click the **Reports** folder or a sub-folder and select **Create New Report**. You will see the new custom report listed below the selected folder.
2) In the attribute window, define the following attributes for the report:
   - **Name**: Enter a name for the report. The name you define here will be displayed in the relevant editor in the Alfabet user interface. The name of the report may exceed the conventional 64 character limit.

     In the **Permission Rules** tab of the **Compliance Policy** editor, all queries defined to select persons are listed regardless of the object class for which the person is searched for in the query. Therefore, the name of the report should provide adequate information about the relevant object class specified in the query as well as the relationship of the user to that object class.

   - **Type**: The type must be set to `Query` for an Alfabet query, and to `NativeSql` for a native SQL query. Please note that only configured reports of the type `Query` will be selectable in the editor **Compliance Policy**.
   - **Category**: Select the category name defined in the XML object ***UseCaseCategories*** for the use case `Compliance`. For more information about setting categories in the XML object ***UseCaseCategories***, see Assigning a Category for Specific Functional Use to a Configured Report.

     If the **Category** is not correctly defined, the query cannot be selected in the context of the **Compliance Management** capability.

   - **Alfabet Query** / **Native SQL Query** / **Query as Text**: Define the query as needed. For information about defining queries, see the chapter Defining Queries.
   - **Comment**: Optionally provide information about the report that is useful to the person configuring the reports. This comment will not be displayed in the Alfabet interface.
3) To make the query available in the Alfabet user interface, right-click the configured report in the **Reports** explorer and select **Set Report State to 'Active'**. If further changes are required to the configured report or query, you must return the **Report State** attribute to `Plan`.

4) In the toolbar, click the **Save**  button.

Configuring Release Status Definitions for Compliance Projects

A release status definition must be created for the object classes `ComplianceControlSet` (Compliance Control Set) and `ComplianceControlSetInstance` (Compliance Project) in the XML object ***ReleaseStatusDefs*** in the configuration tool Alfabet Expand.

For example, a release status definition for `ComplianceControlSet` (Compliance Control Set):

```
<ReleaseStatusDef
    ClassNames = "ComplianceControlSet"
    StatusSet = "Draft,Approved,Retired,Discarded"
    RetiredStatusSet = "Retired,Discarded"
    EditableStatusSet = "Draft,Approved,Retired,Discarded"
    DefaultStatus = "Draft"
    ApprovedStatus = "Approved">
    <StatusTransition ToStatus="Draft" FromStatuses="" />
    <StatusTransition ToStatus="Discarded" FromStatuses="any"/>
    <StatusTransition ToStatus="Approved" FromStatuses="Draft" />
    <StatusTransition ToStatus="Retired" FromStatuses="Approved" />
    <Status Name="Draft" Hint="Compliance control set is not
    approved." />
    <Status Name="Approved" Hint="Compliance control set is approved
    and can be implemented." />
    <Status Name="Retired" Hint="Compliance control set should not be
    used any more." />
    <Status Name="Discarded" Hint="Compliance control set is marked
    for deletion." />
</ReleaseStatusDef>
```

Please note the following regarding the release status definition for the Compliance Management capaility:

- You should carefully consider the definition of the StatusTransition XML attributes. For example, if a compliance project haw been set ot the release status specified in the XML attribute `ApprovedStatus`, should it be possible to return the compliance project back to a release status that preceeds the approved status. Please note the following changes that can be made to a compliance project that has been approved.
  - If a compliance project has been approved, the compliance policies may be edited. No new compliance policies may be added to the compliance project.
  - If additional objects that wer enot found by the object queries need to be added to the compliance project, a functioanlity is available that allows the ocmpliance project to be amended.

- The XML attribute `ApprovedStatus` must be specified for the object classes `ComplianceControlSet` (Compliance Control Set) and `ComplianceControlSetInstance` (Compliance Project). This is required to indicate that the compliance control set and compliance project have been approved.
- The XML attribute `RetiredReleaseStatusSet` must be specified for the object classes `ComplianceControlSet` (Compliance Control Set) and `ComplianceControlSetInstance` (Compliance Project). Please note however that only one release status may be specified for the XML attribute `RetiredReleaseStatusSet` configured for the objec class `ComplianceControlSetInstance` (Compliance Project).
- For general information about how to configure release statuses, see the section Configuring Release Status Definitions for Object Classes in the chapter Configuring the Class Model.

Making the Compliance Management Functionalities Available to the User Community

You must ensure that the **Compliance Management** functionalities are assigned to the relevant user profiles. For details about how to make the functionalities available to a user profile, see the section Making Functionalities Accessible to a User Profile in the chapter Configuring User Profiles for the User Community.

- **Compliance Configuration** functionality (`ComplianceConfiguration`): The **Compliance Configuration** functionality supports the definition and configuration of a compliance project. When the user configures the project, he/she must define the catalog of questions and the metrics for answering the questions, the rules to find the targeted objects, and the users who are responsible to answer the questions about the objects, which is captured in the compliance control se. The topical or geographical areas in the enterprise for which the compliance project is relevant are defined via the compliance domain. This functionality should be assigned to a user profile made up of advanced Alfabet users who are familiar with solution configuration and the configuration of Alfabet queries or native SQL queries.
- **Compliance Projects** functionality (`ComplianceInstances`): The **Compliance Projects** functionality supports the management of compliance projects. This functionality allows the user to create compliance projects for specific compliance domains and specific timeframes. This functionality should be assigned to a user profile made up users who are responsible for compliance projects
- **Compliance Evaluation** functionality (`Home_ComplianceObjects`): The **Compliance Evaluation** functionality allows users to view and assess the objects assigned to them in a compliance project. This functionality should be assigned to user profiles made up of users responsible to evaluate the objects targeted by the evaluation.
- The *Affecting Compliance Projects Page View* (`AffectingComplianceProjects`) may be added to the custom object view(s) for each object class/object class stereotype that will be targeted by compliance evaluations.

Configuring the Project Management Capability

Because the project planning capability is highly configurable and each project stereotype will be configured with a name unique in your enterprise, all documentation provided by Alfabet uses the generic term "project" when referring to any object created for any project stereotype.

Alfabet 's project management capability allows you to create and configure a project framework that suits the needs of your enterprise. You can define a strict hierarchy of project levels that serves your enterprise's needs in terms of structuring tasks, defining deliverables, monitoring existing projects, scoping project costs and business cases, aligning projects with the enterprise's strategic intentions and demands, designing alternative architecture scenarios, and planning and implementing the enterprise's to-be architecture.

A typical project management hierarchy might have the following levels:

- Program
- Statement of Work
- Project
- Sub-Project
- Project Activity

A project stereotype represents a level in the project management framework. The project hierarchy is made up of an arbitrary number of object class stereotypes defined for the class `Project`. An unlimited number of objects can be created in Alfabet for each project stereotype.

The project hierarchy can be configured as a linear hierarchy or as a branched tree structure that allows complex project structures and hierarchies of stereotypes to be captured. Each project stereotype may define multiple subordinate project stereotypes. The top-level project stereotype represents the most abstract level of a project and the lowest level project stereotype represents the most granular level of project tasks that must be acted upon in order to realize the project. For example, a typical linear project might be made up of the following project stereotypes: Level 1: Program, Level 2: Statement of Work, Level 3: Project, Level 4: Sub-Project, Level 5: Project Activity.

The name, number, and hierarchical ordering of the project stereotypes are configurable. A project stereotype is similar to an object class. Like an object class, the projects based on a project stereotype are instances of the project stereotype. For example, the project stereotype Project Activity will have objects called project activity. Each project stereotype may have only one ascendant project stereotype and only one subordinate project stereotype. However, projects of a specific stereotype do not have to be to be associated with a project of the ascendant project stereotype nor with projects of the subordinate project stereotype.

The definitions that can be made for each project stereotype must be configured. Therefore, the views that are available may differ for each project stereotype in the hierarchy. For example, the configuration will determine for which project stereotype users can bundle demands to projects, document the as-is architecture, plan a to-be architecture, assess alternative project scenarios, track costs via cost centers, and monitor projects via milestones.

In order to configure project stereotypes that make up the project management hierarchy, you must first create object class stereotypes for the object class `Project`. Once the project stereotypes have been created in the class model for the object class `Project`, you can order the hierarchy of project stereotypes in

the XML object ***ProjectManager***. All project management functionalities in Alfabet are available by default for each project stereotype. However, you should refine which functionalities should be available for each project stereotype by means of the XML object ***ProjectManager***. Questions to consider include:

- For which, if any, project stereotypes should project baselining occur? Project baselines capture the scope of a project at the time that the project baseline is created and allows the deviation of the original scope of the base project to be tracked over time in terms of the total project costs and income, resource costs, project evaluations, scheduling and achievement of project milestones, and the changes to the to-be architecture.
- For which, if any, project stereotypes should project scenarios be allowed? Project scenarios allow multiple what-if scenarios of the to-be architecture, project budgeting and cost calculation, project evaluations, high-level resource planning, and project scheduling to be explored, planned, and potentially implemented.
- For which, if any, project stereotypes should the as-is architecture be defined? The as-is architecture includes the IT architecture elements such applications, components, etc. that are impacted or will be impacted in some way by the project. Typically, the same project stereotype is used to define the as-is architecture and the to-be architecture.
- For which, if any, project stereotypes should the to-be architecture be defined? The to-be architecture allows the user to plan and update the existing as-is architecture by planning new objects, updating existing objects, and retiring objects. The planned to-be architecture can then be merged to the project via a project scenario thus updating the as-is architecture. This would typically be the same project stereotype that you define the as-is architecture for.
- For which project stereotypes should business cases and costs be defined?
- For which, if any, project stereotypes should costs centers be defined? A cost center is a means to centrally define costs for a specified period of time and allocate the costs to projects according to a defined allocation scheme.
- For which project stereotype should be used when a project is created for a demand?
- For which, if any, project stereotypes should project planning and project milestones to track the progress of the projects be implemented?
- For which, if any, project stereotypes should resource planning occur? Resource planning includes the planning of skills and resources over time, including the assignment of the persons or organizations to perform the necessary tasks and track the resource costs.

For each project stereotype, you should carefully consider which functionalities should be available and configure the relevant custom object views and object cockpits necessary for the user community to capture and analyze the necessary data. Once defined, a project stereotype is similar to a standard object class. Correspondingly, you can configure the mandate capability to control user access to each project stereotype and to the capability as a whole. Additionally, you can configure custom editors, wizards, class settings, workflows, and reports for each project stereotype, as needed. All project stereotypes can be configured to be searchable and thus selected in the list of searchable object classes displayed in the **Search for** field in the **Simple Search** and **Browse** functionalities.

The configuration is relevant for the functionalities **Portfolio Overview** (`PRJ_Management`), **Capture Projects** (`PRJ_CaptureProjects`), and the **Project Groups** explorer (`PRJG_Explorer`). These functionalities must be assigned to the relevant user profile in order to make the project management functionalities available in the Alfabet interface. For more information, see the section Making Functionalities Accessible to a User Profile in the chapter Configuring User Profiles for the User Community.

The following information is available:

Creating Project Stereotypes for the Project Hierarchy

Project stereotypes must first be created in the **Stereotype** attribute of the object class `Project`. You can define the project hierarchy as a linear hierarchy or as a branched tree structure that allows complex project structures and hierarchies of stereotypes to be captured. Each project stereotype may define multiple subordinate project stereotypes.

For example, if an enterprise supports Agile release trains, the following project structure could be configured:

- The project stereotype "Program" has the sub-projects "Project" and "Agile Release Train".
- The project stereotype "Project" has only the sub-project "Project Step".
- The project stereotype "Agile Release Train" has only the sub-project "Program Increment".

In this case the XML definition in the XML element ***Stereotype*** for the object class `Project` would be configured as follows:

```
<ClassStereotypes>
```

```
        <Stereotype Name="Program" Caption="Program"
        CaptionPlural="Programs" Comments="" HasMandates="true" />

        <Stereotype Name="Project" Caption="Project"
        CaptionPlural="Projects" Comments="" HasMandates="true" />

        <Stereotype Name="ProjectStep" Caption="Project Step"
        CaptionPlural="Project Steps" Comments="" HasMandates="false" />

        <Stereotype Name="AgileReleaseTrain" Caption="Agile Release
        Train" CaptionPlural="Agile Release Trains" Comments=""
        HasMandates="false" />

        <Stereotype Name="ProgramIncrement" Caption="Program Increment"
        CaptionPlural="Program Increments" Comments=""
        HasMandates="false" />

    </ClassStereotypes>
```

Each project stereotype must only be specified once in the XML object ***ProjectManager***. If a project stereotype is specified more than once, only the first occurrence will be used and any subsequent occurrences will be ignored. If project refinements in different hierarchies require the same terminology, different project stereotypes must be created in the **Stereotype** property of the class `Project`. The XML attribute `Caption` of the stereotypes may be the same for different stereotypes and in this way you can address your enterprise's terminology requirements. For more information about specifying project stereotypes, see the section Creating Project Stereotypes for the Project Hierarchy.

Before you create the project framework, you should carefully consider the number of levels required for your enterprise’s project hierarchy as well as at which level such objects such as project scenarios, costs, milestones, etc. should be defined. **Once the enterprise begins to work with the project management capability, you cannot add new or remove existing project stereotypes.**

Once a project stereotype has been created, you can configure its class settings and specify whether the project stereotype is searchable, and which icon and preview properties should be displayed for the project stereotype. For more information about configuring class settings, see the section Configuring Class Settings for Object Classes and Object Class Stereotypes.

To create project stereotypes for the project management capability:

1) Go to the **Meta-Model** tab and navigate to the protected class node  for the object class `Project` in the **Class Model** explorer.
2) Click the object class `Project` in the explorer to open the attribute window.
3) Click the **Browse**  button available for the **Stereotypes** attribute to open the XML editor. Define the following XML attributes in the XML element ***ClassStereotypes***.

An error message will be displayed upon closing the text editor if syntax errors are written in the XML definition of the **Stereotypes** attribute.

- `Stereotype Name`: Enter the technical name for each object class stereotype. You may define a name of up to 64 characters. This name should not be changed once the object class stereotypes are implemented.

Changing the technical name after objects have been created based on the object class stereotype requires such objects to be updated by means of an ADIF scheme. For more information, see the reference manual *Alfabet Data Integration Framework*.

- `Caption`: Enter the caption for the object class stereotype. This is the name that users will see in the Alfabet user interface.

  Please note that the following:

  - The caption of the object class stereotype should be different than the caption of its object class. This is particularly important for the implementation of the search functionality for the object class stereotype. For more information, see the section Configuring Class Settings for Object Classes and Object Class Stereotypes in the chapter Configuring User Profiles for the User Community.
  - The values defined for the XML attribute `Caption` can be translated whereas the values defined for the XML attribute `Stereotype Name` cannot be translated. However, in the table of the **Simple Search** functionality as well as other search selectors, the values defined for the XML attribute `Stereotype Name` of the object class stereotype are displayed in the **Stereotypes** column. If the values defined for the XML attribute `Caption` should be displayed, a custom selector should be defined. For more information, see the section Configuring a Custom Selector for Search Functionalities.
  - If you want to enter a caption (`Caption`) or plural form for the caption (`CaptionPlural`) that contains special characters (for example, a greater then (>) or lesser then (<) symbol), you must replace the special characters with respective XML compliant code, for example:
    - > for >
    - < for <
    - " for "
    - [for [
    -] for]
  - The caption will be available in the vocabularies and can be translated to the secondary languages implemented in your enterprise.

- `Description`: Provide a brief description about the object class stereotype. The description will be displayed in the **Stereotype Selector** that opens when the user must select which stereotype a new object is to be based on. The description should help the user to understand which stereotype the new object should be based on. The description will be available in the vocabularies and can be translated to the secondary languages implemented in your enterprise.
- `CaptionPlural`: Enter a plural form for the caption. This is the name in plural that users will see in the Alfabet user interface.

- `IDPrefix`: Enter no more than 5 characters for the ID prefix used to generate the unique identification number for new objects based on the object stereotype. If the XML attribute `IDPrefix` is not specified, the ID prefix of the object class that the object class stereotype is based on will be used to generate the unique ID. Please note that the integer generated for the unique ID is based on the number of instances created for the object class that the object class stereotype is based on, and includes all instances of all object class stereotypes created for the object class.

  The prefix ID of existing objects based on an object class stereotype can be updated via the ADIF import scheme `SetStereotypeID` available in the `Alfabet Standard Jobs` folder. For more information, see the section *Predefined ADIF Schemes* in the reference manual *Configuring Alfabet with Alfabet Expand*.

- `Comments`: Enter text in order to provide information about the object class stereotype. This information is only for the purposes of configuration. It is not displayed in the Alfabet user interface.

- `HasMandates`: Enter "`true`" if the mandate capability should be available for the object class stereotype. Enter "`false`" if the mandate capability should not be available for the object class stereotype. If the XML attribute `HasMandates` is defined as "`false`" for an object class stereotype, objects based on the object class stereotype will be visible to users with any mandate implemented in your enterprise. For information about additional configuration requirements necessary to implement the mandate capability, see the section *Implementing the Mandate Capability for a Federated Architecture* in the chapter Configuring Access Permissions for Alfabet .

- `EnableStatutoryLanguage`: Set to `True` if the statutory language capability shall be available for the object class stereotype. The statutory language capability is available in order to address regulatory requirements that mandate that objects are captured in a specific language. When a user creates an object based on a relevant object class/object class stereotype, a statutory language selector will open in which the language can be selected. In the object editor that opens, the user can capture all attributes that support automated translation in the statutory language. If the XML attribute `EnableStatutoryLanguage` is not set, the object class stereotype will inherit the definition of the **Enable Statutory Language** attribute specified for the object class. Specifying a Statutory Language for the Enterprise

4) Click the **Save**  button to save your changes.

Configuring Mandates for the Project Management Capability

The mandate functionality is typically configured when the project stereotypes are created. However, the mandate assignment can be edited, as needed. The mandate capability can be activated or deactivated for the entire project planning capability as well as explicitly activated or deactivated for specific project stereotypes.

The mandate configuration may differ for the project stereotypes defined. Per default, the XML attribute `HasMandates` is defined as "`false`" for all project stereotypes. This means that the default setting is that projects based on a project stereotype will be visible to users with any mandate implemented in your enterprise. Therefore, if visibility should be controlled for the projects based on a project stereotype, you must explicitly define the mandate capability for each project stereotype.

For more information about the mandates capability as well as how to create mandates for your enterprise, see the section *Implementing the Mandate Capability for a Federated Architecture* in the chapter Configuring Access Permissions for Alfabet .

To configure the mandate capability for your project hierarchy:

1) Go to the **Meta-Model** tab and navigate to the protected class node for the object class `Project` in the **Class Model** explorer.
2) Click the object class `Project` in the explorer to open the attribute window.
3) Set the **Can Have Mandates** attribute to `True` if the mandate capability should be available for the project management capability as a whole. Select `False` if the mandate capability should not be available.
4) Next, you must explicitly define the mandates capability for each project stereotype. Click the **Browse** button available for the **Stereotypes** attribute to open the XML editor.
5) To implement the mandate capability for a project stereotype, the XML attribute `HasMandates` must be defined as "`true`". If you do not want to implement the mandate capability for a project stereotype, the XML attribute `HasMandates` must be defined as "`false`". If the XML attribute `HasMandates` is defined as "`false`" for a project stereotype, projects based on the stereotype will be visible to permissible users with any mandate implemented in your enterprise.
6) Close the XML definition of the **Stereotypes** attribute by clicking **OK** in the XML editor.
7) In the toolbar, click the **Save** button to save your changes.

Configuring the Attributes and Functionalities Available for a Project Stereotype

Once the project stereotypes have been created for the object class `Project`, you can enable the respective functionalities for project scenarios and project baselines and specify functionality for each project stereotype in the XML object ***ProjectManager***. You can define the project hierarchy as a linear hierarchy or as a branched tree structure that allows complex project structures and hierarchies of stereotypes to be captured. Each project stereotype may define multiple subordinate project stereotypes.

For example, if an enterprise supports Agile release trains, the following project structure could be configured:

- The project stereotype "Program" has the sub-projects "Project" and "Agile Release Train".
- The project stereotype "Project" has only the sub-project "Project Step".
- The project stereotype "Agile Release Train" has only the sub-project "Program Increment".

The order of the project stereotypes listed in the XML object ***ProjectManager*** determines the order of the levels in the project hierarchy. Each project stereotype begins with the XML element ***Stereotype***. The first level of project stereotypes in the XML object represents the most ascendant level in the hierarchy. To change the order of the project stereotypes, select the entire project stereotype and cut and paste it to the

correct position in the order. Be sure to include the syntactic constructs (< and />), otherwise you will see an error message at the bottom of the XML editor.

If more than one project stereotype can be defined as a subordinate project, the < **Sub-Projects** > page views (`PRJ_SubProjects`) in the user interface will display the captions of all possible project stereotypes that may be created as a subordinate project of the selected project that the user is working with. The project stereotypes will be separated by a slash (/). Likewise, if a user is creating a new sub-project, the captions of all permissible project stereotypes that may be created for the selected project will be displayed in the **Create...** option in the **New** menu. When a user creates a project, the stereotype selector will open if the new project may be based on more than one project stereotype. The user must select the relevant stereotype that the new project shall be based on and then the relevant **Project** editor will open. If only one project stereotype is permissible, the new project will automatically be based on the project stereotype and the relevant **Project** editor will open

Please note that the visibility of workspaces and page views was configured via the XML attributes `HasSolutions`, `HasAsIsArchitecture`, and `HasToBeArchitecture` in releases prior to Alfabet release 10.0. The visibility of workspaces and page views is now configured via the XML object ***ObjectViewCustomFilters*** and is explained in the section Making the Project Scenarios Capability Available. If you require further explanation about the XML attributes `HasSolutions`, `HasAsIsArchitecture`, and `HasToBeArchitecture`, please see the reference manual *Configuring Alfabet with Alfabet Expand* published for Alfabet release 9.12.

To edit the XML object ***ProjectManager***:

1) Go to the **Presentations** tab, expand the **XML Objects** folder, and expand the **SolutionManagers** folder.
2) Right-click the XML object ***ProjectManager*** and select **Edit XML**. The XML editor is displayed in the center pane. For general information about editing XML objects in Alfabet Expand, see the section Working with XML Objects.
3) Specify the following XML elements below the root node ***ProjectManager***:
   - `ProjectClassName`: Displays the object class name `Project`. This value should not be changed.
   - `Solutions`: Enter "`true`" to implement the project solutions capability. Please note that it is highly recommended that you work with project scenarios rather than project solutions when planning and implementing alternative scenarios for your projects. Project scenarios are an extension of the project solutions concept but provide much more flexibility and functionality in the planning and implementation of what-if scenarios. For more information, see the section Making the Project Scenarios Capability Available.

     If the XML attribute `Solutions` is set to "`true`", then the XML attribute `Scenarios` should be set to "`false`".

   - `Scenarios`: Enter "`true`" to implement the project scenarios capability. Project scenarios allow multiple what-if scenarios to be explored, planned, and potentially implemented for the to-be architecture, project budgeting and cost calculation, project evaluations, high-level resource planning, and project scheduling. For more information about the functionality and configuration of project scenarios, see the section Making the Project Scenarios Capability Available.

If the XML attribute `Scenarios` is set to "`true`", then the XML attribute `Solutions` should be set to "`false`".

- `Baselines`: Enter "`true`" to implement the project baselines capability. Project baselines capture the scope of the base project at the time that the project baseline is created and allows the deviation of the current project from its original scope to be measured in terms of the total project costs and income, resource costs, project evaluations, scheduling and achievement of project milestones, and the changes to the to-be architecture. For more information about the functionality and configuration of project scenarios, see the section Making the Project Scenarios Capability Available.

- `ConflictStatuses`: Specify the release statuses configured for the project stereotypes specified in the XML object ***ReleaseStatusDefs*** that may be displayed in the **Project Release Status** filter in the **Check-In To-Be Architecture** page view. If no release statuses are specified here, then all release statuses available for all project stereotypes specified in the XML object ***ReleaseStatusDefs*** will be displayed. For more information about configuring release statuses for the project stereotypes, see the section Configuring Release Status Definitions for Projects.

  The **Project Release Status** filter allows users to select one or more release statuses to specify that only projects with the selected release status(es) will be checked for possible conflicts before the to-be architecture is checked in to the inventory. Defining this filter improves performance by reducing the potentially excessive number of projects that are scanned for conflicts prior to check-in.

- `WorkdayHours`: Enter a number that specifies the number of hours that constitute one workday. The default is 8. This definition allows the hours specified as time-track entries in the *My Tasks and Time Reporting Functionality* to be computed as days in relevant project planning views.

4) Create an XML element ***Stereotype*** for each top-level node of the tree structure.

- `ProjectClassName`: Displays the object class name `Project`. This value should not be changed.

- `Name`: Enter the technical name of the object class stereotype defined for the object class `Project`. This is the name defined in the XML attribute `Name` specified in the **Stereotypes** attribute for the object class `Project`. The stereotype name is passed on to the objects that users create for the selected project stereotype.

  You must spell the technical name of the project stereotype exactly as it is spelled in the **Stereotypes** attribute of the object class `Project`.

- `RDS_Expand`: Enter "`true`" to display the expand/collapse functionality in the dataset in the **Capture Projects** functionality (`PRJ_CaptureProjects`). Enter "`false`" to hide the expand/collapse functionality in the dataset. This will allow users to see only the current project stereotype selected in the **Project Type** filter in the **Capture Projects** functionality.

- `RightsPath`: Enter "`Parent`" if a project stereotype is to inherit the access permissions of its ascendant project stereotype. If the project stereotype should not inherit access permissions from another project stereotype, leave the `RightsPath` attribute undefined.

- `HasMonitoring`: Enter "`true`" if milestones should be created and tracked for objects of this project stereotype. In this case, the **Create Milestones** functionality will be available in the

Project Milestones Page View (`PRJ_Milestones`) for the relevant project stereotype and the **Milestone** editor will be available in the *Project, Skill Request and Resource Request Time Schedule Page View* (`PRJ_TimeSchedule`) in Alfabet. Enter "`false`" if milestones should not be created and tracked for the project stereotype.

Milestone templates must be configured in order to track milestones in the project management capability. For more information, see the section Configuring Milestone Templates to Track Projects.

- `HasCostCenters`: Enter "`true`" if cost centers may be defined for projects of this project stereotype. The costs center allows costs to be defined and then allocated to projects for budgeting purposes. In this case, the *Cost Centers Page View* (`PRJ_CostCenters`) available in the **Finance** workspace will be displayed for the relevant project stereotype. Enter "`false`" if cost centers should not be implemented for the project stereotype.
- `DefaultForDemand`: Enter "`true`" if this project stereotype is the default project stereotype for the creation of a new project for a selected demand. If this attribute is set to "`true`", the *Input Demands Page View* (`PRJ_InputDemands`) available in the **Project Alignment** workspace will be displayed for the relevant project stereotype. Additionally, projects based on this stereotype can be created for or added to a demand in the **Demand Management** functionality (`DEM_Management`) or the demand's object profile. Enter "`false`" if projects based on this project stereotype may not be created for demands.

  Only one project stereotype should be mapped to demands. If this attribute is set to "`true`" for more than one project stereotype, the user will only be able to create/add a project of the first project stereotype in the **Demand Management** functionality (`DEM_Management`) or demand's object profile.

- `IsDefault`: Enter "`true`" if the project stereotype is the default project stereotype to display in the **Capture Projects** functionalities. The default project stereotype will be automatically selected when the **Capture Projects** functionalities are opened for the first time.
- `ArchitectureClasses`: Enter a comma-separated list of object classes and objects class stereotypes that may be added as affected architecture for the project stereotype. A menu entry with the caption **Add <Object Class>** or **Add <Object Class Stereotype>** will be added to the *Affected Architecture Page View*. If you are defining an object class stereotype in the XML attribute `ArchitectureClasses`, you must use the syntax ObjectClass:ObjectClassStereotype. If you are defining an object class stereotype in the XML attribute `ArchtectureClasses`, you must use the syntax ObjectClass:ObjectClassStereotype. If the XML attribute `ArchitectureClasses` is not defined, the standard object classes preconfigured by Software AG will be displayed.

5) For each subordinate project stereotype, create an XML element ***Stereotype*** as a child element of the parent XML element ***Stereotype*** and define the XML attributes described in the previous step. Continue creating XML elements to structure the project hierarchy. You can define the project hierarchy as a linear hierarchy or as a complex branched tree structure.

   Each project stereotype must only be specified once in the XML object ***ProjectManager***. If a project stereotype is specified more than once, only the first occurrence will be used and any subsequent occurrences will be ignored. If project refinements in different hierarchies require the same terminology, different project stereotypes must be created in the **Stereotype** property of the class `Project`. The XML attribute `Caption` of the stereotypes may be the same for different stereotypes and in this way you can address your

enterprise's terminology requirements. For more information about specifying project stereotypes, see the section Creating Project Stereotypes for the Project Hierarchy.

6) In the toolbar, click the **Save**  button to save the XML definition.

Making the Project Baselines Capability Available

You may enable the project baselining capability for one or more project stereotypes. A project baseline captures the scope of its base project at the time that the project baseline is created and allows the deviation of the base project from its original scope to be tracked over time in terms of the total project costs and income, resource costs, project evaluations, scheduling and achievement of project milestones, and the changes to the to-be architecture. When a project baseline is created, it is created as an independent project where the attribute **Type** = `Baseline`. Multiple project baselines may be created at different points in time for the selected project. The project baseline is for documentation purposes and cannot be modified in any way.

The project baseline is a deep copy of the project that it is based on and will inherit the project stereotype of the project as well as the following:

- Subordinate projects
- Evaluations and milestones
- Business case including planned and budgeted costs, bucket allocation, cashout plan, and cost center allocation
- As-is architecture and to-be architecture definition
- Solution maps and application diagrams
- High-level resource plan. This includes the general definition of skill requests and resource requests but not the granular project resource plan that includes the detailed planning and scheduling of tasks.
- Value nodes
- Documents and web links

Users will be able to navigate to a ReadOnly version of the object view for the project baseline in order to view the details of the original scope of the project. The object view available for a project baseline will be the same custom object view including object cockpits available for the project stereotype that the project baseline is based on, except that the custom object view for the project baseline will consist of a preconfigured subset of workspaces that are relevant for project baselines. The standard subset of available views can be further configured so that specified workspaces, page views, configured reports, and object cockpits may be hidden in the context of the project baseline. An overview of the standard set of workspaces and page views that are displayed per default for the project baseline is available in the section *Standard Workspaces and Views Available for Project Baselines* in the reference manual *Configuring Alfabet with Alfabet Expand - Appendix*.

The following is required to configure the availability of the project baselines capability:

- Enable the project baselines capability in the XML object ***ProjectManager***.

- If necessary, configure visibility of available workspaces, page views, configured reports, or object cockpits in the XML object ***ObjectViewCustomFilters***.
- Ensure that no class keys to implement uniqueness constraints have been defined for the object class `Project`. For more information about the definition of class keys, see the section Configuring Class Keys for Object Classes.

To implement the project baselines capability, specify "`true`" for the XML element `Baselines` in the XML object ***ProjectManager***.

```
<ProjectManager ProjectClassName="Project" Solutions="false"
Scenarios="true"Baselines="true" >
...
</ProjectManager>
```

You may decide that some of the object cockpits and configured reports as well as the workspaces and page views should not be displayed in the context of the project baseline. In this case, you can specify which workspaces, page views, configured reports, and object cockpits should be hidden in the custom objects views configured for a specified project stereotype.

The XML object ***ObjectViewCustomFilters*** allows you to explicitly specify which workspaces, page views, configured reports, or object cockpits should be hidden from the custom object views defined for a specified project stereotype. Please note that the XML object ***ObjectViewCustomFilters*** is a blacklist that allows you to specify the content that shall **not** be available when users access custom object views for the specified project stereotype.

To edit the XML object ***ObjectViewCustomFilters***:

1) Go to the **Presentations** tab, expand the **XML Objects** folder, and expand the **SolutionManagers** folder.
2) Right-click the XML object ***ObjectViewCustomFilters*** and select **Edit XML**. The XML editor is displayed in the center pane. For general information about editing XML objects in Alfabet Expand, see the section Working with XML Objects.
3) In the XML attribute ***ObjectViewFilter***, specify the following XML attributes for each object class stereotype relevant for the project baseline configuration:

For example, to hide an object cockpit displaying cost information:

```
<ObjectViewFilter ClassName="Project" Stereotype="Project"
Property="Type" Value="Baseline" >
<Item Type="Cockpit"
Name="PRJ_ObjectView_Project_PS_Financials" />
</ObjectViewFilter>
```

- `ClassName`: Enter "`Project`"
- `Stereotype`: Enter the name of the project stereotype that the project is based on.
- `Property`: Enter "`Type`"
- `Value`: Enter "`Baseline`"

4) Add a child XML element ***Item*** for each workspace, page view, configured report, or object cockpit that should be hidden for the specified project stereotype:

   - `Type`: Enter any of the following:
     - "`WS`" to specify a workspace that should be hidden.
     - "`View`" to specify a page view or configured report that should be hidden.
     - "`Cockpit`" to specify an object cockpit that should be hidden.
   - `Name`: Enter the technical name of the relevant workspace, page view, configured report, or object cockpit that should be hidden.

5) In the toolbar, click the **Save** button to save the XML definition.

Making the Project Scenarios Capability Available

In the XML object ***ProjectManager***, you can specify whether project scenarios should be implemented to capture what-if scenarios for projects. Project scenarios are an alternative to the project solution concept and it is highly recommended that you work with project scenarios rather than project solutions when planning and implementing alternative scenarios for your projects. Project scenarios allow multiple alternative what-if scenarios to be explored, planned, and potentially implemented for the to-be architecture, project budgeting and cost calculation, project evaluations, resource planning, and project scheduling. Project scenarios are an extension of the project solutions concept but provide much more flexibility and functionality in the planning and implementation of what-if scenarios. A project scenario is an independent copy of the project that it is based on.

Unlike a project solution, which is created from scratch, a project scenario copies relevant attributes, custom properties, and other definitions from the base project to the project scenario. Furthermore, unlike the check-in process of a project solution whereby the project solution irrevocably replaces the base project upon the final check-in, the project scenario concept allows the project scenario to be merged to the base project so that only relevant aspects are updated. In this case, objects in the to-be architecture, evaluations, costs, high-level resources of the project scenario that have been added, removed, or modified are updated to the base project but the rest of the base project is not changed or replaced. The project scenario as well as the base project continue to exist and both can be further modified, if needed. The project scenario can be merged multiple times.

Please note that merging a project scenario with its base project can be done at any time by anyone in with access permissions to the project scenario. If the merge action should be governed in any way, then it is recommended that you configure a workflow that ensures some type of an approval process before the merge can be executed. For more information about configuring a workflow, see the chapter Configuring Workflows.

When a project scenario is created, it is created as an independent project where the attribute **Type** = `Scenario`. The project scenario is a deep copy of the project that it is based on and will inherit the project stereotype of the project as well as the following:

- Authorized user and user groups, mandates, roles, and providing organization
- Evaluations and milestones
- Business case including planned and budgeted costs, bucket allocation, and cashout plan

- As-is architecture and to-be architecture definitions. Please note the following:
  - Only solution objects in the base project that do not have a corresponding inventory object with an **Active** object state will be added to the to-be architecture of the project scenario when it is created. If a solution object in the base project has a corresponding inventory object with the object state **Active** set, the inventory object will be added to the as-is architecture of the project scenario.
  - The project scenario cannot be merged if the to-be architecture has been checked in for the base project. If your enterprise is planning projects via project scenarios, the to-be architecture should be planned in the context of the project scenario rather than the base project. When the project scenario is merged to the base project, the to-be architecture will be updated and the solution objects will be added to the inventory.
  - For more information about additional configuration required for the to-be architecture, see the section Making the As-Is Architecture and To-Be Architecture Capabilities Available.
- Solution maps and application diagrams
- High-level resource plan. This includes the general definition of skill requests and resource requests but not the granular project resource plan tasks are planned and scheduled in detail.
- Migrations
- Input demands
- Contract deliverables
- Value nodes
- Documents and web links

Users will be able to navigate to a ReadWrite version of the object view for the project scenario in order to define the details of the project scenario. The object view available for a project scenario will be the same custom object view including object cockpits available for the project stereotype that the project scenario is based on, except that the custom object view for the project scenario will include only a subset of the workspaces. An overview of the standard set of workspaces and page views that are displayed per default for the project scenario is available in the section *Standard Workspaces and Views Available for Project Scenarios* in the reference manual *Configuring Alfabet with Alfabet Expand - Appendix*.

The following is required to configure the availability of the project scenarios capability:

- Enable the project scenarios capability in the XML object ***ProjectManager***.
- If necessary, configure visibility of available workspaces, page views, configured reports, or object cockpits in the XML object ***ObjectViewCustomFilters***.
- Ensure that no class keys to implement uniqueness constraints have been defined for the object class `Project`. For more information about the definition of class keys, see the section Configuring Class Keys for Object Classes.

To implement the project scenarios capability, specify "`true`" for the XML element `Scenarios` in the XML object ***ProjectManager***.

```
<ProjectManager ProjectClassName="Project"
Solutions="false"Scenarios="true"Baselines="true">

...

</ProjectManager>
```

Or, to implement the project solutions capability, specify "`true`" for the XML element `Solutions` in the XML object ***ProjectManager***. Please note that it is highly recommended that you work with project scenarios rather than project solutions when planning and implementing alternative scenarios for your projects. Project scenarios are an extension of the project solutions concept but provide much more flexibility and functionality in the planning and implementation of what-if scenarios.

Please note the following regarding the configuration of the XML object ***ProjectManager***:

- Your enterprise may not simultaneously enable project scenarios and project solutions. If both the XML attribute `Scenarios` and the XML attribute `Solutions` are set to "`true`", the system will automatically set the XML attribute `Scenarios` to "`false`".
- The visibility of workspaces and page views for project solutions was configured via the XML attribute `HasSolution` in releases prior to Alfabet 10.0. If the XML element `Solutions` is set to "`false`" and the XML attribute `HasSolutions` is set to "`true`", the XML element `Solutions` = "`false`" will have precedence. Furthermore, if the XML attributes `HasSolutions` is set to "`true`" in the XML object ***ProjectManager*** and the solution designer then configures to hide the workspace `PRJ_SolutionAssesstment` via the XML object ***ObjectViewCustomFilters***, then the XML object ***ObjectViewCustomFilters*** definition will take precedence and the workspace will not be available for the relevant project stereotypes.

You may decide that some of the object cockpits and configured reports as well as the workspaces and page views should not be displayed in the context of the project scenario. In this case, you can specify which workspaces, page views, configured reports, and object cockpits should be hidden in the custom objects views configured for a specified project stereotype.

The XML object ***ObjectViewCustomFilters*** allows you to explicitly specify which workspaces, page views, configured reports, or object cockpits should be hidden from the custom object views defined for a specified project stereotype. Please note that the XML object ***ObjectViewCustomFilters*** is a blacklist that allows you to specify the content that shall **not** be available when users access custom object views for the specified project stereotype.

To edit the XML object ***ObjectViewCustomFilters***:

1) Go to the **Presentations** tab, expand the **XML Objects** folder, and expand the **SolutionManagers** folder.
2) Right-click the XML object ***ObjectViewCustomFilters*** and select **Edit XML**. The XML editor is displayed in the center pane. For general information about editing XML objects in Alfabet Expand, see the section Working with XML Objects.
3) In the XML attribute ***ObjectViewFilter***, specify the following XML attributes for each object class stereotype relevant for the project scenario configuration:

For example, to hide an object cockpit displaying cost information:

```
<ObjectViewFilter ClassName="Project" Stereotype="Project"
Property="Type" Value="Scenario" >

<Item Type="Cockpit"
Name="PRJ_ObjectView_Project_PS_Financials" />

</ObjectViewFilter>
```

- `ClassName`: Enter `"Project"`
- `Stereotype`: Enter the name of the project stereotype that the project is based on.
- `Property`: Enter `"Type"`
- `Value`: Enter `"Scenario"`

4) Add a child XML element ***Item*** for each workspace, page view, configured report, or object cockpit that should be hidden for the specified project stereotype:
   - `Type`: Enter any of the following:
     - `"WS"` to specify a workspace that should be hidden.
     - `"View"` to specify a page view or configured report that should be hidden.
     - `"Cockpit"` to specify an object cockpit that should be hidden.
   - `Name`: Enter the technical name of the relevant workspace, page view, configured report, or object cockpit that should be hidden.

5) In the toolbar, click the **Save**  button to save the XML definition.

Making the As-Is Architecture and To-Be Architecture Capabilities Available

When creating project stereotypes, you should consider for which project stereotypes the as-is architecture definition and to-be architecture definition functionalities should be available.

The as-is architecture comprises all architecture elements that are actively used as well as architecture elements that are planned to be used in the future. The as-is architecture serves as the baseline for the process of planning and proposing new architecture elements for the IT landscape. In the context of a project, the as-is architecture defines the scope of the IT environment that the project addresses. This is typically the set of architecture elements that is the subject of the change or that may be affected by the changes proposed.

The to-be architecture allows the user to plan and update the existing as-is architecture by planning new objects, updating existing objects, and retiring objects. A project's to-be architecture may include inventory objects from the as-is architecture that may be affected by the proposed architectural changes as well as new solutions objects such as solution applications, solution information flows, and solution business supports created in the context of the to-be architecture. The solution objects are considered to be "shadow" objects — copies of the base applications, information flows, etc. that they were derived from. Solution objects may be modified within the context of the to-be architecture without affecting the inventory objects they are based on. Any architectural changes defined in the context of the proposed to-be architecture can be checked in to the inventory. All architecture elements added to the inventory via the proposed to-be architecture will have an object state indicating that the object is planned. The object state

must be manually changed to an active object state when operational use of the to-be architecture element begins, which is typically upon completion of the project's implementation.

Architecture elements assigned to the as-is architecture or to-be architecture will not be inherited from one project stereotype to the next in Alfabet. Architecture elements must be manually assigned to a relevant object for each level in the project hierarchy.

The following information is available:

- Configuring the As-Is Architecture Capability
- Configuring the To-Be Architecture Capability

Configuring the As-Is Architecture Capability

The as-is architecture includes the IT architecture elements such applications, components, etc. that are impacted in some way by the project. Objects belonging to any of the following classes can be defined as architecture elements that are affected by a project: `Application`, `BusinessData`, `BusinessFunction`, `BusinessObject`, `BusinessProcess`, `Component`, `CustomerSegment`, `Device`, `Domain`, `ICTObject`, `InformationFlow`, `MarketProduct`, `MasterPlatform`, `OrgaUnit`, `Peripheral`, `SalesChannel`, `SystemBuildingBlock`, `StandardPlatform` and, `VendorProduct`. In order to make these object classes available for assignment to the as-is architecture, you must ensure that the exclusion of an object class via a class setting definition does not pose a conflict.

All project management functionalities in Alfabet are available by default for each project stereotype. However, you can refine the availability of these functionalities by adding or removing them from the relevant custom object views defined for a specific project stereotype In order for users to configure and analyze the as-is architecture, the **As-Is Architecture Definition** (`PRJ_AsIsArchitecture`) and **Affected Architecture Analysis** (`PRJ_AffectedArchitectureAnalysis`) workspaces should be available for the relevant project stereotype. For an overview of the standard views available for each workspace, see the section *Standard Workspaces and Views Available for Projects* in the reference manual *Configuring Alfabet with Alfabet Expand - Appendix*.

Please note that the availability of the as-is architecture definition capability was configured via the XML attribute `HasAsIsArchitecture` in releases prior to Alfabet release 10.0. If the XML attributes `HasAsIsArchitecture` is set to "`true`" in the XML object ***ProjectManager*** and the solution designer then configures to hide the workspaces `PRJ_AsIsArchitecture` and `PRJ_AffectedArchitectureAnalysis` via the XML object ***ObjectViewCustomFilters***, then the XML object ***ObjectViewCustomFilters*** definition will have precedence and the workspaces will not be available for the relevant project stereotypes. If you require further explanation about the XML attribute `HasAsIsArchitecture`, please see the reference manual *Configuring Alfabet with Alfabet Expand* published for Alfabet release 9.12.

Configuring the To-Be Architecture Capability

When planning the to-be architecture, users work with solution objects, which are copies of inventory objects that exist only in the context of the to-be architecture and are not visible in the inventory. In the context of the to-be architecture, users can manipulate these objects without making any actual changes to the inventory. Solution objects can be created for the following object classes: `SolutionApplication`, `SolutionBusinessData`, `SolutionBusinessService`, `SolutionBusinessSupport`, `SolutionComponent`, `SolutionDevice`,`SolutionFunctionalModule`, `SolutionInformationFlow`,

SolutionLocalComponent, SolutionPlatform, SolutionPlatformElement, SolutionPlatformInformationFlow, SolutionService, SolutionServiceOperation, and SolutionStandardPlatform.

Once all architectural conflicts have been resolved for the proposed to-be architecture, the changes to the to-be architecture can be checked in to the inventory. At this point, all new objects created in the context of the to-be architecture will be added to the inventory, objects that have been modified in the context of the to-be architecture will overwrite their corresponding inventory objects, and the object states of inventory objects that have been retired in the to-be architecture will be set to retired.

Please note the following configuration requirements in order to work with solution objects:

- If object class stereotypes are configured for an object class that can be defined in the *To-Be Architecture Page View* (such as Application, Component, Device, or StandardPlatform) then you must create an identical configuration for the corresponding solution object class (for example, for SolutionApplication or SolutionComponent, SolutionDevice, or SolutionStandardPlatform). For example, the configuration defined in the **Stereotypes** attribute for the object class Application should be copied and pasted to the **Stereotypes** attribute for the object class SolutionApplication. If the configuration is not the same, errors may occur when solution objects are checked in to the Alfabet inventory in the context of project and solution planning. For more information about configuring object class stereotypes, see the section Configuring Object Class Stereotypes for Object Classes in the chapter Configuring the Class Model.

- Users must be able to add any inventory objects that are either to be modified, retired, or used as a basis for new solution objects to the architectural scope of the relevant project. (Objects belonging to any of the following classes can be defined as architecture elements that are affected by a project: Application, BusinessData, BusinessFunction, BusinessObject, BusinessProcess, Component, CustomerSegment, Device, Domain, ICTObject, InformationFlow, MarketProduct, MasterPlatform, OrgaUnit, Peripheral, SalesChannel, SystemBuildingBlock, StandardPlatform and, VendorProduct.)

- All project management functionalities in Alfabet are available by default for each project stereotype. However, you can refine the availability of these functionalities by adding or removing them from the relevant custom object views defined for a specific project stereotype In order for users to configure and analyze the as-is architecture, the **As-Is Architecture Definition** (PRJ_AsIsArchitecture) and **Affected Architecture Analysis** (PRJ_AffectedArchitectureAnalysis) workspaces should be available for the relevant project stereotype. Additionally the PRJ_ToBeArchitecture and PRJ_ToBeArchitectureAnalysis workspaces must be available for the relevant project stereotype. For an overview of the standard views available for each workspace, see the section *Standard Workspaces and Views Available for Projects* in the reference manual *Configuring Alfabet with Alfabet Expand - Appendix*.

- You should specify the release statuses configured for the project stereotypes specified in the XML object ***ReleaseStatusDefs*** that may be displayed in the **Project Release Status** filter in the **Check-In To-Be Architecture** page view. If no release statuses are specified here, then all release statuses available for all project stereotypes specified in the XML object ***ReleaseStatusDefs*** will be displayed. The **Project Release Status** filter allows users to select one or more release statuses to specify that only project's with the selected release status(es) will be checked for possible conflicts before the to-be architecture is checked in to the inventory. Defining this filter improves performance by reducing the potentially excessive number of projects that are scanned for conflicts prior to check-in.

Please note that the availability of the to-be architecture definition capability was configured via the XML attribute HasToBeArchitecture in releases prior to Alfabet release 10.0. If the XML attributes HasToBeArchitecture is set to "true" in the XML object ***ProjectManager*** and the

solution designer then configures to hide the workspaces `PRJ_ToBeArchitecture` and `PRJ_ToBeArchitectureAnalysis` via the XML object ***ObjectViewCustomFilters***, then the XML object ***ObjectViewCustomFilters*** definition will take precedent and the workspaces will not be available for the relevant project stereotypes. If you require further explanation about the XML attribute `HasToBeArchitecture`, please see the reference manual *Configuring Alfabet with Alfabet Expand* published for Alfabet release 9.12.

Making Skill Capacity Planning Available

In order to implement the **Assign Capacity** option in the **Project Resource Planning** page view of a project as well as the **Skill Capacity Planning** page view of an organization or organization group, a custom wizard must be configured with the **Assign Capacity** `(SKLR_AssignedCapacity)` page view embedded in the wizard. The custom wizard must be assigned to the class setting for the class `SkillRequest` to be implemented in the views.

For more information about configuring custom wizards, see Configuring Wizards.

Configuring Release Status Definitions for Projects

The release status definition for project stereotypes is specified in the XML object ***ReleaseStatusDefs*** in Alfabet Expand.

A release status definition must be created for the object class `Project` and for each object class stereotype created for the object class `Project`. The release status definition for the object class `Project` must include the complete set of release statuses implemented in the project management functionalities. These must be specified in the XML attribute `StatusSet` in the release status definition for the object class `Project`. Furthermore, an element `Project:<ProjectStereotype>` should be defined in the XML object ***ReleaseStatusDefs*** for each project stereotype in your enterprise's project framework.

Please note the following regarding the release status definition for projects:

- **Multiple release status set definitions should not be defined for the project management functionalities.** You should conceptualize one release status set that includes all possible release statuses for all project stereotypes. The release statuses in the XML attribute `StatusSet` can be configured as needed for each project stereotype specified in the XML attribute `ClassNames`. Release statuses that are irrelevant for a given project stereotype may be excluded in the XML attribute `StatusSet` of that stereotype.

  For example, the XML attribute `StatusSet`of the overall project is conceptualized to include the release statuses: `New, Discarded, Described, InReview, ReviewFailed, Reviewed, Planned, Closed, Discarded`.

  - For the object class Project, the following is specified: `StatusSet = "New,Discarded,Described,InReview,ReviewFailed,Reviewed,Planned,Closed,Discarded"`
  - For the object class Project:Program, the following is specified: `StatusSet = "New,Discarded,Described,Reviewed,Planned,Closed"`

- For the object class Project:Project, the following is specified:
  `StatusSet = "New,Described,InReview,ReviewFailed,Reviewed,Planned,Closed,Discarded"`
- For the object class Project:ProjectStep, the following is specified:
  `StatusSet = "New,Described,Planned,Closed,Discarded"`

- It is recommended that the release status values `Draft` and `Closed` are not included in the XML attribute `RetiredStatusSet`. The status `Draft` typically indicates a new request for a project and the status `Closed` typically indicates that a project is completed. When configuring the retired release status definition for projects, it is recommended that the statuses `Discarded` or `Archived` are implemented in the `RetiredStatusSet`.
- Each project stereotype requires a release status to indicate that the project is approved. This is configured in the XML attribute `ApprovedStatus`. For more information about defining an approval workflow for projects, see the section Configuring the Release Status for Objects Requiring Approval.
- For general information about how to configure release statuses in the XML object ***ReleaseStatusDefs***, see the section Configuring the XML Object ReleaseStatusDefs.

Configuring Cost and Budgeting Data for Projects

Default values for business cases including the period, tax rate, and cost of capital as well as the cost definition types for project cost assessment and reporting must be configured in the XML object ***CostManagerDef*** in the configuration tool Alfabet Expand. The configuration applies to all project stereotypes configured for the project planning capability. The following cost views are relevant for projects:

- *Cost Report Page View*
- *Cost Accrual Page View*
- *Business Case Page View*
- *Business Case Comparison Page View*
- *Project, Skill Request and Resource Request Time Schedule Page View*
- *Cash Out Planning Page View*

Please note that the `Obligation` cost definition is a core concept for cash-out planning in projects. Therefore, the configuration of the cost definition `Obligation` is not relevant for the cash-out planning capability. In other words, if you specify that the `Obligation` cost definition should not be visible in the XML object ***CostManagerDef***, it will nevertheless be visible in the *Cash Out Planning Page View*.

For more information about configuring the default values for business cases as well as the cost definition types for project cost assessment and reporting, see the section Configuring Cost Management Capabilities.

All cost types and income types relevant for cost planning and analysis must be defined for the object class `Project` in the **Reference Data** functionality in the **Configuration** module. For more information, see

Configuring Cost Types and Income Types for Cost Management Capabilities in the reference manual *Configuring Evaluation and Reference Data in Alfabet*.

Configuring Milestone Templates to Track Projects

In Alfabet, users can create milestones in order to track and manage projects. The XML object ***MilestoneManager*** allows you to configure milestone templates that users can select when defining milestones for a project.

Please note that enterprise milestones are also configured in the XML object ***MilestoneManager***. There is no need to use a similar or identical set of milestones for enterprise releases and projects. However, it is recommended that the two milestone concepts are aligned with one another. For more information about configuring enterprise milestones, see the section Configuring Milestone Templates to Track Enterprise Releases.

Milestone templates are defined according to the project methodology pursued by the enterprise in order to assess the stage gates or milestones of the project methodology or enterprise release cycle.

A milestone template bundles a set of milestones including the definition of the color scheme used for tracking and reporting milestones and the sequence and tolerance period for each milestone. The color of the milestone serves as an indicator providing information about the difference between the original planned date of the milestone and the current target date. Users may either assign a configured milestone template directly to a project or enterprise release or, in the case of projects, they may select a configured project template and assign it to the project.

Projected target dates are automatically set for each milestone based on the configuration defined in the milestone template, but these dates may be manually edited for each milestone. Alfabet users may delete any milestone from a project or enterprise release that they deem unnecessary. Only one milestone template may be assigned to a project or enterprise release. The realization of milestones can be tracked for the enterprise release or, in the case of project milestones, on the level of the project, project group, or bucket.

In order to track projects in a consistent manner, it is recommended that all project stereotypes in a project hierarchy are assigned the same milestone template. Milestone templates are assigned to a project in Alfabet via the *Project Milestones Page View* (`PRJ_Milestones`) of the relevant project and can be tracked in the *Project Tracking Overview Report Page View* (`PRJ_TimeScheduleReport`).

The captions and descriptions configured in the XML object ***MilestoneManager*** will be available in the vocabularies and can be translated. For more information about translating terms for the Alfabet interface, see the section Modifying, Translating and Managing the Vocabularies in the chapter Localization and Multi-Language Support for the Alfabet Interface.

To edit the XML object ***MilestoneManager***:

1) Go to the **Presentation** tab and expand the **XML Objects** folder by clicking the + symbol. You will see all XML objects that can be edited.
2) Right-click the XML object ***MilestoneManager*** and select **Edit XML**. The XML editor is displayed in the center pane. For general information about editing XML objects in Alfabet Expand, see Working with XML Objects.
3) The table below displays the XML attributes that can be edited for the XML object ***MilestoneManager***:

XML Element (bold) / XML Attribute	Explanation
MilestoneTemplate	The milestone template bundles a set of milestones. The XML element ***MilestoneTemplate*** contains the XML attributes that allow you to configure the name, caption, type of duration (date or percentage of completion) that the milestone measures, and a description of the milestone template. You can configure multiple ***MilestoneTemplate*** elements.
`Name`	Enter text to define the name of the milestone template. This is the name that users will see in the Alfabet interface. The name may not exceed 16 characters.
`DurationType`	The completion of milestones can be configured to represent either the number of days or the percentage of the completed milestone: • Enter "`Days`" if the milestone dates should be computed based on the number of days defined in the XML attribute `Duration` in the XML element ***MilestoneDef***. The milestone dates are computed based on the value specified in the XML attribute `Duration` plus the date of the previous milestone. • Enter "`Percents`" if the milestone dates should be computed based on the percentages of number of days completed as defined in the XML attribute `Duration` in the XML element ***MilestoneDef***. The dates are computed based on the project's start and end date and the percentage specified in the XML attribute `Duration`. The computed milestone dates will be displayed in the *Project Milestones Page View* (`PRJ_Milestones`), where they can be modified if necessary.
`Caption`	Enter text to define the caption of the milestone template. The caption serves as explanatory text about the milestone template when it is selected in the **Select Milestone Template** field in the **Create Milestones** editor available in the *Project Milestones Page View* (`PRJ_Milestones`).
`Description`	Enter text to define a description about the milestone template. The description is displayed in the **Create Milestones** editor available in the *Project Milestones Page View* (`PRJ_Milestones`) and should help the user to understand the milestone template.
MilestoneColorDef	This element allows you to configure the information to display on the milestones to indicate the milestone status. Each XML element ***MilestoneColorDef*** includes, a caption, colors, the interval of time when the status color should be displayed. The color serves as an indicator for the difference between the original planned date of the milestone and the current target date. For example,

XML Element (bold) / XML Attribute	Explanation

	you could configure the following information for the milestone statuses `Completed`, `Normal`, `Warning`, and `Danger`:
	
	`...`
	
	`<MilestoneColorDef Caption="Completed" Completed="true" BackColor="LightGrey" ForeColor="Green" TextColor="Blue" />`
	
	`<MilestoneColorDef Caption="Normal" ToDays="0" BackColor="Green" ForeColor="Black" TextColor="Blue" />`
	
	`<MilestoneColorDef Caption="Warning" FromDays="0" ToDays="9" BackColor="Yellow" ForeColor="Green" TextColor="Blue" />`
	
	`<MilestoneColorDef Caption="Danger" FromDays="10" BackColor="Red" ForeColor="Green" TextColor="Blue" />`
	
	`...`
	
	In this example definition, the following would occur:
	
	• A milestone that is marked as `Completed` in the **Milestone** editor will be colored light grey.
	• If there is no difference (0 days) between the original target date and the current target date, the milestone will be colored green.
	• If there is a difference of 0-9 days between the original target date and the current target date, the milestone will be colored yellow.
	• If there is a difference of 10 or more days between the original target date and the current target date, the milestone will be colored red.
	
	A legend will be displayed in the *Project Tracking Overview Report Page View* (`PRJ_TimeScheduleReport`) describing the color scheme.

`Caption`	Enter text to define the caption that should be displayed to describe the milestone status in the legend in the *Project Tracking Overview Report Page View* (`PRJ_TimeScheduleReport`). For example, a milestone status could be "Normal" or "Warning", etc.
`Completed`	Enter "`true`" if the color set (defined in the attributes `BackColor`, `ForeColor`, and `TextColor`) should be displayed when a user checks the **Completed** field in the **Milestone** editor to indicate that the milestone has been completed. Enter "`false`" if the color set should not be displayed when the milestone has been completed. The attribute `Completed` should only be set to "`true`" for one

XML Element (bold) / XML Attribute	Explanation
	XML element ***MilestoneColorDef*** definition. In this case, the `FromDays` and `ToDays` attributes are not necessary.
`FromDays`	Enter an integer that defines the period for which the color set should be displayed. The period of validity is the interval between the initial date of the milestone plus the `FromDays` value and the initial date of the milestone plus the `ToDays` value.
`ToDays`	Enter an integer that defines the period for which the color set should be displayed. The period of validity is the interval between the initial date of the milestone plus the `FromDays` value and the initial date of the milestone plus the `ToDays` value.
`BackColor`	Enter text to define the color of the outline of the box representing the milestone in the *Project Tracking Overview Report Page View* (`PRJ_TimeScheduleReport`). The value entered should be a Windows, Web, hexadecimal, or RGB color value.
`ForeColor`	Enter text to define the color of the interior of the box representing the milestone in the *Project Tracking Overview Report Page View* (`PRJ_TimeScheduleReport`). The value entered should be a Windows, Web, hexadecimal, or RGB color value.
`TextColor`	Enter text to define the color of the short name text in the box representing the milestone in the *Project Tracking Overview Report Page View* (`PRJ_TimeScheduleReport`). The value entered should be a Windows, Web, hexadecimal, or RGB color value.
MilestoneDef	This element allows you to configure the milestones that are bundled in the milestone template. An XML element ***MilestoneDef*** should be created for each milestone. Whenever a user selects a milestone template for a project, the milestone dates will be initially computed based on the `DurationType` and the `Duration` definitions. The computed dates can be manually adjusted. The milestones will be added automatically to the project and a legend will be displayed in the *Project Tracking Overview Report Page View* (`PRJ_TimeScheduleReport`).
`Priority`	Enter an integer that defines the position of the milestone in the set of milestones. The position also determines the priority ranking for milestones that have the same value and must Therefore, be stacked in the *Project Milestones Page View* (`PRJ_Milestones`). For example, a value of 1 indicates that this milestone should be the first that must be completed and will be stacked on top if milestones have the same

XML Element (bold) / XML Attribute	Explanation
	value. (If the milestone template consists of 5 milestones, you should define an integer in the range 1-5 for each XML element ***MilestoneDef***.)
`Duration`	Enter an integer that defines the default period between milestones. The milestone dates will be automatically defined in Alfabet, but one or more can be manually changed by a user. If no integer is defined for the XML attribute `Duration`, then the default is the integer "`1`" (`Duration` = one day or 1%.) The duration you define will depend on the definition of the XML attribute `DurationType`. See the explanation of the XML attribute `DurationType` to understand how the duration values are computed. If a user manually changes a milestone date, the subsequent dates will NOT be automatically adjusted.
`Name`	Enter text to define the name of the milestone. The name of the milestone is not displayed in the Alfabet interface.
`Caption`	Enter text to define the caption of the milestone. The caption typically describes the milestone and will be displayed in the *Project Milestones Page View* (`PRJ_Milestones`) and the legend of the *Project Tracking Overview Report Page View* (`PRJ_TimeScheduleReport`). For example, if the milestones are based on the XML attribute `DurationType` = "`Percents`", then it would be informative to the user to define such captions describing the percentage of project completion (for example, `25% Completed`, `50% Completed`, etc.) If the milestones are based on the XML attribute `DurationType` = "`Days`", then it would be informative to define a caption that describes the phase of the project completed by the milestone (for example, "`Design Complete`" and "`Test Complete`")
`ShortName`	Enter text to define a short name for the milestone. The short name is displayed in the box representing the milestone in the *Project Tracking Overview Report Page View* (`PRJ_TimeScheduleReport`). The milestone's short name and caption will be displayed in the legend. **Standard Milestones - Abbreviation** D *Design Complete* B *Build Complete* T *Test Complete* For reasons of usability, a short name should only be 1 or 2 characters long. Thus, for a milestone `25% Completed`, it is recommended to implement a short name such as `25`. For milestones `Design Complete` and `Test Completed`, it is

XML Element (bold) / XML Attribute	Explanation
	recommended to implement a short name using initials such as `D` and `T`.
`Description`	Enter text that describes the milestone. This text will be displayed to the user in the milestone's object profile and preview in the *Project Milestones Page View* (`PRJ_Milestones`).

4) In the toolbar, click the **Save**  button to save the XML definition.

Configuring Class Settings for Project Stereotypes

If you want to define class settings for a project stereotype, you must manually add the project stereotypes configured by your enterprise to the **Class Settings** folder in the **Presentation** tab. To add a project stereotype to the **Class Settings** folder, navigate to and right-click the relevant class setting for the object class `Project` and select either:

- **New Class Settings as Copy** to create a class setting as copy for the selected class, or
- **New Class Settings for Stereotype as Copy** to create a class setting for a stereotype of the selected class. In the dialog that opens, select the project stereotype and click **OK**. You must use this function if there are no class settings already defined for the new stereotype.

The project stereotype will be added with the naming convention `Project:ProjectStereotype`. The class settings can be edited, as needed. The class setting for the project stereotype can be configured in the same manner as class settings for other object classes.

Please keep in mind that excluding an object class from the Alfabet interface via the class setting definition may have consequences for the views in the **As-Is Architecture Definition** and **Affected Architecture Analysis** workspaces that are determined by the attribute `HasAsIsArchitecture`. For example, if you exclude the object class ICT Object via a class setting, ICT objects cannot be defined or displayed in the views in the **As-Is Architecture Definition** and **Affected Architecture Analysis** workspaces.

Please note that the colors of the projects displayed in *Project, Skill Request and Resource Request Time Schedule (Gantt) Page View*, Project Time Schedule (Gantt) page view, Skill Offer page view, and Skill Analysis page view are based on the class setting for the relevant project stereotype. The color of the outline of the box representing the start and end of the project stereotype is configured in the attribute `BackColor` in the XML object ***ProjectManager***.

For more information about configuring class settings, see the section Configuring Class Settings for Object Classes and Object Class Stereotypes in the chapter Configuring User Profiles for the User Community.

Configuring Wizards for Project Stereotypes

Wizards can be defined for the project management capability. Like class settings for other object classes, each class setting defined for a project stereotype may have a different wizard assigned to it.

Please note, however, that when a wizard is created and defined, it is first defined independent of the project stereotype that it is relevant for. Thus, when defining the wizard, you must select the value `Project` for the **Class Name** attribute. The wizard is then assigned to a class setting for the relevant project stereotype. A wizard may be reused for multiple project stereotypes.

For more information about configuring wizards, see the chapter Configuring Wizards.

Configuring Projects for the Strategy Deduction Capability

Project stereotypes can be mapped to a specific value node stereotype in the **Strategy Deduction** capability. By mapping a project stereotype to a value node stereotype, users will be able to define the relevant projects as impacted by the value node in the *Affected Architecture Page View* of a value node. Typically, projects are associated with the leaf-level value node stereotype in the value node hierarchy because the projects usually represent the strategic initiatives that must be acted upon in order to realize the abstract strategic intentions.

To map a project stereotype to a value node, you must include the project stereotype in the `MappingClasses` attribute. The project stereotype must be written with the correct naming convention: `Project:ProjectStereotype`

For more information about configuring the **Strategy Deduction** capability, see the section Configuring the Strategy Deduction Capability.

About Project Stereotypes in Alfabet Query-Based Reports

To define the release status for a project stereotype in a report view, you must define the project stereotype that the release status definition is for in the **Custom Attribute** field in the attribute window.

The object class `Project` can be defined for the base class or `JOIN` of an Alfabet query. A project stereotype is an attribute for the object class `Project`. If a report is to be configured for the object class `Project` and the report should show objects of a specific project stereotype, then a `WHERE` clause must be added to the Alfabet query. For more information about configuring Alfabet queries, see the chapter Defining Queries.

For example:

```
WHERE Project.Stereotype LIKE 'StatementOfWork'
```

Configuring Domain Models and Domain Planning

The domain model capability in Alfabet is highly configurable and each domain stereotype will be configured with a name unique to your enterprise. Please note that all documentation provided by Software AG uses the generic term "domain" when referring to any object created for any domain stereotype.

The information below describes the configuration required so that users can work with domain models. A domain model describes a hierarchy of domains in the enterprise. Each domain represents a functional entity in the domain model and allows the enterprise architecture to be hierarchically partitioned into disjoint segments and structured, for example, from a functional or technological point of view. An enterprise may have only one domain model or may have multiple domain models. Each domain model consists of one or more configured domain stereotypes.

You can configure each domain stereotype and specify the permissible object classes (`BusinessProcess`, `BusinessObject`, `BusinessFunction`, `ICTObject`, `Application`, `Component`, `MarketProduct`, `StandardPlatform`, and `VendorProduct`) that mayare are permissible to be a domain owner may create for a domain as well as which object classes a domain owner may associate with a domain.

Once defined, a domain stereotype is similar to a standard object class. Correspondingly, you can configure the mandate capability to control user access to the domain model as a whole or to each domain stereotype in the domain model hierarchy. All domain stereotypes can be configured to be searchable and thus selected in the list of searchable object classes displayed in the **Search for** field in the **Simple Search** and **Browse** functionalities. Additionally, you can configure custom editors, wizards, custom object views, class settings, workflows, and reports for each domain stereotype, as needed.

Users may work with domains in the following functionalities.

- **Domains** explorer (`DOM_Explorer`): This business function allows users to create and define one or more domain models that reflect the critical areas in the enterprise. The explorer displays all domain models with their domains and the object classes specified as visible in the explorer for each domain. For more information about the configuration of evaluation groups, evaluation types (and their indicators), etc. required to evaluate business capabilities, see the chapter *Documenting the Enterprise's Functional Domains* in the reference manual *Portfolio Management Basic*.
- **Domain Planning** functionality (`DomainPlanning`). This business function allows users to plan and restructure a section of the domain model in the context of a solution domain project. In the solution domain project, users can restructure the domain hierarchy by creating new domains, deleting existing domains, and proposing successor domains for the objects referenced by the deleted domains. This occurs in the context of the solution domain project so that the actual domain model is not actually modified during the planning phase. Once the solution domain project is checked in to the Alfabet inventory, the solution domain project will overwrite the corresponding section of the domain model. This feature requires that the object class stereotypes that are configured for the object class `Domain` are also configured for the object class `SolutionDomain`. The specific configuration required to implement the **Domain Planning** functionality is explained in the section Configuring Solution Domains and the Domain Planning Capability
- **Capability Management** functionality (`CapabilityManagement` or `CAPM_Explorer`):This business function allows the business to be described by means of business capabilities instead of domains. Please note that there is no explicit class for capability in Alfabet. Capabilities are represented by the domains and business functions that have been defined in domain model. Therefore, to work with business capabilities, a domain model should be configured with domain stereotypes whereby business functions must be allowed for the domain stereotype on the lowest level of the domain

hierarchy. Permissible users must then first define the domains. Once the domains are defined, they are added by a permissible user to a business capability map via the **Capability Maps** explorer. The domains are then considered business capabilities and all functionalities relevant for business capabilities will be available. Other than the configuration of domain stereotypes, no additional configuration is required in Alfabet Expand. For more information about the configuration of evaluation groups, evaluation types (and their indicators), etc. required to evaluate business capabilities, see the chapter *Documenting the Enterprise's Business Capabilities* in the reference manual *Portfolio Management Basic*.

The following configuration steps are necessary to work with domain models:

- Create all relevant domain stereotypes for the object class `Domain` via the **Stereotypes** attribute.
- Specify the hierarchy of the domain stereotypes for each domain model in the XML object ***DomainManager***. Here you can also specify whether a domain stereotype is recursive, which architecture elements may be created or assigned to the domains based on the domain stereotypes, and which architecture elements that are owned by a domain are displayed in the **Domains** explorer.
- Configure mandates for the domain model, if necessary. In contrast to the implementation of mandates for other object classes, the mandate definition for the object class `Domain` is propagated from the root domains in the domain model to all subordinate domains. In other words, sub-domains will inherit the mandate definition from their parent domain and users cannot explicitly define a mandate for any domain subordinate to the root domain. If the mandate definition is changed for a root domain, then the mandate definition will be propagated to its sub-domains.
- Configure the domain glossary capability, if necessary. A domain glossary can be created in order to allow users to define and search for domain-specific terminology for objects assigned to a selected domain.
- Define the necessary custom editors, wizards, custom object views, class settings, workflows, and reports for each domain stereotype, as needed.
- Assign the relevant functionalities and views to the relevant user profile.

To map domain stereotypes to the **Strategy Deduction** capability, see the section Configuring the Strategy Deduction Capability.

The following information is available:

- Creating Domain Stereotypes for the Domain Model
- Configuring the Sequence of the Domain Stereotypes in the Domain Model
- Configuring Functionality for Domain Stereotypes in the XML Object DomainManager
- Implementing Mandates for the Domain Model
- Configuring the Domain Glossary Capability
- Configuring Solution Domains and the Domain Planning Capability
- Making the Domain Management and Domain Planning Functionalities Available to User Profiles

- Configuring Capability Maps for the Domains Explorer

Creating Domain Stereotypes for the Domain Model

Before you create one or more domain models, you should carefully consider the number of levels required for each domain model as well as which object classes may be mapped to a domain stereotype. Once the enterprise begins to work with the domain planning functionalities, you cannot easily add new or remove existing domain stereotypes.

You must create all object class stereotypes relevant for all domain models in the **Stereotypes** attribute for the object class `Domain`. For example, you plan to create two domains models, one domain to capture functionality relevant to the business and another to capture functionality relevant to the technology. In the example below, the business domain model consists of the domain stereotypes Area, Sub-Area, and Domain and the technology domain model consists of the domain stereotype Technology Domain. All domain stereotypes for all domain models must be configured in the **Stereotypes** attribute for the object class `Domain`:

Example of the XML definition in the **Stereotypes** attribute for the object class `Domain`:

```
<ClassStereotypes>
   <Stereotype Name="Area" Caption="Area" CaptionPlural="Areas"
   Comments="" HasMandates="false"/>
   <Stereotype Name="SubArea" Caption="Sub-Area" CaptionPlural="Sub-
   Areas" Comments="" HasMandates="false" />
   <Stereotype Name="Domain" Caption="Domain"
   CaptionPlural="Domains" Comments="" HasMandates="false" />
   <Stereotype Name="TechnologyDomain" Caption="Technology Domain"
   CaptionPlural="Technology Domains" Comments=""
   HasMandates="false" />
</ClassStereotypes>
```

When you create the domain stereotypes in the **Stereotypes** attribute for the object class `Domain`, you also specify which domain stereotypes the mandate capability applies to. Once a domain stereotype has been created, you can configure its class settings and specify whether the domain stereotype is searchable, and which icon and preview properties should be displayed for the domain stereotype. For more information about configuring class settings, see the section Configuring Class Settings for Object Classes and Object Class Stereotypes.

Later on when the domain models are configured in the XML object ***DomainManager***, the solution designer will configure the business domain model to have the hierarchy levels Area > Sub-Area > Domain and the technology domain model to have the domain stereotype Technology Domain to be recursive so that a technology domain can have subordinate technology domains.

To define the domain stereotypes:

1) Go to the **Meta-Model** tab and navigate to the protected class node  for the object class `Domain` in the **Class Model** explorer.
2) Click the object class `Domain` in the explorer to open the attribute window.

3) Set the **Can Have Mandates** attribute to `True` if the mandate capability should be available for the domain planning capability. Select `False` if the mandate capability should not be available.

4) Click the **Browse** button available for the **Stereotypes** attribute to open the XML editor. For each domain stereotype in your domain model hierarchy, define the following XML attributes:

   - `Stereotype Name`: Enter the technical name for each domain stereotype. You may define a name of up to 64 characters. This name cannot be changed once the stereotypes are implemented.
   - `Caption`: Enter the caption for the domain stereotype. This is the name that users will see in the Alfabet interface.
   - `CaptionPlural`: Enter a plural form for the caption. This is the name in plural that users will see in the Alfabet interface.
   - `Comments`: Enter text in order to provide information about the domain stereotype. This information is only for the purposes of configuration. It is not displayed in the Alfabet user interface.
   - `HasMandates`: Enter True if the mandate capability should be available for the domain stereotype. To implement the mandate capability for a domain model, the root domain stereotype must be set to `HasMandates="true"` and all subordinate domain stereotypes must also be set to `HasMandates="true"`. Enter False if the mandate capability should not be available for the stereotype.

     The configuration of mandates for a domain model is determined by the domain stereotype that is at the root node of the domain hierarchy. All subordinate domain stereotypes in the domain model require the same mandate configuration as the root domain stereotype. For a more detailed explanation, see the section Implementing Mandates for the Domain Model.

5) Click the **Save** button to save your changes.

Configuring the Sequence of the Domain Stereotypes in the Domain Model

The sequence of the domain stereotypes in the domain model is determined in the XML object ***DomainManager***. The order of the domain stereotypes listed in the XML object determines the order of the levels in the domain hierarchy. Each domain model begins with the root domain stereotype specified in the first ***Stereotype*** element in the XML object ***DomainManager***, followed by its child domain stereotype in the next ***Stereotype*** element, followed by its child domain stereotype in the next ***Stereotype*** element, etc.

```
<DomainManager DomainClassName="Domain">
    <Stereotype Name="Area"
                AllowedArtifacts=""
                AllowAssociatedObjects="false">
        <Stereotype Name="SubArea"
                    AllowedArtifacts="BusinessProcess"
                    AllowAssociatedObjects="false">
            <Stereotype Name="Domain"
                        AllowedArtifacts="BusinessFunction,Application,
                        ICTObject,MarketProduct,BusinessProcess,BusinessObject"
                        CreateClasses="BusinessFunction,MarketProduct,BusinessObject"
                        AllowAssociatedObjects="false"
                        IsRecursive="true">
            </Stereotype>
        </Stereotype>
    </Stereotype>
<Stereotype Name="TechnologyDomain"
            AllowedArtifacts="Component,StandardPlatform,VendorProduct"
            CreateClasses="Component,StandardPlatform,VendorProduct"
            AllowAssociatedObjects="true"
            IsRecursive="true">
</Stereotype>
</DomainManager>
```

In the example above, the first domain model structures in the domain stereotypes in the hierarchy levels Area > Sub-Area, and Domain. The domain stereotype Technology Domain does not have subordinate domain stereotypes but has been defined as recursive so that any technology domain can have subordinate technology domains.

For more information about defining all elements in XML object ***DomainManager***, see the section Configuring Functionality for Domain Stereotypes in the XML Object DomainManager.

Configuring Functionality for Domain Stereotypes in the XML Object DomainManager

Once the domain stereotypes have been created for the object class `Domain`, you can specify one or more domain stereotype hierarchies in the XML object FeatureManager***DomainManager***. A domain stereotype may have multiple subordinate domain stereotypes. Furthermore, a domain stereotype may be configued to be recursive, thereby allowing subordinate domains to be defined that are based on the same domain stereotype. The order of the domain stereotypes listed in the XML object determines the order of the levels in the domain hierarchy. When a user creates a domain in the user interface, the stereotype selector will open if the new domain may be based on more than one domain stereotype. The user must select the relevant stereotype that the new domain shall be based on and then the relevant **Domain** editor will open. If only one domain stereotype is permissible, the new domain will automatically be based on the domain stereotype and the relevant **Domain** editor will open.

Additionally, you can specify whether business functions, business objects, business processes, applications, ICT objects, functional modules, components, standard platforms, market products and vendor products may be created for or associated with the domain stereotype.

To edit the XML object ***DomainManager***:

1) Go to the **Presentations** tab, expand the **XML Objects** folder, and expand the **SolutionManagers** folder.
2) Right-click the XML object ***DomainManager*** and select **Edit XML**. For general information about editing XML objects in Alfabet Expand, see Working with XML Objects.

3) Edit the XML attributes, as needed The table below displays the XML attributes that can be edited for the XML object ***DomainManager***:

XML Elements (bold) and Attributes	Explanation
DomainManager	
Domain-Class-Name	Enter `Domain`.

Stereotype	An XML element ***Stereotype*** should be created for each domain stereotype. The root domain stereotype should be the first ***Stereotype*** element, with the child stereotype element nested below the XML element ***Stereotype*** of its parent.
	For example:
	`<Stereotype Name="Area"AllowedArtifacts=""AllowAssociatedObjects="false">`
	`<Stereotype Name="SubArea" AllowedArtifacts="BusinessProcess" AllowAssociatedObjects="false">`
	`<Stereotype Name="Domain" AllowedArtifacts="BusinessFunction,Application" CreateClasses="BusinessFunction,MarketProduct,BusinessObject" AllowAssociatedObjects="false" IsRecursive="true">`
	`</Stereotype>`
	`</Stereotype>`
	`</Stereotype>`

Name	The domain stereotype name must be spelled exactly as defined in the XML attribute `Name` in the **Stereotypes** attribute for the object class `Domain`.
AllowedArtifacts	Enter the technical names of the object classes or their object class stereotypes that may be created for or associated with the domain stereotype. Possible object classes include `BusinessProcess`, `BusinessObject`, `BusinessFunction`, `FunctionalModule`, `ICTObject`, `Application`, `Component`, `MarketProduct`, `StandardPlatform`, and `VendorProduct`.

XML Elements (bold) and Attributes	Explanation
	The `AllowedArtifacts` attribute should include the following: • All object classes that can be created by an authorized user of a domain based on the domain stereotype. The object classes must also be specified in the XML attribute `CreateClasses`. • All object classes that can be associated with a domain based on the domain stereotype. If you set the XML attribute `AllowAssociatedObjects` to `"true"`, the domains based on this domain stereotype can be defined as associated domains for all object classes specified in the XML attribute `AllowedArtifacts`. All objects based on object classes specified in the XML attribute `AllowedArtifacts` that are owned by a domain will be displayed below that domain in the **Domains** explorer.
`CreateClasses`	Enter all relevant object classes listed in the XML attribute `AllowedArtifacts` that may be created for the domain stereotype. Possible object classes include `BusinessProcess`, `BusinessObject`, `BusinessFunction`, `FunctionalModule`, `ICTObject`, `Application`, `Component`, `MarketProduct`, `StandardPlatform`, and `VendorProduct`. **NOTE**: The object class must also be defined in the XML attribute `AllowedArtifacts` in order to be created for the domain stereotype. Please note that object class stereotypes are not allowed in the XML attribute `CreateClasses`. For every object class specified in the XML attribute `CreateClasses`, the **Create <ObjectClass>** menu option will be displayed in the respective page view in the domain stereotype's object profile. For example, if the object class `BusinessProcess` is defined in the XML attribute `CreateClasses`, then the **New** > **Create New Business Process** will be displayed in the *Business Processes Page View* (`DOM_BusinessProcesses`). For the object classes `ICTObject`, `Application`, `Component`, and `StandardPlatform`, the **Create New <ObjectClass> as Copy** menu option will also be displayed. Please note that for object classes not specified in the XML attribute `CreateClasses`, the relevant page view will be available in the domain's object profile but the **Create <ObjectClass>** menu option will be disabled. This page view may be deleted from a custom object view or removed from a user profile if it is not needed. For more information about hiding page views, see the section Refining Visibility Issues in the View Scheme in the chapter Configuring User Profiles for the User Community.
`AllowAssociatedObjects`	Enter `"true"` if objects based on any object class or object class stereotype listed in the XML attribute `AllowedArtifacts` may be added to the domain stereotype as associated objects. The menu option **New** > **Associate Existing <ObjectClass> to <DomainStereotype>** will be displayed in the respective page view in the relevant domain stereotype's object profile. If you define `"false"` for this attribute, the option **New** >

XML Elements (bold) and Attributes	Explanation
	Associate Existing <ObjectClass> to <DomainStereotype> will not be displayed in the respective page view. **NOTE**: Please note that the *Associated Domains Page View* (`OBJ_AssociatedDomains`) will be available per default in standard object views of the object classes `BusinessProcess`, `BusinessObject`, `BusinessFunction`, `FunctionalModule`, `ICTObject`, `Application`, `Component`, `MarketProduct`, `StandardPlatform`, and `VendorProduct`. If the XML attribute `AllowAssociatedObjects` is set to "`false`" for an object class, the *Associated Domains Page View* (`OBJ_AssociatedDomains`) should not be available in the relevant user profile. In this case, the view should be explicitly hidden from the relevant standard or custom object views. For more information about hiding page views, see the section Refining Visibility Issues in the View Scheme in the chapter Configuring User Profiles for the User Community. **NOTE**: Please note that the object class or object class stereotype must also be defined in the XML attribute `AllowedArtifacts` in order to be associated with the domain stereotype.
`IsRecursive`	Enter "`true`" if a child domain based on the same domain stereotype may be created for this domain stereotype. Enter "`false`" if a child domain based on the same domain stereotype may not be created for this domain stereotype.

4) In the toolbar, click the **Save** button to save the XML definition.

Implementing Mandates for the Domain Model

Some enterprises have a federated architecture. If this is the case in your enterprise, then mandates may be implemented to control the visibility of Alfabet objects. If you want the visibility of the domains in your domain model to also be controlled by the mandates implemented in your enterprise, then you will need to explicitly configure the mandate capability for all domain stereotypes in the domain hierarchy.

In contrast to the implementation of mandates for other object classes, the mandate definition for the object class `Domain` is propagated from the root domains in the domain model to all subordinate domains. In other words, sub-domains will inherit the mandate definition from their parent domain and users cannot explicitly define a mandate for any domain subordinate to the root domain. If the mandate definition is changed for a root domain, then the mandate definition will be propagated to its sub-domains.

The mandate configuration is typically defined when the domain stereotypes are created. However, the mandate configuration can be changed, as needed. Please keep the following in mind regarding the implementation of mandates for the domain model:

- The **Can Have Mandates** attribute of the object class `Domain` must be set to "`true`" in order to implement the mandate capability as a whole for the domain models in your enterprise as well as to display the *Mandates Page View* (`ObjectMandates`) in the object view of the root domain stereotype. The *Mandates Page View* will only be displayed on the root domains in the domain model.

You need to ensure that the *Mandates Page View* is assigned to all relevant object views for the user profiles that may define mandates. For general information about the mandates concept, see the section *Implementing the Mandate Capability for a Federated Architecture* in the chapter Configuring Access Permissions for Alfabet.

- The configuration of mandates for a domain model is determined by the domain stereotype that is at the root node of the domain hierarchy. All subordinate domain stereotypes in the domain model require the same mandate configuration as the root domain stereotype.
  - To implement the mandate capability for the domain model, the `HasMandates` attribute in the XML definition of the **Stereotypes** attribute of the object class `Domain` must be defined as "`true`" for the root domain stereotype as well as all subordinate domain stereotypes.
  - To deactivate the mandate capability for the domain model, the `HasMandates` attribute in the XML definition of the **Stereotypes** attribute of the object class `Domain` must be defined as "`false`" for the root domain stereotype as well as all subordinate domain stereotypes. Additionally, the solution designer must ensure that the **Mandates** page view (`ObjectMandates`) is removed from all relevant object views.
- For an overview of mandate configuration in the context of the various access permission concepts in Alfabet, see the chapter Configuring Access Permissions for Alfabet.

To implement the mandate capability for the object class `Domain`:

1) Go to the **Meta-Model** tab and navigate to the object class `Domain` in the **Class Model** explorer. Click the object class `Domain` in the explorer to open the attribute window.
2) Set the **Can Have Mandates** attribute to `True` if the mandate capability should be available for the domain model functionalities. Select `False` if the mandate capability should not be available.
3) Next, define the mandate capability for the object class. Click the **Browse** button available for the **Stereotypes** attribute to open the XML editor.
4) To implement the mandate capability for a domain model, the attribute `HasMandates` must be defined as "`true`" for the root domain stereotype and all subordinate domain stereotypes. If you do not want to implement the mandate capability for a domain model, the attribute `HasMandates` must be defined as "`false`" for the root domain stereotype and all subordinate domain stereotypes.
5) Close the editor by clicking **OK** in the editor.
6) Click the **Save** button to save your changes.

Configuring the Domain Glossary Capability

Alfabet provides a capability that allows a domain glossary to be created in order to allow users to define and search for domain-specific terminology for objects assigned to a selected domain. The domain glossary is defined by a relevant user in the *Domain Glossary Page View* in Alfabet and users can then search for the domain glossary term in the *Full-Text Search* page view. In order to implement this capability, you must ensure that the *Domain Glossary Page View* (`DOM_Glossary`) and *Full-Text Search* page view (`SRCH_FullTextSearch`) is included in the relevant object views.

If a domain glossary is defined, a search group must be configured in order to index, search, and display results for the domain glossary. In the XML object ***SearchManager***, you need to create at least one search group for the base class `Domain`. The search group should contain an Alfabet query for each object class that can be associated with a domain and for which users will be defining glossary items. These classes include: `Application`, `BusinessFunction`, `BusinessObject`, `Component`, `ICTObject`, `BusinessProcess`, `StandardPlatform`, and `VendorProduct`.

If domain stereotypes have been configured in your enterprise, the **Domain Glossary** functionality will be available for all domain stereotypes as long as the *Domain Glossary Page View* and *Full-Text Search* page view are included in the domain stereotype's object view. Therefore, if the domain glossary capability should not be available for a domain stereotype, then the *Domain Glossary Page View* and *Full-Text Search* page view should not be included in the domain stereotype object view. For more information about adding views to an object view, see the section Adding Page Views to the Object Profile Independent of a Workspace in the chapter Configuring Object Views.

- You must ensure that the attribute `Active` in the ***SearchManager*** element of the XML object ***SearchManager*** is defined as "`true`". This ensures that an index can be created for all existing search groups. If an index cannot successfully be created in the *Domain Glossary Page View*, users will not be able to use the capability. For more information about enabling the creation of an index, see the section Configuring the Full-Text Search Capability.
- In order to create an index and execute a search, a path must be defined by your system administrator describing where the search indexes needed for the full-text search functionalities are found. For more information, see the section *Installation* in the reference manual *System Administration* or contact your system administration.
- Please note that Alfabet provides another glossary capability that can be searched via the **Full-Text Search** functionality in the **Search** module. This glossary and its glossary items must be created in the **Glossary** functionality in the **Search** module. For more information about configuring a search group for the **Glossary** functionality, see the section Configuring the Glossary Search Functionality.

To edit the XML object ***SearchManager*** for a global search:

1) Go to the **Presentation** tab and expand the **XML Objects** folder by clicking the + symbol. You will see all XML objects that can be edited.
2) Right-click the XML object ***SearchManager*** and select **Edit XML**. The XML editor is displayed in the center pane. For general information about editing XML objects in Alfabet Expand, see Working with XML Objects.
3) Define the remaining XML attributes, as needed. The table below provides a general explanation about the XML attributes that can be edited for the XML object ***SearchManager***:

XML Element (bold) / XML Attribute	Explanation
SearchGroup	
`Name`	Enter text that defines the name of the search group. This is the name that users will see when they select the search group in order to execute a search.
`Type`	Enter "`Object`" to define an object-centric search. **NOTE**: Relevant only for the definition of an object-centric search. The search is by default a global search. To define a global search, leave the **Type** attribute empty.
`BaseClass`	Enter "`Domain`" as the base class for the search. **NOTE**: If domain stereotypes have been configured in your enterprise, the domain glossary functionality will be available for all domain stereotypes as long as the *Domain Glossary Page View* and *Full-Text Search* page view are included in the domain stereotype's object view. Therefore, if the domain glossary capability should not be available for a domain stereotype, then the *Domain Glossary Page View* and *Full-Text Search* page view should not be included in the domain stereotype object view.
Query	You should create a query for each object class that can be associated with a domain and for which users will be defining glossary items. These classes may include: `Application`, `BusinessFunction`, `BusinessObject`, `Component`, `ICTObject`, `BusinessProcess`, `StandardPlatform`, and `VendorProduct`.
`Name`	Enter the name of the Alfabet query that shall be implemented in the object-centric search.
`ClassName`	Enter "`GlossaryItem`".
`Query`	Enter the Alfabet query to search for the objects that the index should be generated for (via the object class properties defined in the `ExportProps` attribute). For more information about defining an Alfabet query, see the chapter Defining Queries.
`ShowProps`	This attribute specifies the defined object class properties for all objects found by the search. Enter a comma-separated list of object class properties to be displayed in the search results for the objects found by the search. For example, you may want `Application.Version` or `Application.ShortName` to be displayed for all applications displayed in the results. The object

XML Element (bold) / XML Attribute	Explanation
	class properties are visualized in the results displayed via a data set as well as record-by-record. Please keep the following in mind. • Any object class properties defined in the `ImageProps` attribute should not be redefined again in the `ShowProps` attribute since the object class properties defined in the `ImageProps` attribute will already be displayed. • The results will display matches for any of the object class properties defined in the `ExportProps` attribute. For example, if `Application.Description` is defined in the `ExportProps` and the search term is found in value defined for an application's `Description` property, then the description will be displayed in the results with the matching words highlighted, even if `Application.Description` is not defined in the `ShowProps` attribute.
`ExportProps`	The attribute specifies the object class properties to be indexed. Enter a comma-separated list of object class properties to define all object class properties of the object class to be indexed. The `ExportProps` definition must include all object class properties defined in the `ShowProps` and `ImageProps` attributes.
`ImageProps`	Because the title line should be brief, the object class property `Description` should not be included in the `ImageProps` attribute. The attribute specifies the object class properties to display in the title line of the search results. Enter a comma-separated list of object class properties to create a concatenation that serves as the title line for each search result. The sequence of the object class properties listed in the `ImageProps` attribute determines the sequence displayed in the concatenated title. The object class properties defined in the `ImageProps` attribute are read from the Alfabet database when the index is created. The concatenation is displayed in the results displayed via a data set as well as record-by-record.
`ExportReference`	Enter "`GlossaryItem.ArtifactReference`". The attribute specifies that the search results should not display the glossary item found by the search, but rather the object specified in the Alfabet query that references the glossary item. (For example, the applications, business functions, etc.)

4) In the toolbar, click the **Save** button to save the XML definition.

Configuring Solution Domains and the Domain Planning Capability

If the **Domain Planning** functionality (`DomainPlanning`) is implemented in your enterprise, it is highly recommended that changes to the relationships between domains in the domain model are executed solely in the context of the domain planning capability.

If a sub-tree of the domain model is checked out of the inventory for the purposes of domain planning, the targeted domain and its subordinate domains can still be accessed and modified by users in the inventory. However, any changes that these users make to the inventory domain or its subordinate domains will NOT be written to the corresponding solution domain project.

Therefore, if the domain planning capability is implemented in your enterprise, it is recommended that users do not create or delete domains in the **Domains** explorer (`DOM_Explorer`) or *<Sub-Domains> Page View* (`DOM_SubDomains`) available via the domain object profile. Instead, domains should only be created and deleted in the context of a solution domain project in the *<Sub-Domains> Page View* (`SLNDOM_SubDomains`) of a solution domain.

If you plan to implement the **Domain Planning** functionality (`DomainPlanning`) in Alfabet, then you should configure the object class `SolutionDomain` so that it has the same configuration as the object class `Domain`. Consider the following aspects in order to configure the domain planning capability.

- Release statuses must be configured for the object class `SolutionDomainProject` in the XML object ***ReleaseStatusDefs*** in the configuration tool Alfabet Expand. Please note that the definition of the `ApprovedStatus` attribute is required so that a solution project domain can be checked in to the inventory. Be sure to click the **Save** button to save your changes. For more information about the configuration of release status definitions, see the section Configuring Release Status Definitions for Object Classes in the chapter Configuring the Class Model.
- If domain stereotypes are implemented in your enterprise, then you must configure the same domain stereotype definitions for the object classes `Domain` and `SolutionDomainProject`. To do so, copy the definition in the **Stereotypes** attribute for the object class `Domain` in the **Meta-Model** tab and paste the definition to the **Stereotypes** attribute for the object class `SolutionDomain`. Be sure to click the **Save** button to save your changes. For more information about the configuration of the stereotypes, see the section Configuring Object Class Stereotypes for Object Classes in the chapter Configuring the Class Model.
- You must define the class settings for each domain stereotype. It is recommended that the same icons are configured for the solution domains as for their corresponding domain. For more information about configuring class settings, see the section Configuring Class Settings for Object Classes and Object Class Stereotypes in the chapter Configuring User Profiles for the User Community.
- If custom object class properties have been configured for the object class `Domain` and users should view or edit the custom object class properties in the context of a solution domain, then the relevant custom object class properties must be recreated for the object class `SolutionDomain`. The custom object class properties must have the same **Name** attribute definition for the object class `SolutionDomain` as the object class `Domain`. Be sure to click the **Save** button to save your changes. For more information about creating a custom object class property, see the section Configuring Custom Properties for Protected or Public Object Classes in the chapter Configuring the Class Model.

- Once the custom object class properties have been created, you can create a custom editor for the object class `SolutionDomain`. Be sure to click the **Save** button to save your changes. For more information about configuring custom object class properties, see the chapter Configuring Custom Editors.
- If necessary, you can also create a wizard for the object class `SolutionDomain`. Please note, however, that when a wizard is defined, it is first defined for the object class `SolutionDomain` and is independent of the solution domain stereotype that it is intended for. Thus, when defining the wizard, you must select the value `SolutionDomain` for the **Class Name** attribute. The wizard is alter assigned to a class setting for the relevant solution domain stereotype. Be sure to click the **Save** button to save your changes. For more information about configuring custom wizards, see the chapter *Configuring Wizards*.
- If custom editors or custom wizards are to be implemented for a solution domain stereotype or, if no stereotypes are implemented, for the object class `SolutionDomain`, then you must configure the class settings for the relevant object class (`SolutionDomain`:Stereotype or `SolutionDomain`). Be sure to click the **Save** button to save your changes. For more information about configuring class settings, see the section Configuring Class Settings for Object Classes and Object Class Stereotypes in the chapter Configuring User Profiles for the User Community.

It is recommended that you configure reports in order to track the changes made to the domain model. For example, reports could be configured for the object classes `SolutionDomain`, `SolutionDomainProject`, and/or `Domain` in order to capture the data relevant to the enterprise. Users could then export the data to a Microsoft Excel, Microsoft Word or PDF file for archiving purposes and attach the document to the relevant object via the *Attachments Page View*. For more information about configuring reports, see the chapter Configuring Reports.

Making the Domain Management and Domain Planning Functionalities Available to User Profiles

Please take the following functionalities and views into consideration when configuring object views and user profiles:

- **Domains** explorer (`DOM_Explorer`): The **Domains** explorer displays all domain models with their domain hierarchies as well as the objects owned by the domains that have been configured to be displayed in the **Domains** explorer. This explorer should be available to all user profiles that work with domains.
- **Domain Admin Desktop** functionality (`DOM_AdminDesktop`): This functionality is available to the user profile `Admin` only and allows a user or solution administrator to address modifications in the ownership of objects that result from changes to the domain structure. For more information about the **Domain Admin Desktop** functionality, see the section *ManagingAlfabetObjects in the Context of Changes in the Enterprise* in the reference manual *User and Solution Administration*.
- *Domain Glossary Page View* (`DOM_Glossary`) and *Full-Text Search* page view (`SRCH_FullTextSearch`): These views should be available to the relevant user profiles if a domain glossary is implemented.

- *Domain Exchange Desktop Page View* (`DOM_ExchangeDesktop`):This view is an administrative view available in the standard object view for the object class `Domain` and is used for the quick maintenance of the entire domain model and allows the user to move business processes, applications, business functions, business objects, or functional modules from one domain to another. Please note that there is no validation mechanism regarding permissibility for this view and Therefore, should only be available to user profiles that are authorized to modify the domain model.

- Relevant page views needed to create or associate objects with a domain. In the XML object ***DomainManager***, the solution designer can specify that objects in the object classes `BusinessProcess`, `BusinessObject`, `BusinessFunction`, `FunctionalModule`, `ICTObject`, `Application`, `Component`, `MarketProduct`, `StandardPlatform`, and `VendorProduct` may be created for a domain stereotype and associated with a domain stereotype. For example, if the object class `BusinessProcess` is defined in the `CreateClasses` attribute, then the **New** > **Create New Business Process** will be displayed in the *Business Processes Page View* (`DOM_BusinessProcesses`) and if a business process may be associated with the domain, the menu option **New** > **Associate Existing <ObjectClass> to <DomainStereotype>** will be displayed in the *Business Processes Page View*. If an object class cannot be created or associated with a domain, you may want to remove this view from the domain's object profile. For more information about hiding page views, see the section Refining Visibility Issues in the View Scheme in the chapter Configuring User Profiles for the User Community.

- *Associated Domains Page View* (`OBJ_AssociatedDomains`): This page view will be available per default in standard object views of the object classes `BusinessProcess`, `BusinessObject`, `BusinessFunction`, `FunctionalModule`, `ICTObject`, `Application`, `Component`, `MarketProduct`, `StandardPlatform`, and `VendorProduct` regardless of the specification in the XML object ***DomainManager***. If the `AllowAssociatedObjects` attribute in the XML object is set to "`false`", the *Associated Domains Page View* (`OBJ_AssociatedDomains`) should not be available in the object profiles of the object classes `BusinessProcess`, `BusinessObject`, `BusinessFunction`, `FunctionalModule`, `ICTObject`, `Application`, `Component`, `MarketProduct`, `StandardPlatform`, and `VendorProduct` in the relevant user profile. In this case, the view should be explicitly hidden from the relevant standard or custom object views. For more information about hiding page views, see the section Refining Visibility Issues in the View Scheme in the chapter Configuring User Profiles for the User Community.

- **Domain Planning** functionality (`DomainPlanning`): The **Domain Planning** functionality allows users to plan and design an alternative hierarchy of domains for a section of the domain model in the context of a solution domain project. This feature requires that the same object class stereotypes that are configured for the object class `Domain` are also configured for the object class `SolutionDomain`.

For more information about assigning functionalities to user profiles, see the section Making Functionalities Accessible to a User Profile in the chapter Configuring User Profiles for the User Community. For more information about hiding page views in user profiles, see the section Refining Visibility Issues in the View Scheme in the chapter Configuring User Profiles for the User Community.

Configuring Capability Maps for the Domains Explorer

The XML object ***SolutionOptions*** allows you to define whether domains and business functions should be displayed in the **Domains** explorer or whether business capability maps should be displayed in the **Domains** explorer.

To edit the XML object ***SolutionOptions***:

1) Go to the **Presentation** tab and expand the **XML Objects** folder.
2) Right-click the XML object ***SolutionOptions*** and select **Edit XML**. The XML editor is displayed in the center pane. For general information about editing XML objects in Alfabet Expand, see Working with XML Objects.
3) In the XML attribute `BusinessFunctionType`, enter `BusinessFunction` to display domains and business functions in the **Domains** explorer tree. Enter `Capability` to display business capability maps in the **Domains** explorer tree.
4) In the toolbar, click the **Save** button to save the XML definition.

Configuring the Strategy Deduction Capability

The **Strategy Deduction** capability in Alfabet is highly configurable and each value node stereotype will be configured with a name unique to your enterprise. Therefore, all documentation provided by Software AG uses the generic term "value node" when referring to any object created for any value node stereotype.

The aim of the **Strategy Deduction** capability is to close the gaps between abstract strategic intentions and the day-to-day activities that are relevant to the architecture. After a high-level strategic intention is specified, strategic planners define a network of interrelated and increasingly more refined strategic intentions. This process of refinement enables planners to identify the areas of the enterprise requiring change and thus formulate the projects or initiatives needed to realize the corporate strategy.

In Alfabet Expand, you can configure the strategy network that will be made available to your Alfabet community in the **Strategy Deduction** functionality (`VM_StrategyDeduction`).

A strategy network is made up of an arbitrary number of levels called value node stereotypes. The top-level value node stereotype represents the most abstract level of strategic intention, and the lowest leaf-level value node stereotype represents those strategic initiatives that must be acted upon in order to realize the abstract strategic intentions. For example, a typical strategy network might be made up of the following value node stereotypes: Level 1: Vision, Level 2; External Trends, Level 3: Business Drivers, Level 4: Business Requirements, Level 5: Architectural Requirements, Level 6: Initiatives. The name, number, and hierarchical ordering of value node stereotypes is configurable.

A value node is thus defined for a specific value node stereotype. Any pair of value nodes that are related to one another in the strategy network must belong to different value node stereotypes that are adjacent to each other in the hierarchy. In other words, value nodes are related via a parent-child relationship. The relationship between two value nodes is represented by value node arcs, which allow the relative ranking of the strategic intentions to be computed.

Depending on the configuration of each value node stereotype, objects in specified object classes may be defined as impacted by a value node in the *architecture elements* of the relevant value node. One or more object classes can be mapped to a value node stereotype.

The following steps should be carried out for the configuration of the **Strategy Deduction** capability.

- First, you must create the value node stereotypes that make up the strategy network. A value node stereotype must be configured for each hierarchy level in the strategy network. Multiple value node stereotypes may be created for the root node of the value node hierarchy and multiple child value node stereotypes may be created for a parent value node stereotype. The object class stereotypes must be created as an XML definition in the **Stereotypes** attribute for the object class `ValueNode` in the **Meta-Model** tab. For more information about configuring the value node stereotypes, see the section Creating Value Node Stereotypes for the Strategy Network.
- Next, you must specify the hierarchical order and mapping classes for each value node stereotype in the XML object ***ValueManager***. For more information, see the section and Configuring the Value Node Hierarchy and Attributes via the XML Object ValueManager.
- Configure solution requirements for each value node stereotype as you would for a conventional object class. You can configure one or more custom editors, custom selectors, custom wizards, custom object views, custom reports, etc. for each value node stereotype. You must ensure that the *Affected Architecture Page View* (`VMND_ArchitectureElements`) is assigned to the custom object view of the relevant value node stereotype and the *Impacting Value Nodes Page View* (`ObjectValueNodes`) is assigned to the standard or custom object views of the object classes defined in the `MappingClasses` attribute in the XML object ***ValueManager***.
- Configure the names for the object states implemented for value nodes if they should differ from the standard object state names `Plan`, `Active`, and `Retired`. For more information about the configuration of object states, see the section Configuring Object State Definitions for Object Classes in the chapter Configuring the Class Model.
- Configure the class settings for each value node stereotype as you would for a conventional object class. A node for each value node stereotype will be automatically added to the **Class Settings** folder in the **Presentation** tab. For more information about configuring class settings, see the section Configuring Class Settings for Object Classes and Object Class Stereotypes in the chapter Configuring User Profiles for the User Community.
- Ensure that the **Strategy Deduction** functionality (`VM_StrategyDeduction`) is available in the relevant user profile in the **User Profiles** folder in the **Admin** tab. For more information, see the section Making Functionalities Accessible to a User Profile in the chapter Configuring User Profiles for the User Community.

The following information is available:

- Creating Value Node Stereotypes for the Strategy Network
- Configuring the Value Node Hierarchy and Attributes via the XML Object ValueManager
- Configuring Alfabet to Capture Legal Ownership of Organizations
- Configuring Affected Architecture for Measure Types

- Configuring Icons for the Value Nodes Displayed in the Strategy Network Explorer
- Making the Strategy Deduction Capability Available to User Profiles

Creating Value Node Stereotypes for the Strategy Network

Before you create a strategy network, you should carefully consider the number of levels required as well as which object classes may be mapped to a value node stereotype. Once the enterprise begins to work with the **Strategy Deduction** capability, you cannot easily add new or remove existing value node stereotypes.

You must create a value node stereotype for each level in the strategy network. Multiple value node stereotypes may be created for the root node of the value node hierarchy and multiple child value node stereotypes may be created for a parent value node stereotype.

The value node stereotypes are hierarchically structured in the XML object ***ValueManager***. For more information, see the section Configuring the Value Node Hierarchy and Attributes via the XML Object ValueManager.

Once a value node stereotype has been created, you can configure its class settings and specify whether the value node stereotype is searchable, and which icon and preview properties should be displayed for the value node stereotype. For more information about configuring class settings, see the section Configuring Class Settings for Object Classes and Object Class Stereotypes.

To define the value node stereotypes:

1) Go to the **Meta-Model** tab and navigate to the protected class node  for the object class `ValueNode` in the **Class Model** explorer.
2) Click the object class `ValueNode` in the explorer to open the attribute window.
3) Set the **Can Have Mandates** attribute to `True` if the mandate capability should be available for the value node hierarchy as a whole. Select `False` if the mandate capability should not be available.
4) Click the **Browse**  button available for the **Stereotypes** attribute to open the XML editor. You will see a text template that defines the value node stereotypes that make up the value node hierarchy. For each value node stereotype in your value node hierarchy, define the following XML attributes:

An error message will be displayed upon closing the text editor if syntax errors are written in the XML definition of the **Stereotypes** attribute.

- `Stereotype Name`: Enter the technical name for each object class stereotype. You may define a name of up to 64 characters. This name should not be changed once the object class stereotypes are implemented.

Changing the technical name after objects have been created based on the object class stereotype requires such objects to be updated by means of an ADIF scheme. For more information, see the reference manual *Alfabet Data Integration Framework*.

- `Caption`: Enter the caption for the object class stereotype. This is the name that users will see in the Alfabet user interface.

  Please note that the following:

  - The caption of the object class stereotype should be different than the caption of its object class. This is particularly important for the implementation of the search functionality for the object class stereotype. For more information, see the section Configuring Class Settings for Object Classes and Object Class Stereotypes in the chapter Configuring User Profiles for the User Community.
  - The values defined for the XML attribute `Caption` can be translated whereas the values defined for the XML attribute `Stereotype Name` cannot be translated. However, in the table of the **Simple Search** functionality as well as other search selectors, the values defined for the XML attribute `Stereotype Name` of the object class stereotype are displayed in the **Stereotypes** column. If the values defined for the XML attribute `Caption` should be displayed, a custom selector should be defined. For more information, see the section Configuring a Custom Selector for Search Functionalities.
  - If you want to enter a caption `(Caption)` or plural form for the caption (`CaptionPlural`) that contains special characters (for example, a greater then (>) or lesser then (<) symbol), you must replace the special characters with respective XML compliant code, for example:
    - > for >
    - < for <
    - " for "
    - [for [
    -] for]
  - The caption will be available in the vocabularies and can be translated to the secondary languages implemented in your enterprise.

- `Description`: Provide a brief description about the object class stereotype. The description will be displayed in the **Stereotype Selector** that opens when the user must select which stereotype a new object is to be based on. The description should help the user to understand which stereotype the new object should be based on. The description will be available in the vocabularies and can be translated to the secondary languages implemented in your enterprise.
- `CaptionPlural`: Enter a plural form for the caption. This is the name in plural that users will see in the Alfabet user interface.
- `IDPrefix`: Enter no more than 5 characters for the ID prefix used to generate the unique identification number for new objects based on the object stereotype. If the XML attribute `IDPrefix` is not specified, the ID prefix of the object class that the object class stereotype is based on will be used to generate the unique ID. Please note that the integer generated for the unique ID is based on the number of instances created for the object class that the object

class stereotype is based on and includes all instances of all object class stereotypes created for the object class.

The prefix ID of existing objects based on an object class stereotype can be updated via the ADIF import scheme `SetStereotypeID` available in the `Alfabet Standard Jobs` folder. For more information, see the section *Predefined ADIF Schemes* in the reference manual *Configuring Alfabet with Alfabet Expand*.

- `Comments`: Enter text in order to provide information about the object class stereotype. This information is only for the purposes of configuration. It is not displayed in the Alfabet user interface.
- `HasMandates`: Enter "`true`" if the mandate capability should be available for the object class stereotype. Enter "`false`" if the mandate capability should not be available for the object class stereotype. If the XML attribute `HasMandates` is defined as "`false`" for an object class stereotype, objects based on the object class stereotype will be visible to users with any mandate implemented in your enterprise. For information about additional configuration requirements necessary to implement the mandate capability, see the section *Implementing the Mandate Capability for a Federated Architecture* in the chapter Configuring Access Permissions for Alfabet .
- `EnableStatutoryLanguage`: Set to `True` if the statutory language capability shall be available for the object class stereotype. The statutory language capability is available in order to address regulatory requirements that mandate that objects are captured in a specific language. When a user creates an object based on a relevant object class/object class stereotype, a statutory language selector will open in which the language can be selected. In the object editor that opens, the user can capture all attributes that support automated translation in the statutory language. If the XML attribute `EnableStatutoryLanguage` is not set, the object class stereotype will inherit the definition of the **Enable Statutory Language** attribute specified for the object class. Specifying a Statutory Language for the Enterprise

5) Click the **Save** button to save your changes.

Configuring the Value Node Hierarchy and Attributes via the XML Object ValueManager

Once the value node stereotypes have been created for the object class `ValueNode`, you can define the value node hierarchy in the XML object ***ValueManager***. You can define the value node hierarchy as a linear hierarchy or as a branched tree structure that allows complex value node structures to be captured. A value node stereotype may have multiple subordinate value node stereotypes. Furthermore, a value node stereotype may be configured to be recursive, thereby allowing subordinate value nodes to be defined that are based on the same value node stereotype. The order of the value node stereotypes listed in the XML object determines the order of the levels in the value node hierarchy.

When a user creates value node in the Alfabet user interface, the stereotype selector will open if the new value node may be based on more than one value node stereotype. The user must select the relevant stereotype that the new value node shall be based on and then the relevant **Value Node** editor will open. If only one value node stereotype is permissible, the new value node will automatically be based on the value node stereotype and the relevant **Value Node** editor will open. A *(Subordinate Value Nodes) Page View* (`VMND_SubNodes`) page view will be displayed for each value node stereotype subordinate to a root value node stereotype, whereby the caption of the *(Subordinate Value Nodes) Page View* will automatically

display the caption of the relevant subordinate value node stereotype that may be assigned to the selected value node.

In addition to defining the value node hierarchy, you must also define the object classes that can be mapped to a value node stereotype in order to specify which objects are impacted by a value node. One or more object classes can be mapped to a value node stereotype. Any object class representing an artifact in Alfabet can be assigned to a value node stereotype in the `MappingClasses` attribute in the XML object ***ValueManager***. It is recommended to map the lowest level value node stereotype to the object classes `Demand`, `Project`, or `Principle` in order to operationalize the strategy expressed by the value nodes in that branch of the value node hierarchy. However, you can specify any value node stereotype as permissible for the creation of demands, projects, or principles.

To edit the XML object ***ValueManager***:

1) Go to the **Presentations** tab, expand the **XML Objects** folder, and expand the **SolutionManagers** folder.
2) Right-click the XML object ***ValueManager*** and select **Edit XML**. The XML object can be edited in the center pane. For general information about editing XML objects in Alfabet Expand, see Working with XML Objects.
3) Specify the following XML attributes as child elements of the root node `ValueManager`:
   - `Gaps`: Enter texts or symbols that represent the relative gap or difference in importance between adjacent value nodes. The number of gaps required depends on the number of value node stereotypes defined. The gaps should be ordered from least important to most important. Please note that if you want to enter a string that contains special characters, you must replace the special characters with respective XML compliant code. For example, a greater than (>) must be entered as > or lesser than (<) symbol must be entered as <
   - `TimeSeriesGroup`: Enter the name of the time series group to implement for the strategy network. A time series group bundles a set of time series evaluation types for which target values can be defined for value nodes that the time series evaluation type is assigned to. For detailed information about working with and configuring time series evaluations, see the section *Creating a Time Series Period* in the reference manual *Configuring Evaluation and Reference Data in Alfabet*. Please note the following:
     - The time series definition is uniform for all measure types and an editor allows the target and rated values to be maintained for the measures based on a measure type. Time series entries may be skipped for those measure types where values are not available.
     - The time series group must first be specified in the protected enumeration `TimeSeriesGroup`. For more information about the protected enumeration `TimeSeriesGroup`, see the chapter *Overview of Protected Enumerations* in the reference manual *Configuring Alfabet with Alfabet Expand - Appendix*.
4) Specify a child XML element `StereotypeDefinition` should be created for each value node stereotype in the value node hierarchy:
   - For each value node stereotype that may be created for the root node of the value node hierarchy, create an XML element `StereotypeDefinition` as a child of the XML element `ValueManager`. Multiple value node stereotypes may be created for the root node of the value node hierarchy.

The first level of value node stereotypes in the XML object represents the most ascendant level in the hierarchy. To change the order of the value node stereotypes, select the entire value node stereotype and cut and paste it to the correct position in the order. Be sure to include the syntactic constructs (< and />), otherwise you will see an error message at the bottom of the XML editor.

- Define the following XML attributes for the XML element `StereotypeDefinition`:
  - `Stereotype`: Enter the technical name of the value node stereotype. This is the name defined in the with the XML attribute `Name` in the XML specification of the **Stereotypes** attribute for the object class `ValueNode`. The stereotype name is passed on to the objects that users create for the selected value node stereotype.
  - `MappingClasses`: Users can define objects in the object classes specified here as impacted by value nodes based on the value node stereotype. Enter a comma-separated list of object classes that may be mapped to the value nodes assigned to the value node stereotype. Please note that if the class `Demand`, `Project`, or `Principle` shall be added to the XML attribute `CreateClasses`, then it must also be included in the XML element `MappingClasses`. Please note the following:
    - The following object classes may be defined in the `MappingClasses` attribute: `Application`, `Brand`, `BusinessFunction`, `BusinessData`, `BusinessObject`, `BusinessProcess`, `Component`, `CustomerSegment`, `Demand`, `Device`, `Domain`, `ICTObject`, `InformationFlow`, `ITStrategy`, `ITStrategyMap`, `Market`, `MarketProduct`, `MasterPlan`, `MasterPlanMap`, `MasterPlatform`, `OrgaUnit`, `Peripheral`, `Principle`, `Project`, `SalesChannel`, `SystemBuildingBlock`, `StandardPlatform`, `StrategicBusinessSupport`, `TacticalBusinessSupport`, and `VendorProduct`. You must enter the value of the `Name` attribute of the object classes.

      If master plan maps and IT strategy maps are to be defined for a value node, then the object classes `BusinessProcess`/`Domain`, `OrgaUnit`/`MarketProduct` must be mapped to the relevant value node stereotype because objects in these classes are used in business support maps.

    - To map object class stereotypes to a value node (for example, a project stereotype or an application stereotype), add each relevant object class stereotype to the `MappingClasses` attribute for the value node stereotype. The object class stereotype must be written using the correct naming convention (for example: `Project`:ProjectStereotype).
    - The specified object classes will automatically be added to the **New** drop-down menu in the *Affected Architecture Page View* (`VMND_ArchitectureElement`). If the `MappingClasses` attribute is not defined for a value node stereotype, the *Affected Architecture Page View* (`VMND_ArchitectureElement`) will be displayed in the object profile but will not be functional. If no object classes are specified in the `MappingClasses` attribute, then the *Affected Architecture Page View* will be automatically removed from the object views of all value nodes.
    - For each relationship defined between an object in a mapped class and a value node, an object of the object class `ValueNodeArch` will be created. If the definition of the `MappingClasses` attribute is changed AFTER objects of the object class `ValueNodeArch` have been created, the existing relationships

defined (in other words, the objects of the object class `ValueNodeArch`) will continue to be available even though the mapped object class may no longer be referenced for the value nodes stereotype. In this case, the user will still be able to detach the mapped object from the value node.

- Please ensure that the exclusion of an object class via a class setting definition does not conflict with the definition of the XML attribute `MappingClasses`.

- `CreateClasses`: Demands, projects, and principles or their object stereotypes may be created in the *Affected Architecture Page View* as objects that operationalize that value node. Enter a comma-separated list of the object classes `Demand`, `Project`, or `Principle` or their object stereotypes that may be created for the value node stereotype. Please note that any classes specified for the XML attribute `CreateClasses` must also be specified in the XML attribute `MappingClasses`. The options **Create New Demand**, **Create New Project**, and **Create New Principle** (or any of their stereotypes) will be available in the *Affected Architecture Page View* of the relevant value node.

- `HasObjectives`: Enter "`true`" if objectives may be defined for the value node stereotype. Objectives allow the value node to be refined and specified.

- For each permissible child value node of a parent value node, create an XML element `ChildStereotype` as a child of the parent XML element `Stereotype Definition`. Multiple child XML elements `ChildStereotype` may be created for a parent value node stereotype. Add the XML attribute `Name` to each XML element `ChildStereotype` and enter the technical name of the value node stereotype.

5) In the toolbar, click the **Save**  button to save the XML definition.

Configuring Alfabet to Capture Legal Ownership of Organizations

Alfabet provides a functionality that allows the legal ownership of organizations to be captured. Please note the following configuration required to implement this functionality:

- Custom properties may be captured for the object class `LegalOwnership` in order to capture relevant data regarding the legal ownership relationships in your enterprise. For more information, see the section Configuring Custom Properties for Protected or Public Object Classes.

- The **Legal Owners** page view (`ORG_LegalOwnerships`) and the **Legally-Owned Organizations** page view (`ORG_LegalSubordinations`) must be assigned to the custom object views configured for the relevant object class stereotypes configured for the object class `OrgaUnit`. The **Legal Owners** page view (`ORG_LegalOwnerships`) should be available for the organization stereotype that owns other legal entities and the **Legally-Owned Organizations** page view (`ORG_LegalSubordinations`) should be available for the organization stereotype that represents organizations owned by other legal entities. The percentage that various organizations own a given organization is defined for the owned organization in the **Legal Owners** page view (`ORG_LegalOwnerships`). For more information, see the sections Configuring Object Class Stereotypes for Object Classes and Configuring Object Views.

- The values available for the **Ownership Type** attribute in the **Legal Ownership** editor (`LEGOWN_Editor`) may be configured via the enumeration ***OwnershipType***. For more information, see the section Defining Protected and Custom Enumerations.

Configuring Affected Architecture for Measure Types

You can specify the object classes and objects class stereotypes that may be added as affected architecture for measure types.

1) Go to the **Presentations** tab, expand the **XML Objects** folder, and expand the **Solution Managers** folder
2) Right-click the XML object ***AffectedArchManager*** and select **Edit XML**. For general information about editing XML objects in Alfabet Expand, see Working with XML Objects.
3) Create an XML element `ClassEntry` and define the following XML attributes:
   - `ClassName`: Enter the technical name `VMMeasureType`.
   - `ArchitectureClasses`: Enter a comma-separated list of object classes and objects class stereotypes that may be added as affected architecture for risk mitigation templates. A menu entry with the caption **Add <Object Class>** or **Add <Object Class Stereotype>** will be added to the *Architecture Elements Page View*. If you are defining an object class stereotype in the XML attribute `ArchitectureClasses`, you must use the syntax ObjectClass:ObjectClassStereotype. If the XML attribute `ArchitectureClasses` is not defined, the standard object classes preconfigured by Software AG will be displayed.
4) In the toolbar, click the **Save** button to save the XML definition.

Configuring Icons for the Value Nodes Displayed in the Strategy Network Explorer

The icons to display for value nodes in the **Strategy Network** explorer (`VMND_Explorer`) which is implemented in the **Strategy Deduction** functionality (`VM_StrategyDeduction`) are configured via the class settings of each value node stereotype. You must configure a class setting for each value node stereotype.

Please note that the icon definition for a value node stereotype will only be displayed for value nodes with an `Active` object state. Value nodes that do not have an `Active` object state are automatically displayed with different icons in the explorer tree. All value nodes with the object state `Plan` will be displayed with the icon and all value nodes with the object state `Retired` will display the icon.

For more information about configuring class settings, see the section Configuring Class Settings for Object Classes and Object Class Stereotypes in the chapter Configuring User Profiles for the User Community. For more information about the configuration of object states, see the section Configuring Object State Definitions for Object Classes in the chapter Configuring the Class Model.

Making the Strategy Deduction Capability Available to User Profiles

Please take the following functionalities and views into consideration when configuring object views and user profiles:

- Ensure that the **Strategy Deduction** functionality (`VM_StrategyDeduction`) is available in the relevant user profile in the **User Profiles** folder in the **Admin** tab. For more information, see the section Making Functionalities Accessible to a User Profile in the chapter Configuring User Profiles for the User Community.

- Ensure that the *Affected Architecture Page View* (`VMND_ArchitectureElements`) is assigned to the relevant object view implemented for each value node stereotype.

  The visibility of the **Add Existing <Object Class>** options available in the **Affected Architecture** (`VMND_ArchitectureElements`) page view for a value node can be controlled in the **Customization Editor** available for the view. For each object class mapped to a value node stereotype via the XML attribute `MappingClasses` in the XML object `ValueManager`, an entry will be added below the **New** menu entry in the **Customization Editor**. The solution designer may exclude the menu option from the use profile as well as specify a custom selector for the option. For more information about configuring the visibility of menu options, see the section Hiding Functionalities in a Page View or Configured Report .

- Ensure that the *Objectives Page View* (`VMND_Objectives`) is assigned to the relevant object view implemented for this relevant value node stereotype.
- If desired, assign the *Impacting Value Nodes Page View* (`ObjectValueNodes`) to the object views of the object classes defined in the `MappingClasses` attribute.

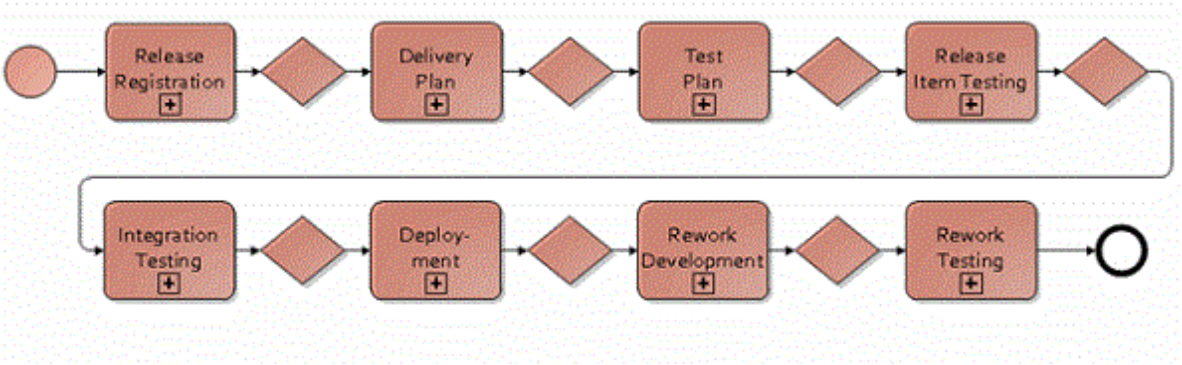
Configuring the Capture Enterprise Releases Capability

The **Capture Enterprise Releases** functionality supports the enterprise in capturing and managing project deliverables designed to provide architectural change to the IT landscape in a coordinated and managed process. In the context of the **Capture Enterprise Releases** functionality, requirements for each enterprise release cycle can be documented and enforced, thus reducing the risk of failure, inadequate performance, and security breaches or disruption to services resulting from change. Proposed projects associated with the enterprise release are required to go through a formal assessment and approval process before they can be registered as part of the enterprise release. The implementation of stage gates ensures that each phase in the execution of the enterprise release is managed and governed in alignment with the enterprise release calendar.

The enterprise release consists of enterprise release items which express the deliverables that will be provided with the enterprise release. Release statuses are implemented in order to manage the different stages of the enterprise release and the approval process for each individual delivery comprised in the enterprise release. Typically, an enterprise release item is based on a project that has been defined alongside with the architectural changes it provides. Alternatively, enterprise release items can be based on applications, components, or standard platforms. For each enterprise release, a set of milestones with target dates constitute the stage gates for the approval and execution of the release and allow the enterprise release cycle to be tracked and controlled. In order to manage the activities that must be realized for each milestone in the enterprise release, the Enterprise Release capability is typically implemented in conjunction with Alfabet 's workflow capability.

To implement the **Capture Enterprise Releases** functionality (`ENTRLS_CaptureReleases`), the following must be configured:

- The **Capture Enterprise Releases** functionality (`ENTRLS_CaptureReleases`) must be assigned to the relevant user profile(s).
- Release status definitions must be configured for the object class `EnterpriseRelease`. The release status definition for the enterprise release specifies the statuses of the enterprise release cycle as a whole. Suggested statuses for the enterprise release are:
  - New: Initial status after enterprise release is created.
  - Planned: Enterprise release is being considered for implementation.
  - InExecution: Enterprise release is being actively pursued. Defined milestones are relevant for an enterprise release in the InExecution status.
  - Closed. Enterprise release item has been executed and is complete.
- A milestone template must be configured for the enterprise release. The milestones configured are implemented during the InExecution status of the enterprise release. Typical milestones that could be configured for the **Enterprise Release** milestone template are:



- Release Registration: Initial execution phase. Enterprise release items must be submitted for registration in the enterprise release. Submission of enterprise release items is limited to this phase.
- Delivery Plan: Participating enterprise release items must submit a delivery plan.
- Test Plan: Test Plan document must be attached to the enterprise release items
- Release Item Testing: Stand-alone testing of enterprise release items must be completed and documented
- Integration Testing: Integration testing of all enterprise release items completed and documented.
- Deployment: Enterprise release items must be ready for deployment.
- Rework Development: Development revisions to enterprise release items that have been conditionally approved.
- Rework Testing: Testing of revisions to conditionally approved items.
- Completion: All milestone phases completed and all items in status Closed.

- Release status definition must be configured for the object class `ReleaseItem`. The release status definition for enterprise release items should include the following status definitions:
  - The statuses relevant for an enterprise release item to be approved/rejected for the release during the phase prior to the Release Registration milestone.
  - The statuses relevant for an enterprise release item when the enterprise release is completed.
  - The statuses relevant for the milestones representing the execution stages of the release cycle (for example, Delivery Plan, Test Plan, Testing, etc.)

    Please note that if enterprise release items are based on projects, the projects may also have milestones configured that are relevant for the approval and execution process of the project.

Suggested statuses for enterprise release items are:

- Accepted: Enterprise release item has been accepted for participation in release execution.
- Rejected: Not accepted during registration phase.
- In Preparation: Pending delivery for requirements of Registration milestone.

  - Under Review: Project Manager/release item responsible has submitted the required delivery for the current stage. The delivery is under review by the Release Manager.
  - Rework required: The delivery of the enterprise release item must be revised. The enterprise release item is still active.
  - Passed: Current stage passed, ready to enter next.
  - Cond. Passed: Current stage not OK, pass anyway. May require rework in later stage.
  - Retracted: Project Manager withdraws.
  - Excluded: Kicked out during execution, not passed.
  - Closed: Reached final milestone, open for postmortem changes.
  - Archived: Final state. No more changes possible.
- A workflow should be configured for each enterprise release milestone in the enterprise release cycle in order to standardize the tasks required to fulfill the milestone by the specified target date.
- Typical roles involved in the enterprise release management process include Release Manager, Project Manager, and Application Owner. You must ensure that relevant user profiles are available and that the views relevant to the user profile and your enterprise's implementation of the **Capture Enterprise Releases** functionality (`ENTRLS_CaptureReleases`) are available.

The following configurations are available for the **Capture Enterprise Releases** functionality (`ENTRLS_CaptureReleases`). The configuration should be carried out according to conventional configuration procedures described in this manual.

- Searchability of the object classes `EnterpriseRelease` and `ReleaseItem`.
- Mandate configuration for the object classes `EnterpriseRelease` and `ReleaseItem`.
- Monitor configuration for relevant target dates, review dates, etc. for the object classes `EnterpriseRelease` and `ReleaseItem`.
- Configuration of custom editors, wizards, custom object views, custom class settings, workflows, and configured reports.

The following information is available:

- Configuring Release Status Definitions for the Capture Enterprise Releases Capability
- Configuring Milestone Templates to Track Enterprise Releases
- Configuring User Profiles and Visibility of Views in the Enterprise Release Capability

Configuring Release Status Definitions for the Capture Enterprise Releases Capability

A release status definition must be created for the object classes `EnterpriseRelease` and `ReleaseItem` in the XML object ***ReleaseStatusDefs*** in the configuration tool Alfabet Expand. The release status definition includes the complete set of release statuses implemented in the context of the `ENTRLS_CaptureReleases` functionality as well as the possible sequences permissible for the release statuses to reach a specific target status.

Please note that the `RetiredStatusSet` property for the object class `EnterpriseRelease` should be defined. Otherwise, all release statuses will be considered a retired status for an enterprise release and can be deleted.

For information about how to configure the release status definition in the XML object ***ReleaseStatusDefs***, see the section Configuring Release Status Definitions for Object Classes in the chapter Configuring the Class Model.

Configuring Milestone Templates to Track Enterprise Releases

In Alfabet, users can create milestones in order to track and manage enterprise release. The XML object ***MilestoneManager*** allows you to configure milestone templates that users can select when defining milestones for an enterprise release.

Please note that project milestones are also configured in the XML object ***MilestoneManager***. There is no need to use a similar or identical set of milestones for enterprise releases and projects. However, it is recommended that the two milestone concepts are aligned with one another. For more information about configuring project milestones, see the section Configuring Milestone Templates to Track Projects.

Milestone templates are defined according to the project methodology pursued by the enterprise in order to assess the stage gates or milestones of the project methodology or enterprise release cycle.

A milestone template bundles a set of milestones including the definition of the color scheme used for tracking and reporting milestones and the sequence and tolerance period for each milestone. Users may either assign a configured milestone template directly to a project or enterprise release or, in the case of projects, they may select a configured project template and assign it to the project.

Projected target dates are automatically set for each milestone based on the configuration defined in the milestone template, but these dates may be manually edited for each milestone. Users may delete any milestone from a project or enterprise release that they deem unnecessary. Only one milestone template may be assigned to a project or enterprise release. The realization of milestones can be tracked for the enterprise release or, in the case of project milestones, on the level of the project, project group, or bucket.

Enterprise release milestones must be configured in the XML object ***MilestoneManager***. The enterprise release milestones represent the stage gates and the requirements that must be fulfilled to pass from one stage to the next. If enterprise release items are based on projects, the projects may also have milestones configured that are relevant for the approval and execution process of the project. There is no need to use a similar or identical set of milestones for enterprise releases and projects. However, it is recommended that the two milestone concepts are aligned with one another.

To edit the XML object ***MilestoneManager***:

1) Go to the **Presentation** tab and expand the **XML Objects** folder by clicking the + symbol. You will see all XML objects that can be edited.
2) Right-click the XML object ***MilestoneManager*** and select **Edit XML**. The XML editor is displayed in the center pane. For general information about editing XML objects in Alfabet Expand, see Working with XML Objects. The following is an example of a typical definition of milestones for the **Capture Enterprise Releases** capability.

3) The table below displays the XML attributes that can be edited for the XML object ***MilestoneManagerxml***:

XML Element (bold) / XML Attribute	Explanation
MilestoneTemplate	The milestone template bundles a set of milestones. The ***MilestoneTemplate*** element contains the attributes that allow you to configure the name, caption, type of duration (date or percentage of completion) that the milestone measures, and a description of the milestone template.
`Name`	Enter text to define the name of the milestone template. This is the name that users will see in the Alfabet interface.
`DurationType`	Enter "`Days`" to indicate that the duration of the milestone completion should be computed based on the number of days defined in the `Duration` attributes in the `MilestoneDef` elements. The milestone dates are computed based on the enterprise release's start date plus the value specified in the `Duration` attribute. The computed milestone dates will be displayed in the *Enterprise Release Milestones Page View*, where they can be modified if necessary. **NOTE**: The value "`Percents`" is typically only relevant in the context of project milestones and should not be implemented in the context of enterprise release milestones.
`Caption`	Enter text to define the caption of the milestone template. The caption serves as explanatory text about the milestone template when it is selected in the **Select Milestone Template** field in the **Create Milestone** editor available in the *Enterprise Release Milestones Page View*.
`Description`	Enter text to define a description about the milestone template. The description is displayed in the **Create Milestones** editor available in the *Enterprise Release Milestones Page View* and should help the user to understand the milestone template.
MilestoneColorDef	This element allows you to configure the milestone statuses to display on the milestones. Each ***MilestoneColorDef*** element includes a caption, color definition, and the period of time that the milestone is valid. For example, you could configure the milestone statuses Completed, Normal, Warning, and Danger. A legend will be displayed in the *Project Milestones Page View* describing the color scheme.

XML Element (bold) / XML Attribute	Explanation
	`Caption`	Enter text to define the caption that should be displayed to describe the milestone status in the legend in the *Project Milestones Page View*. For example, a milestone status could be "Normal" or "Warning", etc.
`Completed`	Enter "`True`" if the color set (defined in the attributes `BackColor`, `ForeColor`, and `TextColor`) should be displayed when the milestone has been completed. Enter "`False`" if the color set should not be displayed when the milestone has been completed. The attribute `Completed` should only be set to "`True`" for one ***MilestoneColorDef***. In this case, the `FromDays` and `ToDays` attributes are not necessary.
`FromDays`	Enter an integer that defines the period for which the color set should be displayed. The period of validity is the interval between the initial date of the milestone plus the `FromDays` value and the initial date of the milestone plus the `ToDays` value.
`ToDays`	Enter an integer that defines the period for which the color set should be displayed. The period of validity is the interval between the initial date of the milestone plus the `FromDays` value and the initial date of the milestone plus the `ToDays` value.
`BackColor`	Enter text to define the color of the outline of the box representing the milestone in the *Enterprise Release Milestones Page View*. The value entered should be a Windows, Web, hexadecimal, or RGB color value.
`ForeColor`	Enter text to define the color of the interior of the box representing the milestone in the *Enterprise Release Milestones Page View*. The value entered should be a Windows, Web, hexadecimal, or RGB color value.
`TextColor`	Enter text to define the color of the short name text in the box representing the milestone in the *Enterprise Release Milestones Page View*. The value entered should be a Windows, Web, hexadecimal, or RGB color value.
MilestoneDef	This element allows you to configure the milestones that are bundled in the milestone template. Whenever a user selects a milestone template for an enterprise release, the milestone dates will be initially computed based on the

XML Element (bold) / XML Attribute	Explanation
	`DurationType` and the `Duration` definitions. The computed dates can be manually adjusted. The milestones will be added automatically to the enterprise release and a legend will be displayed in the *Enterprise Release Milestones Page View*.
`Priority`	Enter an integer that defines the position of the milestone in the set of milestones. The position also determines the priority ranking for milestones that have the same value and must Therefore, be stacked in the *Enterprise Release Milestones Page View*. For example, a value of 1 indicates that this milestone should be the first that must be completed and will be stacked on top if milestones have the same value. (If the milestone template consists of 5 milestones, you should assign an integer from the range 1-5 to each ***MilestoneDef***.)
`Duration`	Enter an integer that defines the default period between milestones. The milestone dates will be automatically defined in Alfabet, but any or all can be manually changed by a user. For example, if you define a value of 50, the first milestone's start date will be automatically set to 50 days after the start date of the enterprise release, the second milestone's start date will be automatically set to 50 days after the first milestone's start date, etc. **NOTE**: If a milestone date is manually changed, the subsequent dates will NOT be automatically adjusted. If no integer is defined for the `Duration` attribute, then the default is the integer 1 (`Duration` = one day)
`Name`	Enter text to define the name of the milestone. The name of the milestone is not displayed in the Alfabet interface.
`Caption`	Enter text to define the caption of the milestone. The caption typically describes the milestone and will be displayed in the *Project Milestones Page View* and the legend of the *Enterprise Release Milestones Page View*. Since the milestones are based on the `DurationType` = "`Days`", then it would be informative to define a caption that describes the phase of the enterprise release completed by the milestone (for example, "Release Registration" and "Release Delivery Date")
`ShortName`	Enter text to define a short name for the milestone. The short name is displayed in the box representing the milestone in the *Enterprise Release Milestones Page View*. The milestone's short name and caption will be displayed in the legend.

XML Element (bold) / XML Attribute	Explanation
	Standard Milestones - Abbreviation D *Design Complete* B *Build Complete* T *Test Complete* **WARNING**: For reasons of usability, a short name should only be 1 or 2 characters long. Thus, for milestones Release Registration and Release Delivery Plan, it is recommended to implement a short name using initials such as RR and RD.
`Description`	Enter text that describes the milestone. This text will be displayed to the user in the milestone's preview in the *Project Milestones Page View* when the milestone is selected.

4) In the toolbar, click the **Save**  button to save the XML definition.

Configuring User Profiles and Visibility of Views in the Enterprise Release Capability

Please keep the following in mind regarding the configuration of user profiles and visibility issues.

- Ensure that the **Capture Enterprise Releases** functionality (`ENTRLS_CaptureReleases`) is available to the relevant user profile. For more information about assigning functionalities to user profiles, see the section Making Functionalities Accessible to a User Profile in the chapter Configuring User Profiles for the User Community.
- It is highly recommended that the enterprise release items in your enterprise are based on projects. Per default, the *Enterprise Release Items Page View* (`ENTRLS_Objects`) allows projects, applications, components, and standard platforms to be defined for enterprise release items. It is recommended that the menu items **New** > **Add** <Object Class> are excluded for all classes not used in the context of the enterprise release.
- The *Associated Enterprise Releases Page View* (`ENTRLS_ObjectReleases`) should also be removed from the object views of the object classes `Project`, `Application`, `Component`, or `StandardPlatform` if enterprise release items cannot be created for these classes.
- If enterprise release items are NOT based on projects, then the *Project Dependency Map Page View* (`ENTRLS_PRojectDependencyMap`) should be removed from the **Enterprise Release** object view.
- If enterprise release items are NOT based on projects or applications, then the *Business Support Map Report Page View* (`EITMPM_ObjectMatrixReport`) should be removed from the **Enterprise Release** object view.

Configuring the Contract Management Capability

The **Contract Management** functionality supports the enterprise in managing contracts and thus provides transparency to the use of contracts and the enterprise architecture. This capability ensures that the responsibility for contracts or aspects of a contract is understood in the enterprise and that necessary measures required to maintain or terminate contracts are timely and cost-effective. The **Contract Management** capability provides transparency regarding the contracts targeting architecture elements in the Alfabet database. The enterprise can document the deliverables required to fulfill a contractual agreement as well as the architecture elements in the IT landscape that consume the contract deliverables.

Users can define contract deliverables that specify the architecture elements and resources needed to fulfill the contract agreement, individual contract items that different organizations are responsible for, and a payment schedule relevant to each contract. Commercial contracts as well as free and open source contracts can be captured and managed. The contract deliverables for commercial contracts are typically captured directly for the contract or contract item in the *Contract Deliverables Page View* (`CNTR_Deliverables`) of the relevant contract or contract item. n the case of free and open-source contracts, contract deliverables are typically defined from the perspective of a vendor, component, local component or standard platform. To this end, the contract deliverables would be captured in the *Contract Deliverables Page View* (`CNTR_ArtifactDeliverables`) In this context, the referenced contract would be considered the free or open source license type being used for the delivery or use of the object.

Multiple non-hierarchical stereotypes can be configured for the object classes `Contract`, `ContractItem`, and `ContractDeliverable`. Contract stereotypes could be, for example, license contracts, maintenance contracts, Help Desk management contracts, etc. Custom object views, custom editors, custom wizards, custom selectors, configured reports, and custom class settings may be configured for these object classes/object class stereotypes. If free and open source contracts will be captured, for example, it is recommended that a solution designer configure custom selectors that ensure that the contract stereotypes representing free and open software are associated with the relevant contract deliverable.

The **Contract Management** functionality (`ContractManagement`) must be made available to the relevant user profiles. The mandate capability can be implemented for any configured contract stereotype in order to control user access to contracts in the `ContractManagement` functionality. Workflows may be configured for the **Contract Management** functionality (`ContractManagement`), as needed.

The following information is available:

- Creating Object Class Stereotypes for Contracts
- Configuring Release Status Definitions for the Contract Management Object Classes
- Configuring the Protected Enumerations Implemented in Contract Management
- Configuring Monitors or Workflows for Maintaining Contracts
- Configuring Class Settings for Contracts/Contract Stereotypes and Contract Items/Contract Item Stereotypes
- Configuring Wizards for the Contract Management Capability

Creating Object Class Stereotypes for Contracts

You may create an unlimited number of contract stereotypes for the object classes `Contract` and `ContractItem`. Please note that these are not hierarchical stereotypes.

Example of the XML definition in the **Stereotypes** attribute for the object class `Contract`:

```
<ClassStereotypes>
   <Stereotype Name="LicenseContract" Caption="License Contract"
   CaptionPlural="License Contracts" Comments="Contracts for
   software licences" HasMandates="true" />
   <Stereotype Name="MaintenanceLicense" Caption="Maintenance
   License" CaptionPlural="MaintenanceLicense" Comments="Contracts
   for maintenance agreements" HasMandates="false" />
</ClassStereotypes>
```

To create object class stereotypes for the object classes `Contract` and `ContractItem`:

1) Go to the **Meta-Model** tab and navigate to the protected class node for the object class `Contract` or `ContractItem` in the **Class Model** explorer.
2) Click the object class in the explorer to open the attribute window.
3) Click the **Browse** button available for the **Stereotypes** attribute to open the XML editor. Define the following XML attributes:

   An error message will be displayed upon closing the text editor if syntax errors are written in the XML definition of the **Stereotypes** attribute.

   - `Stereotype Name`: Enter the technical name for each object class stereotype. You may define a name of up to 64 characters. This name should not be changed once the object class stereotypes are implemented.

     Changing the technical name after objects have been created based on the object class stereotype requires such objects to be updated by means of an ADIF scheme. For more information, see the reference manual *Alfabet Data Integration Framework*.

   - `Caption`: Enter the caption for the object class stereotype. This is the name that users will see in the Alfabet user interface.

     Please note that the following:

     - The caption of the object class stereotype should be different than the caption of its object class. This is particularly important for the implementation of the search functionality for the object class stereotype. For more information, see the section Configuring Class Settings for Object Classes and Object Class Stereotypes in the chapter Configuring User Profiles for the User Community.
     - The values defined for the XML attribute `Caption` can be translated whereas the values defined for the XML attribute `Stereotype Name` cannot be translated. However, in the table of the **Simple Search** functionality as well as other search selectors, the values defined for the XML attribute `Stereotype Name` of the object class stereotype are displayed in the **Stereotypes** column. If the values defined for the XML attribute `Caption` should be displayed, a custom selector should be defined. For more

information, see the section Configuring a Custom Selector for Search Functionalities.

- If you want to enter a caption (`Caption`) or plural form for the caption (`CaptionPlural`) that contains special characters (for example, a greater then (>) or lesser then (<) symbol), you must replace the special characters with respective XML compliant code, for example:
  - > for >
  - < for <
  - " for "
  - [for [
  -] for]
- The caption will be available in the vocabularies and can be translated to the secondary languages implemented in your enterprise.

- `Description`: Provide a brief description about the object class stereotype. The description will be displayed in the **Stereotype Selector** that opens when the user must select which stereotype a new object is to be based on. The description should help the user to understand which stereotype the new object should be based on. The description will be available in the vocabularies and can be translated to the secondary languages implemented in your enterprise.
- `CaptionPlural`: Enter a plural form for the caption. This is the name in plural that users will see in the Alfabet user interface.
- `IDPrefix`: Enter no more than 5 characters for the ID prefix used to generate the unique identification number for new objects based on the object stereotype. If the XML attribute `IDPrefix` is not specified, the ID prefix of the object class that the object class stereotype is based on will be used to generate the unique ID. Please note that the integer generated for the unique ID is based on the number of instances created for the object class that the object class stereotype is based on and includes all instances of all object class stereotypes created for the object class.

  The prefix ID of existing objects based on an object class stereotype can be updated via the ADIF import scheme `SetStereotypeID` available in the `Alfabet Standard Jobs` folder. For more information, see the section *Predefined ADIF Schemes* in the reference manual *Configuring Alfabet with Alfabet Expand*.

- `Comments`: Enter text in order to provide information about the object class stereotype. This information is only for the purposes of configuration. It is not displayed in the Alfabet user interface.
- `HasMandates`: Enter "`true`" if the mandate capability should be available for the object class stereotype. Enter "`false`" if the mandate capability should not be available for the object class stereotype. If the XML attribute `HasMandates` is defined as "`false`" for an object class stereotype, objects based on the object class stereotype will be visible to users with any mandate implemented in your enterprise. For information about additional configuration requirements necessary to implement the mandate capability, see the section *Implementing the Mandate Capability for a Federated Architecture* in the chapter Configuring Access Permissions for Alfabet.

- `EnableStatutoryLanguage`: Set to `True` if the statutory language capability shall be available for the object class stereotype. The statutory language capability is available in order to address regulatory requirements that mandate that objects are captured in a specific language. When a user creates an object based on a relevant object class/object class stereotype, a statutory language selector will open in which the language can be selected. In the object editor that opens, the user can capture all attributes that support automated translation in the statutory language. If the XML attribute `EnableStatutoryLanguage` is not set, the object class stereotype will inherit the definition of the **Enable Statutory Language** attribute specified for the object class. Specifying a Statutory Language for the Enterprise

4) Click the **Save** button to save your changes.

Configuring Release Status Definitions for the Contract Management Object Classes

Release status definitions must be created for the following object classes:

- `Contract`
- `ContractItem`
- `ContractDeliverable`
- `ContractPayment`

The release status definition includes the complete set of release statuses implemented in the `Contract-Management` functionality. Each object class can have a different release status definition, as needed. If contract stereotypes are implemented, each contract stereotype may have a different release status. The technical name "`Contract`:<StereotypeName>" must be specified in the attribute `ClassNames`.

The release statuses must be defined in the XML object ***ReleaseStatusDefs*** available in the **XML Objects** folder in the **Presentation** tab. For detailed information about how to define the XML object ***ReleaseStatusDefs***, see the section Configuring Release Status Definitions for Object Classes in the chapter Configuring the Class Model.

Configuring the Protected Enumerations Implemented in Contract Management

The following protected enumerations are implemented in the **Contract Management** functionality (`ContractManagement`) and can be edited, as needed:

- `ContractDeliverableUnit`: This enumeration allows you to specify the values that can selected by users for the **Unit** field in the **Contract Deliverable** editor. Typical units for contract deliverables could be, for example, Licenses, Floating Licenses, Support Hours, Man/Days, etc. For more information about the **Unit** field for a contract deliverable, see the section *Contract Deliverables Page View* in the Alfabet online help.
- `ContractDependencyType`: This enumeration allows you to specify the values that can selected by users for the **Dependency Type** field in the **Contract Dependency** editor in the context of the `ContractManagement` functionality. Typical dependency types for contracts could be, for example,

Contract Successors or Contract Amendments. For more information, see the *Contract Dependencies Page View* in the Alfabet online help.

- `ContractPaymentType`: This enumeration allows you to specify the values that can selected by users for the **Type** field in the **Contract Payment** editor in the context of the `ContractManagement` functionality. Typical payment types for contracts could be, for example, Income or Expenditure. For more information, see the *Contract Payment Schedule Page View* in the Alfabet online help.

The protected enumerations are modified in the **Enums** folder in the **Meta-Model** tab. For detailed information about how to edit protected enumerations, see the section Defining Protected and Custom Enumerations in the chapter Configuring the Class Model.

Configuring Monitors or Workflows for Maintaining Contracts

You may consider implementing monitors in order to alert users responsible for contracts with impending review dates or configuring workflows that initiate contract reviews in order to ensure that contracts are maintained, renewed, or cancelled in a timely manner.

Possible relevant use cases for the configuration of monitors or workflows in the context of the **Contract Management** functionality (`ContractManagement`) include monitoring or managing any of the following:

- The object class property `EndDate` of the object class `Contract` or a configured contract stereotype. The object class property `EndDate` specifies the date that a contract is concluded.
- The object class properties `StartState` or `End Date` of the object class `ContractItem`. These object class properties are optional for the object class `ContractItem`.
- The object class property `ReviewDate` of the object class `Contract` that has been associated with a via the **Contract Schedule** view. The object class property `ReviewDate` specifies the date that the contract should be reviewed in the context of the master contract that it is assigned to.
- The object class property `DeliveryDate` of the object class `ContractDeliverable`. The object class property `DeliveryDate` specifies the date that the contract deliverable is due.
- The object class property `ExecutionDate` of the object class `ContractPayment`. The object class property `ExecutionDate` specifies the date that a contract payment should be made.

Monitors are configured in the **Monitors** functionality accessible in Alfabet via the `Admin` user profile, see the section *Configuring Monitors to Track Objects in Alfabet* in the reference manual *User and Solution Administration* as well as the section Configuring Monitors in this manual.

For more information about the configuration of workflows, see the chapter Configuring Workflows.

Configuring Class Settings for Contracts/Contract Stereotypes and Contract Items/Contract Item Stereotypes

If you want to define class settings for a object class stereotypes defined for the object classes `Contract` and `ContractItem`, you must manually add the stereotypes configured by your enterprise to the **Class Settings** folder in the **Presentation** tab. To add a project stereotype to the **Class Settings** folder, navigate to and right-click the relevant class setting for the object classes `Contract` and `ContractItem` and select either:

- **New Class Settings as Copy** to create a class setting as copy for the selected class, or
- **New Class Settings for Stereotype as Copy** to create a class setting for a stereotype of the selected class. In the dialog that opens, select the contract/contract item stereotype and click **OK**. You must use this function if there are no class settings already defined for the new stereotype.

The contract/contract item stereotype will be added with the naming convention `Contract`:<ContractStereotype> or `ContractItem`:<ContractItemStereotype>. The class settings can be edited, as needed. The class settings for the contract/contract item stereotypes can be configured in the same manner as class settings for other object classes.

For more information about configuring class settings, see the section Configuring Class Settings for Object Classes and Object Class Stereotypes in the chapter Configuring User Profiles for the User Community.

Configuring Wizards for the Contract Management Capability

Wizards can be implemented in the context of the **Contract Management** functionality (`ContractManagement`). Similar to class settings for other object settings, each class setting defined for a contract stereotype may have a different wizard assigned to.

Please note, however, that when a wizard is defined, it is first defined independent of the contract stereotype that it is relevant for. Thus, when defining the wizard, you must select the value `Contract` for the **Class Name** attribute. The wizard is then assigned to a class setting for the relevant contract stereotype. A wizard may be reused for multiple contract stereotypes.

For more information about configuring wizards, see the chapter Configuring Wizards.

Configuring the Resource Management Capability

Alfabet provides a Resource Management capability to support the planning of the availability of requested resources. The Resource Management capability is highly configurable and typically relies on the specification of object class stereotypes for the object class **Resource Request** (`ITResource`).

A resource request is any entity that is needed as a source of support for another entity in the IT enterprise. A resource request can be provided by an application, component, device, deployment, service product, standard platform, and organization (or any of their object class stereotypes). A resource request is requested by a resource requester which is typically a project, application, component, device, deployment, service product, standard platform, and organization. For example, the project stereotype Project Step may request the resource Development Organization which specifies that an organization based on the object class stereotype Business Unit may be requested. The project stereotype Project Step may also request the resource Project Development which specifies that a service product based on the object class stereotype System Hosting may be requested. Resource requests can then be planned in detail in the context of resource planning for projects, for example.

A resource request is associated with a cost type and includes the specification of the amount needed for the resource as well as the total cost of the use of the requested resource. An object requesting a resource may request multiple resources and an object that is requested as a resource may be requested by multiple objects.

The Resource Management capability is available in the workspace **Resource Management** (`RSRC_ResourceManagement`), which per default contains the *Required Resources Page View* (`RSRC_RequestorResources`), *Requested Resources Time Schedule Page View* (`RSRC_RequestorGantt`), and *Provided Resources Time Schedule Page View* (`RSRC_ProviderGantt`).

The following information is available:

- Configuring Object Class Stereotypes for Resource Management
- Specifying the Object Classes That Can Request a Resource in the XML Object ResourceManager
- Configuring Custom Selectors for Resource Management
- Configuring Custom Object Views and User Profiles for Resource Management

Configuring Object Class Stereotypes for Resource Management

Before you begin to configure the object class stereotypes needed for the Release Management capability, you should carefully consider which object class stereotypes are required for the object class `ITResource` as well as the object classes/object class stereotypes that may provide and request the resources. For example, typical object class stereotypes for the object class `ITResource` might be Organizational Resource, Service Product Resource, and Person Resource.

All object class stereotypes for the object class `ITResource` that you will configure in the XML object ***ResourceManager*** must be configured in the **Stereotypes** attribute for the object class `ITResource`. This is described below. Once the enterprise begins to work with the Resource Management capability, you should not remove existing object class stereotypes. If you do so, any existing objects must be updated to the new configuration by means of a customized ADIF scheme. For more information about configuring an ADIF scheme, see the reference manual *Alfabet Data Integration Framework*.

To create object class stereotypes for the object class `ITResource`:

1) Go to the **Meta-Model** tab and navigate to the protected class node  for the object class `ITResource` in the **Class Model** explorer.
2) Click the relevant object class in the explorer to open the attribute window.
3) Click the **Browse**  button available for the **Stereotypes** attribute to open the XML editor. Define the following XML attributes:

An error message will be displayed upon closing the text editor if syntax errors are written in the XML definition of the **Stereotypes** attribute.

- `Stereotype Name`: Enter the technical name for each object class stereotype. You may define a name of up to 64 characters. This name should not be changed once the object class stereotypes are implemented.

  Changing the technical name after objects have been created based on the object class stereotype requires such objects to be updated by means of an ADIF scheme. For more information, see the reference manual *Alfabet Data Integration Framework*.

- `Caption`: Enter the caption for the object class stereotype. This is the name that users will see in the Alfabet user interface.

  Please note that the following:

  - The caption of the object class stereotype should be different than the caption of its object class. This is particularly important for the implementation of the search functionality for the object class stereotype. For more information, see the section Configuring Class Settings for Object Classes and Object Class Stereotypes in the chapter Configuring User Profiles for the User Community.
  - The values defined for the XML attribute `Caption` can be translated whereas the values defined for the XML attribute `Stereotype Name` cannot be translated. However, in the table of the **Simple Search** functionality as well as other search selectors, the values defined for the XML attribute `Stereotype Name` of the object class stereotype are displayed in the **Stereotypes** column. If the values defined for the XML attribute `Caption` should be displayed, a custom selector should be defined. For more information, see the section Configuring a Custom Selector for Search Functionalities.
  - If you want to enter a caption (`Caption`) or plural form for the caption (`CaptionPlural`) that contains special characters (for example, a greater then (>) or lesser then (<) symbol), you must replace the special characters with respective XML compliant code, for example:
    - > for >
    - < for <
    - " for "

- [for [
-] for]

- The caption will be available in the vocabularies and can be translated to the secondary languages implemented in your enterprise.

- `Description`: Provide a brief description about the object class stereotype. The description will be displayed in the **Stereotype Selector** that opens when the user must select which stereotype a new object is to be based on. The description should help the user to understand which stereotype the new object should be based on. The description will be available in the vocabularies and can be translated to the secondary languages implemented in your enterprise.
- `CaptionPlural`: Enter a plural form for the caption. This is the name in plural that users will see in the Alfabet user interface.
- `IDPrefix`: Enter no more than 5 characters for the ID prefix used to generate the unique identification number for new objects based on the object stereotype. If the XML attribute `IDPrefix` is not specified, the ID prefix of the object class that the object class stereotype is based on will be used to generate the unique ID. Please note that the integer generated for the unique ID is based on the number of instances created for the object class that the object class stereotype is based on and includes all instances of all object class stereotypes created for the object class.

  The prefix ID of existing objects based on an object class stereotype can be updated via the ADIF import scheme `SetStereotypeID` available in the `Alfabet Standard Jobs` folder. For more information, see the section *Predefined ADIF Schemes* in the reference manual *Configuring Alfabet with Alfabet Expand*.

- `Comments`: Enter text in order to provide information about the object class stereotype. This information is only for the purposes of configuration. It is not displayed in the Alfabet user interface.
- `HasMandates`: Enter "`true`" if the mandate capability should be available for the object class stereotype. Enter "`false`" if the mandate capability should not be available for the object class stereotype. If the XML attribute `HasMandates` is defined as "`false`" for an object class stereotype, objects based on the object class stereotype will be visible to users with any mandate implemented in your enterprise. For information about additional configuration requirements necessary to implement the mandate capability, see the section *Implementing the Mandate Capability for a Federated Architecture* in the chapter Configuring Access Permissions for Alfabet .
- `EnableStatutoryLanguage`: Set to `True` if the statutory language capability shall be available for the object class stereotype. The statutory language capability is available in order to address regulatory requirements that mandate that objects are captured in a specific language. When a user creates an object based on a relevant object class/object class stereotype, a statutory language selector will open in which the language can be selected. In the object editor that opens, the user can capture all attributes that support automated translation in the statutory language. If the XML attribute `EnableStatutoryLanguage` is not set, the object class stereotype will inherit the definition of the **Enable Statutory Language** attribute specified for the object class. Specifying a Statutory Language for the Enterprise

4) Click the **Save** button t to save your changes.

Specifying the Object Classes That Can Request a Resource in the XML Object ResourceManager

Once all object class stereotypes have been created for the object class `ITResource`, you can refine the definition of functionality for each resource request stereotype in the XML object ***ResourceManager***.

To edit the XML object ***ResourceManager***:

1) Go to the **Presentations** tab, expand the **XML Objects** folder, and expand the **Solution Managers** folder.
2) Right-click the XML object ***ResourceManager*** and select **Edit XML**. The XML editor is displayed in the center pane. For general information about editing XML objects in Alfabet Expand, see the section Working with XML Objects.
3) Edit the XML attributes, as needed. The table below displays the XML attributes that can be edited for the XML object ***ResourceManager***:

XML Elements (bold) and Attributes	Explanation
ResourceManager	
Stereotype	Define the following attributes for each object class that may request resources.
`ClassName`	Enter the technical name of the object class that may request resources. You may enter any of the following object classes: `Application`, `Component`, `Device`, `Deployment`, `ServiceProduct`, `StandardPlatform`, `Project`, and `OrgaUnit` **NOTE**: You must spell the technical name of the object class stereotype exactly as it is spelled in the **Stereotypes** attribute of the relevant object class.
`Name`	Enter the technical name of the object class stereotype configured for the object class in the `ClassName` attribute that may request resources. Leave this attribute empty if an object class stereotype is not relevant. **NOTE**: You must spell the technical name of the object class stereotype exactly as it is spelled in the **Stereotypes** attribute of the relevant object class.
Stereotype	Define the following attributes for each object class that may provide resources.
`ClassName`	Enter the technical name of the object class that may fulfill resource requests. You may enter any of the following object class: `Application`,

XML Elements (bold) and Attributes	Explanation
	`Component`, `Device`, `Deployment`, `ServiceProduct`, `StandardPlatform`, `Project`, and `OrgaUnit` **NOTE**: You must spell the technical name of the object class stereotype exactly as it is spelled in the **Stereotypes** attribute of the relevant object class.
`Name`	Enter the technical name of the object class stereotype configured for the object class in the XML attribute `ClassName` that may provide resources. Leave this attribute empty if an object class stereotype is not relevant.
`ResourceStereotype`	Enter the technical name of the stereotype that is requested. You must spell the technical name of the object class stereotype exactly as it is spelled in the **Stereotypes** attribute of the object class `ITResource`.
`Selector`	Enter the name of the custom selector to implement to find the objects based on the object class/object class stereotype that may provide resources. For more information about configuring custom selectors, see the section Configuring a Custom Selector for Search Functionalities.
`CostType`	Enter the name of the cost type assigned to this resource request. Cost types are configured in the **Reference Data** functionality. For more information, see the chapter *Configuring Cost Types and Income Types for Cost Management Capabilities* in the reference manual *Configuring Evaluation and Reference Data in Alfabet*.
`ButtonCaption`	Enter the text that should appear in the **New** menu in the *Required Resources Page View* (`RSRC_RequestorResources`) when a user creates the resource. This text can help the user to understand the type of resource request that they are creating. For example, **Create New Application Management Resource** could be displayed in the **New** menu to find the organizations relevant for providing application management. The custom selector defined in the `Selector` attribute that would then open would ideally only display those organizations relevant for providing application management.

4) In the toolbar, click the **Save** button to save the XML definition.

Configuring Custom Selectors for Resource Management

Custom selectors may be configured as needed for any of the object classes associated with the Resource Management capability. The custom selector can be specified in the XML object ***ResourceManager*** to specify which custom selector to implement to find the objects referenced by the relevant object class stereotype based on the class `ITResource`. For more information about configuring custom selectors, see the ssection Configuring a Custom Selector for Search Functionalities.

Configuring Custom Object Views and User Profiles for Resource Management

In order to ensure that the relevant users can access the functionalities necessary to work with the Resource Management capability, you should consider which user profiles have access to the page views that allow users to create resource requests and analyze resource use. You should take into careful consideration which user profiles will need to access which object class stereotypes. This will require the configuration of custom object views as well as custom class settings. For more information, see the chapters Configuring Object Views and Configuring User Profiles for the User Community.

It is recommended that class settings are specified for each object class stereotype and that a different color is defined for each of these object class stereotypes. This will help support users working with the Gantt charts available in the context of resource management as well as resource planning in the context of projects.

The workspace **Resource Management** (`RSRC_ResourceManagement`) is available in the standard object views for the object classes `Application`, `Component`, `Device`, `Deployment`, `ServiceProduct`, `StandardPlatform`, `Project`, and `OrgaUnit`. The **Resource Management** workspace contains the *Required Resources Page View*, *Requested Resources Time Schedule Page View* (`RSRC_RequestorGantt`), and *Provided Resources Time Schedule Page View* (`RSRC_ProviderGantt`).

To make this capability available to the user community, the entire workspace or individual views must be added to a custom object view configured for the object classes `Application`, `Component`, `Device`, `Deployment`, `ServiceProduct`, `StandardPlatform`, and `OrgaUnit` and the custom object views must be available in the relevant user profiles. For more information about assigning a workspace to an object view, see the section Configuring Workspaces for an Object Profile in the chapter Configuring Object Views.

Furthermore, resource requests can be created in the context of project planning in the *Project, Skill Request and Resource Request Time Schedule Page View* (`PRJ_TimeSchedule`), *Project, Skill Request and Resource Request Time Schedule (Gantt) Page View* (`PRJ_TimeScheduleGantt`), and *Project Resource Planning Page View* (`PRJ_ResourcePlanning`). You must ensure that these views are available in the custom object of the relevant object class stereotype created for the object class `Project`.

Configuring the Service Product Portfolio Management Capability

Alfabet provides a capability that allows you to define and track the service products that are offered by an organization. This capability is highly configurable and typically relies on the specification of object class stereotypes for the object classes `ServiceProduct`, `ServiceItem`, and `SLA`.

For an overview of the methodology of Service Product Portfolio Management, see the section *Service Product Portfolio Management* in the reference manual *Portfolio Management Complete*.

In order to work with the Service Product Portfolio Management capability, the following configuration may be required:

- Typically, object class stereotypes are to be configured for the object classes `ServiceProduct`, `ServiceItem`, and `SLA` (Service Level Agreement (SLA)), these must be configured in the configuration tool Alfabet Expand. In this case, the solution designer should consider which service product stereotypes are required, what kind of service product items are required to provide each service product stereotype, whether the service product hierarchy should be recursive for a service product stereotype, and which service level agreement stereotype should be assigned to which service product stereotype. Object class stereotypes may also be necessary for the object classes `Contract` and `Market Product`. You should consider whether a service product stereotype should only be associated with a specific contract stereotype and whether a specific service product stereotype should only be associated with specific market product stereotype.
- The relationship between the object class stereotypes configured for SLAs and the object class stereotypes for service products must be configured in the XML object ***ServiceProductManager***.
- Custom properties may be configured as needed for the object classes `Service Product Group`, `ServiceProduct`, `ServiceItem`, and `SLA`. Please note that the object class `SLA` has only basic standard properties and it is typically necessary to configure custom attributes to capture relevant details about the SLA.
- Service products have a lifecycle, object state, and release status definition.
- Custom editors and custom selectors must be configured for each object class stereotype in order to capture data for the custom attributes.
- Please note the following additional configuration requirements:
  - If IT resources are to be specified for service products, then object class stereotypes may be defined for the object class Resource. You must also specify that service products may request service products in the XML object ***ResourceManager***. Details about the necessary configuration are described in the section Configuring the Resource Management Capability in the reference manual *Configuring Alfabet with Alfabet Expand*.
  - If contracts are to be specified for service products, then object class stereotypes may be defined for the object class Contract. Details about the necessary configuration are described in the section Configuring the Contract Management Capability in the reference manual *Configuring Alfabet with Alfabet Expand*.

The following information is available:

- Configuring Object Class Stereotypes for Service Product Portfolio Management
- Specifying the Relationships for the Service Product, Service Product Item, and SLA Stereotypes in the XML Object ServiceProductManager

- Configuring Lifecycle, Object State, and Release Status Definitions
- Configuring Custom Properties and Editors for Service Product Portfolio Management
- Configuring Custom Selectors for Service Product Portfolio Management
- Configuring Custom Object Views and User Profiles for Service Product Portfolio Management
- Configuring Mandates for Service Product Portfolio Management

Configuring Object Class Stereotypes for Service Product Portfolio Management

Before you begin to configure the object class stereotypes needed for the Service Product Portfolio Management capability, you should carefully consider which object class stereotypes are required for the object classes `ServiceProduct`, `ServiceItem`, and `SLA`. as well as the object classes/object class stereotypes that may provide the service product items. You should consider the following questions:

- Which service product stereotypes are required. Typical service product stereotypes could be, for example:
  - Application Business Service
  - Application Maintenance
  - Application Development
  - User Support Service
  - User License Service
  - System Hosting
  - Information Business Service
  - Terminal Service
- What kind of service level agreements (SLA) are required for each service product stereotype? In Alfabet, users may only specify one SLA per service product. Each service product stereotype is configured to have one permissible SLA stereotype that the SLA is based on. An SLA stereotype is typically configured for a specific service product stereotype in order to capture details including the units of measurements relevant to the service product stereotype. Each SLA stereotype typically requires the configuration of custom attributes and a custom editor.

  For example, an SLA stereotype User Support Service SLA for the service product stereotype User Support Service could have the custom attributes Service Desk Support Hours, 2nd Level Support Hours, 3rd Level Support Hours, Target Resolution Time, Support Availability. The Application Development SLA for the service product stereotype Application Development could have the custom attributes, Target Resolution Time, Defect Backlog Size Limit, Maximum Number of Test Failures.

- What kind of service product items are required to provide each service product stereotype? In Alfabet, multiple service product items of various object class stereotypes may provide a service product. Users associate each service product item with an object from an object class/object class stereotype that is permissible for the service product item. The base object classes include `Application`, `Component`, `Device`, `Deployment`, `StandardPlatform`, `OrgaUnit`, and

`ServiceProduct`. The association of object classes with the service product item is configured in the XML object ***ServiceProductManager***.

For example, the service product stereotype User Support Service could have the service product stereotypes. Application User Support Service which would be associated with a specified application or application stereotype, Deployment User Support Service which would be associated with a specified deployment or deployment stereotype, and Device User Support Service, which would be associated with a specified device or device stereotype.

- Should the service product hierarchy for a service product stereotype be recursive? In other words, should the service product hierarchy allow service product stereotypes to be subordinate to other service product stereotypes? If so, then the subordinate service product stereotypes must be specified as service product items in the XML object ***ServiceProductManager***. All service product stereotypes, whether on a parent level or child level, must be configured in the **Stereotypes** attribute for the object class ServiceProduct.

  For example, the service product stereotype Application Business Service is configured to be the parent service product stereotype in the service product hierarchy. The service product items that provide the service product Application Business Service are other service products. In other words, the service product items are associated with the relevant object class stereotypes for the object class `ServiceProduct` such as System Hosting, Application Maintenance, Application Development, User License Services, and User Support Services.

  Therefore, in addition to the service product stereotype Application Business Service, the service product stereotypes System Hosting, Application Maintenance, Application Development, User License Services, and User Support Services must be configured in the **Stereotypes** attribute for the object class ServiceProduct. Their relationship to the parent service product stereotype must be configured in the XML object ***ServiceProductManager***.

- Are object class stereotypes required for other object classes that are relevant to service products. For example, should the ownership of service product based on a service product stereotype be assigned to a specific organization stereotype? Should a service product based on a service product stereotype be defined for a specific contract stereotype? Should a service product based on a service product stereotype be associated with specific market product stereotype?

All object class stereotypes for the object classes `ServiceProduct`, `ServiceItem`, and `SLA` that you will configure in the XML object ***ServiceProductManager*** must be configured in the **Stereotypes** attribute for that object class. This is described below. **Once the enterprise begins to work with the Service Product Portfolio Management capability, you should not remove existing object class stereotypes. If you do so, any existing objects must be updated to the new configuration by means of a customized ADIF scheme.** For more information about configuring an ADIF scheme, see the reference manual *Alfabet Data Integration Framework*.

Example of the XML definition in the ***Stereotype*** element for the object class ServiceProduct:

```
<ClassStereotypes>

   <Stereotype Name="ApplicationBusinessService"
   Caption="Application Business Service" CaptionPlural="Application
   Business Services" Comments="" HasMandates="false" />

   <Stereotype Name="InformationBusinessService"
   Caption="Information/Data Business Service"
```

```
CaptionPlural="Information/Data Business Services" Comments=""
HasMandates="false" />

<Stereotype Name="SystemHosting" Caption="Server/System Hosting"
CaptionPlural="Server/System Hosting" Comments=""
HasMandates="false" />

<Stereotype Name="ApplicationMaintenance" Caption="Application
Maintenance" CaptionPlural="Application Maintenance" Comments=""
HasMandates="false" />

<Stereotype Name="ApplicationDevelopment" Caption="Application
Development" CaptionPlural="Application Development" Comments=""
HasMandates="false" />

<Stereotype Name="UserLicenseService" Caption="User/License
Management Service" CaptionPlural="User/License Management
Services" Comments="" HasMandates="false" />

<Stereotype Name="UserSupportService" Caption="User Support
Service" CaptionPlural="User Support Services" Comments=""
HasMandates="false" />

<Stereotype Name="DataService" Caption="Data Service"
CaptionPlural="Data Services" Comments="" HasMandates="false" />

<Stereotype Name="TerminalService" Caption="Terminal Service"
CaptionPlural="Terminal Services" Comments="" HasMandates="false"
/>

</ClassStereotypes>
```

To create object class stereotypes for the object classes `ServiceProduct`, `ServiceItem` and `SLA`:

1) Go to the **Meta-Model** tab and navigate to the protected class node  for the object classes `ServiceProduct`, `ServiceItem` and `SLA` in the **Class Model** explorer.
2) Click the relevant object class in the explorer to open the attribute window.
3) lick the **Browse**  button available for the **Stereotypes** attribute to open the XML editor. Define the following XML attributes:

An error message will be displayed upon closing the text editor if syntax errors are written in the XML definition of the **Stereotypes** attribute.

- `Stereotype Name`: Enter the technical name for each object class stereotype. You may define a name of up to 64 characters. This name should not be changed once the object class stereotypes are implemented.

  Changing the technical name after objects have been created based on the object class stereotype requires such objects to be updated by means of an ADIF scheme. For more information, see the reference manual *Alfabet Data Integration Framework*.

- `Caption`: Enter the caption for the object class stereotype. This is the name that users will see in the Alfabet user interface.

  Please note that the following:

- The caption of the object class stereotype should be different than the caption of its object class. This is particularly important for the implementation of the search functionality for the object class stereotype. For more information, see the section Configuring Class Settings for Object Classes and Object Class Stereotypes in the chapter Configuring User Profiles for the User Community.
- The values defined for the XML attribute `Caption` can be translated whereas the values defined for the XML attribute `Stereotype Name` cannot be translated. However, in the table of the **Simple Search** functionality as well as other search selectors, the values defined for the XML attribute `Stereotype Name` of the object class stereotype are displayed in the **Stereotypes** column. If the values defined for the XML attribute `Caption` should be displayed, a custom selector should be defined. For more information, see the section Configuring a Custom Selector for Search Functionalities.
- If you want to enter a caption (`Caption`) or plural form for the caption (`CaptionPlural`) that contains special characters (for example, a greater then (>) or lesser then (<) symbol), you must replace the special characters with respective XML compliant code, for example:
  - > for >
  - < for <
  - " for "
  - [for [
  -] for]
- The caption will be available in the vocabularies and can be translated to the secondary languages implemented in your enterprise.

- `Description`: Provide a brief description about the object class stereotype. The description will be displayed in the **Stereotype Selector** that opens when the user must select which stereotype a new object is to be based on. The description should help the user to understand which stereotype the new object should be based on. The description will be available in the vocabularies and can be translated to the secondary languages implemented in your enterprise.
- `CaptionPlural`: Enter a plural form for the caption. This is the name in plural that users will see in the Alfabet user interface.
- `IDPrefix`: Enter no more than 5 characters for the ID prefix used to generate the unique identification number for new objects based on the object stereotype. If the XML attribute `IDPrefix` is not specified, the ID prefix of the object class that the object class stereotype is based on will be used to generate the unique ID. Please note that the integer generated for the unique ID is based on the number of instances created for the object class that the object class stereotype is based on and includes all instances of all object class stereotypes created for the object class.

The prefix ID of existing objects based on an object class stereotype can be updated via the ADIF import scheme `SetStereotypeID` available in the `Alfabet`

`Standard Jobs` folder. For more information, see the section *Predefined ADIF Schemes* in the reference manual *Configuring Alfabet with Alfabet Expand*.

- `Comments`: Enter text in order to provide information about the object class stereotype. This information is only for the purposes of configuration. It is not displayed in the Alfabet user interface.
- `HasMandates`: Enter "`true`" if the mandate capability should be available for the object class stereotype. Enter "`false`" if the mandate capability should not be available for the object class stereotype. If the XML attribute `HasMandates` is defined as "`false`" for an object class stereotype, objects based on the object class stereotype will be visible to users with any mandate implemented in your enterprise. For information about additional configuration requirements necessary to implement the mandate capability, see the section *Implementing the Mandate Capability for a Federated Architecture* in the chapter Configuring Access Permissions for Alfabet .
- `EnableStatutoryLanguage`: Set to `True` if the statutory language capability shall be available for the object class stereotype. The statutory language capability is available in order to address regulatory requirements that mandate that objects are captured in a specific language. When a user creates an object based on a relevant object class/object class stereotype, a statutory language selector will open in which the language can be selected. In the object editor that opens, the user can capture all attributes that support automated translation in the statutory language. If the XML attribute `EnableStatutoryLanguage` is not set, the object class stereotype will inherit the definition of the **Enable Statutory Language** attribute specified for the object class. Specifying a Statutory Language for the Enterprise

4) Click the **Save** button to save your changes.

Specifying the Relationships for the Service Product, Service Product Item, and SLA Stereotypes in the XML Object ServiceProductManager

Once all object class stereotypes have been created for the object classes `ServiceProduct`, `ServiceItem` and `SLA`, you can refine the definition of functionality for each service product stereotype in the XML object ***ServiceProductManager***.

To edit the XML object ***ServiceProductManager***:

1) Go to the **Presentations** tab, expand the **XML Objects** folder, and expand the **SolutionManagers** folder.
2) Right-click the XML object ***ServiceProductManager*** and select **Edit XML**. The XML editor is displayed in the center pane. For general information about editing XML objects in Alfabet Expand, see the section Working with XML Objects.
3) Edit the XML attributes, as needed. The table below displays the XML attributes that can be edited for the XML object ***ServiceProductManager***:

XML Elements (bold) and Attributes	Explanation
ServiceProductManager	
Stereotype	Define the following attributes for each service product stereotype.
`Name`	Enter the technical name of the object class stereotype defined for the object class `ServiceProduct`. This is the name defined in the XML attribute `Name` in the **Stereotypes** attribute for the object class `ServiceProduct`. You must spell the technical name of the service product stereotype exactly as it is spelled in the **Stereotypes** attribute of the object class `ServiceProduct`.
`SLA_Stereotype`	Enter the technical name of the object class stereotype defined for the object class `SLA` that is available for the service product stereotype. Only one SLA stereotype may be specified per service product stereotype. Enter the name defined in the `Name` parameter in the **Stereotypes** attribute for the object class `SLA`. You must spell the technical name of the SLA stereotype exactly as it is spelled in the **Stereotypes** attribute of the object class `SLA`.
Stereotype	Define the following attributes for each service product item stereotype.
`ClassName`	The object class or object class stereotype that is referenced by the service product item stereotype relevant for the service product. You must spell the technical name of the object class stereotype exactly as it is spelled in the **Stereotypes** attribute of the relevant object class.
`Name`	Allows you to specify a recursive definition in the service product hierarchy. Enter the name of the child service product stereotype that is referenced by the parent service product stereotype identified in the ascendant ***Stereotype*** `Name` element.
`Selector`	The selector to implement to find the objects referenced by the service product item stereotype. For more information about configuring custom selectors, see the section Configuring a Custom Selector for Search Functionalities.

XML Elements (bold) and Attributes	Explanation
ServiceItemStereotype	The technical name of the object class stereotype of the service product item that will be used when creating a new service item object. The new service product item object will be based on the specified object class stereotype. The caption configured for the object class stereotype will be displayed in the menu for the creation of a service product item object. If this attribute is not defined, the object class/object class stereotype specified in the ClassName attribute will automatically be referenced. You must spell the technical name of the stereotype exactly as it is spelled in the **Stereotypes** attribute of the object class ServiceItem.
AllowDuplications	Enter "true" if the same object may be used to create multiple independent service product items assigned to the same service product. For example, if one application should be used to provide three service products Product Environment, Text Environment, and Development Environment. Enter "false" if the same object may not be used to create multiple independent service product items assigned to the same service product.

4) In the toolbar, click the **Save** button to save the XML definition.

Configuring Lifecycle, Object State, and Release Status Definitions

The object class ServiceProduct supports the configuration of lifecycles, object states, and release statuses. These must be configured in the relevant XML object as described in the following sections in the chapter Configuring the Class Model:

- Configuring Release Status Definitions for Object Classes
- Configuring Object State Definitions for Object Classes
- Configuring Lifecycle Definitions for Object Classes

Configuring Custom Properties and Editors for Service Product Portfolio Management

Custom properties may be configured as needed for the object classes ServiceProduct, ServiceItem, and SLA. Please note that the object class SLA in particular typically requires the configuration of custom properties in order to capture details regarding the units of measurements relevant to the service product stereotype.

All custom properties needed for the configured object class stereotypes should be configured for the base object class. In other words, all custom properties needed by all SLA stereotypes should be defined for the object class SLA. This is described in detail in the chapter Configuring Custom Properties for Protected or Public Object Classes.

Once the custom properties have been defined, you can configure custom editors in order to capture the custom properties relevant for the stereotype. This is described in detail in the chapter Configuring Custom Editors.

Configuring Custom Selectors for Service Product Portfolio Management

Custom selectors may be configured as needed for any of the object classes associated with the Service Product Portfolio Management capability. A selector definition is available in the XML object ***ServiceProductManager*** to specify which custom selector to implement to find the objects referenced by a service product item stereotype. For more information about configuring custom selectors, see the section Configuring a Custom Selector for Search Functionalities.

Configuring Custom Object Views and User Profiles for Service Product Portfolio Management

In order to ensure that the relevant users can access the functionalities necessary to work with the Service Product Portfolio Management capability, you should consider which user profiles have access to the following business functions (explorers), object views, and page views.

This capability typically includes a high level of configuration, in particular because object class stereotypes can be configured for the object classes `ServiceProduct`, `ServiceItem`, `SLA`, `OrgaUnit`, as well as the object classes that can be configured to provide service product items. Therefore, you should take into careful consideration which user profiles will need to access which object class stereotypes. This will require the configuration of custom object views as well as custom class settings. For more information, see the chapters Configuring Object Views and Configuring User Profiles for the User Community.

The following business functions are relevant for the Service Product Portfolio Management capability:

- **Service Product Groups** explorer (`SRVPRDG_Explorer`): Provides access to the object classes `ServiceProductGroup`, `ServiceProduct`, `ServiceItem`, and `SLA`. The following object views and page views are relevant for the **Service Product Groups** explorer:
  - `SRVPPRDG_ObjectView`/custom object views should include any necessary **Basic Data** page views and the following views:
    - *Sub-Groups Page View* (`SRVPRDG_SubGroups`)
    - *Service Products Page View* (`SRVPRDG_Products`)
    - *Service Product Portfolio Page View* (`SRVPRDG_ServiceProductPortfolio`)
  - `SRVPRD_ObjectView`/custom object views should include any necessary **Basic Data** page views and the following views:
    - *Service Product Items Page View* (`SRVPRD_Items`)
    - *Subordinate Value Stream Groups Page View* (`SRVPRD_Lifecycle`)

- *Service Product Overlap Report Page View* (`SRVPRD_OverlapReport`)
- *Service Product Usage Gantt Page View* (`SRVPRD_UsageGantt`)
- *Existing Contracts Page View* (`SRVPRD_Contracts`)

- `SRVITM_ObjectView`/custom object views (standard object view contains only the *Attachments Page View*)
- `SLA_ObjectView`/custom object views (standard object view contains only the *Attachments Page View*)

- **Enterprise Service Products Catalog** (`SRVPRD_Explorer`): Provides access to the object class `OrgaUnit`. The `ORG_ObjectView`/custom object views should include the following views:
  - *Service Product Portfolio Page View* (`ORG_ServiceProductPortfolio`)
  - *Owned Service Products Page View* (`ORG_ServiceProducts`)
- The relevant object views for the object class `MarketProduct` (`PROD_ObjectView`/custom object views) should include the *Service Products Page View* (`PROD_ServiceProducts`)
- The relevant object views for object classes/object class stereotypes referenced as providers of a service product item should include the *Existing Service Product Contracts Page View* (`SRVPRD_ArtifactContracts`).

Configuring Mandates for Service Product Portfolio Management

The mandate functionality is typically configured when the service product stereotypes are created. However, the mandate assignment can be edited, as needed. The mandate capability can be activated or deactivated for the entire service product capability as well as explicitly activated or deactivated for specific service product stereotypes.

The mandate configuration may differ for the service product stereotypes defined. Per default, the XMl attribute `HasMandates` is defined as "`false`" for all service product stereotypes. This means that the default setting is that service products based on a service product stereotype will be visible to users with any mandate implemented in your enterprise. Therefore, if visibility should be controlled for the service products based on a service product stereotype, you must explicitly define the mandate capability for each service product stereotype.

For more information about the mandates capability as well as how to create mandates for your enterprise, see the section *Implementing the Mandate Capability for a Federated Architecture* in the chapter Configuring Access Permissions for Alfabet.

To configure the mandate capability for your service product hierarchy:

1) Go to the **Meta-Model** tab and navigate to the protected class node  for the object class `ServiceProduct` in the **Class Model** explorer.
2) Click the object class `ServiceProduct` to display the attribute window.
3) Set the **Can Have Mandates** attribute to `True` if the mandate capability should be available for the service product capability as a whole. Select `False` if the mandate capability should not be available.

4) Next, you must explicitly define the mandates capability for each service product stereotype. Click the **Browse** button available for the **Stereotypes** attribute.

5) To implement the mandate capability for a service product stereotype, the XML attribute `HasMandates` must be defined as "`true`". If you do not want to implement the mandate capability for a service product stereotype, the XML attribute `HasMandates` must be defined as "`false`". If the XML attribute `HasMandates` is defined as "`false`" for a service product stereotype, service products based on the stereotype will be visible to permissible users with any mandate implemented in your enterprise.

6) Close the XML definition of the **Stereotypes** attribute by clicking **OK** in the editor.

7) In the toolbar, click the **Save** button to save your changes.

Configuring the ICT Object Hierarchy

You can create multiple ICT object stereotypes, as needed. The ICT objects based on an ICT object stereotype are instances of the ICT object stereotype.

You must first configure the ICT object stereotypes in the **Stereotypes** attribute of the object class `ICTObject`. Once the ICT object stereotypes have been created, you can specify which object classes, or their object class stereotypes may be owned by an ICT object stereotypes. Possible object classes and their configured stereotypes include `Application`, `Component`, `Device`, `LocalComponent`, `StandardPlatform`, `SystemBuildingBlock`, and `VendorProduct`. This is configured in the XML object ***ICTObjectManager***.

For a methodological overview of ICT objects, see the section *Application Architecture Definition* in the reference manual *Enterprise Architecture Management*.

Once defined, an ICT object stereotype is similar to a standard object class. Correspondingly, you can configure the mandate capability to control user access to each ICT object stereotype. Additionally, you can configure custom editors, wizards, workflows, and reports for each ICT object stereotype, as needed.

You can configure a class setting for each individual ICT object stereotype, if needed. If class settings are not configured for a stereotype, the class setting specified for the class `ICTObject` will be used. Please note the following logic of which editor/wizard opens when the **Create ICT Object** option is configured is as follows:

1) The editor/wizard defined in the default class setting (**Default** attribute set to `True`) specified for the relevant view scheme associated with the user's user profile.
2) The editor/wizard defined in the default class setting (**Default** attribute set to `True`) specified for the ICT object stereotype
3) The editor/wizard defined in the default class setting (**Default** attribute set to `True`) specified for the class **ICT Object**.

The following information is available:

- Creating Object Class Stereotypes for ICT Objects
- Configuring the Attributes and Functionalities Available for an ICT Object Stereotype

Creating Object Class Stereotypes for ICT Objects

To create ICT object stereotypes:

1) Go to the **Meta-Model** tab and navigate to the protected class node for the object class ICT object in the **Class Model** explorer.
2) Click the object class `OrgaUnit` in the explorer to open the attribute window.
3) Click the **Browse** button available for the **Stereotypes** attribute to open the XML editor. Define the following XML attributes:

An error message will be displayed upon closing the text editor if syntax errors are written in the XML definition of the **Stereotypes** attribute.

- `Stereotype Name`: Enter the technical name for each object class stereotype. You may define a name of up to 64 characters. This name should not be changed once the object class stereotypes are implemented.

  Changing the technical name after objects have been created based on the object class stereotype requires such objects to be updated by means of an ADIF scheme. For more information, see the reference manual *Alfabet Data Integration Framework*.

- `Caption`: Enter the caption for the object class stereotype. This is the name that users will see in the Alfabet user interface.

  Please note that the following:

  - The caption of the object class stereotype should be different than the caption of its object class. This is particularly important for the implementation of the search functionality for the object class stereotype. For more information, see the section Configuring Class Settings for Object Classes and Object Class Stereotypes in the chapter Configuring User Profiles for the User Community.
  - The values defined for the XML attribute `Caption` can be translated whereas the values defined for the XML attribute `Stereotype Name` cannot be translated. However, in the table of the **Simple Search** functionality as well as other search selectors, the values defined for the XML attribute `Stereotype Name` of the object class stereotype are displayed in the **Stereotypes** column. If the values defined for the XML attribute `Caption` should be displayed, a custom selector should be defined. For more information, see the section Configuring a Custom Selector for Search Functionalities.
  - If you want to enter a caption `(Caption)` or plural form for the caption (`CaptionPlural`) that contains special characters (for example, a greater then (>) or lesser then (<) symbol), you must replace the special characters with respective XML compliant code, for example:
    - > for >
    - < for <
    - " for "
    - [for [
    -] for]
  - The caption will be available in the vocabularies and can be translated to the secondary languages implemented in your enterprise.

- `Description`: Provide a brief description about the object class stereotype. The description will be displayed in the **Stereotype Selector** that opens when the user must select which

stereotype a new object is to be based on. The description should help the user to understand which stereotype the new object should be based on. The description will be available in the vocabularies and can be translated to the secondary languages implemented in your enterprise.

- `CaptionPlural`: Enter a plural form for the caption. This is the name in plural that users will see in the Alfabet user interface.
- `IDPrefix`: Enter no more than 5 characters for the ID prefix used to generate the unique identification number for new objects based on the object stereotype. If the XML attribute `IDPrefix` is not specified, the ID prefix of the object class that the object class stereotype is based on will be used to generate the unique ID. Please note that the integer generated for the unique ID is based on the number of instances created for the object class that the object class stereotype is based on and includes all instances of all object class stereotypes created for the object class.

  The prefix ID of existing objects based on an object class stereotype can be updated via the ADIF import scheme `SetStereotypeID` available in the `Alfabet Standard Jobs` folder. For more information, see the section *Predefined ADIF Schemes* in the reference manual *Configuring Alfabet with Alfabet Expand*.

- `Comments`: Enter text in order to provide information about the object class stereotype. This information is only for the purposes of configuration. It is not displayed in the Alfabet user interface.
- `HasMandates`: Enter "`true`" if the mandate capability should be available for the object class stereotype. Enter "`false`" if the mandate capability should not be available for the object class stereotype. If the XML attribute `HasMandates` is defined as "`false`" for an object class stereotype, objects based on the object class stereotype will be visible to users with any mandate implemented in your enterprise. For information about additional configuration requirements necessary to implement the mandate capability, see the section *Implementing the Mandate Capability for a Federated Architecture* in the chapter Configuring Access Permissions for Alfabet .
- `EnableStatutoryLanguage`: Set to `True` if the statutory language capability shall be available for the object class stereotype. The statutory language capability is available in order to address regulatory requirements that mandate that objects are captured in a specific language. When a user creates an object based on a relevant object class/object class stereotype, a statutory language selector will open in which the language can be selected. In the object editor that opens, the user can capture all attributes that support automated translation in the statutory language. If the XML attribute `EnableStatutoryLanguage` is not set, the object class stereotype will inherit the definition of the **Enable Statutory Language** attribute specified for the object class. Specifying a Statutory Language for the Enterprise

4) Click the **Save** button to save your changes.

Configuring the Attributes and Functionalities Available for an ICT Object Stereotype

Once the ICT object stereotypes have been created for the object class `ICTObject`, you can refine the definition of functionality for each ICT object stereotype in the XML object ***ICTObjectManager***.

To edit the XML object ***ICTObjectManager***:

1) Go to the **Presentations** tab, expand the **XML Objects** folder, and expand the **SolutionManagers** folder.
2) Right-click the XML object ***ICTObjectManager*** and select **Edit XML**. For general information about editing XML objects in Alfabet Expand, see Working with XML Objects.
3) Edit the XML attributes, as needed. The table below displays the XML attributes that can be edited for the XML object ***ICTObjectManager***:

XML Elements (bold) and Attributes	Explanation
ICT ICTObjectManager	
Stereotype	Each ICT object stereotype begins with the element ***Stereotype*** in the XML object. Define the following attributes for each ICT object stereotype.
`Name`	Enter the technical name of the ICT object stereotype. This is the name defined in the `Name` attribute in the **Stereotypes** attribute for the object class `ICTObject`. The stereotype name is passed on to the objects that users create for the selected ICT object stereotype.

`AllowedArtifacts`	Enter the names of the object classes or object class stereotypes that may be created for the ICT object stereotype.
	Possible object classes and their configured stereotypes include `Application`, `Component`, `Device`, `LocalComponent`, `StandardPlatform`, `SystemBuildingBlock`, and `VendorProduct`.
	FOR EXAMPLE:
	`<ICTObjectManager`
	`<Stereotype Name="TechnicalICTO"`
	`AllowedArtifacts="Application:TechnicalApplication"`
	`CreateClasses="Application" />`
	`<Stereotype Name="BusinessICTO"`

XML Elements (bold) and Attributes	Explanation

	<pre>AllowedArtifacts="Application:BusinessApplication"
	CreateClasses="Application" />
	<Stereotype Name="ComponentICTO"
	AllowedArtifacts="Component"
	CreateClasses="Component" />
	</ICTObjectManager></pre>
	NOTE: to define an object class, use the value of the Name attribute of the object class. To define an object class stereotype, use the value of the **Name** attribute of the object class and the XML attribute `Name` of the XML definition of the stereotype in the **Stereotype** attribute of the object class. Object class name and object class stereotype name are separated with a colon.

4) In the toolbar, click the **Save**  button to save the XML definition.

Configuring the Demand Hierarchy

A branching hierarchy of demand stereotypes may be configured. You can create multiple demand stereotypes and configure multiple demand hierarchies, including which demand stereotypes are permissible for a demand group stereotype. A demand stereotype may have multiple subordinate demand stereotypes. Furthermore, a demand stereotype may be configured to be recursive, thereby allowing subordinate demands to be defined that are based on the same demand stereotype. Thus, a demand stereotype may be configured to allow subordinate demands based on the same demand stereotype to be defined as well as a subordinate demands based on a permissible subordinate demand stereotype to be defined. The name, number, and hierarchical ordering of the demand stereotypes are configurable.

You must first configure the demand stereotypes in the **Stereotypes** attribute of the object class `Demand`. Once the demand stereotypes have been created, you can order the hierarchy of demand stereotypes in the XML object ***DemandManager***

Once defined, a demand stereotype is similar to a standard object class. Correspondingly, you can configure the mandate capability to control user access to each demand stereotype. All demand stereotypes can be configured to be searchable via class settings and thus selected in the list of searchable object classes displayed in the **Search for** field in the **Simple Search** and **Browse** functionalities. Additionally, you can configure custom editors, wizards, workflows, and reports for each demand stereotype, as needed.

The following information is available:

- Creating Object Class Stereotypes for Demands
- Configuring the Attributes for the XML Object DemandManager

Creating Object Class Stereotypes for Demands

To create demand stereotypes:

1) Go to the **Meta-Model** tab and navigate to the protected class node  for the object class `Demand` in the **Class Model** explorer.
2) Click the object class `Demand` in the explorer to open the attribute window.
3) Click the **Browse**  button available for the **Stereotypes** attribute to open the XML editor. Define the following XML attributes:

An error message will be displayed upon closing the text editor if syntax errors are written in the XML definition of the **Stereotypes** attribute.

- `Stereotype Name`: Enter the technical name for each object class stereotype. You may define a name of up to 64 characters. This name should not be changed once the object class stereotypes are implemented.

Changing the technical name after objects have been created based on the object class stereotype requires such objects to be updated by means of an ADIF scheme. For more information, see the reference manual *Alfabet Data Integration Framework*.

- `Caption`: Enter the caption for the object class stereotype. This is the name that users will see in the Alfabet user interface.

  Please note that the following:

  - The caption of the object class stereotype should be different than the caption of its object class. This is particularly important for the implementation of the search functionality for the object class stereotype. For more information, see the section Configuring Class Settings for Object Classes and Object Class Stereotypes in the chapter Configuring User Profiles for the User Community.
  - The values defined for the XML attribute `Caption` can be translated whereas the values defined for the XML attribute `Stereotype Name` cannot be translated. However, in the table of the **Simple Search** functionality as well as other search selectors, the values defined for the XML attribute `Stereotype Name` of the object class stereotype are displayed in the **Stereotypes** column. If the values defined for the XML attribute `Caption` should be displayed, a custom selector should be defined. For more information, see the section Configuring a Custom Selector for Search Functionalities.
  - If you want to enter a caption `(Caption)` or plural form for the caption (`CaptionPlural`) that contains special characters (for example, a greater then (>) or lesser then (<) symbol), you must replace the special characters with respective XML compliant code, for example:
    - > for >
    - < for <
    - " for "
    - [for [
    -] for]
  - The caption will be available in the vocabularies and can be translated to the secondary languages implemented in your enterprise.

- `Description`: Provide a brief description about the object class stereotype. The description will be displayed in the **Stereotype Selector** that opens when the user must select which stereotype a new object is to be based on. The description should help the user to understand which stereotype the new object should be based on. The description will be available in the vocabularies and can be translated to the secondary languages implemented in your enterprise.
- `CaptionPlural`: Enter a plural form for the caption. This is the name in plural that users will see in the Alfabet user interface.
- `IDPrefix`: Enter no more than 5 characters for the ID prefix used to generate the unique identification number for new objects based on the object stereotype. If the XML attribute `IDPrefix` is not specified, the ID prefix of the object class that the object class stereotype is based on will be used to generate the unique ID. Please note that the integer generated for the unique ID is based on the number of instances created for the object class that the object

class stereotype is based on and includes all instances of all object class stereotypes created for the object class.

The prefix ID of existing objects based on an object class stereotype can be updated via the ADIF import scheme `SetStereotypeID` available in the `Alfabet Standard Jobs` folder. For more information, see the section *Predefined ADIF Schemes* in the reference manual *Configuring Alfabet with Alfabet Expand*.

- `Comments`: Enter text in order to provide information about the object class stereotype. This information is only for the purposes of configuration. It is not displayed in the Alfabet user interface.
- `HasMandates`: Enter "`true`" if the mandate capability should be available for the object class stereotype. Enter "`false`" if the mandate capability should not be available for the object class stereotype. If the XML attribute `HasMandates` is defined as "`false`" for an object class stereotype, objects based on the object class stereotype will be visible to users with any mandate implemented in your enterprise. For information about additional configuration requirements necessary to implement the mandate capability, see the section *Implementing the Mandate Capability for a Federated Architecture* in the chapter Configuring Access Permissions for Alfabet .
- `EnableStatutoryLanguage`: Set to `True` if the statutory language capability shall be available for the object class stereotype. The statutory language capability is available in order to address regulatory requirements that mandate that objects are captured in a specific language. When a user creates an object based on a relevant object class/object class stereotype, a statutory language selector will open in which the language can be selected. In the object editor that opens, the user can capture all attributes that support automated translation in the statutory language. If the XML attribute `EnableStatutoryLanguage` is not set, the object class stereotype will inherit the definition of the **Enable Statutory Language** attribute specified for the object class. Specifying a Statutory Language for the Enterprise

4) Click the **Save** button to save your changes.

Configuring the Attributes for the XML Object DemandManager

Once the demand stereotypes have been created for the object class `Demand`, you can specify one or more demand stereotype hierarchies in the XML object ***DemandManager***. A demand stereotype may have multiple subordinate demand stereotypes. A demand stereotype may be configured to be recursive, thereby allowing subordinate demands to be defined that are based on the same demand stereotype. The order of the demand stereotypes listed in the XML object determines the order of the levels in the demand hierarchy. Furthermore, you can specify which demand stereotypes are permissible for which demand groups.

When a user creates or redefines a demand in the Alfabet user interface, the stereotype selector will open if the new/redefined demand may be based on more than one demand stereotype. The user must select the relevant stereotype that the new/redefined demand shall be based on and then the relevant **Demand** editor will open. If only one demand stereotype is permissible, the new/redefined demand will automatically be based on the demand stereotype and the relevant **Demand** editor will open. Only the demands configured at the top-level of the demand hierarchy may be created in the *Demand Management Functionality*, *Capture Demands Functionality*, and *Demand Groups Functionality*.

To edit the XML object ***DemandManager***:

1) Go to the **Presentations** tab, expand the **XML Objects** folder, and expand the **Solution Managers** folder
2) Right-click the XML object ***DemandManager*** and select **Edit XML**. For general information about editing XML objects in Alfabet Expand, see Working with XML Objects.
3) As a child of the XML element `DemandManager`, create an XML element `Stereotype` for each object class stereotype on the first hierarchy level. Define the following XML attributes for each XML element `Stereotype`:
   - `Name`: Enter the technical name of the demand stereotype. This is the name defined in the `Name` attribute in the **Stereotypes** attribute for the object class `Demand`. The stereotype name is passed on to the objects that users create for the selected demand stereotype.
   - `IsRecursive`: Enter "`true`" if a sub-demand of this demand stereotype may be created. Enter "`false`" if a sub-demand of the same demand stereotype may not be created for this demand stereotype.
   - `ArchitectureClasses`: Enter a comma-separated list of object classes and objects class stereotypes that may be added as affected architecture for the demand stereotype. A menu entry with the caption **Add <Object Class>** or **Add <Object Class Stereotype>** will be added to the *Affected Architecture Page View*. If you are defining an object class stereotype in the XML attribute `ArchitectureClasses`, you must use the syntax ObjectClass:ObjectClassStereotype. If you are defining an object class stereotype in the XML attribute `ArchitectureClasses`, you must use the syntax ObjectClass:ObjectClassStereotype. If the XML attribute `ArchitectureClasses` is not defined, the standard object classes preconfigured by Software AG will be displayed.

     Please note the following:
     - The order of the demand stereotypes listed in the XML object determines the order of the levels in the demand hierarchy. Each demand stereotype begins with the element ***Stereotype*** in the XML object. The first demand stereotype in the XML object is the demand stereotype that represents the most ascendant level in the hierarchy.
     - To change the order of the demand stereotypes, select the entire demand stereotype and cut and paste it to the correct position in the order. Be sure to include the syntactic constructs (< and />), otherwise you will see an error message at the bottom of the XML editor.
4) If further subordinate hierarchy levels are needed for a stereotype, create the XML element `Stereotype` as child of the parent XML element `Stereotype` and define the XML attributes `Name` and `IsRecursive` as described above.
5) As a child of the XML element `DemandManager`, create an XML element `ClassAccess` for each demand group you want to define and specify the following XML attributes:
   - `ClassName`: Specify `DemandGroup`:<DemandGroupStereotype>, whereby <DemandGroupStereotype> is the `Name` attribute of the XML definition of the demand group stereotype.
   - `Stereotypes`:Enter a a comma-separated list of the permissible demand stereotypes that have been defined at the root node of the XML element `Stereotype`.

6) In the toolbar, click the **Save**  button to save the XML definition.

Configuring the Feature Capability

You can create multiple feature stereotypes and configure multiple feature hierarchies, as needed. The features based on a feature stereotype are instances of the feature stereotype. A feature stereotype may have multiple subordinate feature stereotypes. Furthermore, a feature stereotype may be configured to be recursive, thereby allowing subordinate features to be defined that are based on the same feature stereotype. Thus, a feature stereotype may be configured to allow subordinate features based on the same feature stereotype to be defined as well as subordinate features based on a permissible subordinate feature stereotype to be defined. The name, number, and hierarchical ordering of the feature stereotypes are configurable.

You must first configure the feature stereotypes in the **Stereotypes** attribute of the object class `Feature`. Once the feature stereotypes have been created, you can order the hierarchy of feature stereotypes in the XML object ***FeatureManager***.

You can specify a subset of object classes (`Component`, `Application`, `ICTObject`, `StandardPlatform`, `LocalComponent`, or `PlatformElement`) that the feature may target independent of the affected architecture elements currently defined for the demand. When creating a feature for one those objects, it will automatically be added to the demand's affected architecture.

Once defined, a feature stereotype is similar to a standard object class. Correspondingly, you can configure the mandate capability to control user access to each feature stereotype. All feature stereotypes can be configured to be searchable via class settings and thus selected in the list of searchable object classes displayed in the **Search for** field in the **Simple Search** and **Browse** functionalities. Additionally, you can configure custom editors, wizards, workflows, and reports for each feature stereotype, as needed.

The following information is available:

- Creating Object Class Stereotypes for Features
- Configuring the Attributes and Functionalities Available for a Feature Stereotype

Creating Object Class Stereotypes for Features

To create feature stereotypes:

1) Go to the **Meta-Model** tab and navigate to the protected class node  for the object class `Feature` in the **Class Model** explorer.
2) Click the object class `Feature` in the explorer to open the attribute window.
3) Click the **Browse**  button available for the **Stereotypes** attribute to open the XML editor. Define the following XML attributes:

An error message will be displayed upon closing the text editor if syntax errors are written in the XML definition of the **Stereotypes** attribute.

- `Stereotype Name`: Enter the technical name for each object class stereotype. You may define a name of up to 64 characters. This name should not be changed once the object class stereotypes are implemented.

  Changing the technical name after objects have been created based on the object class stereotype requires such objects to be updated by means of an ADIF scheme. For more information, see the reference manual *Alfabet Data Integration Framework*.

- `Caption`: Enter the caption for the object class stereotype. This is the name that users will see in the Alfabet user interface.

  Please note that the following:

  - The caption of the object class stereotype should be different than the caption of its object class. This is particularly important for the implementation of the search functionality for the object class stereotype. For more information, see the section Configuring Class Settings for Object Classes and Object Class Stereotypes in the chapter Configuring User Profiles for the User Community.
  - The values defined for the XML attribute `Caption` can be translated whereas the values defined for the XML attribute `Stereotype Name` cannot be translated. However, in the table of the **Simple Search** functionality as well as other search selectors, the values defined for the XML attribute `Stereotype Name` of the object class stereotype are displayed in the **Stereotypes** column. If the values defined for the XML attribute `Caption` should be displayed, a custom selector should be defined. For more information, see the section Configuring a Custom Selector for Search Functionalities.
  - If you want to enter a caption `(Caption)` or plural form for the caption (`CaptionPlural`) that contains special characters (for example, a greater then (>) or lesser then (<) symbol), you must replace the special characters with respective XML compliant code, for example:
    - > for >
    - < for <
    - " for "
    - [for [
    -] for]
  - The caption will be available in the vocabularies and can be translated to the secondary languages implemented in your enterprise.

- `Description`: Provide a brief description about the object class stereotype. The description will be displayed in the **Stereotype Selector** that opens when the user must select which stereotype a new object is to be based on. The description should help the user to understand which stereotype the new object should be based on. The description will be available in the vocabularies and can be translated to the secondary languages implemented in your enterprise.

- `CaptionPlural`: Enter a plural form for the caption. This is the name in plural that users will see in the Alfabet user interface.
- `IDPrefix`: Enter no more than 5 characters for the ID prefix used to generate the unique identification number for new objects based on the object stereotype. If the XML attribute `IDPrefix` is not specified, the ID prefix of the object class that the object class stereotype is based on will be used to generate the unique ID. Please note that the integer generated for the unique ID is based on the number of instances created for the object class that the object class stereotype is based on and includes all instances of all object class stereotypes created for the object class.

  The prefix ID of existing objects based on an object class stereotype can be updated via the ADIF import scheme `SetStereotypeID` available in the `Alfabet Standard Jobs` folder. For more information, see the section *Predefined ADIF Schemes* in the reference manual *Configuring Alfabet with Alfabet Expand*.

- `Comments`: Enter text in order to provide information about the object class stereotype. This information is only for the purposes of configuration. It is not displayed in the Alfabet user interface.
- `HasMandates`: Enter "`true`" if the mandate capability should be available for the object class stereotype. Enter "`false`" if the mandate capability should not be available for the object class stereotype. If the XML attribute `HasMandates` is defined as "`false`" for an object class stereotype, objects based on the object class stereotype will be visible to users with any mandate implemented in your enterprise. For information about additional configuration requirements necessary to implement the mandate capability, see the section *Implementing the Mandate Capability for a Federated Architecture* in the chapter Configuring Access Permissions for Alfabet .
- `EnableStatutoryLanguage`: Set to `True` if the statutory language capability shall be available for the object class stereotype. The statutory language capability is available in order to address regulatory requirements that mandate that objects are captured in a specific language. When a user creates an object based on a relevant object class/object class stereotype, a statutory language selector will open in which the language can be selected. In the object editor that opens, the user can capture all attributes that support automated translation in the statutory language. If the XML attribute `EnableStatutoryLanguage` is not set, the object class stereotype will inherit the definition of the **Enable Statutory Language** attribute specified for the object class. Specifying a Statutory Language for the Enterprise

4) Click the **Save** button to save your changes.

Configuring the Attributes and Functionalities Available for a Feature Stereotype

Once the feature stereotypes have been created for the object class `Feature`, you can specify one or more feature stereotype hierarchies in the XML object ***FeatureManager***. A feature stereotype may have multiple subordinate feature stereotypes. Furthermore, a feature stereotype may be configured to be recursive, thereby allowing subordinate features to be defined that are based on the same feature stereotype. The order of the feature stereotypes listed in the XML object determines the order of the levels in the feature hierarchy.

When a user creates a feature in the user interface, the stereotype selector will open if the new feature may be based on more than one feature stereotype. The user must select the relevant stereotype that the new feature shall be based on and then the relevant **Feature** editor will open. If only one feature stereotype is permissible, the new feature will automatically be based on the feature stereotype and the relevant **Feature** editor will open.

Additionally, you can specify the relevant object classes for which features may be defined. The *Features Page View* (`OBJ_Features`) should be added to the custom object views of these classes in order to allow features to be defined for the relevant objects.

To edit the XML object ***FeatureManager***:

1) Go to the **Presentations** tab, expand the **XML Objects** folder, and expand the **Solution Managers** folder
2) Right-click the XML object ***FeatureManager*** and select **Edit XML**. For general information about editing XML objects in Alfabet Expand, see Working with XML Objects.
3) For the root XML element `FeatureManager`, create an XML attribute `AvailableClasses` and specify comma-separated list of classes that constitutes the subset of object classes for which features may be defined. You may enter any of the following: `Component`, `Application`, `ICTObject`, `StandardPlatform`, `LocalComponent`, or `PlatformElement`.
4) As a child of the XML element `FeatureManager`, create an XML element `Stereotype` for each object class stereotype on the first hierarchy level. Define the following XML attributes for each XML element `Stereotype`:
   - `Name`: Enter the technical name of the feature stereotype. This is the name defined in the `Name` attribute in the **Stereotypes** attribute for the object class `Feature`. The stereotype name is passed on to the objects that users create for the selected feature stereotype.
   - `IsRecursive`: Enter "`true`" if a sub-feature of this feature stereotype may be created. Enter "`false`" if a sub-feature of the same feature stereotype may not be created for this feature stereotype.

   Please note the following:
   - The order of the feature stereotypes listed in the XML object determines the order of the levels in the feature hierarchy. Each feature stereotype begins with the element ***Stereotype*** in the XML object. The first feature stereotype in the XML object is the feature stereotype that represents the most ascendant level in the hierarchy.
   - To change the order of the feature stereotypes, select the entire feature stereotype and cut and paste it to the correct position in the order. Be sure to include the syntactic constructs (< and />), otherwise you will see an error message at the bottom of the XML editor.
5) If further subordinate hierarchy levels are needed for a stereotype, create the XML element `Stereotype` as child of the parent XML element `Stereotype` and define the XML attributes `Name` and `IsRecursive` as described above.
6) In the toolbar, click the **Save** button to save the XML definition.

Configuring the Policy Hierarchy

You can create multiple policy stereotypes as well as well as specify which policy stereotypes are permissible for a policy group stereotype. The policies based on a policy stereotype are instances of the policy stereotype. Policy stereotypes are not structured as a policy hierarchy with a parent policy and multiple level of subordinate policies. Instead, the policy stereotype concept is a flat list of potential stereotypes. However, you can specify which policy stereotypes are permissible for a policy when a policy is redefined in the *Redefining Policies Page View* (`ITPLC_RedefiningPolicies`.

For a methodological overview of managing the enterprise's policies, see the section *Business IT Synchronization* in the reference manual *IT Planning Basic*.

You must first configure the policy stereotypes in the **Stereotypes** attribute of the object class `ITPolicy`. Once the policy stereotypes have been created, you can specify which policy stereotypes are permissible for redefined policies in the XML object ***ITPolicyManager***.

Once defined, a policy stereotype is similar to a standard object class. Correspondingly, you can configure the mandate capability to control user access to each policy stereotype. All policy stereotypes can be configured to be searchable via class settings and thus selected in the list of searchable object classes displayed in the **Search for** field in the **Simple Search** and **Browse** functionalities. Additionally, you can configure custom editors, wizards, workflows, and reports for each policy stereotype, as needed.

The following information is available:

- Creating Object Class Stereotypes for Policies and Policy Groups
- Configuring Affected Architecture and Redefined Policies for Policy Stereotypes

Creating Object Class Stereotypes for Policies and Policy Groups

Object class stereotypes may be configured for the object classes **Policy** (`ITPolicy`) and **Policy Group** (`ITPolicyGroup`). To create policy stereotypes:

1) Go to the **Meta-Model** tab and navigate to the protected class node  for the object class `ITPolicy` or `ITPolicyGroup` in the **Class Model** explorer.
2) Click the object class `ITPolicy` in the explorer to open the attribute window.
3) Click the **Browse**  button available for the **Stereotypes** attribute to open the XML editor. Define the following XML attributes:

An error message will be displayed upon closing the text editor if syntax errors are written in the XML definition of the **Stereotypes** attribute.

- `Stereotype Name`: Enter the technical name for each object class stereotype. You may define a name of up to 64 characters. This name should not be changed once the object class stereotypes are implemented.

Changing the technical name after objects have been created based on the object class stereotype requires such objects to be updated by means of an ADIF scheme.

For more information, see the reference manual *Alfabet Data Integration Framework*.

- `Caption`: Enter the caption for the object class stereotype. This is the name that users will see in the Alfabet user interface.

  Please note that the following:

  - The caption of the object class stereotype should be different than the caption of its object class. This is particularly important for the implementation of the search functionality for the object class stereotype. For more information, see the section Configuring Class Settings for Object Classes and Object Class Stereotypes in the chapter Configuring User Profiles for the User Community.
  - The values defined for the XML attribute `Caption` can be translated whereas the values defined for the XML attribute `Stereotype Name` cannot be translated. However, in the table of the **Simple Search** functionality as well as other search selectors, the values defined for the XML attribute `Stereotype Name` of the object class stereotype are displayed in the **Stereotypes** column. If the values defined for the XML attribute `Caption` should be displayed, a custom selector should be defined. For more information, see the section Configuring a Custom Selector for Search Functionalities.
  - If you want to enter a caption (`Caption`) or plural form for the caption (`CaptionPlural`) that contains special characters (for example, a greater then (>) or lesser then (<) symbol), you must replace the special characters with respective XML compliant code, for example:
    - > for >
    - < for <
    - " for "
    - [for [
    -] for]
  - The caption will be available in the vocabularies and can be translated to the secondary languages implemented in your enterprise.

- `Description`: Provide a brief description about the object class stereotype. The description will be displayed in the **Stereotype Selector** that opens when the user must select which stereotype a new object is to be based on. The description should help the user to understand which stereotype the new object should be based on. The description will be available in the vocabularies and can be translated to the secondary languages implemented in your enterprise.
- `CaptionPlural`: Enter a plural form for the caption. This is the name in plural that users will see in the Alfabet user interface.
- `IDPrefix`: Enter no more than 5 characters for the ID prefix used to generate the unique identification number for new objects based on the object stereotype. If the XML attribute `IDPrefix` is not specified, the ID prefix of the object class that the object class stereotype is

based on will be used to generate the unique ID. Please note that the integer generated for the unique ID is based on the number of instances created for the object class that the object class stereotype is based on and includes all instances of all object class stereotypes created for the object class.

The prefix ID of existing objects based on an object class stereotype can be updated via the ADIF import scheme `SetStereotypeID` available in the `Alfabet Standard Jobs` folder. For more information, see the section *Predefined ADIF Schemes* in the reference manual *Configuring Alfabet with Alfabet Expand*.

- `Comments`: Enter text in order to provide information about the object class stereotype. This information is only for the purposes of configuration. It is not displayed in the Alfabet user interface.
- `HasMandates`: Enter "`true`" if the mandate capability should be available for the object class stereotype. Enter "`false`" if the mandate capability should not be available for the object class stereotype. If the XML attribute `HasMandates` is defined as "`false`" for an object class stereotype, objects based on the object class stereotype will be visible to users with any mandate implemented in your enterprise. For information about additional configuration requirements necessary to implement the mandate capability, see the section *Implementing the Mandate Capability for a Federated Architecture* in the chapter Configuring Access Permissions for Alfabet .
- `EnableStatutoryLanguage`: Set to `True` if the statutory language capability shall be available for the object class stereotype. The statutory language capability is available in order to address regulatory requirements that mandate that objects are captured in a specific language. When a user creates an object based on a relevant object class/object class stereotype, a statutory language selector will open in which the language can be selected. In the object editor that opens, the user can capture all attributes that support automated translation in the statutory language. If the XML attribute `EnableStatutoryLanguage` is not set, the object class stereotype will inherit the definition of the **Enable Statutory Language** attribute specified for the object class. Specifying a Statutory Language for the Enterprise

4) Click the **Save** button to save your changes.

Configuring Affected Architecture and Redefined Policies for Policy Stereotypes

Once the policy stereotypes have been created for the object class `ITPolicy`, you can specify the object class stereotypes for the class `ITPolicy` that are permissible when redefining policies in the *Redefining Policies Page View* (`ITPLC_RedefiningPolicies`). When a user redefines a policy in the user interface, the stereotype selector will open if the redefined policy may be based on more than one policy stereotype. The user must select the relevant stereotype that the redefined policy shall be based on and then the relevant **Policy** editor will open. If only one policy stereotype is permissible, the new policy will automatically be based on the policy stereotype and the relevant **Policy** editor will open.

Furthermore, you can specify which policy stereotypes are permissible for which policy groups.

Only the policy stereotypes specified on the parent level of the policy hierarchy in the XML object ***ITPolicyManager***will be displayed in the *Policies Page View* (`ITPLCG_Policies`) for a policy group. In other words, if a policy stereotype is only available as a child stereotype and thus only available for purposes of redefining its parent stereotype, the policy based on the child stereotype will not be displayed in the view.

To edit the XML object ***ITPolicyManager***:

1) Go to the **Presentations** tab, expand the **XML Objects** folder, and expand the **Solution Managers** folder

2) Right-click the XML object ***ITPolicyManager*** and select **Edit XML**. For general information about editing XML objects in Alfabet Expand, see Working with XML Objects.

3) As a child of the XML element `ITPolicyManager`, create an XML element `Stereotype` for each object class stereotype on the first hierarchy level. Define the following XML attributes for each XML element `Stereotype`:

   - `Name`: Enter the technical name of the policy stereotype. This is the name defined in the `Name` attribute in the **Stereotypes** attribute for the object class `ITPolicy`. The stereotype name is passed on to the objects that users create for the selected policy stereotype.
   - `IsRecursive`: Enter "`true`" if a sub-policy of this policy stereotype may be created. Enter "`false`" if a sub-policy of the same policy stereotype may not be created for this feature stereotype.
   - `ArchitectureClasses`: Enter a comma-separated list of object classes and objects class stereotypes that may be added as affected architecture for the policy stereotype. A menu entry with the caption **Add <Object Class>** or **Add <Object Class Stereotype>** will be added to the *Affected Architecture Elements Page View* and *Implementing Architecture Elements Page View*. If you are defining an object class stereotype in the XML attribute `ArchitectureClasses`, you must use the syntax ObjectClass:ObjectClassStereotype. If the XML attribute `ArchitectureClasses` is not defined, the standard object classes preconfigured by Software AG will be displayed.

     Please note the following:

     - The order of the policy stereotypes listed in the XML object determines the order of the levels in the policy hierarchy. Each policy stereotype begins with the element ***Stereotype*** in the XML object. The first policy stereotype in the XML object is the policy stereotype that represents the most ascendant level in the hierarchy.
     - To change the order of the policy stereotypes, select the entire policy stereotype and cut and paste it to the correct position in the order. Be sure to include the syntactic constructs (< and />), otherwise you will see an error message at the bottom of the XML editor.

4) If further subordinate hierarchy levels are needed for a stereotype, create the XML element `Stereotype` as child of the parent XML element `Stereotype` and define the XML attributes `Name` and `IsRecursive` as described above.

5) As a child of the XML element `ITPolicyManager`, create an XML element `ClassAccess` for each policy group you want to define and specify the following XML attributes:

   - `ClassName`: Specify `ITPolicyGroup`:<PolicyGroupStereotype>, whereby <PolicyGroupStereotype> is the `Name` attribute of the XML definition of the policy group stereotype.
   - `Stereotypes`:Enter a comma-separated list of the permissible policy stereotypes that have been defined at the root node of the XML element `Stereotype`.

6) In the toolbar, click the **Save** button to save the XML definition.

Configuring the Organizational Hierarchy

You can create multiple organization stereotypes and configure multiple organization hierarchies, as needed. The organizations based on an organization stereotype are instances of the organization stereotype. An organization stereotype may have only one ascendant organization stereotype but may have multiple subordinate organization stereotypes. Furthermore, an organization stereotype may be configured to be recursive, thereby allowing subordinate organizations to be defined that are based on the same organization stereotype. Thus, an organization stereotype may be configured to allow subordinate organizations based on the same organization stereotype to be defined as well as a subordinate organizations based on a permissible subordinate organization stereotype to be defined. The name, number, and hierarchical ordering of the organization stereotypes are configurable.

For a methodological overview of working with organizations in the context of the enterprise architecture, see the section *Organization Definition* in the reference manual *Configuring Alfabet with Alfabet Expand*.

Organization stereotypes will be available in the **Organizations** explorer (`ORG_Explorer`), **Organization Groups** explorer (`ORG_Explorer`), **Applications by Consumer** explorer (`ORG_APP_Consumer_Explorer`), **Applications by Owner** explorer (`ORG_APP_Owner_Explorer`), **Business Processes by Organizations** explorer (`ORG_PROC_Explorer`), and **Organization Admin Desktop** functionality (`ORG_AdminDesktop`).

You must first configure the organization stereotypes in the **Stereotypes** attribute of the object class `OrgaUnit`. Once the organization stereotypes have been created, you can order the hierarchy of organization stereotypes in the XML object ***OrganizationManager***.

Once defined, an organization stereotype is similar to a standard object class. Correspondingly, you can configure the mandate capability to control user access to each organization stereotype. All organization stereotypes can be configured to be searchable via class settings and thus selected in the list of searchable object classes displayed in the **Search for** field in the **Simple Search** and **Browse** functionalities. Additionally, you can configure custom editors, wizards, workflows, and reports for each organization stereotype, as needed.

The following information is available:

- Creating Object Class Stereotypes for Organizations
- Configuring the Attributes and Functionalities Available for an Organization Stereotype
- Configuring Alfabet to Capture Legal Ownership of Organizations

Creating Object Class Stereotypes for Organizations

To create organization stereotypes:

1) Go to the **Meta-Model** tab and navigate to the protected class node  for the object class organization in the **Class Model** explorer.
2) Click the object class `OrgaUnit` in the explorer to open the attribute window.
3) Click the **Browse**  button available for the **Stereotypes** attribute to open the XML editor. Define the following XML attributes:

An error message will be displayed upon closing the text editor if syntax errors are written in the XML definition of the **Stereotypes** attribute.

- `Stereotype Name`: Enter the technical name for each object class stereotype. You may define a name of up to 64 characters. This name should not be changed once the object class stereotypes are implemented.

  Changing the technical name after objects have been created based on the object class stereotype requires such objects to be updated by means of an ADIF scheme. For more information, see the reference manual *Alfabet Data Integration Framework*.

- `Caption`: Enter the caption for the object class stereotype. This is the name that users will see in the Alfabet user interface.

  Please note that the following:

  - The caption of the object class stereotype should be different than the caption of its object class. This is particularly important for the implementation of the search functionality for the object class stereotype. For more information, see the section Configuring Class Settings for Object Classes and Object Class Stereotypes in the chapter Configuring User Profiles for the User Community.
  - The values defined for the XML attribute `Caption` can be translated whereas the values defined for the XML attribute `Stereotype Name` cannot be translated. However, in the table of the **Simple Search** functionality as well as other search selectors, the values defined for the XML attribute `Stereotype Name` of the object class stereotype are displayed in the **Stereotypes** column. If the values defined for the XML attribute `Caption` should be displayed, a custom selector should be defined. For more information, see the section Configuring a Custom Selector for Search Functionalities.
  - If you want to enter a caption `(Caption)` or plural form for the caption (`CaptionPlural`) that contains special characters (for example, a greater then (>) or lesser then (<) symbol), you must replace the special characters with respective XML compliant code, for example:
    - > for >
    - < for <
    - " for "
    - [for [
    -] for]
  - The caption will be available in the vocabularies and can be translated to the secondary languages implemented in your enterprise.

- `Description`: Provide a brief description about the object class stereotype. The description will be displayed in the **Stereotype Selector** that opens when the user must select which

stereotype a new object is to be based on. The description should help the user to understand which stereotype the new object should be based on. The description will be available in the vocabularies and can be translated to the secondary languages implemented in your enterprise.

- `CaptionPlural`: Enter a plural form for the caption. This is the name in plural that users will see in the Alfabet user interface.
- `IDPrefix`: Enter no more than 5 characters for the ID prefix used to generate the unique identification number for new objects based on the object stereotype. If the XML attribute `IDPrefix` is not specified, the ID prefix of the object class that the object class stereotype is based on will be used to generate the unique ID. Please note that the integer generated for the unique ID is based on the number of instances created for the object class that the object class stereotype is based on and includes all instances of all object class stereotypes created for the object class.

  The prefix ID of existing objects based on an object class stereotype can be updated via the ADIF import scheme `SetStereotypeID` available in the `Alfabet Standard Jobs` folder. For more information, see the section *Predefined ADIF Schemes* in the reference manual *Configuring Alfabet with Alfabet Expand*.

- `Comments`: Enter text in order to provide information about the object class stereotype. This information is only for the purposes of configuration. It is not displayed in the Alfabet user interface.
- `HasMandates`: Enter "`true`" if the mandate capability should be available for the object class stereotype. Enter "`false`" if the mandate capability should not be available for the object class stereotype. If the XML attribute `HasMandates` is defined as "`false`" for an object class stereotype, objects based on the object class stereotype will be visible to users with any mandate implemented in your enterprise. For information about additional configuration requirements necessary to implement the mandate capability, see the section *Implementing the Mandate Capability for a Federated Architecture* in the chapter Configuring Access Permissions for Alfabet .
- `EnableStatutoryLanguage`: Set to `True` if the statutory language capability shall be available for the object class stereotype. The statutory language capability is available in order to address regulatory requirements that mandate that objects are captured in a specific language. When a user creates an object based on a relevant object class/object class stereotype, a statutory language selector will open in which the language can be selected. In the object editor that opens, the user can capture all attributes that support automated translation in the statutory language. If the XML attribute `EnableStatutoryLanguage` is not set, the object class stereotype will inherit the definition of the **Enable Statutory Language** attribute specified for the object class. Specifying a Statutory Language for the Enterprise

4) Click the **Save** button to save your changes.

Configuring the Attributes and Functionalities Available for an Organization Stereotype

Once the organization stereotypes have been created for the object class `OrgaUnit`, you can specify one or more organization stereotype hierarchies in the XML object ***OrganizationManager***. An organization stereotype may have multiple subordinate organization stereotypes. Furthermore, an organization stereotype may be configued to be recursive, thereby allowing subordinate organizations to be defined that are based on the same organization stereotype. The order of the organization stereotypes listed in the XML object determines the order of the levels in the organization hierarchy.

When a user creates an organization in the user interface, the stereotype selector will open if the new organization may be based on more than one organization stereotype. The user must select the relevant stereotype that the new organization shall be based on and then the relevant **Organization** editor will open. If only one organization stereotype is permissible, the new organization will automatically be based on the organization stereotype and the relevant **Organization** editor will open.

To edit the XML object ***OrganizationManager***:

1) Go to the **Presentations** tab, expand the **XML Objects** folder, and expand the **Solution Managers** folder
2) Right-click the XML object ***OrganizationManager*** and select **Edit XML**. For general information about editing XML objects in Alfabet Expand, see Working with XML Objects.
3) Edit the XML attributes, as needed. The table below displays the XML attributes that can be edited for the XML object ***OrganizationManager***:

XML Elements (bold) and Attributes	Explanation
OrganizationManager	
Stereotype	The order of the organization stereotypes listed in the XML object determines the order of the levels in the organization hierarchy. Each organization stereotype begins with the element ***Stereotype*** in the XML object. The first organization stereotype in the XML object is the organization stereotype that represents the most ascendant level in the hierarchy. To change the order of the organization stereotypes, select the entire organization stereotype and cut and paste it to the correct position in the order. Be sure to include the syntactic constructs (< and />), otherwise you will see an error message at the bottom of the XML editor. Define the following attributes for each organization stereotype.
`Name`	Enter the technical name of the organization stereotype. This is the name defined in the `Name` attribute in the **Stereotypes** attribute for the object class `OrgaUnit`. The stereotype name is passed on to the objects that users create for the selected organization stereotype.

XML Elements (bold) and Attributes	Explanation
	NOTE: You must spell the technical name correctly.
`IsRecursive`	Enter "`true`" if a sub-organization of this organization stereotype may be created. Enter "`false`" if a sub-organization of the same organization stereotype may not be created for this organization stereotype.

4) In the toolbar, click the **Save** button to save the XML definition.

Configuring Alfabet to Capture Legal Ownership of Organizations

Alfabet provides a functionality that allows the legal ownership of organizations to be captured. Please note the following configuration required to implement this functionality:

- Custom properties may be captured for the object class `LegalOwnership` in order to capture relevant data regarding the legal ownership relationships in your enterprise. For more information, see the section Configuring Custom Properties for Protected or Public Object Classes.
- The **Legal Owners** page view (`ORG_LegalOwnerships`) and the **Legally-Owned Organizations** page view (`ORG_LegalSubordinations`) must be assigned to the custom object views configured for the relevant object class stereotypes configured for the object class `OrgaUnit`. The **Legal Owners** page view (`ORG_LegalOwnerships`) should be available for the organization stereotype that owns other legal entities and the **Legally-Owned Organizations** page view (`ORG_LegalSubordinations`) should be available for the organization stereotype that represents organizations owned by other legal entities. The percentage that various organizations own a given organization is defined for the owned organization in the **Legal Owners** page view (`ORG_LegalOwnerships`). For more information, see the sections Configuring Object Class Stereotypes for Object Classes and Configuring Object Views.
- The values available for the **Ownership Type** attribute in the **Legal Ownership** editor (`LEGOWN_Editor`) may be configured via the enumeration ***OwnershipType***. For more information, see the section Defining Protected and Custom Enumerations.

Configuring Affected Architecture for Risk Mitigation Templates

You can specify the object classes and objects class stereotypes that may be added as affected architecture for risk mitigation templates.

1) Go to the **Presentations** tab, expand the **XML Objects** folder, and expand the **Solution Managers** folder
2) Right-click the XML object ***AffectedArchManager*** and select **Edit XML**. For general information about editing XML objects in Alfabet Expand, see Working with XML Objects.
3) Create an XML element `ClassEntry` and define the following XML attributes:
   - `ClassName`: Enter the technical name `RiskMitigationTemplate`.
   - `ArchitectureClasses`: Enter a comma-separated list of object classes and objects class stereotypes that may be added as affected architecture for risk mitigation templates. A menu entry with the caption **Add <Object Class>** or **Add <Object Class Stereotype>** will be added to the *Affected Architecture Page View*. If you are defining an object class stereotype in the XML attribute `ArchitectureClasses`, you must use the syntax ObjectClass:ObjectClassStereotype. If the XML attribute `ArchitectureClasses` is not defined, the standard object classes preconfigured by Software AG will be displayed.
4) In the toolbar, click the **Save** button to save the XML definition.

Configuring Object Class Stereotypes for Technical Services

A technical service is a service provided by a component or local component in order to fulfill technical needs that are necessary to support business service requests. Technical services can be defined only for components and local components for which the **Component Type** attribute is set to `Service`. For each technical service, technical service operations can be defined that describe how the technical service is to be provided by a component. Technical service methods provide the details about the implementation of the technical service operation (for example, `GET`, `POST`, `DELETE`, etc.).

For a methodological overview of working with technical services in the context of the technical architecture, see the section *Technology Architecture Definition* in the reference manual *Enterprise Architecture Management*.

You can create multiple object class stereotypes for the object classes **Technical Service** (`Service`), **Technical Service Operation** (`ServiceOperation`), and **Technical Service Operation Method** (`ServiceOperationMethod`). If your enterprise configures object class stereotypes for technical services, then typically object class stereotypes will also be configured for technical service operations and technical service operation methods. In this case, only certain technical service operations will be relevant for a particular technical service, and only certain technical service operation methods will be relevant for a particular technical service operation. The XML object ***TechServiceManager*** allows you to map the following:

- For each technical service stereotype, specify which technical service operation stereotypes are permissible.
- For each technical service operation stereotype, specify which technical service operation method stereotypes are permissible.

- If your enterprise supports solution planning and technical services and technical service operations are included as part of the to-be architecture, then you must create an identical configuration for the corresponding solution object classes `SolutionService` and `SolutionServiceOperation`.

Technical services may be created explicitly in Alfabet or may be created based on imported assets from another repository such as CentraSite®, webMethods® API Gateway, or webMethods® API Portal as well as based on WSDL and OpenAPI Specificaiton Swagger (JSON) files. Therefore, you should consider your source for technical services when configuring the object class stereotypes for the object classes **Technical Service** (`Service`), **Technical Service Operation** (`ServiceOperation`), and **Technical Service Operation Method** (`ServiceOperationMethod`).

The following information is available:

- Creating Object Class Stereotypes for Technical Services, Technical Service Operations, and Technical Service Operation Methods
- Mapping Object Class Stereotypes with Technical Services and Technical Service Operations

Creating Object Class Stereotypes for Technical Services, Technical Service Operations, and Technical Service Operation Methods

You can create multiple object class stereotypes for the object classes **Technical Service** (`Service`), **Technical Service Operation** (`ServiceOperation`), and **Technical Service Operation Method** (`ServiceOperationMethod`). Technical services may be created explicitly in Alfabet or may be created based on imported assets from another repository such as CentraSite®, webMethods® API Gateway, or webMethods® API Portal. Therefore, you should consider your source for technical services when configuring the object class stereotypes for the object classes **Technical Service** (`Service`), **Technical Service Operation** (`ServiceOperation`), and **Technical Service Operation Method** (`ServiceOperationMethod`).

If your enterprise supports solution planning and technical services and technical service operations are included as part of the to-be architecture, then you must create an identical configuration for the corresponding solution object classes `SolutionService`, `SolutionServiceOperation`, and `SolutionServiceMethod`. For example, the configuration defined in the **Stereotypes** attribute for the object class `Service` should be copied and pasted to the **Stereotypes** attribute for the object class `SolutionService`. If the configuration is not the same, errors may occur when solution objects are checked in to the Alfabet inventory in the context of project and solution planning. For more about configuring the solution planning capability, see the section Making the As-Is Architecture and To-Be Architecture Capabilities Available.

To create object class stereotypes for the object classes `Service`, `ServiceOperation`, and `ServiceOperationMethod` (as well as the corresponding solution object classes `SolutionService`, `SolutionServiceOperation`, and `SolutionServiceMethod`):

1) Go to the **Meta-Model** tab and navigate to the protected class node  for the relevant object class in the **Class Model** explorer.
2) Click the object class in the explorer to open the attribute window.
3) Click the **Browse**  button available for the **Stereotypes** attribute to open the XML editor. Define the following XML attributes:

An error message will be displayed upon closing the text editor if syntax errors are written in the XML definition of the **Stereotypes** attribute.

- `Stereotype Name`: Enter the technical name for each object class stereotype. You may define a name of up to 64 characters. This name should not be changed once the object class stereotypes are implemented.

  Changing the technical name after objects have been created based on the object class stereotype requires such objects to be updated by means of an ADIF scheme. For more information, see the reference manual *Alfabet Data Integration Framework*.

- `Caption`: Enter the caption for the object class stereotype. This is the name that users will see in the Alfabet user interface.

  Please note that the following:

  - The caption of the object class stereotype should be different than the caption of its object class. This is particularly important for the implementation of the search functionality for the object class stereotype. For more information, see the section Configuring Class Settings for Object Classes and Object Class Stereotypes in the chapter Configuring User Profiles for the User Community.
  - The values defined for the XML attribute `Caption` can be translated whereas the values defined for the XML attribute `Stereotype Name` cannot be translated. However, in the table of the **Simple Search** functionality as well as other search selectors, the values defined for the XML attribute `Stereotype Name` of the object class stereotype are displayed in the **Stereotypes** column. If the values defined for the XML attribute `Caption` should be displayed, a custom selector should be defined. For more information, see the section Configuring a Custom Selector for Search Functionalities.
  - If you want to enter a caption `(Caption)` or plural form for the caption (`CaptionPlural`) that contains special characters (for example, a greater then (>) or lesser then (<) symbol), you must replace the special characters with respective XML compliant code, for example:
    - > for >
    - < for <
    - " for "
    - [for [
    -] for]
  - The caption will be available in the vocabularies and can be translated to the secondary languages implemented in your enterprise.

- `Description`: Provide a brief description about the object class stereotype. The description will be displayed in the **Stereotype Selector** that opens when the user must select which

stereotype a new object is to be based on. The description should help the user to understand which stereotype the new object should be based on. The description will be available in the vocabularies and can be translated to the secondary languages implemented in your enterprise.

- `CaptionPlural`: Enter a plural form for the caption. This is the name in plural that users will see in the Alfabet user interface.
- `IDPrefix`: Enter no more than 5 characters for the ID prefix used to generate the unique identification number for new objects based on the object stereotype. If the XML attribute `IDPrefix` is not specified, the ID prefix of the object class that the object class stereotype is based on will be used to generate the unique ID. Please note that the integer generated for the unique ID is based on the number of instances created for the object class that the object class stereotype is based on, and includes all instances of all object class stereotypes created for the object class.

  The prefix ID of existing objects based on an object class stereotype can be updated via the ADIF import scheme `SetStereotypeID` available in the `Alfabet Standard Jobs` folder. For more information, see the section *Predefined ADIF Schemes* in the reference manual *Configuring Alfabet with Alfabet Expand*.

- `Comments`: Enter text in order to provide information about the object class stereotype. This information is only for the purposes of configuration. It is not displayed in the Alfabet user interface.
- `HasMandates`: Enter "`true`" if the mandate capability should be available for the object class stereotype. Enter "`false`" if the mandate capability should not be available for the object class stereotype. If the XML attribute `HasMandates` is defined as "`false`" for an object class stereotype, objects based on the object class stereotype will be visible to users with any mandate implemented in your enterprise. For information about additional configuration requirements necessary to implement the mandate capability, see the section *Implementing the Mandate Capability for a Federated Architecture* in the chapter Configuring Access Permissions for Alfabet .
- `EnableStatutoryLanguage`: Set to `True` if the statutory language capability shall be available for the object class stereotype. The statutory language capability is available in order to address regulatory requirements that mandate that objects are captured in a specific language. When a user creates an object based on a relevant object class/object class stereotype, a statutory language selector will open in which the language can be selected. In the object editor that opens, the user can capture all attributes that support automated translation in the statutory language. If the XML attribute `EnableStatutoryLanguage` is not set, the object class stereotype will inherit the definition of the **Enable Statutory Language** attribute specified for the object class. Specifying a Statutory Language for the Enterprise

4) Click the **Save** button to save your changes.

Mapping Object Class Stereotypes with Technical Services and Technical Service Operations

A technical service operation is a detailed description about how a technical service is to be provided by a component in order to support a component in providing a business service. If your enterprise configures object class stereotypes for technical services, then typically object class stereotypes will also be configured for technical service operations and technical service operation methods. In this case, only certain technical service operations will be relevant for a particular technical service, and only certain technical service operation methods will be relevant for a particular technical service operation.

Once all object class stereotypes have been created for the object classes **Technical Service** (`Service`), **Technical Service Operation** (`ServiceOperation`), and **Technical Service Operation Method** (`ServiceOperationMethod`), you should map the object class stereotypes in the XML object ***TechServiceManager***:

- For each technical service stereotype, specify which technical service operation stereotypes are permissible.
- For each technical service operation stereotype, specify which technical service operation method stereotypes are permissible.
- If your enterprise supports solution planning and technical services and technical service operations are included as part of the to-be architecture, then you must create an identical configuration for the corresponding solution object classes `SolutionService`, `SolutionServiceOperation`, and `SolutionServiceMethod`.

The following example displays the mapping for the stereotype `SOAPService` configured for the object class `Service`:

```
<TechServiceManager>
   <Stereotype ClassName="Service" Name="SOAPService">
      <Stereotype ClassName="ServiceOperation"
      Name="SOAPOperation">
         <Stereotype ClassName="ServiceOperationMethod"
         Name="AHTTPPOST" MethodType="HTTPPOST"
         <Stereotype ClassName="ServiceOperationMethod"
         Name="AHTTPGET" MethodType="HTTPGET" />
         <Stereotype ClassName="ServiceOperationMethod"
         Name="ASOAP12" MethodType="SOAP12"/>
         <Stereotype ClassName="ServiceOperationMethod"
         Name="ASOAP" MethodType="SOAP"/>
      </Stereotype>
   </Stereotype
</TechServiceManager>
```

If your enterprise supports solution planning, you must create an identical configuration for the corresponding solution object class and ensure that the mapping defined for the solution object classes `SolutionService`, `SolutionServiceOperation`, and `SolutionServiceMethod` is identical to the mapping defined the respective object classes `Service`, `ServiceOperation`, and `SolutionOperationMethod`. In other words, you should also map the object class stereotypes specified for the object class

`SolutionService` and to the relevant object class stereotypes specified for the object class `Solution-ServiceOperation`.

To edit the XML object ***TechServiceManager***:

1) Go to the **Presentations** tab, expand the **XML Objects** folder, and expand the **SolutionManagers** folder.
2) Right-click the XML object ***TechServiceManager*** and select **Edit XML**. The XML editor is displayed in the center pane. For general information about editing XML objects in Alfabet Expand, see the section Working with XML Objects.
3) Below the root XML element ***TechServiceManager***, create a child XML element `Stereotype` and specify the following XML attributes:
   - `ClassName`: Enter `Service` (or `SolutionService`) to create the parallel mapping for solution planning):
   - `Name`: Enter the technical name of the object class stereotype defined for the object class `Service` (or `SolutionService`). This is the name defined in the XML attribute `Name` in the **Stereotypes** attribute for the object class.

     ⚠ You must spell the technical name of the technical service stereotype exactly as it is spelled in the **Stereotypes** attribute of the relevant object class.

   - `FileExtension`: Enter `wsdl` or `json` if a technical service based on this stereotype may be based on the respective file type (WSDLor JSON). For more inforamtion about the requirements to work with WSDL and JSON files in the context of technical services, see the section *Configuring the Creation/Export of Technical Services Based on WSDL and OpenAPI Specification Files* in the reference manual *API Integration with Third-Party Components*.
4) Below the XML element `Stereotype` for the class `Service`, create another XML element `Stereotype` and specify the following XML attributes:
   - `ClassName`: Enter `ServiceOperation` (or `SolutionServiceOperation`) to create the parallel mapping for solution planning):
   - `Name`: Enter the technical name of the object class stereotype defined for the object class `ServiceOperation` (or `SolutionServiceOperation`). This is the name defined in the XML attribute `Name` in the **Stereotypes** attribute for the object class.
5) Below the XML element `Stereotype` for the class `ServiceOperation`, create another XML element `Stereotype` and specify the following XML attributes:
   - `ClassName`: Enter `ServiceOperationMethod` (or `SolutionServiceMethod`) to create the parallel mapping for solution planning):
   - `Name`: Enter the technical name of the object class stereotype defined for the object class `ServiceOperationMethod` (or `SolutionServiceMethod`). This is the name defined in the XML attribute `Name` in the **Stereotypes** attribute for the object class.
   - `MethodType`: Enter the method type used for the technical service operation method.
6) In the toolbar, click the **Save** button to save the XML definition.

Configuring Standard Data Capture Environments

The following functionalities are standard data capture environments. Each must be specifically configured for the relevant user profiles that will be working with the functionality:

- **Capture Applications** (`APP_CaptureApplication`)
- **Document Applications** (`APP_UserApplications`)
- **Capture Components** (`COM_CaptureComponents`)
- **Document Components** (`COM_UserComponents`)
- **Capture Demands** (`DEM_CaptureDemands`)
- **Capture Devices** (`DVC_CaptureDevices`)
- **Document Devices** (`DVC_UserDevices`)
- **Capture ICT Objects** (`ICTO_CaptureICTObjects`)
- **Document ICT Objects** (`ICTO_UserICTObjects`)
- **Capture Master Plan Maps** (`ITMPM_CaptureMaps`)
- **Capture Peripherals** (`PRF_CapturePeripherals`)
- **Document Peripherals** (`PRF_UserPeripherals`)
- **Capture Projects** (`PRJ_CaptureProjects`)
- **Sub-Projects** page view (`PRJ_SubProjects`)

Before the data capture environment can be configured, you must first configure the following:

- Ensure that the functionality is assigned to the relevant user profile. For more information, see Making Functionalities Accessible to a User Profile in the chapter Configuring User Profiles for the User Community.
- Configure the class settings for the relevant object class for which data will be captured in the functionality. For example, to implement the `APP_CaptureApplication` functionality, you must configure the `Application` class settings. For more information, see Configuring Class Settings for Object Classes and Object Class Stereotypes in the chapter Configuring User Profiles for the User Community.
- Create a view scheme for the user profile and assign the class setting to the view scheme. Assign the view scheme to the user profile. For more information, see Configuring a View Scheme for a User Profile in the chapter Configuring User Profiles for the User Community.

Editors can be configured for the functionalities `APP_UserApplications`, `COM_UserComponents`, `DVC_UserDevices`, `ICTO_UserICTObjects`, and `PRF_UserPeripherals` that allow multiple objects to be maintained and updated in one editor. For more information about the configuration of mass-update editors, see the section Configuring Editors for the Mass Update of Data Capture Objects and Information Flows in the chapter Configuring Custom Editors.

To configure the data capture environment for a user profile:

1) Go to the **Admin** tab and expand the **User Profiles** node.
2) Right-click the user profile  that is associated with the data capture environment and select **Configure User Profile**. The Alfabet solution opens.
3) Navigate through Alfabet to the relevant functionality.
4) On the far right of the toolbar, click the **Configure**  button to open the **View Configuration** editor.
5) In the **Excluded** column, set an X for each button that should be hidden from the display.

   Any button name appended with the word `Simple` indicates that the button represents a standard editor. If the word `Simple` is not in the button name, the button represents a standard wizard.

6) Click **OK** to save the view configuration.
7) To update the interface and review the view configuration, click your browser's back button and then reopen the functionality. The configuration of the data capture functionality will be updated to include the view configuration definition.

Configuring Text Templates for Email Notifications

A text template is the predefined text in an email that is automatically generated as the result of an action triggered by a user. Text templates for email messages are available for the following contexts:

The text template defines the email text in English, the relevant references to objects and object class properties in Alfabet, and hyperlinks to the relevant objects in Alfabet. The content displayed in the English-language text template can be edited to suit the needs of your enterprise. Locale text templates can be created in order to translate the content of the text template to the non-English languages implemented in your solution interface.

The following are examples of the use of text templates in the generation of emails in Alfabet:

- A new assignment is created. The assignee is immediately sent an email informing him/her about the new assignment.
- A user responsible for a workflow step does not carry out the task by the deadline. The responsible user, the original workflow owner, and the current workflow owner will all be sent emails informing them that the workflow step has not been completed in time.
- A discussion has been initiated about an object. All members in the discussion group will be notified that a new discussion has been launched about the object.
- A notepad entry is made about a strategic business support in the context of a business support map. The user responsible for the associated IT strategy is sent an email information him/her that information has been communicated about the strategic business support.

Protected text templates  are available in Alfabet Expand for all functionalities supporting email functionality. The protected text templates are predefined and used as the template for the relevant email, per

default. Protected text templates can be edited as needed. For an overview of all available protected text templates and the meaning of the variables available for them, see the chapter *Overview of Preconfigured Text Templates and Their Variables* in the reference manual *Configuring Alfabet with Alfabet Expand - Appendix*.

In the case of workflows, consistency monitors, notification monitors, and discussion groups, public text templates  can be created based on protected text templates. This allows you, for example, to create text templates for different types of workflows where different text or information is required depending on the purpose of the workflow or for different notification monitors which will target different aspects of the architecture. The public text template must then be explicitly assigned to the relevant configuration available for the workflows, consistency monitors, notification monitors, and discussion groups that they have been created for.

Please note that text templates for notification monitors and consistency monitors must be located in their respective folder. The `NotificationMonitorDefault` text template or any copy thereof must be located in the text template folder ***M_NOTE*** and the `ConsistencyMonitorDefault` and `ConsistencyMonitorMail` text templates or any copy thereof must be located in the text template folder ***M_CON***. The names of the text template folders must not be changed. Furthermore, all existing protected text templates as well as any new text templates for workflows must be stored in the ***WF*** folder.

For additional information regarding additional configuration required to implement email notifications in the context of workflows, see the section Configuring Email Notifications for Workflows.

The following configuration requirements must be completed by the system administrator in the tool Alfabet Administrator:

- All Alfabet functionalities for which the email capability is to be implemented require the setup of a connection to an SMTP server for outgoing email. For more information, see the section *Activating the Dispatch of Email Notifications in Alfabet* in the reference manual *System Administration*.
- The user profile used to open the Alfabet views targeted by hyperlinks in the email is, by default, the user profile that the sender was logged in with when the view was sent/triggered. However, your system administrator may configure that Alfabet views in email notifications are to be opened using the recipient's user profile. For more information, see the section *Configuring the Setup To Open the Alfabet Interface via Links in Email Notifications* in the reference manual *System Administration*.

The language displayed for a user's email notifications is specified by a user administrator in the **Email Notification Language** attribute for the relevant user in the **User Administration** functionality accessible via an administrative user profile. For more information, see the section *Defining and Managing Users* in the reference manual *User and Solution Administration*.

The following information is available:

- Editing a Protected Text Template
- Creating a Custom Text Template
- Defining a Query for a Text Template

- Sending a Test Email Based on a Text Template
- Creating a Translation of a Text Template
- Specifying Custom Text Templates for Password Generation
- Deleting a Public Text Template

Editing a Protected Text Template

The text templates define the email text, relevant references to objects and their object class properties, and hyperlinks to the relevant objects in the solution interface. You can change or replace the text in the email although you must be careful not to change the expressions in the predefined standard variables available in the text templates. The text templates may either be specified in ASCII or HTML format, whereby HTML must be XML-conform HTML, compliant with HTML 5, and use standard HTML tags. Locale texts can be created for each text template in order to provide the email in the relevant secondary languages supported by your enterprise.

The text templates define the email text, relevant references to objects and their object class properties, and hyperlinks to the relevant objects in the solution interface. You can make the following changes to any text template available in Alfabet Expand:

- The **Subject** field of the email can be specified via the **Caption** attribute of the text template.
- The text template can be either formatted as ASCII or HTML. Please note that the HTML must be XML-conform HTML, compliant with HTML 5, and use standard HTML tags.
- There are three different types of variables that can be included in a text template:
  - Predefined standard variables: These are variables that are predefined by Software AG and serve the purpose of referencing the relevant data in the Alfabet database. For example, the variable `{Object:RefImage}` typically allows the base object referenced by the text template to be included in the text template. You can add, remove, or move the entire variable via copy and paste. If the expression in the curly brackets `{XXX}` is changed, the text template may fail to work correctly.
  - Object variables: A specified set of variables is available that allows information such as the object targeted by the notification or a user referenced by the object. The syntax of these references are {<ObjectClass>:<ObjectClassProperty>}, whereby the set of object classes that can be specified in <ObjectClass> are predefined. Any scalar property defined for the <ObjectClass> expression can be referenced in the <ObjectClassProperty>. For example, if an application is the base object referenced by the email, you would enter `{Object:ID}` to include the ID of an application or `{Object:Description}` to include the description of an application. You can add, remove, or move the entire variable via copy and paste.
  - Query variables: It is possible to specify an Alfabet query or SQL query to add more complex references to the text template that cannot be captured via scalar properties (for example, additional referenced information or a document link). If you plan to specify an Alfabet query or native SQL query to the text template, you must enter the variable {`Query:` <QueryName>} to the text template, whereby the <QueryName> expression is determined by the value of the **Name** attribute specified for the query text configuration object.
- The text displayed in the templates can be edited, as needed.

- Locale texts can be created for each text template in order to provide the email in the relevant secondary languages supported by your enterprise.

For an overview of the predefined variables as well as the object variables available for each protected text template, see the chapter *Overview of Preconfigured Text Templates and Their Variables* in the reference manual *Configuring Alfabet with Alfabet Expand - Appendix*.

All protected text templates  may be edited as needed. To edit a protected text template:

1) Go to the **Presentation** tab and expand the **Text Templates** folder by clicking the + symbol. The following folders are available containing predefined text templates that may be edited.

   - ***AE***: The ***AE*** folder contains text templates for email notifications associated with the activation of a user password. For an overview of the predefined variables as well as the object variables available for each protected text template, see the section *Text Templates for Activation of User Passwords* chapter *Overview of Preconfigured Text Templates and Their Variables* in the reference manual *Configuring Alfabet with Alfabet Expand - Appendix*. For more information about specifying the message in the emails or configuring custom text templates to use in place of the standard text templates, see the section Specifying Custom Text Templates for Password Generation.

   - ***ASMT***: The ***ASMT*** folder contains text templates for email notifications sent in the context of the *Assignment Functionalities*. For an overview of the predefined variables as well as the object variables available for each protected text template, see the section *Text Templates for Assignments* chapter *Overview of Preconfigured Text Templates and Their Variables* in the reference manual *Configuring Alfabet with Alfabet Expand - Appendix*. For an overview of the configuration required to implement the assignments capability, see the section Configuring the Assignment Capability in the reference manual *Configuring Alfabet with Alfabet Expand*.

   - ***DSC*** and ***DSC_Activation***: The ***DSC*** and ***DSC_ActivationStandard*** folders contain text templates for email notifications associated with the *Managing and Contributing to the Discussion*. Email notifications may be sent when a discussion is initiated about an object or a contribution is made to the discussion by a member of a discussion group. For an overview of the predefined variables as well as the object variables available for each protected text template, see the section *Text Templates for Discussions* chapter *Overview of Preconfigured Text Templates and Their Variables* in the reference manual *Configuring Alfabet with Alfabet Expand - Appendix*. For more information about the configuration of the discussion functionality, see the section *Defining Discussion Groups for Collaborative Discussions* in the reference manual *User and Solution Administration*.

   - ***ITMAP***: The ***ITMapFolder*** contains a protected text template that is relevant when users create notes in the notepad capability when working with business support maps. For an overview of the predefined variables as well as the object variables available for each protected text template, see the section *Text Templates for Business Support Maps* chapter *Overview of Preconfigured Text Templates and Their Variables* in the reference manual *Configuring Alfabet with Alfabet Expand - Appendix*. For more information, see the section *Communicating about Business Supports via the Notepad Functionality* in the reference manual *IT Planning Basic*.

   - ***M_CON***: The ***M_CON*** folder contains protected text templates that can be used as to send email notifications about the assignments triggered by the execution of consistency monitors. For an overview of the predefined variables as well as the object variables available for each protected text template, see the section *Text Templates for Consistency Monitors* chapter *Overview of Preconfigured Text Templates and Their Variables* in the reference

manual *Configuring Alfabet with Alfabet Expand - Appendix*. For more information about the configuration of consistency monitors, see *Defining Consistency Monitors* in the reference manual *User and Solution Administration*.

- ***M_NOTE***: The ***M_NOTE*** folder contains a text template that can be used for email notifications that are triggered for notification monitors. Notification monitors are based on configured queries that determine when a monitor should be triggered for an object and to whom email notifications should be sent. For an overview of the predefined variables as well as the object variables available for each protected text template, see the section *Text Templates for Notification Monitors* chapter *Overview of Preconfigured Text Templates and Their Variables* in the reference manual *Configuring Alfabet with Alfabet Expand - Appendix*. For detailed information about the configuration of notification monitors and their text templates, see the section Configuring Notification Monitors in the reference manual *Configuring Alfabet with Alfabet Expand*.
- ***MON***: The ***MON*** folder contains text templates for email notifications associated with the execution of activity, inactivity, and date monitors. A monitor is triggered whenever a defined property is either changed (activity monitor), not changed (inactivity monitor), or reaches a specified date. For an overview of the predefined variables as well as the object variables available for each protected text template, see the section *Text Templates for Activity, Inactivity, and Date Monitors* chapter *Overview of Preconfigured Text Templates and Their Variables* in the reference manual *Configuring Alfabet with Alfabet Expand - Appendix*. For more information about monitors, see the section *Keeping Track of Objects via Monitors* in the reference manual *User and Solution Administration*.
- ***ORG***: The ***ORG*** folder contains text templates used for the email notifications that are automatically generated in the context of an organizational change made in the *Organizational Changes Page View*. For an overview of the predefined variables as well as the object variables available for each protected text template, see the section *Text Templates for Organizational Changes* chapter *Overview of Preconfigured Text Templates and Their Variables* in the reference manual *Configuring Alfabet with Alfabet Expand - Appendix*.
- ***PROC***: The ***PROC*** folder contains text templates used for the email notifications that are automatically generated in the context of a business process change in the *Business Process Changes Page View*. For an overview of the predefined variables as well as the object variables available for each protected text template, see the section *Text Templates for Business Process Changes* chapter *Overview of Preconfigured Text Templates and Their Variables* in the reference manual *Configuring Alfabet with Alfabet Expand - Appendix*.
- ***WF***: The ***WF*** folder contains text templates for the email notifications sent in the context of the workflows capability. The ***WF*** folder contains all text templates for email notifications associated with workflow activities. A text template is available for each action involved in a workflow that requires notification to the relevant responsible users. For detailed information about configuring email notifications for workflows, see the section Configuring Email Notifications for Workflows. For an overview of the predefined variables as well as the object variables available for each protected text template, see the section *Text Templates for Workflows* chapter *Overview of Preconfigured Text Templates and Their Variables* in the reference manual *Configuring Alfabet with Alfabet Expand - Appendix*.

2) Expand the relevant text template folder  and click the relevant protected text template  to display its attribute window. Define the following attributes, as needed:

- **Caption**: Enter text for the subject line for the email message. The caption is displayed in the **Subject** field of the email. You can define text as well as any variables for the subject line that can be added to the body of the text template.
- **Group**: Displays the text template folder where the text template is stored. Please note that text templates must be stored in their respective folders. Otherwise, errors may occur with the email notification.
- **Is HTML**: Select `True` if the email should have HTML formatting instead of ASCII format. If you set this attribute to `True`, the HTML code must be entered in the **Text** attribute. Select `False` if the email should have ASCII format.

  Please note that if email notifications are consolidated for workflow templates and the **Is HTML** attribute is set to `True` for the associated text template, the consolidated email will also have HTML formatting. For additional information regarding additional configuration required to implement email notifications in the context of workflows, see the section Configuring Email Notifications for Workflows.

  Please note that you should not set the **Is HTML** attribute to `True` in the context of the text templates available in the ***ORG*** or ***PROC*** folder.

- **Text**: Revise the existing text and variables, as needed, to write the text in the email. Please note the following:
  - If you set the **Is HTML** attribute to `True`, enter the HTML code.
    - The HTML must be XML-conform HTML, compliant with HTML 5, and use standard HTML tags.
    - Variables in curly brackets `{XXX}` can be used but must be placed in a `<span>` tag.
    - The formatting of the HTML can either be written explicitly in the `<body>` element or can be specified via a stylesheet that is stored in the **Internal Document Selector** . In this case, the HTML must refer to the target CSS file in a `<link>` element. For more information about uploading documents to the functionality. See the chapter *Uploading Documents and Managing User Permissions to Document Folders in the Internal Document Selector* in the reference manual *User and Solution Administration*.
  - If you set the **Is HTML** attribute to `False`, edit ASCII text as needed.
  - Regardless of whether you are defining HTML formatting or ASCII format, please keep the following in mind:
    - The text can be edited as needed. You can add, delete or revise text in the text template.

3) To specify an Alfabet query or SQL query in order to add a query variable {`Query:` <QueryName>} to the text template, right-click the text template and select **Create Text Query**. The text query  is added below the text template node. Click the text query  to open the attribute grid and define the following, as needed:

- Define a name for the text query in the **Name** attribute. The name must be included in the <QueryName> expression of the variable {`Query:` <QueryName>} that you include in the **Text** attribute of the text template.
- Define either an Alfabet query in the **Alfabet Query** attribute or a native SQL query in the **Native SQL** attribute. For more information about configuring Alfabet queries and native SQL queries, see the chapter Defining Queries.

The following native SQL query returns a document link for the application that is the current object of a workflow step:

```
SELECT URL.LINK FROM ALFA_URI URL
JOIN APPLICATION APP ON URL.OBJECT=APP.REFSTR
WHERE APP.REFSTR=@OBJECT
AND URL.CATEGORY='Manual'
```

The following native SQL query returns all outgoing information flows of a workflow's base application:

```
SELECT NULL, INFORMATIONFLOW.ID, INFORMATIONFLOW.NAME FROM
INFORMATIONFLOW, APPLICATION, WORKFLOW
WHERE INFORMATIONFLOW.A_FROM = APPLICATION.REFSTR AND
WORKFLOW.ARTIFACT = APPLICATION.REFSTR
AND WORKFLOW.REFSTR = @WORKFLOW
```

- For Alfabet queries, parameters must be defined with the prefix: (colon symbol).
- For native SQL queries, parameters must be specified with the @ (at sign)
- For native SQL query, `REFSTR` is required as the first column.
- Parameters in queries return the `REFSTR` of the object they refer to.
- You can use the following parameters in the query:
  - `SENDER` to refer to the user who is triggering the notification
  - `PERSON` to refer to the recipient of the notification.
  - `OBJECT` to refer to the object targeted by the workflow step
  - All objects returned by the query will be added to the text using one line per item.
  - For text templates sent in the context of workflows only: `WORKFLOW` to refer to the current workflow. Please note that this parameter cannot be used for a text template that is based on a query if the text template is assigned to the first workflow step of a workflow.
  - For text templates sent in the context of workflows only: `WORKFLOWSTEP` to refer to the current workflow step. Please note that this parameter cannot be used for a text template that is based on a query if the text template is assigned to the first workflow step of a workflow.
  - All object class properties defined as show properties in the **Alfabet Query** or in the `SELECT` statement of the native SQL query will be displayed concatenated in the email.

- The results of the query can be formatted in HTML. Please note the following:
  - The **Is HTML** attribute must be set to `True` for the text template.
  - The **Returns HTML** attribute must be set to `True` for query object defined for the text template.
  - The first column of the text template query must return the `REFSTR` and the column with the HTML content must have a column name.
  - Special characters in the formatted string must be correctly escaped.
- It is possible to create more than one query per text template.

4) In the toolbar, click the **Save** button to save your changes.

Creating a Custom Text Template

It may be that your enterprise needs to create custom text templates in order to provide customized information in the context of workflows, consistency monitors, notification monitors, and discussion groups.

It is possible to create a custom text template for workflows, consistency monitors, notification monitors, and discussion groups based on any of the existing protected templates provided by Software AG.

Public text templates should not be created for assignments, activity monitors, inactivity monitors, date monitors, IT map notepad entries, and organization or business process changes. In these contexts, only the protected text templates are implemented and all public text templates will be ignored.

In order to create a custom text template, you must create a new text template and then copy an existing text template to the new text template and then modify the text or placement of variables, as needed. For example, to create a custom text template `StageGateExpired` sent in the context of a workflow targeting enterprise release management, you would copy the protected text template `WorkflowStepEscalated`, which is typically sent when a responsible user does not perform a workflow step by a targeted deadline and therefore, the status of the workflow step is escalated. In the custom text template, you could specify a subject line, include other users in the CC field to ensure that they are informed about the expired stage gate deadline, add additional explanatory text that clarifies the issue, and add additional information via the inclusion of the targeted object's scalar properties. The custom text template would then be assigned to the notification action configured for the relevant workflow step of the workflow template. All custom templates will be included in the batch processing of email notifications if batch processing is specified for the workflow template.

Although it is technically possible to create custom text templates for other contexts such as assignments or notepad entries, only the protected text templates are implemented, and all public text templates will be ignored by the system. Only public text templates for workflows, consistency monitors, notification monitors, and discussion groups will be implemented.

All existing protected text templates as well as custom text templates must be stored in the appropriate text template folder . The following is required in order to implement custom text templates:

- Custom text templates for user password generation must be located in the `AE` folder. For information about specifying custom text templates for email notifications for password generation, see the section Specifying Custom Text Templates for Password Generation.
- Custom text templates for workflows must be located in the `WF` folder. For information about specifying email notifications for workflows, see the section Configuring Email Notifications for Workflows.
- Custom text templates for consistency monitors must be located in the `M_CON` folder. For information about specifying email notifications for consistency notifications, see the section *Defining Consistency Monitors* in the reference manual *User and Solution Administration*.
- Custom text templates for notification monitors must be located in the `M_NOTE` folder. For information about specifying email notifications for notification monitors, see the section *Defining Notification Monitors* in the reference manual *User and Solution Administration*.
- Custom text templates for discussion groups must be located in the `DSC_Activation` folder. For information about specifying email notifications for discussion groups, see the chapter *Defining Discussion Groups for Collaborative Discussions* in the reference manual *User and Solution Administration*.
- For more information about the predefined standard variables and configurable object variables allowed for each relevant text template, see the chapter *Overview of Preconfigured Text Templates and Their Variables* in the reference manual *Configuring Alfabet with Alfabet Expand - Appendix*.

To create a new text template:

1) Go to the **Presentation** tab and expand the **Text Templates** folder by clicking the + symbol.
2) Right-click the relevant text template folder  and select **New Text Template**.
3) Click the new public text template  to display its attribute window. Define the technical name for the text template in the **Name** attribute.

   A validation mechanism checks for correct syntax when defining a technical name. The technical name of a configuration object may not begin with an empty space nor include any of the following special characters: **\ / * ? " > < | ':**

   Furthermore, please note that names may not begin with an empty space nor include special characters. For a list of the special characters that are not allowed, see the section Defining Attributes for Configuration Objects in the chapter Getting Started with Alfabet Expand.

   Furthermore, if the technical name of a configuration object is changed, the name will be correctly updated in other configuration objects referencing the changed object during design time. Please note that the name of a changed configuration object will not be updated in guide pages nor if the guide pages reference a configuration object listed in the **Show Usage** functionality. If you plan to change the name of a configuration object, the reference in the guide page should be changed prior to changing the configuration object name.

4) In the **Group** attribute, enter the name of the folder in which the text template should be stored. Please note that text templates must be stored in their respective folders. Otherwise, errors may occur with the email notification. Please note the following:

- Specify `AE` to store text templates for password generation. See the section Specifying Custom Text Templates for Password Generation for further configuration requirements to implement custom templates for password generation.
- Specify `M_CON` to store text templates for consistency monitors.
- Specify `M_NOTE` to store text templates for notification monitors.
- Specify `WF` to store text templates for workflow notifications.
- Specify `DSC_Activation` to store text templates for discussion groups.

5) You now need to create the email message for the new text template. To do so, you should copy an existing text template including its text and variables and paste it in the new text template. You can then modify the text and cut and paste the variables, as needed.
   - To copy the text of a standard text template for workflows, select the relevant text template and open the text editor by clicking the **Browse** button available for the **Text** attribute. Select the text and right-click and select **Copy**.
   - To paste the text to the new text template, select the new text template and open the text editor by clicking the **Browse** button available for the **Text** attribute. Right-click in the editor and select **Paste**.
6) Define the attributes in the attribute grid for the public text template as described in the section Editing a Protected Text Template. For more information about the predefined standard variables and configured object variables that are allowed for each text template, see the chapter *Overview of Preconfigured Text Templates and Their Variables* in the reference manual *Configuring Alfabet with Alfabet Expand - Appendix*.
7) In the toolbar, click the **Save** button to save your changes.

Sending a Test Email Based on a Text Template

A **Send Test Mail** functionality has been added to text templates configured in the configuration tool. If selected, the email will be registered in the `ALFA_EMAIL_BUS` database table. Once the Alfabet Server is running, the email will be sent to the user configured for the test email in the server alias settings or the **Alfabet Configuration Overrides** functionality.

To test the text template, right-click the text template and select **Send Test Mail**. Confirm the info message by clicking **OK**. The sent email can be tracked in the **Email Message Log** functionality, described in the section *Tracking the Email Messages Sent in the Context of AlfabetFunctionalities* of the reference manual *User and Solution Administration*.

The **Alfabet Configuration Overrides** functionality allows solution designers that do not have access to the Alfabet Administrator and need to test a configuration in which emails are triggered to override the test email account and sender email address definitions made in the server alias configuration of the Alfabet Web Application. The email settings defined via the user interface will override settings made in the server alias configuration of the Alfabet Web Application. For more information about the **Alfabet Configuration Overrides** functionality, see the section *Overriding Server Configurations for Testing Purposes* in the reference manual *User and Solution Administration*. For more information about the configuration of the email functionality, see

the section *Activating the Dispatch of Email Notifications in Alfabet* in the reference manual *System Administration*.

Creating a Translation of a Text Template

A locale text template is a localized version of a standard or custom text template in which the text can be translated to another language. Text templates can be generated in multiple languages, allowing the translated email notifications generated within Alfabet to be displayed for a selected culture.

Please note that in the context of email notifications, regardless of whether or not a locale text template is created, any translated captions of object classes, object class stereotypes, object class properties, etc. will be displayed in the email if the user triggering the email has the relevant language selected for the Alfabet interface.

The language displayed for a user's email notifications is specified by a user administrator in the **Email Notification Language** attribute for the relevant user in the **User Administration** functionality accessible via the `Admin` user profile. For more information, see the section *Defining and Managing Users* in the reference manual *User and Solution Administration*.

To create and translate a locale text template:

1) Go to the **Presentation** tab and expand the **Text Templates** node. Expand the relevant text template folder.
2) Right-click the text template that you want to create a language version for and select **Create Locale Text**. You will see a copy of the text template  appear in the explorer tree below the original English-language text template.

   The locale text template must be stored in the appropriate folder with its parent text template. For example, all text templates for workflows must be stored in the `WF` folder, all text templates for consistency monitors must be stored in the `M_CON` folder, etc.

3) Click the new locale text template to open the attribute window and define the following attributes:
   - **Locale Name**: Select the base culture specified in the culture that this local text template is translated for.
   - **Text**: Edit the text of the email message as you would for any protected text template. Please note the following:
     - The text displayed in the templates can be translated, as needed.
     - Predefined variables as well as configurable object variables can be moved via copy and paste within a text template.
     - The expression in curly brackets `{XXX}` in predefined variables may not be edited.
     - For detailed information about specifying a text template, see the section *Editing a Protected Text Template*.

4) In the toolbar, click the **Save**  button to save your changes.

Specifying Custom Text Templates for Password Generation

The standard protected text templates `ActivationEmailNewPassword` is used when a new user password is generated for a user and `ActivationEmailURLLink` is used when a new user password is generated for a user. However, you can create custom templates to replace these protected text templates. To create the custom text templates, following the instructions as described in the section Creating a Custom Text Template. Please note that the custom text templates for user password generation must be located in the `AE` folder.

For an overview, of the variables available for text templates in the context of password generation, the section *Text Templates for Activation of User Passwords* in the reference manual *Configuring Alfabet with Alfabet Expand - Appendix*. For more information about the password regeneration functionality, see the section *Defining, Clearing, and Resetting a User's Password* in the reference manual *User and Solution Administration*.

Once the custom text templates have been created, you must specify which custom text templates to implement instead of the default text templates `ActivationEmailNewPassword` and `ActivationEmailURLLink`:

1) Go to the **Presentation** tab and expand the **XML Objects** folder.
2) Right-click the XML object ***SolutionOptions*** and select **Edit XML**. The XML editor is displayed in the center pane. For general information about editing XML objects in Alfabet Expand, see Working with XML Objects.
3) In the XML attribute `GeneratePassWordMailTemplate_Pass`, enter specify the name of the custom text template that will replace the default text template `ActivationEmailNewPassword`.
4) In the XML attribute `GeneratePassWordMailTemplate_Link`, enter specify the name of the custom text template that will replace the default text template `ActivationEmailURLLink`.
5) In the toolbar, click the **Save**  button to save the XML definition.

Deleting a Public Text Template

Before a public text template is deleted, you should check to see if the text template is implemented in other configuration objects that are configured in Alfabet Expand such as workflow templates.

Public text templates implemented in notification monitors, consistency monitors, and discussion groups will not be reported in the **Show Usage** functionality because they are not configured in Alfabet Expand but rather in the context of the Solution Configuration functionality in the Alfabet interface that can be accessed via the `Admin` user profile. You must manually check the configuration of these objects before you delete them. For more information, see the sections *Defining Consistency Monitors*, *Defining Notification Monitors*, and *Defining Discussion Groups for Collaborative Discussions* in the reference manual *User and Solution Administration*.

To do so, right-click the text template and click **Show Usage**. A window will be displayed showing the configuration objects using the selected text template. For more information regarding the **Show Usage**

functionality, see the section Using the Show Usage Functionality in the chapter Getting Started with Alfabet Expand.

1) In the **Presentation** tab, click the + symbol next to the relevant text template folder.
2) Right-click the text template that you want to delete and select **Delete**.
3) Confirm the warning by clicking **Yes**. The text template is deleted from the explorer.

Configuring Monitors

Alfabet provides a number of different monitors that help your enterprise maintain accurate and up-to-date data. Monitoring allows you to keep track of specified objects for activity (the object has been edited), inactivity (the object has not been edited), or an approaching date (such as an end date) for a specific object or all objects in an object class, and consistency of data. When a monitor is activated, all users defined as listeners to the monitor are automatically sent an email notification. The users defined will be able to access the object that the monitor is about via a hyperlink in the email notification by means of a specified user profile.

Alfabet provides a variety of monitors to alert Alfabet users about changes that have occurred to specific objects which may require further activity, reviews that did not occur as intended, or transactions that were expected to occur. The following monitor types are available in Alfabet:

- **Activity Monitor**: An activity monitor alerts specified users about changes that have been made to specified objects in an object class. The monitor owner must specify a set of attributes that are to be monitored and may specify a set of users that are to be alerted if the monitor is triggered. An email will be sent to the monitor owner and all defined users when the monitor is triggered.

  The monitor owner and specified users should be alerted about changes made to the start and end dates of information flows defined for a specific set of applications. In this case, you would define an activity monitor of the type **Application** with the monitored context **Application - Information Flows**. You would then define the attributes **Start Date** and **End Date** to track.

The following configuration is required:

- The activity monitor is created in the **Monitors** functionality that may be accessed via an administrative user profile. For more information about defining activity monitors, see the section *Defining Activity Monitors for Specific Objects* in the reference manual *Getting Started with Alfabet*.
- Configure the following in Alfabet Expand:
  - Set `True` for the **Audit** attribute for the object classes that are to be monitored.
  - Set `True` for the **Enabled** attribute for the monitor template.
  - Set `True` for the **Enabled** attribute for the monitor contexts.
  - Configure the text template `MonitorObjectChanged` in the ***MON*** folder. This is used for email notifications about an object that has been changed.

- **Inactivity Monitor**: An inactivity monitor alerts the monitor owner and specified users about the absence of activity occurring to specified objects in an object class. The monitor owner must specify

a set of objects that are to be monitored and may specify a set of users that are to be alerted if the monitor is triggered. An email will be sent to the monitor owner and all defined users if a specified object is not changed or reviewed within a specified period of time. The monitor owner can specify the monitor object as reviewed via the **Mark as Reviewed** button in the object profile of the targeted object.

The monitor owner and specified users should be alerted if no changes are made to an application. Specified applications should be reviewed on a monthly basis. In this case, you would define an inactivity monitor of the type **Application** with a monthly frequency.

The following configuration is required:

- An inactivity monitor is created in the **Monitors** functionality that may be accessed via an administrative user profile. For more information about defining inactivity monitors, see the section *Defining Inactivity Monitors for Specific Objects* in the reference manual *Getting Started with Alfabet*.
- Configure the following in Alfabet Expand:
  - Set `True` for the **Audit** attribute for the object classes that are to be monitored.
  - Set `True` for the **Enabled** attribute for the monitor template.
  - Set `True` for the **Enabled** attribute for the monitor contexts.
  - Configure the text template `MonitorObjectChanged` in the ***MON*** folder. This is used for email notifications about an object that has been changed.

- **Date Monitor**: A date monitor allows you to keep track of the approach of a date (start date, end date, target date, etc.) for specified objects or the date of related objects. The monitor owner must specify a set of objects that are to be monitored and may specify a set of users that are to be alerted if the monitor is triggered. An email will be sent to the monitor owner and all defined users when the monitor is triggered.

The monitor owner and specified users should be alerted about the approaching end date of the business supports provided by specific applications. In this case, you would define a date monitor of the type **Application** with the monitored context **Application Business Support**. You would then specify that the end date should be tracked.

The following configuration is required:

- A date monitor is created in the **Monitors** functionality that may be accessed via an administrative user profile. For more information about defining inactivity monitors, see the section *Defining a Date Monitor for Specific Objects* in the reference manual *Getting Started with Alfabet*.
- Configure the following in Alfabet Expand:
  - Set `True` for the **Enabled** attribute for the monitor template.
  - Set `True` for the **Enabled** attribute for the monitor contexts.
  - Configure the text template `MonitorObjectDateAlert` in the ***MON*** folder. This is used for email notifications about an object's specified date falls in the review period.

- **Notification Monitor**: A notification monitor allows email notifications to be automatically triggered based on configured Alfabet queries or native SQL queries. The queries specify the objects and attributes that are targeted as well as the users who shall be notified about the objects found by the queries.

  Users who have a specified role for applications should be alerted about any new information flows that are created for the applications that they are associated with.

The following configuration is required:

- A notification monitor is created in the **Notification Monitors** functionality that may be accessed via an administrative user profile. For more information about defining notification monitors, see the section *Defining Notification Monitors* in the reference manual *User and Solution Administration*.
- Configure the following in Alfabet Expand:
  - Configure the text template `NotificationMonitorDefault` located in the text template folder ***M_NOTE***. This is used for email notifications about notification monitors. Please note that text templates for notification monitors must be located in the text template folder ***M_NOTE***. The name of the text template folders must not be changed.

- **System Date Monitor**: A system date monitor is a time-triggered monitor for an object class on a system-wide basis. A system date monitor allows you to keep track of the approach of a date for all objects in a specified object class and their related objects (such as an object's start date, end date, target date, etc.). When a specified date approaches for an object in the object class, an assignment will be generated for the object's authorized user. The authorized user will also receive an email information them of their new assignment.

  All users responsible for any application should be alerted about business supports that have an end date later than the applications providing the business support.

The following configuration is required:

- A system date monitor is created in the **System Date Monitors** functionality that may be accessed via an administrative user profile. For more information about defining system date monitors, see the section *Defining System Date Monitors* in the reference manual *User and Solution Administration*.
- Set `True` for the **Enabled** attribute for the monitor template.
- Set `True` for the **Enabled** attribute for the monitored contexts.
- Configure the XML object ***SystemMonitorDefaultDef*** to configure the assignments generated in the context of system date monitors
- Configure the text template `AssignmentNew` in the `ASMT` folder. This is used for email notifications about the assignments generated for the monitor.
- Configured the text template `MonitorObjectCountdownReview` in the ***MON*** folder. This is used to fill the **Description** attribute of the assignments that are created.

- **Consistency Monitor**: A consistency monitor supports the system-wide maintenance of objects in the Alfabet database. The consistency monitor is specified to periodically search for inconsistencies

among objects. Each consistency monitor is based on an Alfabet query or native SQL query that defines the object classes targeted by the query as well as the inconsistent attributes to be detected. If an inconsistency is found by the query, an assignment will be generated for the object's authorized user. The authorized user will also receive an email information them of their new assignment. The timely completion of the assignment triggered by a consistency monitor can be tracked by the solution administrator.

Users responsible for applications should be alerted about business supports that have an end date later than the applications providing the business support.

The following configuration is required:

- Consistency monitors are created in the **Consistency Monitors** functionality that may be accessed via an administrative user profile. For more information about defining consistency monitors, see the section *Defining Consistency Monitors* in the reference manual *User and Solution Administration*.
- The following text templates should be configured in the configuration tool Alfabet Expand for the email notifications sent when an assignment is created if a consistency monitor is triggered. For more information, see the section Configuring Text Templates for Email Notifications in the reference manual *Configuring Alfabet with Alfabet Expand*. See the chapter *Overview of Preconfigured Text Templates and Their Variables* in the reference manual *Configuring Alfabet with Alfabet Expand - Appendix* for an overview of the available text templates for notification monitors and their permissible variables.
  - The text template `ConsistencyMonitorDefault` located in the text template folder ***M_CON*** is used for the assignments generated in the context of the consistency monitors. The relevant text template must be selected for a consistency monitor in the **Text Template** attribute in the **Consistency Monitor** editor. The text template is used to fill the **Description** attribute of the assignment. The name of the assignment is copied from the name of the consistency monitor. Please note that text templates for consistency monitors must be located in the text template folder ***M_CON***. The name of the text template folders must not be changed.
  - The text template `ConsistencyMonitorMail` ocated in the text template folder ***M_CON*** is used when an assignment is generated via batch process for an inconsistent object found by a consistency monitor. If a batch process is configured, the email notification will be sent to the authorized user of an object when a specified consistency is detected. For more information about setting up a batch process, see the section *Batch Processing for Monitors and Change Management with AlfaBatchExecutor.exe* in the reference manual *System Administration*.

Please note that text templates for consistency monitors must be located in the text template folder ***M_CON***. The name of the text template folders must not be changed.

The following must be configured in order to work with monitors in Alfabet:

- In order for any monitor to be executed and email notifications to be sent to relevant users, a batch process must be configured by your system administrator. For more information about setting up a batch process, see the section *Batch Processing for Monitors and Change Management with AlfaBatchExecutor.exe* in the reference manual *System Administration*.

- All Alfabet functionalities for which the email capability is to be implemented require the setup of a connection to an SMTP server for outgoing email in the tool Alfabet Administrator. For more information, see the section *Activating the Dispatch of Email Notifications in Alfabet* in the reference manual *System Administration*.
- Text templates for email notifications may be customized for all monitors in the configuration tool Alfabet Expand. For more information, see Configuring Monitors in the reference manual *Configuring Alfabet with Alfabet Expand*.
- For each monitor created, the monitor owner must define the **User Profile to Access Object in Notification** field in the monitor's editor in the relevant monitor functionality in the **Solution Admin** tab that may be accessed via an administrative user profile. This is described for each monitor type in the chapter *Configuring Monitors to Track Objects in Alfabet* in the reference manual *User and Solution Administration*.
- Access permissions must be available for the user profile so that relevant users receiving the email notification can access the relevant objects that are targeted by the hyperlink in the email notification. For more information about the configuration of access permissions, see the section Configuring Access Permissions for Alfabet in the reference manual *Configuring Alfabet with Alfabet Expand*.
- All object classes that are to be monitored via activity monitors and inactivity monitors have history tracking enabled in the configuration tool Alfabet Expand and therefore, the **Audit** attribute must be set to `True` for these object classes. Please note that this is not necessary for date, system date, consistency, and notification monitors. These monitors will be implemented even if the **Audit** attribute is set to `False` for the relevant object class. For more information, see the section Specifying History Tracking for an Object Class in the chapter Configuring the Class Model in the reference manual *Configuring Alfabet with Alfabet Expand*.

The following information is available:

Enabling the Monitoring Capability for Activity and Inactivity Monitors

In order to implement activity or inactivity monitors for an object class, you must carry out two configuration steps:

- The **Audit** attribute must be set to `True` for the object classes that are to be monitored by activity and inactivity monitors. For more information about the auditing functionality, see the section Specifying History Tracking for an Object Class in the chapter Configuring the Class Model.

- Monitor templates and monitored contexts must be enabled for activity monitors in the **Monitor Templates** node in the **Presentations** tab.
  - Monitor templates allows you to specify and enable the object classes for which activity and inactivity monitors can be created. All object classes that are configured for monitoring will be displayed in the **Monitor Type** field in the **Activity Monitor** editor and **Inactivity Monitor** editor.
  - Monitored contexts are available for activity monitors and allow users to monitor a specific context, such as the lifecycle or information flows associated with an object. All monitored contexts that are enabled will be displayed in the **Monitored Context** field in the **Activity Monitor** editor. Monitored contexts are preconfigured by Software AG.

To configure an object class for monitoring:

1) First, you should configure the relevant object class for the auditing capability. In the **Classes** folder in the **Meta Model** tab, click the protected class or public class that you want to implement the auditing functionality for.
2) In the attribute window, set the **Audit** attribute to `True`. If you select `False`, activity and inactivity monitors cannot be created for the selected object class. This does not impact date, system date, notification, or consistency monitors.
3) Next, you must enable the relevant monitor template for monitoring. For example, if you have set the **Audit** attribute to `True` for the object class `Application`, then you must now configure the monitor template `Application`. In the **Presentation** tab, expand the **Monitor Templates** node in the explorer, and click the relevant monitor template to open its attribute window.
4) In the attribute window, set the **Enabled** attribute to `True` to allow monitors to be created for the associated object class. If you select `False`, activity and inactivity monitors cannot be created for the selected object class.
5) Expand the monitor template to display its monitored contexts. For each monitored context that should be displayed in the **Monitored Context** field in the **Activity Monitor** editor, click the relevant monitored context to open its attribute window. Set the **Enabled** attribute to `True` to enable the selected monitored context for the monitor template or select `False` to disable the selected monitored context for the monitor template.
6) In the toolbar, click the **Save** button to save your changes.

Enabling the Monitoring Capability for Date Monitors

Monitor templates and monitored contexts must be enabled for date monitors in the **Monitor Templates** node in the **Presentations** tab. All object classes that are configured for monitoring will be displayed in the **Monitor Type** field in the **Date Monitor** editor. Monitor templates allows you to specify and enable the object classes for which date monitors can be created. Monitored contexts are

available for date monitors and allow users to monitor a specific context, such as the lifecycle or information flows associated with an object. Monitored contexts are preconfigured by Software AG.

To configure an object class for monitoring:

1) Go to **Presentation** tab, expand the **Monitor Templates** node in the explorer, and click the relevant monitor template to display its attribute window.
2) Set the **Enabled** attribute to `True` to allow monitors to be created for the associated object class. If you select `False`, date monitors cannot be created for the selected object class.
3) Enable the relevant monitored contexts nested below a monitor template. Expand the relevant monitor template to display its monitored contexts.
4) Expand the monitor template to display its monitored contexts. For each monitored context that should be displayed in the **Monitored Context** field in the **Date Monitor** editor, click the relevant monitored context to open its attribute window. Set the **Enabled** attribute to `True` to enable the selected monitored context for the monitor template or select `False` to disable the selected monitored context for the monitor template.
5) In the toolbar, click the **Save** button to save your changes.

Configuring Notification Monitors

A notification monitor is a type of monitor that allows email notifications to be automatically triggered based on configured Alfabet queries or native SQL queries. The queries specify the targeted objects and their object class properties as well as the users who shall be notified about the objects found by the queries.

Notification monitors are primarily configured in the **Notification Monitors** functionality that may be accessed via an administrative user profile. For more information about the creation and configuration of a notification monitor, see the section *Defining Notification Monitors* in the reference manual *User and Solution Administration*.

There are several aspects that must be configured in Alfabet Expand:

- The text templates used for the email notifications sent out when the monitor is triggered may need to be configured via the **Text Templates** node in Alfabet Expand.
- The queries used to find the relevant objects to monitor as well as the users to whom a notification is sent can be defined as an Alfabet query or a native SQL query. All AQL queries defined for notification monitors will be checked for correct syntax upon execution of the **Check All AQL Queries** functionality available in the **Meta-Model** menu in Alfabet Expand.
- Please note that the consolidation of emails for notification monitors must be specified in the XML attribute `ConsolidatedNotificationMail` in the XML object `SystemMonitorDefaultDef`. If set to `"true"`, one email will be sent to the relevant person regarding all objects triggering a notification. If set to `"false"`, a separate email will be sent for each object triggering the notification. The attribute is set to `"true"` per default.

The following information is available:

Creating and Defining a Text Template for Notification Monitors

In the **Notification Monitors** functionality in Alfabet, the creator of the notification monitor can either select a configured text template in the **Notification Monitors** editor or write an ad-hoc text for the notification directly in the **Notification Monitor** editor. If the creator of the notification monitor defines both a preconfigured text template and creates an ad-hoc text for the notification in the editor, then the ad-hoc text template definition will have precedence over the preconfigured text template selected in the editor.

Please note however that an ad-hoc text cannot be translated to other languages. If the Alfabet solution implemented in your enterprise is used for more than one language, then it is recommended that a text template is configured in Alfabet Expand so that additional language versions of the template can also be defined.

The default text template `NotificationMonitorDefault` is available in the `MON` folder for notification monitors. The default text template will be used for the generation of email notifications if no custom text template is defined and therefor no text template selected in the **Notification Monitor** editor, and if no ad-hoc text is written in the **Notification Monitor** editor. If the default text template `NotificationMonitorDefault` is used, the subject line of the email notification will be automatically generated and display Notification Monitor <NameOfMonitor>, whereby the name of the monitor is taken from the object class property `Name` defined for the notification monitor in the **Notification Monitor** editor in Alfabet. For more information, see the section *Defining Notification Monitors* in the reference manual *User and Solution Administration*.

All Alfabet functionalities for which the email capability is to be implemented require the setup of a connection to an SMTP server for outgoing emails. For more information, see the section *Activating the Dispatch of Email Notifications in Alfabet* in the reference manual *System Administration*. Furthermore, in order for email notifications to be sent in the context of the monitor functionality, your system administrator must configure a batch process. For more information about setting up a batch process, see the section *Batch Processing for Monitors and Change Management with AlfaBatchExecutor.exe* in the reference manual *System Administration*.

To create a custom text template for the notification monitors:

1) Go to the **Presentation** tab and expand the **Text Templates** folder by clicking the + symbol.
2) Right-click either the `MON` node and select **New Text Template**.
3) Click the new text template to display its attribute window. In the attribute window, define the technical name for the text template in the **Name** attribute.
4) Set the **Group** attribute to `M_NOTE`. This is the folder in which you will store text templates for notification monitors.
5) For the **Caption** attribute, enter text for the subject line for the email message.
6) You now need to create the email message for the new text template. To do so, you should copy an existing text template including its text and the variables and paste it in the new text template. You can then modify the text and cut and paste the variables, as needed.

- To copy the text of a standard text template for workflows, select the relevant text template and click the **Browse** button available for the **Text** attribute. Select the text and right-click and select **Copy**.
- To paste the text to the new text template, select the new text template and click the **Browse** button available for the **Text** attribute. Right-click in the editor and select **Paste**.

7) Edit the text, as described above. See the chapter *Overview of Preconfigured Text Templates and Their Variables* in the reference manual *Configuring Alfabet with Alfabet Expand - Appendix* for an overview of the available text templates for notification monitors and their permissible variables.

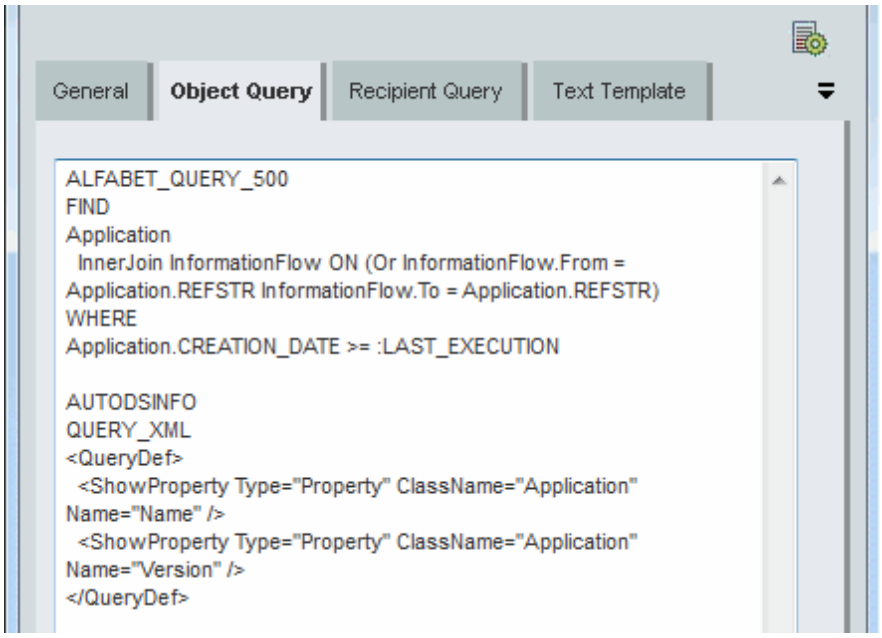
8) If other language versions need to be defined for the text template, create a local language version by right-clicking the new text template and selecting **Create Locale Text**. For more information, see the section Creating a Translation of a Text Template.

9) In the toolbar, click the **Save** button to save your changes.

Configuring the Queries Used in Notification Monitors

Notification monitors are created and defined in the **Notification Monitors** functionality in order to define objects to be monitored and notifications to be sent based to relevant users. This is achieved by defining rules to find 1) the objects that are the target of the monitor as well as 2) the persons to whom the notification email. The persons identified to receive the notification could be the authorized users of the target objects, persons having roles defined for the target objects, or persons who are not directly associated with the target object.

In the **Notification Monitor** editor in which notification monitors are created and edited, the user defining the monitor must enter a relevant Alfabet query or SQL query to find the monitored objects as well as a relevant Alfabet query or SQL query to find the persons to whom the notification should be sent.



A valid Alfabet query or native SQL query must be defined in the **Object Query** tab to find the objects for which the monitor shall be executed. Please keep the following in mind:

- The `FIND` class of the Alfabet query should be the object class that shall be monitored.
- `JOIN` and `WHERE` clauses may be used to define a subset of objects of the base class to be evaluated.
- The Show properties defined in the Alfabet query determine the information displayed about the objects in the **Objects** page view of the notification monitor.
- All Alfabet queries defined for notification monitors will be checked for correct syntax upon execution of the **Check All AQL Queries** functionality available in the **Meta-Model** menu in Alfabet Expand.
- When defining a native SQL query, the first `SELECT` property must return the values of the `REFSTR` property of the selected object. All following `SELECT` properties define the information displayed about the objects in the **Objects** page view of the notification monitor.
- Both Alfabet queries and native SQL queries may use the variable `LAST_EXECUTION` to compare date information of the objects with the last execution date for the monitor.
- For information about defining Alfabet queries and about the rules that apply to the definition of native SQL queries in the context of Alfabet, see Defining Queries. For more information about reviewing query syntax, see the section Testing Queries for Compliance with the Current Release.

A valid Alfabet query or native SQL query must be defined in the **Recipient Query** tab to find the users to whom the notification shall be sent. Please keep the following in mind:

- The `FIND` class of the Alfabet query should be the object class Person.
- The relation to the object class for which objects are to be evaluated must be defined via `JOIN`s and `WHERE` clauses.
- The query may use the parameter `BASE` to specify that the recipient query is executed for each of the objects found by the object query.
- The `REFSTR` property of the base class `PERSON` and of the object class of the objects to be monitored by the person found by the Alfabet query must be included in the show property definition of the Alfabet query.
- When defining a native SQL query, the first `SELECT` property must return the values of the `REFSTR` property of objects of the object class `PERSON`.

Configuring Assignments for System-Wide Date Monitors

System-wide date monitors are time-triggered monitors defined for an object class on a system-wide basis. When a specified date (usually a start, end, or target date) approaches, users responsible for objects in that object class will automatically be sent an assignment and notification per email asking them to review the object. System-wide date monitors can be configured for a specific object class in the **System Date Monitors** functionality that may be accessed via an administrative user profile. The XML object ***SystemMonitorDefaultDef*** allows you to configure the assignments generated in the context of system-wide date monitors.

- For more information about system-wide date monitors, see the section *Defining System Date Monitors* in the reference manual *User and Solution Administration*.

- Software AG provides a variety of monitors including another type of date monitor that can be configured to monitor specified objects in an object class. For more information about the available monitors in Alfabet, see *Keeping Track of Objects via Monitors* in the reference manual *User and Solution Administration*.

The following must also be configured before the system date monitor functionality can be implemented:

- Monitored contexts are available for date monitors and allow users to monitor a specific context, such as the lifecycle or information flows associated with an object. All monitored contexts that are enabled will be displayed in the **Monitored Context** field in the **System Date Monitor** editor. Monitored contexts are preconfigured by Software AG . To specify the monitored contexts that should be available for the system date monitors, expand the monitor template to display its monitored contexts. For each monitored context that should be displayed in the **Monitored Context** field in the **System Date Monitor** editor, click the relevant monitored context to open its attribute window. Set the **Enabled** attribute to `True` to enable the selected monitored context for the monitor template or select `False` to disable the selected monitored context for the monitor template.
- The text displayed in automatically-generated email notifications is also configured by your solution designer in the configuration tool Alfabet Expand. For more information, see the section Configuring Text Templates for Email Notifications. See the chapter *Overview of Preconfigured Text Templates and Their Variables* in the reference manual *Configuring Alfabet with Alfabet Expand - Appendix* for an overview of the available text templates for date monitors and their permissible variables.
- All Alfabet functionalities for which the email capability is to be implemented require the setup of a connection to an SMTP server for outgoing emails. For more information, see the section *Activating the Dispatch of Email Notifications in Alfabet* in the reference manual *System Administration*.
- In order for email notifications to be sent in the context of the monitor functionality, your system administrator must configure a batch process. For more information about setting up a batch process, see the section *Batch Processing for Monitors and Change Management with AlfaBatchExecutor.exe* in the reference manual *System Administration*.

To edit the XML object ***SystemMonitorDefaultDef***:

1) Go to the **Presentation** tab and expand the **XML Objects** folder.
2) Right-click the XML object ***SystemMonitorDefaultDef*** and select **Edit XML**. The XML editor is displayed in the center pane. For general information about editing XML objects in Alfabet Expand, see Working with XML Objects.
3) Define the XML attributes, as needed. The table below displays the XML elements and XML attributes that can be edited for the XML object ***SystemMonitorDefaultDef***:

XML Element (bold) / XML Attribute	Explanation
SystemMonitorDefaultDef	
`Assignee`	Enter the user name of the default user that should receive assignments associated with an object if the impacted object has no authorized user defined.
`Originator`	Enter the user name of the default user that is the creator of the automatically-generated assignment. This user would have to follow-up on assignments that have not been completed by the target date and have Therefore, been returned as the result of the assignment's expiration.
`CountdownReviewTime`	Enter an integer to establish the target date when the assignee should complete the review/update of the relevant object. The target date is computed based on the date when the assignment is generated plus the value defined in the `CountdownReviewTime` attribute.  If the `CountdownReviewTime` is defined as 30, the assignee will have 30 days after the date that the assignment was generated to complete the assignment. An assignment generated on Jan. 1, 2008 will have a target date of Jan. 30, 2008.

4) In the toolbar, click the **Save**  button to save the XML definition.

Configuring the Diagram Capability

In Alfabet Expand you can configure custom diagram item templates to use for the display of diagram items in diagrams. Furthermore, you can configure custom diagrams that allow users to design and view diagrams that visualize objects and references between objects that are not addressed by the standard diagrams.

You can also configure the visualization of connection items such as information flows in standard diagrams as well as the default settings for the Alfabet Diagram Designer.

The following information is available:

Configuring Custom Diagram Item Templates

In Alfabet, diagrams are used to visualize objects in the IT landscape and their relationships. For example, an application diagram allows your enterprise to design a landscape diagram showing the application groups, applications, local components, peripherals and information flows relevant to a selected application. From a technical perspective, each application group, application, local component, peripheral and information flow displayed in the diagram is a diagram item. All diagram items are based on diagram item templates, which determine the visualization of the diagram item for the relevant object class. For example, standard diagram item templates for applications are rectangles that are colored powder blue, show the standard icon for the object class Application, and display a standard set of attributes. Diagram item templates are available for all object classes that are visualized in diagrams, but your enterprise can configure custom diagram item templates to use in place of or in addition to the standard diagram item templates.

Custom diagram templates allow you to configure alternative visualizations of diagram item templates. The custom diagram item templates you create in Alfabet Expand are based on selected preconfigured diagram item templates that are relevant for a specific type of diagram such as an application diagram or platform diagram. You can then modify the custom diagram item template as needed. For example, you can change the color, shape, borders, and size of the custom diagram item template. You can alter the attributes displayed on the diagram view item or add additional text. Furthermore, you can change the icon displayed on the diagram item template and even design it so that it appears to consist of an icon only or another shape rather than a rectangle.

The custom diagram item templates you configure can also be assigned to diagram view items in the **Configuration** functionality. The custom diagram item template can be selected in the **Diagram Item Template** field in the **Diagram View Item** editor. For more information, see the section *Configuring Diagram Views for Diagrams* in the reference manual *Configuring Evaluation and Reference Data in Alfabet*.

The following information is available:

- Creating a Custom Diagram Item Template
- Configuring the Color, Border, and Static Text of the Custom Diagram Item Template
- Configuring Attributes or Text to Display on the Custom Diagram Item Template
- Configuring Icons to Display on the Custom Diagram Item Template
- Configuring a Connection Item as a Custom Diagram Item Template
- Configuring a Different Shape for the Custom Diagram Item Template

Creating a Custom Diagram Item Template

When you create a custom diagram item template, you must base it on a selected preconfigured diagram item template that is relevant for a specific type of diagram such as an application diagram or platform diagram. A selector provides information about the available diagram item templates in order to help you decide which to use. Although each diagram item template is associated with a type of diagram, not every diagram item template is necessarily associated with one specific object class. For example, the diagram item template Application always represents applications, and their object class stereotypes in application diagrams whereas the diagram item template Migration Node can represent applications, ICT objects, or solution building blocks in migration diagrams.

You can create one or more custom diagram item templates per standard diagram item template. This could be especially relevant if object class stereotypes have been configured for an object class. All custom

diagram item templates you create will be available in the **Toolbox Items** pane for the relevant diagram in the Alfabet Diagram Designer and the user designing the diagram can choose which standard or custom diagram item template to use for each individual object that is to be visualized in the diagram. In the case of application diagrams, for example, the diagram designer could add applications based on different custom diagram item templates that represent different application stereotypes to the application diagram.

When you first create a custom diagram item template, it is displayed per default as a rectangle in the center editor pane in the **Diagrams** tab of Alfabet Expand. The standard icon and attributes predefined for the selected diagram item template will be displayed per default on the custom diagram item template.

To create a custom diagram item template:

1) Go to the **Diagrams** tab and expand the **Diagram Tools** node.
2) Right-click the **Custom Diagram Item Templates** node and select **Create New Custom Diagram Item Template**. The **Diagram Item Template Selector** opens. This selector displays all standard diagram item templates  that you can base a custom diagram item template on. The **Description** column provides general information about each diagram item template in order to help you decide which diagram item template to use.
3) In the **Diagram Item Template Selector** editor, select the diagram item template that is relevant for the custom diagram item template that you want to configure and click **OK**. The new custom diagram item template is displayed in the center editing pane.
4) Right-click the new custom diagram item template node and select **Design Diagram Item Template**.
5) In the attribute window on the right, enter a technical name for the custom diagram item template in the **Name** attribute.

   Please keep the following in mind:

   - The technical name may not begin with an empty space nor include special characters. For a list of the special characters that are not allowed, see the section Defining Attributes for Configuration Objects in the chapter Getting Started with Alfabet Expand.
   - The technical name should only contain standard `ASCII` characters.
   - The technical name should consist of upper-case letters only.
   - The maximum length of a technical name may not exceed 30 characters.
   - The technical name may not coincide with any of the reserved key words of the relational database management system.

   A validation mechanism checks for correct syntax when defining a technical name. Please note that if the technical name of a configuration object is changed, the name will be correctly updated in other configuration objects referencing the changed object during design time. However, the name of a changed configuration object will not be updated in guide pages nor if the guide pages reference a configuration object listed in the **Show Usage** functionality. If you plan to change the name of a configuration object, the reference in the guide page should be changed prior to changing the configuration object name.

6) In the **Description** attribute, amend the standard description of the diagram item template as needed to provide information about the configuration of the custom diagram item template. The description is only visible in Alfabet Expand.

7) To define the size of the custom diagram item template, change the default value by entering an integer in the **Height** and **Width** attributes.

8) To define the visualization of the icon representing the custom diagram item template:

   - In the **Caption** attribute, enter a caption for the custom diagram item template.
   - In the **Icon** attribute, select an icon for the custom diagram item template.
   - In the **Icon Background Color** attribute, select the background color for the icon for the custom diagram item template.
   - In the **Layout Type** attribute, select `Scalable` if the background shapes should be scaled based on the sizing of the custom item. This may be necessary if the diagram item template shall be used as a custom shape used to define the background of a diagram.
   - In the **Hint** attribute, modify the text to provide information to users about the purpose of the custom diagram item template. The initial text in the **Hint** attribute is copied from the base diagram item template. A tooltip containing the hint text will be displayed when the user points to the icon of the custom diagram item template in the **Toolbox Items** pane.

9) To specify that the diagram items in the Alfabet interface are updated if changes are made to the custom diagram item template they are based on, set the **Keep Original Shape Rendering** attribute to `True`. To specify that the diagram items in the Alfabet interface are not updated if changes are made to the custom diagram item template, set the **Keep Original Shape Rendering** attribute to `False`. In this case, the user designing the diagram can manually apply the changes to the diagram item by selecting the **Other Actions** > **Reset Original Shape** option in the Alfabet Diagram Designer. Please note that if the **Keep Original Shape Rendering** attribute is changed from `False` to `True`, the update will only apply to the diagram items that have been created while the **Keep Original Shape Rendering** attribute was set to `True`. In other words, the current setting of the value of the **Keep Original Shape Rendering** attribute is passed on to the diagram item.

10) To specify that the custom diagram item template is not displayed in standard diagrams implementing the standard diagram item template that the custom diagram item template is based on, set the **Show In Toolbox of Base Item** to `False`. If the custom diagram item templates should be displayed in standard diagrams, select `True`.

11) In the toolbar, click the **Save**  button to save the custom diagram item template.

Configuring the Color, Border, and Static Text of the Custom Diagram Item Template

A new custom item template will originally be displayed with the default configuration of the diagram item template that it is based on. The color and border can be changed as needed. Optionally, static text can be added that will be displayed on all diagram items based on the custom diagram item template.

To configure the size, color, and borders of a custom diagram item template:

1) Right-click the custom diagram item template node  and select **Design Diagram Item Template**.

2) To define the color attributes for the custom diagram item template, expand the **Background Shape** section of the attribute window and define the following:

- For the **Back Color** attribute, select a color for the custom diagram item template. Please note that a different color can be assigned to any diagram item in the context of the Alfabet Diagram Designer.
- Set the **Back Brush Type** attribute to `Solid` if the custom diagram item template should display no color gradation, `AutoVerticalGradient` if the custom diagram item template should display a vertical color gradation, or `AutoHorizontalGradient` if the custom diagram item template should display a horizontal color gradation.
- If the user designing the diagram item should determine the color and border, set the **Use Background Shape** attribute to `False`. The color and borders of any diagram item based on the selected custom diagram item template will be transparent and the user designing the diagram can define the color and border of each individual diagram item. If the **Use Background Shape** attribute to `True`, the attributes defined in the **Background Shape** section of the attribute window will be applied when diagram items are added to the diagram.

3) To define the borders of the custom diagram item template:
   - Set the **Rounded Border** attribute to `False` if the custom diagram item template should have square corners. Select `True` if the custom diagram item template should have rounded corners. If the **Rounded Border** attribute is set to `True`, enter an integer in the **Round Size** attribute to specify how large the curves of the rounded corners are. A small number such as 2 draws minimally rounded corners and a large number such as 10 draws significantly rounded corners.
   - Set the **Double Border** attribute to `False` if the custom diagram item template should have a single border. Select `True` if the custom diagram item template should have a double border.
   - Expand the **Pen Attributes** section and define the color, style, and width of the borders in the **Color**, **Style** and **Width** attributes.
4) To define static text that is displayed on the custom diagram item template, enter text in the **Text** attribute. Expand the **Text Attributes** section to define the position, color, size, and style of the text displayed in the custom diagram item template. Please note that the font is determined by the configuration of the ***AlfaGUIScheme*** object. For more information, see the chapter Configuring the Visualization of the Alfabet Interface.
5) In the toolbar, click the **Save**  button to save the custom diagram item template.

Configuring Attributes or Text to Display on the Custom Diagram Item Template

Each diagram item template is preconfigured with one or more rectangle shapes that allow you to display an object's attributes or text. The diagram item template that you base the custom diagram item template on will typically have one or more rectangle shapes on it with predefined attributes. You can modify, add, or delete the existing rectangles.

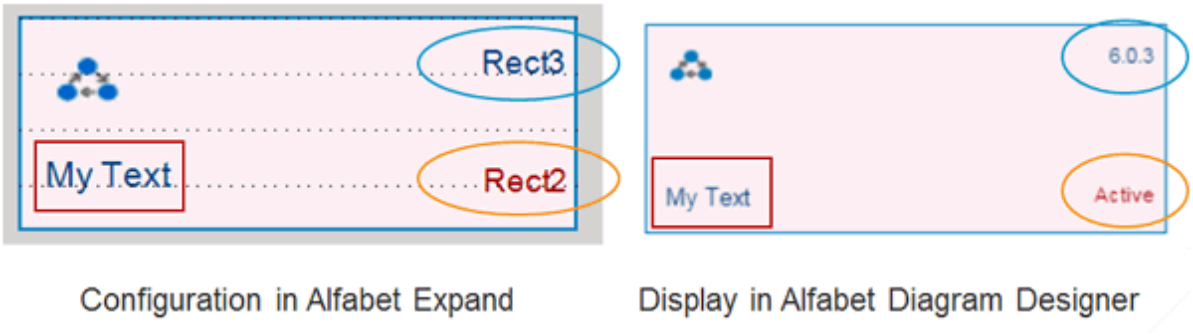


FIGURE: Custom diagram item template with a text and two attribute values

When you create a custom diagram item template, the predefined rectangles will be displayed with the labels `Rect1`, `Rect2`, `Rect3`, etc. Each rectangle with the label `Rect...` is predefined to display an attribute value. Click the rectangle to view its predefined attribute in the **Control Content Into** field. This can be changed as needed.

Per default, the predefined rectangles associated with the diagram item template are transparent and have a transparent border so that only the rectangle content (attribute or text) will be displayed. New rectangles added to the custom diagram item template will be white with borders, per default. You can change this and display the rectangles with color and borders, if necessary. Additionally, you should ensure that the size of the rectangle is large enough so that the content that will be displayed will not be truncated.

To add a rectangle to the custom diagram item template or specify the visualization or content of the custom diagram item template:

1) Right-click the custom diagram item template node and select **Design Diagram Item Template**. The menus and toolbars relevant for configuring custom diagram item templates are displayed.

   If the menus and toolbars are not displayed in Alfabet, you can either right-click the custom diagram item template and select **Design Diagram Item Template** or click the custom diagram item template displayed in the design editor in the center pane.

2) To add a new rectangle to the custom diagram item template, click the **Rectangle** button and click in the custom diagram item template. You can define the following to modify the rectangle:

   - Drag the handles to resize the rectangle. You must ensure that the size of the rectangle is large enough for the content that could be displayed in the diagram item. If the rectangle is not large enough, the content may be truncated.
   - Click-and-drag the rectangle to move it to another location in the custom diagram item template. It is advised that you click the rectangle and define the **Anchor** attribute in order to dock the rectangle to the defined borders if a user resizes the custom diagram item template in the Alfabet interface.
   - To define a color for the rectangle, click the rectangle and set **Back Color** to `Transparent` if the rectangle should have no color or select a color.
   - To define the rectangle border, click the rectangle and expand the **Pen Attributes** section. For the **Color** attribute, select a color for the border or select `Transparent` if the rectangle should have no border. If you have selected a color for the border, define the border style in the **Style** attribute and the width of the border in the **Width** attribute. To further specify the border, you can also define the attributes **Rounded Box**, **Round Size**, and **Shadow**.

3) To specify the content of the rectangles displayed on the custom diagram item template, click the rectangle and define the following in the attribute window.

   - To display an attribute value in the rectangle shape, set the **Content Type** attribute to `PropertyValue`. Enter the name of the standard or custom object class property in the **Control Content Into** attribute. You must manually enter the name of the standard or custom attribute that should be displayed. The name of the standard or custom object class property must be spelled exactly as it is defined in the **Name** attribute of the relevant property. If no attribute value has been defined for the object, then nothing will be displayed in the rectangle shape.

     

     Please note that because the diagram item template Migration Node can represent applications, ICT objects, or solution building blocks in migration diagrams, you must specify the **Control Content Into** attribute only with object class properties that are common to the object classes Application, ICT Object, or Solution Building Block (for example, `Status` or `Version`). Otherwise, an error may occur.

   - To display a text in the rectangle shape, set the **Content Type** attribute to `PlainText`. Enter the text to display in the **Text** attribute. You must manually enter the name of the standard or custom attribute that should be displayed. You must spell the name of the standard or custom object class property correctly.

   - To display text if no attribute has been defined n the rectangle shape, set the **Content Type** attribute to `ConditionalText`. Enter the name of the standard or custom object class property in the **Control Content Into** attribute. You must manually enter the name of the standard or custom attribute that should be displayed. You must spell the name of the standard or custom object class property correctly. Enter the text to display in the **Text** attribute if no attribute value has been defined for the object. If an attribute value is defined it will be displayed in the diagram element, but if no attribute value has been defined for the object, then the configured text will be displayed in the diagram item.

   - To display a value that is assigned to the diagram item template via a diagram view in a configured diagram view report, set the **Content Type** attribute to `QueryValue`. For information about the definition of diagram views including the use of diagram item templates in the diagram views, see Creating Custom Diagram Views for a Custom Diagram View Report.

4) Specify the opacity of the attribute value or text in the rectangle in the **Opacity** attribute by entering a number between 0 and 1 (for example, 0.5). The lower the number, the more transparent will be the attribute value or text.

5) In the toolbar, click the **Save**  button to save the configuration.

Configuring Icons to Display on the Custom Diagram Item Template

Each diagram item template is preconfigured with a standard icon representing the object class for which the custom diagram item template is typically implemented. This icon can be changed, additional icons can be added, or the entire custom diagram item template can be displayed as an icon only with no text, attribute values, or borders, etc.

Depending on your solution configuration, the icon defined for the custom diagram item template might not be displayed in the Alfabet interface:

- An icon configured for a relevant class setting may overrule the icon configured for the custom diagram item template. For more information about the configuration of class settings, see the section Configuring Class Settings for Object Classes and Object Class Stereotypes in the chapter Configuring User Profiles for the User Community.
- An icon defined for an object in the object's editor in the Alfabet interface may overrule the icon configured for the class setting and the custom diagram item template.

To ensure that the icon defined for the custom diagram item template overrules any icon defined for the relevant class setting or for an object, the **Icon Type** attribute must be set to `Manual`.

To specify the icon displayed on the custom diagram item template, click the icon and define the following in the attribute window:

1) Right-click the custom diagram item template node and select **Design Diagram Item Template**. The menus and toolbars relevant for configuring custom diagram item templates are displayed.

   If the menus and toolbars are not displayed in Alfabet, you can either right-click the custom diagram item template and select **Design Diagram Item Template** or click the custom diagram item template displayed in the design editor in the center pane.

2) To add a new icon to the custom diagram item template, click the **Icon** button and click in the custom diagram item template, or to modify an existing icon, click the icon in the custom diagram item template to open the attribute window.
3) Specify the **Icon Gallery** attribute by selecting the icon gallery containing the icon you want to display on the custom diagram item template. The icon gallery you select here will determine which icons are available for the **Icon** attribute. `Small` are icons that are 22x22 pixel in size, `Large` are icons that are 36x36 pixel in size, and `Free` are icons of an arbitrary size. For more information about adding an icon to an icon gallery, see the section in the section Adding and Maintaining Icons for the Alfabet Interface in the chapter Configuring the Visualization of the Alfabet Interface.
4) Specify the **Icon** attribute by selecting the icon that should be displayed on the custom diagram item template in the diagram. The drop-down menu will display all icons available in the icon gallery specified in the **Icon Gallery** attribute.
5) Set the **Icon Type** attribute to `Manual` to ensure that the icon defined in the **Icon** attribute overrides any other icon definition. Select `Object` if the icon defined for the class setting or the icon defined in the object's editor in the Alfabet interface should override the icon selected in the `Icon` attribute.

   Please note that because the diagram item template **Migration Node** can represent applications, ICT objects, or solution building blocks in migration diagrams, you should set the **Icon Type** attribute to `Object` so that the icon displayed on the custom diagram item template is determined by the class setting for migration nodes.

   If the **Icon Type** attribute has been set to `Object` and the diagram item template shall display an object of the class `AlfaMMClassInfo`, you must define the following in order to display the icon of the object class that the custom diagram template shall represent in the diagram:

   - **Control Type**: Select `PropertyValue`.

- **Content Control Info**: Enter `Icon` to display the icon defined in the **Icon** attribute of the object class of the object that shall be displayed.

6) Specify the **Anchor** attribute by selecting one or more edges to lock the icon to. It is recommended that you anchor the icon to the frame of the custom diagram item template so that it is correctly positioned if the diagram item is resized in the Alfabet Diagram Designer.

7) Specify the opacity of the icon in the **Opacity** attribute by entering an integer between 0 and 1 (for example, 0.5). The lower the number, the more transparent will be the icon.

8) In the toolbar, click the **Save** button to save the configuration.

Configuring a Connection Item as a Custom Diagram Item Template

A diagrams, connection items are typically drawn as lines with arrows between two objects. A connection item could be, for example, an information flow between applications or between components in a platform, a migration rule, which describes the migration steps from one application to another, or a role, which describes the functional relationship between an object such as an application and a person or organization.

1) Go to the **Custom Diagram Item Templates** node, create the custom diagram item template based on a diagram item template representing a connection item (for example, migration rule, role, or any type of information flow) and define the basic attributes for the custom diagram item template as described in the section Creating a Custom Diagram Item Template.

2) Right-click the custom diagram item template node and select **Design Diagram Item Template** to display its attribute window.

3) Specify the **Back Color** attribute by selecting a color for the custom diagram item template. Please note that a different color can be assigned to any diagram item in the context of the Alfabet Diagram Designer.

4) Specify the opacity of the connection item in the **Opacity** attribute by entering an integer between 0 and 1 (for example, 0.5). The lower the number, the more transparent will be the connection item.

5) Expand the **Start Arrow** section of the table and **End Arrow** section and define the following for the start and end arrows:

   - **Style**: Specify the shape on the start of the connection item.
   - **Size**: Specify the size of the start arrow.

6) Expand the **Pen Attributes** section and define the color, style, and width of the borders in the **Color**, **Style** and **Width** attributes.

   - **Color**: Specify the color of the connection item.
   - **Style**: Specify the line style of the connection item.
   - **Width**: Specify the line width in pixel of the connection item.

7) In the context of the Alfabet interface, users can display attributes on the connection items. The position, color, size, and style of the text visualizing these attributes can be configured for the custom diagram item template. Expand the **Text Attributes** section to define the position, color, size, and style of text displayed on the custom diagram item template.

The attributes that can be displayed on connection items is configured in the XML object ***DiagramInformationFlowDef***. For more information about configuring the attributes to display on connection items, see the section Configuring Attributes or Text to Display on the Custom Diagram Item Template The font is determined by the configuration of the ***AlfaGUIScheme*** object. For more information, see the chapter Configuring GUI Scheme Definitions for the Alfabet Interface in the chapter Configuring the Visualization of the Alfabet Interface.

8) In the toolbar, click the **Save** button to save the custom diagram item template.

Configuring a Different Shape for the Custom Diagram Item Template

Instead of displaying the default rectangle shape that most custom item diagram templates are based on, you can use any shape displayed in the toolbar for the custom diagram item template. It is important to understand that the default custom diagram item template is configured to be transparent in the editor pane and the shape is placed within the boundaries of the transparent custom diagram item template.

Custom shapes can also be implemented in custom diagrams. The custom diagram item template will be displayed in the **Diagram Standard Shapes Selector** when a new shape is created via the **Shapes** node in the context of the **Custom Diagram Definitions** node. For more information, see the section Adding Shapes to the Custom Diagram.

1) Go to the **Custom Diagram Item Templates** node, create the custom diagram item template based on a diagram item template representing a connection item (for example, migration rule, role, or any type of information flow) and define the basic attributes for the custom diagram item template as described in the section Creating a Custom Diagram Item Template.

2) Right-click the custom diagram item template node and select **Design Diagram Item Template**. The menus and toolbars relevant for configuring custom diagram item templates are displayed.

3) Change the **Height** and **Width** attributes so that the shape will fit inside the template in the center pane.

4) Remove the color of the rectangle and border and content from the custom diagram item template displayed in the center pane:

   - Set the **Back Color** attribute to `Transparent` for the custom diagram item template.
   - Expand the **Pen Attributes** section and specify the following:
     - **Color**: Specify `Transparent` for the custom diagram item template.
     - **Style**: Specify the line style of the custom diagram item template.
     - **Width**: Specify the line width in pixel of the custom diagram item template.
   - Delete the rectangles and icon from the custom digram item template.

5) Ensure that the menus and toolbars relevant for configuring the custom diagram item template is displayed. To do so, right-click the custom diagram item template node and select **Design Diagram Item Template**.

6) To add a new shape to the custom diagram item template, click the relevant shape button in the toolbar and click in the custom diagram item template. Please note that the shape must fit inside the boundaries of the diagram item template.

7) Click the shape and configure the attributes for the color and border the shape as described in the section Configuring the Color, Border, and Static Text of the Custom Diagram Item Template. Please note that a different color can be assigned to any diagram item in the context of the Alfabet Diagram Designer.

8) Click the shape and add rectangles to configure attributes and static text as described in the section Configuring Attributes or Text to Display on the Custom Diagram Item Template.

9) Click the shape and add an icon as described in the section Configuring Icons to Display on the Custom Diagram Item Template.

10) In the toolbar, click the **Save** button to save the custom diagram item template.

Configuring Custom Diagrams

In addition to the standard diagrams available in Alfabet, you can configure custom diagrams that allow users to design and view diagrams that visualize objects and references between objects that are not addressed by the standard diagrams. For example, a custom diagram could be configured to display standard platforms and applications with connection items that represent the references between the standard platforms and applications. The complete infrastructure available for standard diagrams including filters and toolbar buttons will also be available for custom diagrams in the Alfabet user interface. Users with relevant access permissions to the Alfabet Diagram Designer can edit the custom diagrams.

The configuration of a custom diagram requires the definition of a custom diagram definition and a configured report that is specified to handle the diagram functionalities for the custom diagram definition:

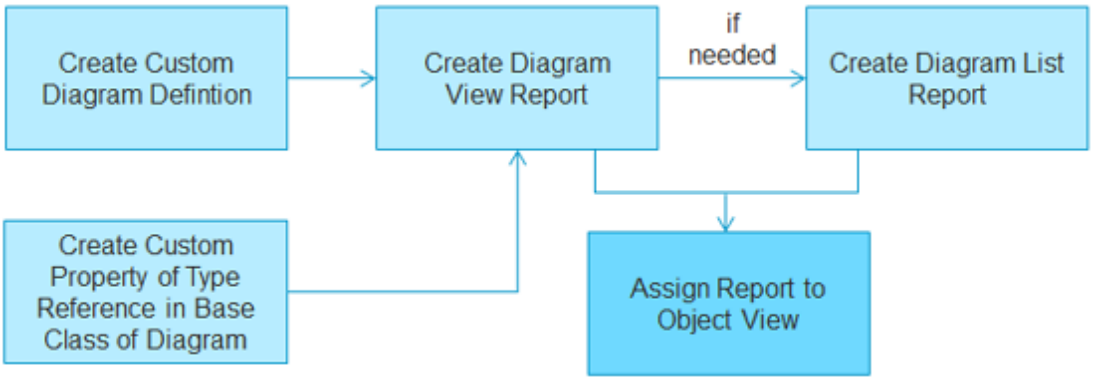

FIGURE: Sequence of configuration steps for custom diagram definition

- The custom diagram definition defines which object classes, connections, toolbox items, and graphic elements are available to the user when designing the diagram. It is the basis for the definition of the diagram that can be designed in the Alfabet Diagram Designer. A new custom diagram definition must be based on an existing standard diagram definition but can be modified as needed. The custom diagram definition includes a set of nodes and connection items that represent the object classes that may be visualized in the diagram, toolbox items that allow objects and connection items to be added to the diagram as well as buttons providing various graphic shapes to help design the

appearance of the diagram. New nodes, connections, toolbox items, and buttons can be created and those provided with the standard diagram definition may be removed as needed.

- A configured report must be configured as the framework to display the diagram in the Alfabet user interface. The report includes filters and the button to open the Alfabet Diagram Designer and displays the diagram that has been designed in the Alfabet Diagram Designer based on the custom diagram definition. When a user opens the Alfabet Diagram Designer via the configured diagram view report and creates a diagram based on a custom diagram definition, the diagram is saved as an object of the object class `ReportDiagram`. This object class stores the content of the diagram together with the information about the custom diagram definition that the diagram is based on as well as the object the diagram is created for.
  - There are two different configuration options that allow users to create diagrams in the Alfabet user interface. You can either define the configured report so that users can create the diagram as the main standard diagram for the object or you can create a configured diagram list report so that users can create multiple diagrams for the object.
  - If a diagram shall be created as the main standard diagram for the object, a custom property of the type `Reference` must be created for the base class for which the diagram shall be created in order to link to the object of the report diagram.
- The reports may be assigned to an object profile or object cockpit so that users can access the diagram view report and design and view the custom diagram. The reports will also be available via the **Configured Reports** functionality. For more information, see the section Integration of Configured Reports in the Alfabet Interface.
- The protected enumeration `CustomDiagramViewType` is available for the definition of diagram views displayed in the context of custom diagrams. The enumeration items defined for the `CustomDiagramViewType` enumeration can be selected in the **Type** field in the **Diagram View** editor. The query specified for the `DiagramView` filter field for the `DiagramViewReport` report must refer to the relevant standard or custom diagram view type. The diagram views based on the standard or custom diagram view type can selected in configured reports based on the `DiagramViewReport` report template. For more information about configuring protected enumerations, see the section *Overview of Protected Enumerations* in the reference manual *Configuring Alfabet with Alfabet Expand - Appendix*. For more information about configuring diagram views, see the section *Configuring Diagram Views for Diagrams* in the reference manual *Configuring Evaluation and Reference Data in Alfabet*.

The following information is available:

- Configuring the Custom Diagram Definition
  - Creating a Custom Diagram Definition
  - Creating Nodes for the Custom Diagram
  - Creating Node Groups for the Custom Diagram
  - Creating Connections for the Custom Diagram
  - Creating a Connected Diagram Definition for the Custom Diagram
  - Creating Toolbox Items for the Custom Diagram
  - Adding Shapes to the Custom Diagram
  - Defining Rules to Automatically Add Objects to New Diagrams

Configuring the Custom Diagram Definition

A new custom diagram definition must be based on an existing standard diagram definition that is then modified. The custom diagram definition includes a set of nodes and connection items that represent the object classes that may be displayed in the diagram, toolbox items that allow objects and connection items to be added to the diagram as well as buttons providing various graphic shapes to help design the visualization of the diagram. New nodes, connections, toolbox items, and buttons can be created and those provided with the standard diagram definition may be removed as needed.

The following configuration is required for the custom diagram definition:

- A node or connection must be defined for every object class that may be visualized in the custom diagram. A node represents an object class such as application, component, information flow, etc. that may be displayed in the diagram. It is especially important to note that the definition of the node or connection does not implicate that object can be created in or explicitly added to the diagram. Some classes may be automatically included in the diagram via their relationships to other objects in the diagram (such as information flows between applications) or when functionalities such as **Add Subordinates** or **Generate Network** are executed in the Alfabet Diagram Designer. Therefore, you must create a node for all relevant object classes that may be visualized in the diagram including those specified via connections and node groups.
- A node group must be specified if a semantic relationship between the node and its referenced objects are to be displayed in the diagram. Node groups are visualized in the diagram as nested diagram items. Nested diagram items are typical, for example, when applications are visualized in the application groups that own them or local components are visualized in the diagram items of the applications that own them.
- A connection must be specified for each connection item that may be visualized in the custom diagram. The definition of the connection node may be either based on a semantic class (such as an `InformationFlow`, `ValueArc`, or `DemandArch`) that reference a source and target object, or a property of type `ReferenceArray` such as `Device.Networks` or `Network.BelongsTo`.
- A toolbox item must be specified for every node and connection item that shall be created, created as a copy, or explicitly added to the custom diagram by the Alfabet user designing the diagram in the Alfabet Diagram Designer. All toolbox items will be available in the top section of the **Toolbox Items** pane in the Alfabet Diagram Designer.
- A shape is required for each graphic element that shall be available to design the diagram. The shapes that may be included in the custom diagram are either preconfigured by Software AG or are

based on configured diagram item templates. All shapes added to the diagram item template will be available in the bottom section of the **Toolbox Items** pane in the Alfabet Diagram Designer.

The following information is available:

- Creating a Custom Diagram Definition
- Creating Nodes for the Custom Diagram
- Creating Node Groups for the Custom Diagram
- Creating Connections for the Custom Diagram
- Creating a Connected Diagram Definition for the Custom Diagram
- Creating Toolbox Items for the Custom Diagram
- Adding Shapes to the Custom Diagram
- Defining Rules to Automatically Add Objects to New Diagrams
  - Defining a Category for the Rules in the XML Object UseCaseCategories
  - Defining the Query for the Rule in a Configured Report
  - Adding the Rule to the Custom Diagram Definition

Creating a Custom Diagram Definition

A new custom diagram definition must be based on an existing standard diagram definition. You should select a standard diagram that already includes some of the object classes that you want to visualize in the diagram. The standard diagram can then be further modified.

To create a custom diagram definition:

1) Go to the **Diagrams** tab and expand the **Diagram Tools** node.
2) Right-click the **Custom Diagram Definitions** node and select **Create New Custom Diagram Definition**.
3) In the **Diagram Definition Selector**, select the standard diagram that the custom diagram definition shall be based on and click **OK**.
4) Click the custom diagram definition  and in the attribute window and define the following attributes:
   - **Name**: Enter a technical name for the custom diagram definition.
   - **Caption**: Specify the caption of the custom diagram. The caption will be displayed in the Alfabet user interface.
   - **Group**: Enter the name of a new folder to store the custom diagram definition below the **Diagram Definitions** node or select an existing folder.
   - **Name Dependency**: Specify the display of information in the diagram header:
     - `OwnName`: The diagram header displays the name of the object. This setting is recommended if multiple diagrams of the diagram type associated with the custom

diagram definition shall be available for the same master object specified in the configured report.

- `MasterName`: The diagram header displays the image properties of the master object specified in the configured report. The actual name of the diagram will be ignored. This setting is useful if there will always be at most one diagram of the diagram type associated with the custom diagram definition for any given master object.
- `PrimaryMasterName`: This is exclusively used for some standard diagram definitions in Alfabet and is not relevant in the context of custom diagram definitions.

Please note that the information displayed in the diagram header is also used as name of the diagram in diagram list reports.

- **Nodes Sequence**: Define the order that the nodes shall be displayed in the explorer in Alfabet Expand. Click the **Browse** button. In the editor, click the **Up/Down** arrows to sequence the nodes in the **Toolbox Items** pane. Click **OK** to close the editor and save the sequence of the nodes.
- **Connections Sequence**: Define the order that the connections shall be displayed in the explorer in Alfabet Expand. Click the **Browse** button. In the editor, click the **Up/Down** arrows to sequence the connections in the **Toolbox Items** pane. Click **OK** to close the editor and save the sequence of the connections.
- **Create Connections on Rescan**: Select `True` if the connections between nodes in the diagram shall be added to the diagram when the diagram is reloaded in the browser.
- **Shape Sequence**: Define the order that the shapes shall be displayed in the bottom section of the **Toolbox Items** pane in the Alfabet Diagram Designer as well as in the explorer in Alfabet Expand. Click the **Browse** button. In the editor, click the **Up/Down** arrows to sequence the shapes in the **Toolbox Items** pane. Click **OK** to close the editor and save the sequence of the shapes.
- **Toolbox Items Sequence**: Define the order that the configured toolbox items shall be displayed in top section of the **Toolbox Items** pane in the Alfabet Diagram Designer as well as in the explorer in Alfabet Expand. Click the **Browse** button. In the editor, click the **Up/Down** arrows to sequence the toolbox items in the **Toolbox Items** pane. Click **OK** to close the editor and save the sequence of the toolbox items.

5) In the toolbar, click the **Save** button to save the custom diagram definition.

Creating Nodes for the Custom Diagram

Nodes are visualized as diagram items in the context of a diagram. A node must be defined for every object class that shall be displayed in the custom diagram. You must create a node for all of the following:

- Every object class that shall be visualized in the diagram.
- Every object class that is specified for a node group.

- Every object class that is specified in a connection.

Please note that the inclusion of the node in the custom diagram definition is necessary for the visualization of the object class in the diagram. The inclusion of a node does not implicate that an object can be explicitly added to or created in the diagram. If the object class shall be added to the diagram or created in the context of the diagram, you must add the node as a toolbox item. For more information, see the section Creating Toolbox Items for the Custom Diagram.

If the node has a semantic reference to other classes and these classes shall be nested in the diagram item of the node, you must also define a node group for the node. Node groups are visualized in the diagram as nested diagram items. Nested diagram items are typical, for example, when applications are visualized in the application groups that own them or local components are visualized in the diagram items of the applications that own them. For more information, see the section Creating Node Groups for the Custom Diagram. For more information about specifying the relationships between classes, see the reference manual *Alfabet Meta-Model*.

To create a node for the custom diagram definition:

1) Expand the custom diagram definition  , right-click the **Nodes**  node and select **New Node**.
2) In the **Select Node Class** editor, select the class that the node is based on and click **OK**.
3) Click the new node and in the attribute window and define the following attributes:
   - **Class Name**: Displays the class that the node is based on.
   - **Node Group Item Only**: Select `True` if the object class may only be visualized as a node group. If set to `True`, you must specify the **Node Group Owner** attribute.
   - **Node Group Owner**: Specify the property that describes the relationship of the node to the node group. The node group must reference this property via the **Back Property** attribute of the node group.
   - **Item Operations**: Specify `True` for each operation that shall be allowed for the node in the context of the Alfabet Diagram Designer. The following operations can be specified:
     - **Cannot Add to Node Group**: The nodes cannot be moved to a node group.
     - **Cannot Remove from Node Group**: The nodes cannot be removed from a node group.
     - **Confirm Deletion**: The deletion of nodes must be confirmed by clicking an **OK** button in a message dialog.
     - **Delete**: The nodes can be deleted from the Alfabet database.
     - **Detach**: The nodes can be removed from the diagram.
     - **Edit**: The nodes can be edited.
     - **Move**: The nodes can be moved from a parent object to another parent object.
     - **Navigate**: The user can navigate to the object profile/object cockpit of the node.
     - **Resize**: The node can be resized.
   - **Diagram Item Template**: Specify a standard or custom diagram item template to visualize the node in the diagram.

- **Enable Substitute**: Select `True` if the **Substitute Object** options shall be available for the node in the **Semantic Actions** menu in the Alfabet Diagram Designer.
- **Enable Change Diagram Item Template**: Select `True` if the **Change Diagram Item Template** option shall be available for the node in the **Other Actions** menu in the Alfabet Diagram Designer.

4) In the toolbar, click the **Save** button to save the node definition.
5) Once all nodes have been defined, you can optionally click the custom diagram definition and in the attribute window and define the order that the nodes shall be displayed in the explorer in Alfabet Expand. For the **Nodes Sequence** attribute, click the **Browse** button. In the editor, click the **Up/Down** arrows to order the nodes in the **Toolbox Items** pane and click **OK** to save the sequence.
6) In the toolbar, click the **Save** button to save the custom diagram definition.

Creating Node Groups for the Custom Diagram

A node group represents the object classes that are semantically nested in the object class defined for the node. A node group must be specified if a semantic relationship between the node and its referenced objects are to be displayed in the diagram. Node groups are visualized in the diagram as nested diagram items. Nested diagram items are typical, for example, when applications are visualized in the application groups that own them or local components are visualized in the diagram items of the applications that own them. The node group is the referenced class that is nested in the node.

Node groups can be specified either via a property, reference, or an Alfabet query or native SQL query. For more information about specify the relationships between classes, see the reference manual *Alfabet Meta-Model*.

To create a node group for the custom diagram definition:

1) Expand the custom diagram definition , right-click the node and select **New Node Group**.
2) Click the node group and define the following attributes:
   - **Class Name**: Select the object class that the node group shall visualize.
   - **Caption**: Specify the caption of the node group. The caption will be displayed on the tab in the selector that opens when the **Add Subordinates for Object** option in the **Semantic Actions** menu in the Alfabet Diagram Designer is selected for a node.
   - **Node Group Type**: Select one of the following to find the objects for the node group definition:
     - `PropertyBased`: Select if the node group shall be visualized based on a property. Specify the referenced property in the **Property** attribute of the node group.

       For example, for a diagram that displays applications as node groups for application groups, the class Application would be a defined as node group for the class Application Group. The following would be defined:

- Create an Application node:
  - **Class Name**: `Application`
- Create an Application Group node group created for the Application node:
  - **Class Name**: `Application`
  - **Node Group Type**: `PropertyBased`
  - **Property**: `Application`

- `BackPropertyBased`: Select if the node group shall be visualized based on a reference. Specify the referenced property in the **Back Property** attribute of the node group. The reference property must be specified in the Node of the node that has the same class as the node group.

  For example, for a diagram that displays local components as node groups for applications, the class Local Component would be a defined as node group for the class Application. The following would be defined:

  - Create a Local Component node:
    - **Class Name**: `LocalComponent`
    - **Node Group Owner**: `Owner`
  - Create a Local Component node group created for the Application node:
    - **Class Name**: `LocalComponent`
    - **Node Group Type**: `BackPropertyBased`
    - **Back Property**: `Owner`

- `QueryBased`: Select if the reference between the node group and node shall be found via an Alfabet query. Specify the Alfabet query in the **Query as Text** attribute.
- `NativeSqlBased`: Select if the reference between the node group and node shall be found via a native SQL query. Specify the native SQL query in the **Native SQL Query** attribute.

- **Property**: If `PropertyBased` has been specified for the **Node Group Type** attribute: Specify the property of the node object class to find the objects in the node group object class.
- **Back Property**: If `BackPropertyBased` has been specified for the **Node Group Type** attribute: Specify the property of the node object class that the node group object class references. This property must be defined in the **Node Group Owner** of the node that the node group is subordinate to.
- **Information Message**: Enter the text that shall be displayed if the **Warn on Semantic Layout Changes** option is selected in the **Diagram Settings** editor in the Alfabet Diagram Designer and user then makes semantic changes in the diagram.

3) In the toolbar, click the **Save** button to save the node group definition.

Creating Connections for the Custom Diagram

A connection represents a reference between objects in a diagram (such as an information flow, business process rule, etc.). A connection must be specified for each reference that may be visualized in the custom diagram. The definition of the connection node may be either based on a semantic class (such as an `InformaionFlow`, `ValueArc`, or `DemandArch`) that reference a source and target object, or a property of type `ReferenceArray` such as `Device.Networks` or `Network.BelongsTo`. Connections representing a link object such as an information flow can be clicked and navigated (depending on the definition in the associated class setting) while connections representing simple references or reference arrays such as `Device.Networks` cannot be clicked or navigated.

This applies in particular to objects that are connected to other objects via a reference or a link object or objects that are defined through semantic groups. Please note that the inclusion of the connection in the custom diagram definition is necessary for the visualization of the connection in the diagram. The inclusion of a connection does not necessarily mean that a connection can be explicitly added to or created in the diagram.

New connections require the definition of the connection node that may be either based on a link (such as information flow, local component, or role) or a source and target relationship such as the reference Responsible Organization on the class Value Node. Connections representing a link object can be clicked and navigated (depending on the definition in the associated class setting) while connections representing simple references or reference arrays cannot be clicked or navigated.

we support only two types of connections: defined by properties of outgoing and incoming nodes, defined by properties of connection object itself.

To create a connection for the custom diagram definition:

1) Expand the custom diagram definition  , right-click the **Connections**  node and select **New Connection**.
2) In the **Select Connection from Class** editor, select the class that shall be the **From Class** of the connection and click **OK**. This class will be displayed in the **From Class** attribute.
3) In the **Select Connection to Class** editor, select the class that shall be the **To Class** of the connection and click **OK**. This class will be displayed in the **To Class** attribute.
4) Click the connection and define the following attributes:
   - **Caption**: Specify a caption of the connection. The caption will be displayed in, for example, the **Generate Network** editor available in the Alfabet Diagram Designer.
   - **Isolated**: The specification of the **Isolated** attribute will determine which attributes must be defined for the connection:
     - Select `True` if the connection represents a semantic class (such as an `InformationFlow`, `ValueArc`, or `DemandArch`) and the connection shall be established based on the **From Property** attribute which identifies the source node and the **To Property** attribute which identifies the target node and the **Link Class** attribute which references the source and target object. If the **Isolated** attribute is set to `True`, define the following:
       - **From Property**: Specify the property that represents the source node of the connection.
       - **To Property**: Specify the property that represents the target node of the connection.

- **Link Class**: Specify the semantic class (such as an `InformationFlow`, `ValueArc`, or `DemandArch`) that references the source and target object.

- Select `False` if the connection in the diagram does not represent a semantic class but rather a property of type `ReferenceArray` such as `Device.Networks` or `Network.BelongsTo`. In this case, the connection will be established based on the intersection of the **Output Property** attribute which identifies the source node and the **Input Property** which identifies the target node. If the **Isolated** attribute is set to `False`, define the following:

  - **Output Property**: Specify the property that identifies the source node of the connection. Specify the property of the source node that intersects with the property identified in the **Input Property** attribute.

  - **Input Property**: Specify the property of the target node that intersects with the property identified in the **Output Property** attribute.

- **Diagram Item Template**: Specify a standard or custom diagram item template to visualize the connection in the diagram.

- **Item Operations**: Select `True` for each operation that shall be allowed for the connection in the context of the Alfabet Diagram Designer. The following operations can be specified:

  - **Confirm Deletion**: The deletion of connections must be confirmed by clicking an **OK** button in a message dialog.

  - **Delete**: The connection can be deleted from the Alfabet database.

  - **Edit**: The connections can be edited.

  - **Move**: The connections can be moved from a parent object to another parent object.

  - **Navigate**: The user can navigate to the object profile/object cockpit of the connection.

  - **Resize**: The connection can be resized.

- **Allow Self Connection**: Select `True` if a connection can have the same source and target object. Select `False` if the source and target object must be different for the connection.

- **Available for Generate Net**: Select `True` if the connection shall be available in the **Include Connection Types to Build Network** field in the **Generate Network** editor available in the Alfabet Diagram Designer.

- **Enable Change Diagram Item Template**: Select `True` if the **Change Diagram Item Template** option shall be available for the connection in the **Other Actions** menu in the Alfabet Diagram Designer.

- **Implicit**: Select `True` if the connection should be displayed as the result of an aggregation. For example, if the **Implicit** attribute is set to `True` then:

  - If information flows are defined between applications and the diagram displays application groups but no applications, the information flows between applications can be displayed as information flows between the application groups that the applications are assigned to.

  - If information flows are defined between local components and the diagram displays application but no local components, the information flows between local components

can be displayed as information flows between the applications that the local components are assigned to.

- If connections are defined between applications and business processes and the diagram displays application groups but no applications, the connections between applications and business process can be displayed as connections between the application groups that the applications are assigned to and the business processes.

5) In the toolbar, click the **Save** button to save the connection definition.

6) Once all connections have been defined, click the custom diagram definition to open the attribute window and define the following:

- **Connections Sequence**: Define the order that the connections shall be displayed in the **Toolbox Items** pane in the Alfabet Diagram Designer. For the **Connections Sequence** attribute, click the **Browse** button. In the editor, click the **Up/Down** arrows to order the connections in the **Toolbox Items** pane and click **OK** to save the sequence.
- **Create Connections on Rescan**: Select `True` if the connections between nodes in the diagram shall be added to the diagram when the diagram is reloaded in the browser.

7) In the toolbar, click the **Save** button to save the custom diagram definition.

Creating a Connected Diagram Definition for the Custom Diagram

Objects displayed in custom diagrams may provide linkage to other diagrams. Only one diagram may be linked per diagram object and only diagram types that are permissible for the selected node may be specified. If an object in a diagram has been configured to be linked to another diagram, the user can click the dark blue **Navigate** icon on the lower-right corner of the diagram object. The name of the target diagram and its base object will be displayed in the tooltip for the **Navigate** icon. Please note that navigation to diagrams is not supported for connections.

You can specify one or more permissible diagram connections for a custom diagram definition. A configured report must be defined to find the target diagram for the navigation. For more information about configuring reports for custom diagrams, see the section Configuring Reports for Custom Diagrams.

1) Expand the custom diagram definition , right-click the **Connected Diagrams** node and select **New Connected Diagram**.
2) In the **Diagram Definition** attribute, select the relevant custom diagram definition that shall be used for the target diagram in the navigation.
3) In the **View Link** attribute, specify the configured report that specifies the target diagram of the navigation.

Creating Toolbox Items for the Custom Diagram

A toolbox item is required for every object class that can be created, created as a copy, or added to the custom diagram. If a connection shall be created via a linked class, you must also create a toolbox item for the classes specified in the **From Class**, **To Class**, and **Link Class** attributes of the connection.

To create a toolbox item for the custom diagram definition:

1) Expand the custom diagram definition , right-click the **Toolbox Items** node and select **New Toolbox Item**.
2) In the **Select Class** editor, select the class that shall be created for or added to the diagram. This class will be displayed in the **Class Name** attribute.
3) Click the toolbox item and in the attribute window and define the following attributes:
   - **Name**: Define a technical name for the toolbox item.
   - **Caption**: Specify a caption of the toolbox item. The caption will be displayed in, for example, the **Generate Network** editor.
   - **Operation**: Specify the operation that may be executed via the toolbox item:
     - `Add`: Select if an object of the relevant object class may be added to the diagram. If `Add` has been specified for the **Operation** attribute, define the following as needed:
       - **Object Selector**: Specify the custom selector that allows users to select the object to add to the diagram. If the **Object Selector** attribute is defined, the **Selected Class** attribute should be empty. If a custom selector is not specified, the selector specification in the **Selector Definition** attribute of the relevant class setting associated with the user profile that the user is logged in with will be used. The custom selectors will replace the standard selector except when a hard-coded selector is required. For more information about configuring a class setting, see the section Configuring a Custom Selector for Search Functionalities.
       - **Multi-Select**: Select `True` if multiple objects may be selected in the object selector and added simultaneously to the diagram via the object selector. Select `False` if only a single object may be selected in the object selector and added to the diagram via the object selector.
     - `Create`: Select if an object of the relevant object class may be created in the context of the diagram. If `Create` or `CreateAsCopy` has been specified for the **Operation** attribute, define the following as needed:
       - **Edit After Create**: Select `True` if the object that has been created in the context of the diagram may be edited in the context of the diagram after it has been created. Select `False` if the object that has been created in the context of the diagram may not be edited after it has been created.
     - `CreateAsCopy`: Select if an object of the relevant object class may be created as a copy of an existing object in the context of the diagram.
   - **Diagram Item Template**: Select the standard or custom diagram item template that shall be displayed in the toolbox pane.

- **Icon**: Specify the icon that shall override the icon defined for the diagram item template selected in the **Diagram Item Template** attribute. Please note the following:
  - The definition of the **Icon** attribute for the toolbox item has precedence over the **Icon** attribute defined in the relevant class settings as specified via the **Selected Class** attribute for the toolbox item.
  - The **Icon** attribute defined in the relevant class settings has precedence over the **Icon** attribute defined for the diagram item template specified in the **Diagram Item Template** attribute of the toolbox item.
- **Hint**: Specify a tooltip to display when the user points to the icon of the diagram item template.
- **Expand Derivatives**: Select `True` if toolbox items should be displayed in the **Toolbox Items** pane in the Alfabet Diagram Designer for all custom diagram item templates that are based on the diagram item template selected in the **Diagram Item Template** attribute. Please note that this may lead to duplicated items being displayed in the **Toolbox Items** pane. Select `False` to display only the diagram item template explicitly selected in the **Diagram Item Template** attribute. In this case, duplicated toolbox items will not be displayed.
- **Selected Class**: Specify the object class that the user shall select on object from when adding the toolbox item to the diagram. The object selector that opens for the selected class will be based on the specification of the **Selector Definition** attribute of the respective class setting. Please note that you can define an explicit selector by means of the **Object Selector** attribute of a toolbox item. In this case, the **Selected Class** attribute should be empty. For more information, see the section Creating Toolbox Items for the Custom Diagram.

4) In the toolbar, click the **Save** button to save the toolbox item definition.

5) Once all toolbox items have been defined, click the custom diagram definition and in the attribute window and define the order that the toolbox items shall be displayed in the **Toolbox Items** pane in the Alfabet Diagram Designer. For the **Toolbox Items Sequence** attribute, click the **Browse** button. In the editor, click the **Up/Down** arrows to order the toolbox items in the **Toolbox Items** pane and click **OK** to save the sequence.

6) In the toolbar, click the **Save** button to save the custom diagram definition.

Adding Shapes to the Custom Diagram

In addition to the diagram item templates that allow object classes to be added to the **Toolbox Items** pane in the Alfabet Diagram Designer, you can specify diagram item templates that allow shapes, lines, and images to be added as graphic elements to the diagram. The shapes that may be added to the diagram definition are predefined by Software AG.

You can also specify diagram item templates as custom shapes to add to the diagram. Such complex shapes are typically used to define the background of a diagram. Please note that for background shapes that should be scaled based on the sizing of the custom item, the value `Scalable` should be selected for the **Layout Type** attribute of the diagram item template.

To create a button for the custom diagram definition:

1) Expand the custom diagram definition , right-click the **Shapes** node and select **New Shape**.
2) In the editor that opens, select a standard shape or configured diagram item template (lsited under the **Custom Shape** section) to add to the diagram. The shape will be added below the **Buttons** node.
3) In the toolbar, click the **Save** button to save the shape definition.
4) Once all nodes have been defined, click the custom diagram definition and in the attribute window and define the order that the shapes shall be displayed in the bottom section of the **Toolbox Items** pane in the Alfabet Diagram Designer. For the **Shape Sequence** attribute, click the **Browse** button. In the editor, click the **Up/Down** arrows to order the shapes in the bottom section of the **Toolbox Items** pane and click **OK** to save the sequence.
5) In the toolbar, click the **Save** button to save the custom diagram definition.

Defining Rules to Automatically Add Objects to New Diagrams

By default, a new diagram based on a custom diagram definition will be empty and must be defined from scratch by the user opening the diagram in the Alfabet Diagram Designer. Optionally, rules can be added to the custom diagram definition that automatically add default objects found by the rule to a diagram on creation of the diagram.

For diagrams created via a diagram list report, the default objects will be added to the diagram on creation of the diagram via the list and will be available when the user accesses the diagram via the navigate button. For diagrams created via a diagram view report that has been added directly to an object profile or object cockpit, the objects will be added the first time that the diagram is opened in the Alfabet Diagram Designer.

Default objects can only be added automatically to diagrams when the diagram is first created. Once a diagram has been created, all updates to the number and kind of default objects in the Alfabet database must be added by a user designing the diagram in the Alfabet Diagram Designer. A menu option **Add Default Objects** has been added to the **Semantic Actions** button to update the diagram with default objects. The existing design will be maintained when the default objects are added. Default objects already added to the diagram will not be added again and will remain in the position and design already defined for them in the diagram.

The following is required to add rules for the automatic assignment of objects to diagrams to the custom diagram definition:

- Defining a Category for the Rules in the XML Object UseCaseCategories
- Defining the Query for the Rule in a Configured Report
- Adding the Rule to the Custom Diagram Definition

Defining a Category for the Rules in the XML Object UseCaseCategories

Reports can only be used for the definition of rules for custom diagram definitions if they are assigned to a category related with the functionality. Category names are assigned to functionalities in the XML object ***UseCaseCategories***. After having assigned a name for the category in the XML object ***UseCaseCategories***, the category must then be assigned to the configured report via the attribute **Category** of the configured report.

To set the category name in the XML object ***UseCaseCategories***:

1) In the **Presentation** tab of Alfabet Expand, expand the explorer node **XML Objects**.
2) Right-click on the XML object ***UseCaseCategories*** in the explorer and select **Edit XML** from the context menu. The XML object opens in the middle pane.
3) Add the following code as child XML element to the XML root element `UseCaseCategories`:

```
<UseCaseInfo UseCase="Diagrams">
<ScopeInfo Scope="Report" Categories="CommaSeparatedListOfCategories" />
</UseCaseInfo>
```

4) Substitute *CommaSeparatedListOfCategories* with a category name. If you enter more than one name comma separated, all names will be valid as category name for the functionality.
5) In the toolbar, click the **Save**  button.

Defining the Query for the Rule in a Configured Report

The rule that finds the default objects to be automatically added to the diagram references a configured report. The following configuration is required for the configured report:

For general information about configured reports, see Configuring Reports. For general information about defining queries for Alfabet configurations, see Defining Queries.

- The **Type** attribute of the configured report must be `Query` or `NativeSQL`.
- The `Category` attribute of the configured report must be set to one of the categories defined for the use case `Diagram` in the XML object ***UseCaseCategories***.
- The rule reads the information about which objects are found via the query. For Alfabet queries, these are the objects defined as `FIND` class. For native SQL queries, the first argument in the `SELECT` statement must return the `REFSTR` of the objects to be added to the diagram. All other data returned via the `SELECT` statement of native SQL queries or the **Show Properties** of Alfabet Queries will be ignored except for the special use case of hierarchically structured objects described below.
- The Alfabet query language parameter `BASE` can be used in the queries to refer to the object the diagram is created for.

For example, the following Alfabet query will add all application groups to the diagram to which the application the diagram is created for is assigned:

```
ALFABET_QUERY_500
FIND ApplicationGroup
```

```
WHERE ApplicationGroup.Applications CONTAINSOR:BASE
```

- If objects should be added in a hierarchical structure, which means a parent object containing a group of subordinate objects, the query must return a grouped data set based on a `GroupBy_Ex` instruction. The structure can have multiple levels.

  For example, the following native SQL query will add for a diagram defined for business data all relevant applications and will also add the local components assigned to the applications as object group subordinate to the applications:

  ```
  SELECT app.REFSTR, app.REFSTR As 'app.REFSTR', lc.REFSTR As
  'lc.REFSTR'

  FROM APPLICATION app, LOCALCOMPONENT lc, BusinessDataUsage
  bdu

  WHERE lc.OWNER = app.REFSTR

  AND bdu.OBJECT = app.REFSTR

  AND bdu.DATA = @BASE

  /* Alfabet Instructions */

  GroupBy_Ex("gr.REFSTR","sub.REFSTR","gr",0);
  ```

- The configured report must have the **State** set to `Active` to be executed for new diagrams.

Adding the Rule to the Custom Diagram Definition

The following configurations are required in an existing custom diagram definition to add a rule for automatic placement of default objects on creation of the diagram. Multiple rules can be defined for a custom diagram definition to automatically add default objects found by multiple queries.

1) Expand the custom diagram definition  , right-click the **Default Objects Queries**  node and select **New Default Objects Query**. The new default objects query will be added below the **Default Objects Query** node.
2) Click the new defaults objects query in the explorer to open the attribute window.
3) In the **Report** attribute, select the configured report providing the query.
4) Make sure that for each object found by the default object query a node is defined in the custom diagram definition. The attribute settings of the node must match the following rules:
   - For nodes that are added via a non-grouped dataset or on the first level of the hierarchy in a grouped dataset, the **Node Group Item** only attribute must be set to `False`.
   - For nodes that are added on a subordinate level of a grouped dataset, the **Node Group Item Only** attribute can be set to `True`. If it is set to `True`, the **Node Group Owner** attribute must be set to the object class property defining the relation to the parent object class.
   - For nodes that are added on a subordinate level of a grouped dataset, a node group must be defined subordinate to the parent object class node.
5) In the toolbar, click the **Save**  button to save the custom diagram definition.

Configuring Reports for Custom Diagrams

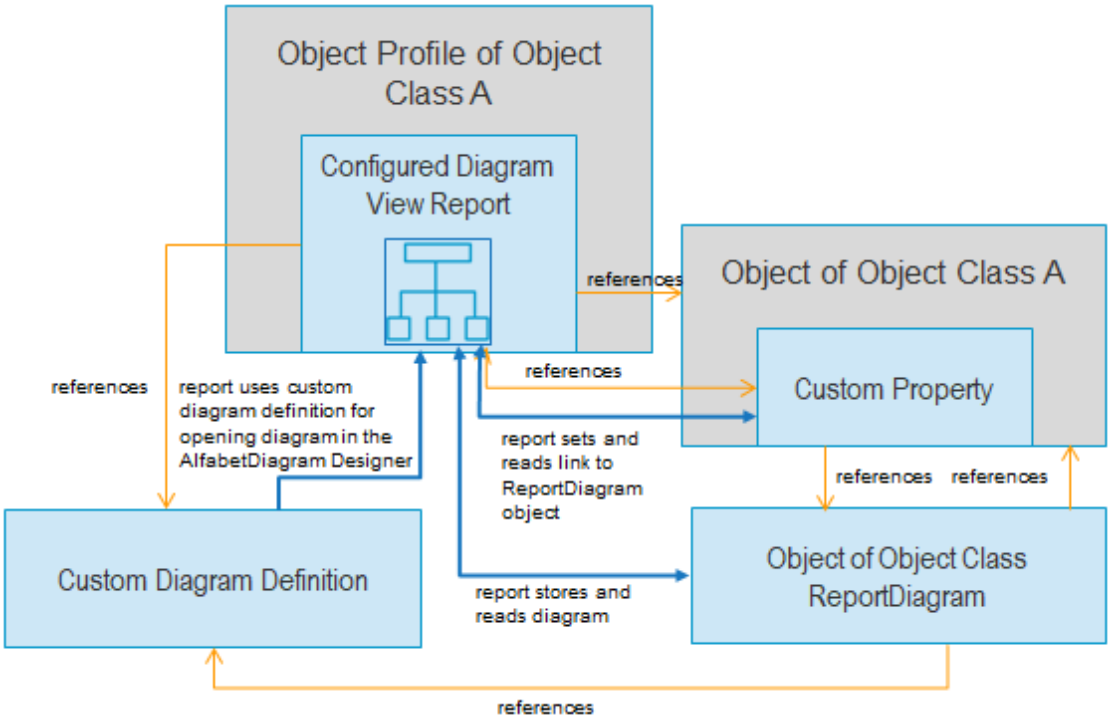
A configured report must be configured to handle the diagram functionalities for the custom diagram definition. A configured report must be created that displays the diagram to the user and provides the button for opening the Alfabet Diagram Designer and editing the diagram. The report must be of the type `Custom` and based on the template `DiagramViewReport`. Upon creation of the configured report view, standard filters and buttons for diagrams will be automatically added to the report. The filters must then be adapted to the requirements of the custom diagram definition. The custom diagram definition that the diagram shall be based on must be selected in the report assistant.

The protected enumeration `CustomDiagramViewType` is available for the definition of diagram views displayed in the context of custom diagrams. The enumeration items defined for the `CustomDiagramViewType` enumeration can be selected in the **Type** field in the **Diagram View** editor. The query specified for the `DiagramView` filter field for the `DiagramViewReport` report must refer to the relevant standard or custom diagram view type. The diagram views based on the standard or custom diagram view type can selected in configured reports based on the `DiagramViewReport` report template. For more information about configuring protected enumerations, see the section *Overview of Protected Enumerations* in the reference manual *Configuring Alfabet with Alfabet Expand - Appendix*. For more information about configuring diagram views, see the section *Configuring Diagram Views for Diagrams* in the reference manual *Configuring Evaluation and Reference Data in Alfabet*.

There are two different configuration options that allow users to create diagrams in the Alfabet user interface. You can either define the configured report so that users can create the diagram as the main standard diagram for the object or so that users can create multiple diagrams for the object:

- **The user can create the diagram as the main standard diagram for the object.** The diagram is available in a configured diagram view report added to the object profile or object cockpit of the object class. The configured diagram view report is designed to show and provide editing for the standard diagram only.

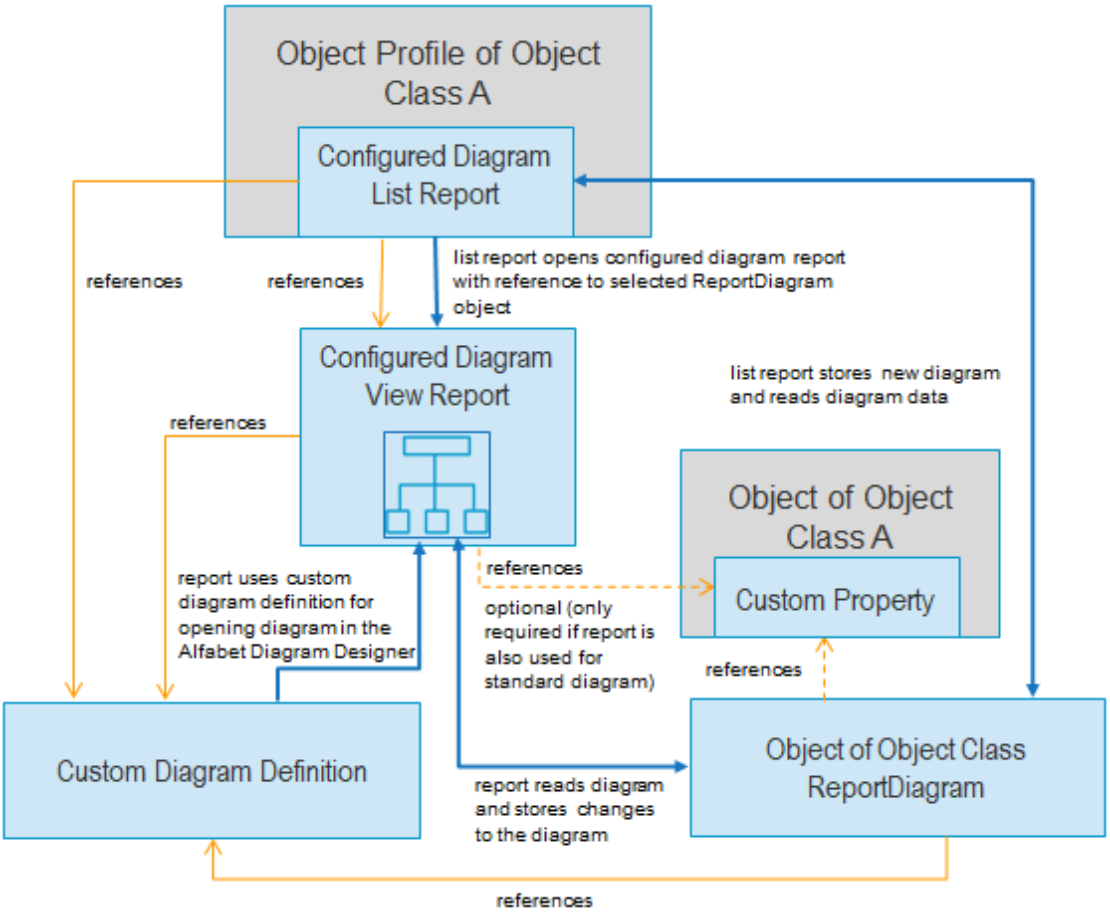
A custom property of the type `Reference` referencing the object class `ReportDiagram` must be defined for the object class. When a user opens the configured diagram view report for an object and creates a diagram, the configured diagram view report will set a reference to the defined `ReportDiagram` object in the custom property. The next time any user opens the configured diagram view report for the object, the configured diagram view report will open the diagram referenced in the custom property.



The following configuration steps are required:

- Creating a Custom Diagram Definition
- Creating a Custom Property with a Reference to the Standard Diagram
- Creating a Configured Diagram View Report
- Adding the configured diagram view report to the object profile or object cockpit of the object class as described in the chapter Configuring Object Views.

- **The user can create multiple diagrams for the object.** The diagrams are then available via a configured diagram list report listing all diagrams in a table. The user can create diagrams via the **New** button in the toolbar of the configured report. The user selects the custom diagram definition he/she want to use for the new diagram in the editor for creating the new diagram. The new diagram is added to the table. The user can open and edit the diagram by double-clicking the diagram in the table. The diagram opens in a configured diagram view report that is defined to handle diagrams based on the custom diagram definition the selected diagram is based on. The configured diagram view report is designed to display and provide editing for any diagram based on the selected custom diagram definition.



The following configuration steps are required:

- Creating a Custom Diagram Definition
- Creating a Configured Diagram View Report
- Creating a Configured Report Listing All Available Diagrams for an Object
- Adding the configured diagram list report to the object profile or object cockpit of the object class as described in the chapter Configuring Object Views.

  This step is optional. The configured list report can also be used to create a diagram independent of a base object. The report should then be made available independent of an object view or object cockpit (for example, in the **Configured Reports** functionality).

The reports may be assigned to an object profile or object cockpit so that users can access the diagram view report and design and view the custom diagram. The reports will also be available via the **Configured Reports** functionality. For more information, see the section Integration of Configured Reports in the Alfabet Interface.

The following information is available:

- Creating a Custom Property with a Reference to the Standard Diagram
- Creating a Configured Diagram View Report

- Creating Custom Diagram Views for a Custom Diagram View Report

- Creating a Configured Report Listing All Available Diagrams for an Object

Creating a Custom Property with a Reference to the Standard Diagram

The object class for which the diagram shall be created must be configured to link to the report diagram object that represents the standard diagram based on a custom diagram definition.

To define the custom object class property:

1) Go to the **Meta-Model** tab and expand the **Classes** node.

2) Right-click the relevant object class  and select **Add New Property**. The **Create New Property** editor opens. Define the following fields:

   - **Property Name**: Enter a unique name for the custom object class property. This value is displayed in the solution interface if the **Caption** attribute is not defined.

   - **Tech Name**: Enter a unique technical name for the custom object class property that will be used in the Alfabet database table. Click **OK** to save the definition.

     Please note that the `Tech Name` is the name of the column that will be created in the database table of the object class for storing values for the custom property. The following rules apply:

     - The technical name may not begin with an empty space nor include special characters. For a list of the special characters that are not allowed, see the section Defining Attributes for Configuration Objects in the chapter Getting Started with Alfabet Expand.

     - The technical name should only contain standard `ASCII` characters.

     - The technical name should consist of upper-case letters only.

     - The maximum length of a technical name may not exceed 30 characters.

     - The technical name may not coincide with any of the reserved key words of the relational database management system.

     A validation mechanism checks for correct syntax when defining a technical name.

3) In the attribute window, define the following attributes:

   - **Property Type**: Select `Reference`.

   - **Comments**: Provide information relevant to solution designers regarding the maintenance of the custom object class property.

   - **Type Info**: Click the **Browse**  button on the right of the field to open the object class selector. Set the checkbox **Semantic Classes** and select the class `ReportDiagram` from the drop-down list. Click **OK**.

4) In the toolbar, click the **Save**  button to save the new custom object class property.

Creating a Configured Diagram View Report

The configured diagram view report displays the diagram and provides the button for opening the Alfabet Diagram Designer and editing the diagram.

You must create at least one configured diagram view report for each custom diagram definition.

A configured diagram view report can be used for the definition of a standard diagram as well as diagrams available via a configured diagram list report. The configured diagram view report will only store the diagram as the standard diagram of an object class if the custom object class property is selected in the report assistant.

To create a configured diagram view report:

1) Go to the **Reports** tab, right-click the **Reports** folder or a sub-folder thereof and select **Create New Report**. You will see the new configured report listed below the selected folder.

As an alternative to defining all attributes for a new configured report, you can copy and paste an existing configured report and make modifications, as needed. To do so, right-click the existing configured report that you want to copy and select **Copy**. Right-click the new configured report and select **Paste**. Modify the necessary attributes described below.

2) In the attribute window, define the following attributes for the configured report.

- **Type**: Select `Custom`.
- **Name**: Optionally, change the technical name of the configured report. The technical name of the configured report must be unique.

The technical name is used for identification of the configured report in the context of technical processes such as merging the report configuration with a report configuration saved as an XML file. Therefore, the following is required when defining the name of a configured report:

- The name must be unique. The name must be unique regardless of the report folder it is structured in.
- The name may not be changed once a configured report has been created.
- A validation mechanism checks for correct syntax when defining a technical name. Please note that names may not begin with an empty space nor include special characters. For a list of the special characters that are not allowed, see the section Defining Attributes for Configuration Objects in the chapter Getting Started with Alfabet Expand.
- If the technical name of the configured report is changed, the name will be correctly updated in other configuration objects referencing the changed report during design time.

Please note that the name of a changed configuration object will not be updated in guide pages or guide views. If you plan to change the name of a configuration object, the reference in the navigation page should be changed prior to changing the configuration object name. You can use the **Show Usage** functionality in the context menu of the configured report to evaluate whether the configured report has been added to a guide view or guide page.

- **Caption**: Enter a caption for the configured report that is displayed on the Alfabet user interfaced for the configured report. The caption of the configured report may exceed the conventional 64 character limit.
- **Description**: Provide a short information about the configured report that is useful to Alfabet users. This comment will be displayed in the object profile under the page view caption as a short description.
- **Technical Comment**: Provide information that is useful for solution designers working with Alfabet Expand in order to better understand the configured report from a technical perspective. The **Technical Comment** will not be displayed in the user interface.
- **Template**: Select `DiagramViewReport`.
- **Apply to Class**: Leave this attribute empty. Diagram view report must be assigned to an object class via the attribute **Base Class** in the **Report Assistant** and not via the **Apply to Class** attribute. If you define htis attribute, navigation For example, via the AlfaBot will not work correctly.
- **Help Index**: Specify the location of the external Help file using the following syntax:(For example:). The external help file will be displayed when the user clicks the context-sensitive Help link in the standardHelp menu.

  Server variables can be used in the Help links. Server variables allow you to define all or part of the URL definition in the server alias configuration of the Alfabet Server instead of directly defining it in the configuration in Alfabet Expand. Use of server variables is useful, for example, in order to change a Web server name defined in multiple URL definitions in Alfabet Expand. Instead of changing all URL definitions, only the variable value in the server alias configuration must be updated. The use of server variables is described in the section Using Server Variables in Web Link and Database Server-Related Specifications in the chapter Configuring Reports.

- **Execute on Enter**: Set to `True` to execute the configured report with empty filter settings when the user opens the configured report in the Alfabet interface. Set to `False` to open the configured report without execution of the Alfabet query with empty filter settings. By default, this attribute is set to `True`. It should only be set to `False` if the configured report would result in an exceedingly big dataset when executed with empty filter settings.

  When you set the **Execute on Enter** attribute to `False`, you must make sure that the **Submit** button is available in the custom report view of the configured report. If the **Submit** button is deleted from the custom report view, the configured report cannot be displayed. The setting and execution of the **Execute on Enter** attribute is independent of the definition of filters for a configured report. A configured report without filters must nevertheless have a **Submit** button when the **Execute on Enter** attribute is set to `False`.

- **Selector Behavior**: This attribute must be set to `NotVisible`. The attribute is set to `Visible` per default and cannot be edited directly in the attribute window. Right-click the configured report and select **Set Report Selector Behavior to 'Not Visible'** from the context menu.

  If the attribute is set to `NotVisible`, the configured report will be excluded from the selector for adding configured reports to the **Configured Reports** functionality. The diagram view report is exclusively for use in object cockpits/object profiles and in configured diagram list reports and should not be accessible anywhere else.

Please note however that this setting does not exclude the configured report from any standard views or customer configured views and selectors but excludes it only from the standard selector for configured reports implemented in Alfabet.

- **Can Create Express View**: Select `True` if an express view may be created for the report. Select `False` if an express view may not be created for the report. Please note that for reports that have a custom report view, the setting must be consistent with the setting of the attribute **Can Create Express View** of the custom report view.

An express view is a link to a specific Alfabet view displaying data that allows individuals inside or outside of the user community to view information in Alfabet. When the express view is created, an email notification is automatically mailed to a specified recipient. The recipient receives a URL that allows him/her to access the current page view in Alfabet. For more information, see the section *Sending and Receiving Express Views* in the reference manual *Getting Started with Alfabet*.

3) In the explorer, right-click the configured report and select **Create Configured Report View**. The view editor opens. In the explorer, the custom report view is displayed as a subordinate object of the configured report. The attributes for the custom report view are displayed in the attribute window. You can optionally edit the following attributes:

- **Name**: Optionally you can change the name for the custom report view. The **Name** must be unique for custom report views.
- **Can Create Bookmark**: Select `True` if a bookmark may be created for the configured report. Select `False` if a bookmark may not be created for the configured report.
- **Can Create Express View**: Select `True` if an express view may be created for the configured report. Select `False` if an express view may not be created for the configured report. Please note that the setting must be consistent with the setting of the attribute **Can Create Express View** of the configured report.
- **Custom Context-Sensitive Help URL**: Enter the URL or server variable that targets the custom context-sensitive help.
- **Standard Context-Sensitive Help Index**: This field will be empty for a configured report.

The custom report view initiates the **Report Assistant**. A custom report view should never be deleted from the configured report after the **Report Assistant** has been used to configure the configured report. When you delete the custom report view of an existing template-based configured report and create a new custom report view, the **Report Assistant** will be reset to the example specified per default and your configuration will be lost.

4) In the view editor, the filter panel shows all filter fields and buttons that are available in the standard page view to display diagrams. You can alter the filter fields of the diagram as follows:

- You can remove any of the filter fields.
- Per default, the `Status` (Object State) filter field limits the applications displayed in the diagram according to the **Object State** attribute. If objects of another object class shall be filtered according to object state values, change the **Parameter** attribute of the `Status` filter to the name of the object class for which the object state shall be filtered in the diagram.
- `LinkProperty` (**Connection Attributes**) filter field: This filter field is a multi-select combobox that allows object class properties of the connection object class and its referenced

object classes to be selected for display in the decoration boxes of the connections in the custom diagram. The content of the filter field depends on the settings in the XML object ***DiagramInformationflowDef***. For more information, see Configuring the Visualization of Connection Items and Subordinate Object in Diagrams.

- The protected enumeration `CustomDiagramViewType` is available for the definition of diagram views displayed in the context of custom diagrams. The enumeration items defined for the `CustomDiagramViewType` enumeration can be selected in the **Type** field in the **Diagram View** editor. The query specified for the `DiagramView` filter field for the `DiagramViewReport` report must refer to the relevant standard or custom diagram view type. The diagram views based on the standard or custom diagram view type can selected in configured reports based on the `DiagramViewReport` report template.

To display the relevant custom diagram views specified for the custom diagram definition in the drop-down list of the `DiagramView` filter field, change the query defined for the filter field in the **Range as Alfabet Query** attribute of the filter field. The `WHERE` condition of the query must be changed to return the diagram views specified with the standard or custom diagram view type:

```
WHERE
    (AND
        Type = 'StandardOrCustomDiagramViewType'
        (OR
            UserProfiles IS NULL
            UserProfiles CONTAINSOR:CURRENT_PROFILE
        )
    )
```

For more information about configuring protected enumerations, see the section *Overview of Protected Enumerations* in the reference manual *Configuring Alfabet with Alfabet Expand - Appendix*. For more information about configuring diagram views, see the section *Configuring Diagram Views for Diagrams* in the reference manual *Configuring Evaluation and Reference Data in Alfabet*.

- You can change the **Caption** and **Hint** attributes of all filter fields as needed.

5) In the explorer, right-click the configured report and select **Start Alfabet Report Assistant**. The **Report Assistant** opens.

6) Specify the following attributes in the **Report Assistant**:

- **Diagram Def**: Select the custom diagram definition that the diagram shall be based on.
- **Base Class**: Select the object class that the diagram shall be created for.
- **Base Property**: This attribute is only required if the configured diagram view report is intended to be used as to create standard diagram of that diagram template for the objects belonging to the base class. Select the custom object class property that you created for the object class defined in the **Base Class** attribute to store the link to the report diagram object created as standard diagram.

7) Click **OK** to save the configuration.

8) In the toolbar, click the **Save** button to save your changes.

9) In the explorer, right-click the configured report and select **Review Report**. The configured report opens in a web browser. If the results are not as expected, you can edit the configured report until the output of the configured report is adequate.

10) Right-click the configured report and select **Set Report State to 'Active'** from the drop-down menu.

Creating Custom Diagram Views for a Custom Diagram View Report

A diagram view is a configuration that is associated with a diagram. It allows users to superimpose qualitative information - such as aggregated indicators or attribute values - associated with these architectural elements. For standard as well as custom diagrams, diagram views can be defined in the *Configuring Diagram Views for Diagrams* functionality on the Alfabet user interface.

For custom diagrams, additional diagram views can be configured as a functionality of the configured diagram view report used for opening the diagram. These report specific diagram views combine the functionalities available for standard diagram views with report specific functionality. The following functionality can be added to a custom diagram via a diagram view defined in the configured diagram view report used to open the diagram:

- Additional filters can be added to the configured diagram view report to filter the content of the diagram. For example, for a diagram displaying applications, display might be limited to applications with a start date after a defined value or for applications that have local components assigned. Objects not matching the filter specification are either displayed in pale grey or completely removed from the dataset.
- The diagram view items used in the diagram to display objects can be exchanged with diagram view items providing additional information for all or a subset of objects displayed in the diagram.
- Icons can be displayed in the diagram view items via the definition of indicator rules. Icons defined via indicator rules are displayed within the diagram view items following the rules that are implemented for all types of configured reports.

To define a diagram view for an existing custom diagram view report:

1) If you would like to use custom diagram items showing addition information specified via a query within the diagram view, define custom diagram item templates that contain rectangles with the Content Type attribute set to `QueryValue`. For information about defining custom diagram view item templates, see Configuring Custom Diagram Item Templates.

2) In the explorer, right-click the configured report and select **Set Report State to 'Plan'**.

3) To add filter fields to the configured diagram view, expand the node of the configured report in the explorer and double-click the child node. The configured report view opens in the middle pane. Add filter fields to the view according to requirements. Please note that **Edit** and **Edit Search** filter fields are not supported. For information about the definition of filter fields, see Defining Filters for Configured Reports and Selectors.

4) In the explorer, right-click the configured report and select **Start Alfabet Report Assistant**. The **Report Assistant** opens.

5) Right-click the root node of the explorer in the **Report Assistant** and select **Add New Diagram View**.

6) Expand the new diagram view node in the explorer of the **Report Assistant**.

7) To add filters and / or display custom diagram view items with rectangles with a content type `QueryValue`, define a query for each object class that you would like to filter or display with additional information. To add a query, right-click the **Queries** node and select **Add New Query**. Set the following attributes of the new query:

   - **Name**: Define a name that is displayed in the explorer to identify the query.
   - **Alfabet Query / Native SQL / Query as Text**: Define an Alfabet Query or native SQL query returning the following information:
     - The row reference class must be the object class displayed in the diagram that shall be filtered or for that additional information shall be provided. The row reference class is by default the `FIND` class of an Alfabet query or for native SQL queries the object class for that the `REFSTR` is returned in the first argument of the `SELECT` statement. The row reference can be changed via a `SetRowReference` instruction.
     - Make sure that the query returns all relevant objects of the row reference object class that may be displayed in the diagram.
     - For each filter that should be applied to the object class a column must be added that returns the value that shall be compared with the value returned in the current filter settings. The filter definition will refer to the column name. If you would like a filter to be applied to multiple object classes, you must add a column with an identical name returning the same value type to each of the queries.
     - For each rectangle of the type `QueryValue` in the custom diagram view item template that shall be used to display the objects in the diagram a column must be added that returns the value that shall be displayed for the object. The column name must be identical to the name of the rectangle in the diagram view item template.

8) For each object class that shall be displayed with another than the diagram specific diagram view item, a custom diagram view item definition must be added to the diagram view. To add a custom diagram view item definition, right-click the **Custom Diagram View Items** node and select **Add New Diagram View Item**. Set the following attributes of the new diagram view item:

   - **Name**: Define a unique name for the diagram view item.
   - **Class Name**: Define the object class name or object class stereotype that the diagram view item shall be displayed for.
   - **Diagram Item Template**: Define the diagram view item template that the diagram view item is based on.

9) To add filters to the custom diagram view, define a filter rule for each filter added to your filter panel. For each object in the diagram, the value to be filtered is read from the query for the corresponding object class defined as sub-node of the **Queries** node. The value returned by the query is compared to the value in the filter field using an operator. If the value returned by the query and the filter settings do not match for an object, the object is hidden. A query rule defines the filter field and query data as well as the operator for the filtering.

   To add a filter rule, right-click the **Diagram Filters** node and select **Add New Filter Rule**. Set the following attributes of the new filter rule:

   - **Name**: Define a unique name that will be used for the rule in the explorer of the **Report Assistant**.

- **Class Name**: Select the object class or object class stereotype for the object that shall be filtered. The data to be compared with the current value of the filter field will be read from the query defined for the object class as sub-node of the **Queries** node.
- **View Control**: Select the filter field the rule should apply to.
- **Comparison Operator**: Select the operator to be used to compare the current filter field value with the value returned in the dataset column defined in the **Data Set Column** attribute.
- **Data Set Column**: Enter the name of the dataset column in the query defined for the object class within the **Queries** node that returns the value to be compared with the filter field using the operator.

10) Indicator rules can be defined for the custom diagram view. The definition of indicator rules is identical to the definition of indicator rules for all configured reports. Indicators will be displayed for the objects both on the diagram view items that are standard for the diagram or the diagram view items that are defined for the custom diagram view. The indicator rule determines which objects will display indicator icons independent from all other configurations in the diagram view.

    To add an indicator rule, right-click the **Indicator Rules** node and select **Add New Indicator Rule**. For information about how to define indicator rules, see Defining Indicator Rules.

Creating a Configured Report Listing All Available Diagrams for an Object

A diagram list report lists the diagrams defined for an object. The diagrams can be based on multiple custom diagram definitions. For each custom diagram definition, a configured diagram view report must first be created to open the diagram. The diagram list report specifies which custom diagram view report shall be used to open diagrams defined for each available custom diagram definition.

The `NAME` property of the object class `ReportDiagram` stores the name that is defined by the user when creating a diagram in the configured diagram list report. If a custom diagram definition is added to the configured diagram list report that is also used to create a standard diagram for the object, the standard diagram will also be added to the listed diagrams. The naming convention for the standard diagram is "<Caption of the custom diagram definition> for <object>", where the information about the object is defined by the image properties defined in the relevant class settings.

To create a diagram list report:

1) Go to the **Reports** tab, right-click the **Reports** folder or a sub-folder thereof and select **Create New Report**. You will see the new configured report listed below the selected folder.

    As an alternative to defining all attributes for a new configured report, you can copy and paste an existing configured report and make modifications, as needed. To do so, right-click the existing configured report that you want to copy and select **Copy**. Right-click the new configured report and select **Paste**. Modify the necessary attributes described below.

2) In the attribute window, define the following attributes for the configured report.
    - **Type**: Select `Custom`.
    - **Name**: Optionally, change the technical name of the configured report. The technical name of the configured report must be unique.

The technical name is used for identification of the configured report in the context of technical processes such as merging the report configuration with a report configuration saved as an XML file. Therefore, the following is required when defining the name of a configured report:

- The name must be unique. The name must be unique regardless of the report folder it is structured in.
- The name may not be changed once a configured report has been created.
- A validation mechanism checks for correct syntax when defining a technical name. Please note that names may not begin with an empty space nor include special characters. For a list of the special characters that are not allowed, see the section Defining Attributes for Configuration Objects in the chapter Getting Started with Alfabet Expand.
- If the technical name of the configured report is changed, the name will be correctly updated in other configuration objects referencing the changed report during design time.

Please note that the name of a changed configuration object will not be updated in guide pages or guide views. If you plan to change the name of a configuration object, the reference in the navigation page should be changed prior to changing the configuration object name. You can use the **Show Usage** functionality in the context menu of the configured report to evaluate whether the configured report has been added to a guide view or guide page.

- **Caption**: Enter a caption for the configured report that is displayed on the Alfabet user interface for the configured report. The caption of the configured report may exceed the conventional 64 character limit.
- **Description**: Provide a short information about the configured report that is useful to Alfabet users. This comment will be displayed in the object profile under the page view caption as short description.
- **Technical Comment**: Provide information that is useful for solution designers working with Alfabet Expand in order to better understand the configured report from a technical perspective. The **Technical Comment** will not be displayed in the user interface.
- **Template**: Select `DiagramListReport`.
- **Help Index**: Specify the location of the external Help file using the following syntax:(For example:). The external help file will be displayed when the user clicks the context-sensitive Help link in the standardHelp menu.

Server variables can be used in the Help links. Server variables allow you to define all or part of the URL definition in the server alias configuration of the Alfabet Server instead of directly defining it in the configuration in Alfabet Expand. Use of server variables is useful, for example, in order to change a Web server name defined in multiple URL definitions in Alfabet Expand. Instead of changing all URL definitions, only the variable value in the server alias configuration must be updated. The use of server variables is described in the section Using Server Variables in Web Link and Database Server-Related Specifications in the chapter Configuring Reports.

- **Execute on Enter**: Set to `True` to execute the configured report with empty filter settings when the user opens the configured report on the Alfabet interface. Set to `False` to open the

configured report without executing the Alfabet query with empty filter settings. By default, this attribute is set to `True`. It should only be set to `False` when a configured report would result in an exceedingly big dataset when executed with empty filter settings.

When you set the **Execute on Enter** attribute to `False`, you must make sure that the **Submit** button is available in the custom report view of the configured report. If the **Submit** button is deleted from the custom report view, the configured report cannot be displayed. The setting and execution of the **Execute on Enter** attribute is independent of the definition of filters for a configured report. A configured report without filters must nevertheless have a **Submit** button when the **Execute on Enter** attribute is set to `False`.

- **Selector Behavior**: The attribute can be used to exclude configured reports that are defined for special purposes from being selectable in the **Configured Reports** table. By default, the attribute is set to `Visible` and the configured report is visible in the selector for adding configured reports to the **Configured Reports** table if all other conditions for access to the configured report apply. If the attribute is set to `NotVisible`, the configured report is excluded from the selector for adding configured reports to the **Configured Reports** functionality. Please note however, that this setting does not exclude the configured report from any standard views or configured views and selectors, but exclusively from the standard selector for configured reports implemented in Alfabet. The attribute cannot be edited directly in the attribute window. To change the setting, right-click the configured report and select **Set Report Selector Behavior to 'Not Visible'**.
- **Can Create Express View**: Select `True` if an express view may be created for the report. Select `False` if an express view may not be created for the report. Please note that for reports that have a custom report view, the setting must be consistent with the setting of the attribute **Can Create Express View** of the custom report view.

An express view is a link to a specific Alfabet view displaying data that allows individuals inside or outside of the user community to view information in Alfabet. When the express view is created, an email notification is automatically mailed to a specified recipient. The recipient receives a URL that allows him/her to access the current page view in Alfabet. For more information, see the section *Sending and Receiving Express Views* in the reference manual *Getting Started with Alfabet*.

3) In the explorer, right-click the configured report and select **Create Configured Report View**. The view editor opens. In the explorer, the custom report view is displayed as a subordinate object of the configured report. The attributes for the custom report view are displayed in the attribute window. You can optionally edit the following attributes:

- **Name**: Optionally you can change the name for the custom report view. The **Name** must be unique for custom report views.
- **Can Create Bookmark**: Select `True` if a bookmark may be created for the configured report. Select `False` if a bookmark may not be created for the configured report.
- **Can Create Express View**: Select `True` if an express view may be created for the configured report. Select `False` if an express view may not be created for the configured report. Please note that the setting must be consistent with the setting of the **Can Create Express View** attribute of the configured report.

The custom report view initiates the **Report Assistant**. A custom report view shall never be deleted from the configured report after the **Report Assistant** has already been used to configure the configured report. When you delete the custom report view of an

existing template-based configured report and create a new one, the **Report Assistant** will be reset to the example specified by default and your configuration is lost.

4) In the view editor, the filter panel displays a filter field to select a custom diagram definition. The name of the filter field is `@DIAGRAMDEF`. If you do not want users to be able to filter the list according to custom diagram definitions, you can remove the filter panel.
5) In the explorer, right-click the configured report and select **Start Alfabet Report Assistant**. The **Report Assistant** opens.
6) For each custom diagram definition that users shall be able to create diagrams for, right-click the **Definitions** node and select **Add New Definition**. A new definition is added as sub-node to the **Definitions** node.
7) Set the following attributes of each added definition node:
   - **Diagram Def**: Select the custom diagram definition that the diagram shall be based on.
   - **Navigation Report**: Select the configured diagram view report that shall be used to display diagrams based on the selected custom diagram definition.
8) Right-click the **Queries** node and select **Add New Query**. A **Query** node is added as sub-node to the **Queries** node.
9) Define the tabular dataset displayed in the configured diagram list report either with a native SQL query in either of the **Native SQL** or **Query as Text** attributes or with an Alfabet query in either the **Alfabet Query** or **Query as Text** attributes.

   The **Query as Text** attribute opens a simple text editor, whereas the **Alfabet Query** attribute opens the Alfabet query builder and the **Native SQL** attribute opens a native SQL editor with a special tab for the definition of Alfabet instructions.

   The query should match the following criteria:

   - If you define an Alfabet query, the `FIND` class must be specified as `ReportDiagram`. If you define a native SQL query, the first argument of the `SELECT` statement must return the `REFSTR` of the object class `ReportDiagram`.
   - If you did not remove the filter panel, the query should contain a `WHERE` statement comparing the setting of the filter field `@DIAGRAMDEF` with the `DIAGRAMDEF` property of the object class `ReportDiagram`. Please note that the parameter definition in the Alfabet query builder results in a parameter:`DIAGRAMDEF` instead of `@DIAGRAMDEF`. This setting must then be changed manually via the **Query as Text** attribute to a parameter name starting with `@`.
   - The tabular dataset returned by the query should be limited to display diagrams for the current object only. A `WHERE` statement should be added that compares the `MASTEROBJECT` property of the object class `ReportDiagram` with the Alfabet query language parameter `@BASE`.

     For example:

```
SELECT REFSTR, DIAGRAMDEF_CAPTION AS 'Diagram Definition',
NAME As 'Diagram Name'

FROM REPORTDIAGRAM

WHERE REPORTDIAGRAM.MASTEROBJECT = @BASE

AND REPORTDIAGRAM.DIAGRAMDEF = @DIAGRAMDEF
```

10) Click **OK** to save the configuration.

11) In the toolbar, click the **Save**  button to save your changes.

12) In the explorer, right-click the configured report and select **Review Report**. The configured report opens in a web browser. If the results are not as expected, you can edit the configured report until the output of the configured report meets your expectations.

13) Right-click the configured report and select **Set Report State to 'Active'** in the drop-down menu.

Configuring the Sizes of Diagram Items in Automatically Generated Diagrams

Automatically-generated diagrams such as the *Information Flow Diagram Page View*, *Interface System Diagram Page View*, or the *Business Data Usage Diagram* typically display an **Item Size** field that allow users to select which size to use to display the diagram items (which typically represent applications) in the diagram. Because some diagrams may be highly complex and display a significant number of objects, you can improve the layout of the diagram by configuring one or more diagram sizes. For example, you can configure that the sizes small (30x13 mm), medium (40x15 mm), and large (50x20 mm). In additional, you can also specify that the icon, object name, and attribute information will not be displayed in the diagram. In this case, the user can point to the diagram item to display a tooltip with the name or click-and-hold to open the preview.

The diagram item sizes are configured in the XML element ***UserItemSizeDef*** in the XML object ***DiagramInformationFlowDef***.

```
<DiagramInformationFlowDef LinkCountDecoration = "true" >
    <InformationFlowClassDef
        ClassName = "InformationFlow"
        Properties = "ID,Name,StartDate,EndDate,ObjectState,
                      Data.Name,InterfaceSystems.Name,
                      TargetService.Operations.Name,ConnectionType.Name,
                      ConnectionMethod.Name,ConnectionFrequency.Name"
        Position = "PureCenter"
        BackColor = "White"
    />

    <UserItemSizeDef
        Name = "Small"
        Caption = "Small"
        Width = "30"
        Height = "13"
        Tiny = "true"
    />
    <UserItemSizeDef
        Name = "Medium"
        Caption = "Medium"
        Width = "40"
        Height = "15"
        Tiny = "true"
    />
    <UserItemSizeDef
        Name = "Large"
        Caption = "Large"
        Width = "50"
        Height = "20"
        Tiny = "false"
    />
</DiagramInformationFlowDef>
```

FIGURE: Configuration of XML element UserItemSizeDef

Please note that the **Item Size** field is only displayed in automatically-generated diagrams and is not relevant for diagrams that are designed in the Alfabet Diagram Designer. The size of diagram

items in diagrams is controlled either by means of the size configured for a custom diagram item template or by the design of the diagram item in the context of the Alfabet Diagram Designer.

To configure the sizes available in the **Item Size** field:

1) Go to the **Presentation** tab and expand the **XML Objects** folder.
2) Right-click the XML object ***DiagramInformationFlowDef*** and select **Edit XML**. The XML editor is displayed in the center pane. For general information about editing XML objects in Alfabet Expand, see Working with XML Objects.
3) Below the XML element ***DiagramInformationFlowDef***, create an XML element ***UserItemSizeDef*** for each option you want to define in the **Item Size** field. Configure the following XML attributes for each XML element ***UserItemSizeDef***, as needed:
   - `Name`: Define the technical name of the diagram item size. The name is not visible in the Alfabet interface.
   - `Caption`: Define a caption for the diagram item size. Captions will be visible in a drop-down field in the Alfabet interface.
   - `Width`: Enter the width of the diagram item size in mm.
   - `Height`: Enter the height of the diagram item size in mm.
   - `Tiny`: Enter "`false`" to specify that information such as name, icon, or attributes IS displayed if the diagram item size is selected. Enter "`true`" to specify that information such as name, icon, or attributes is NOT displayed if the diagram item size is selected. The user can point to the diagram item to display a tooltip with the object's name or click-and-hold to open the preview of the object.
4) In the toolbar, click the **Save**  button to save the XML definition.

Configuring the Visualization of Connection Items and Subordinate Object in Diagrams

Various aspects can be configured in terms of the default visualization of connection items in diagrams in the *Information Flow Diagram Page View*, *Business Data Usage Diagram*, *Interface System Diagram Page View*, *Standard Application Diagram Page View*, *Business Processes Diagram*, *Platform Diagrams Page View*, *Network Diagrams Page View* and the *Migration Diagram Page View* as well as in diagram view reports displaying diagrams based on a custom diagram definition. These views will typically display a filter field such as the **Information Flow Attribute**, **Migration Rule Attribute**, **Network Route Attribute,** or **Connection Attributes** filter field that allows the user to select one or more attributes to display on connection items in the diagram. In the figure below, the **Connection Type** attribute is displayed on the information flows in an application diagram.

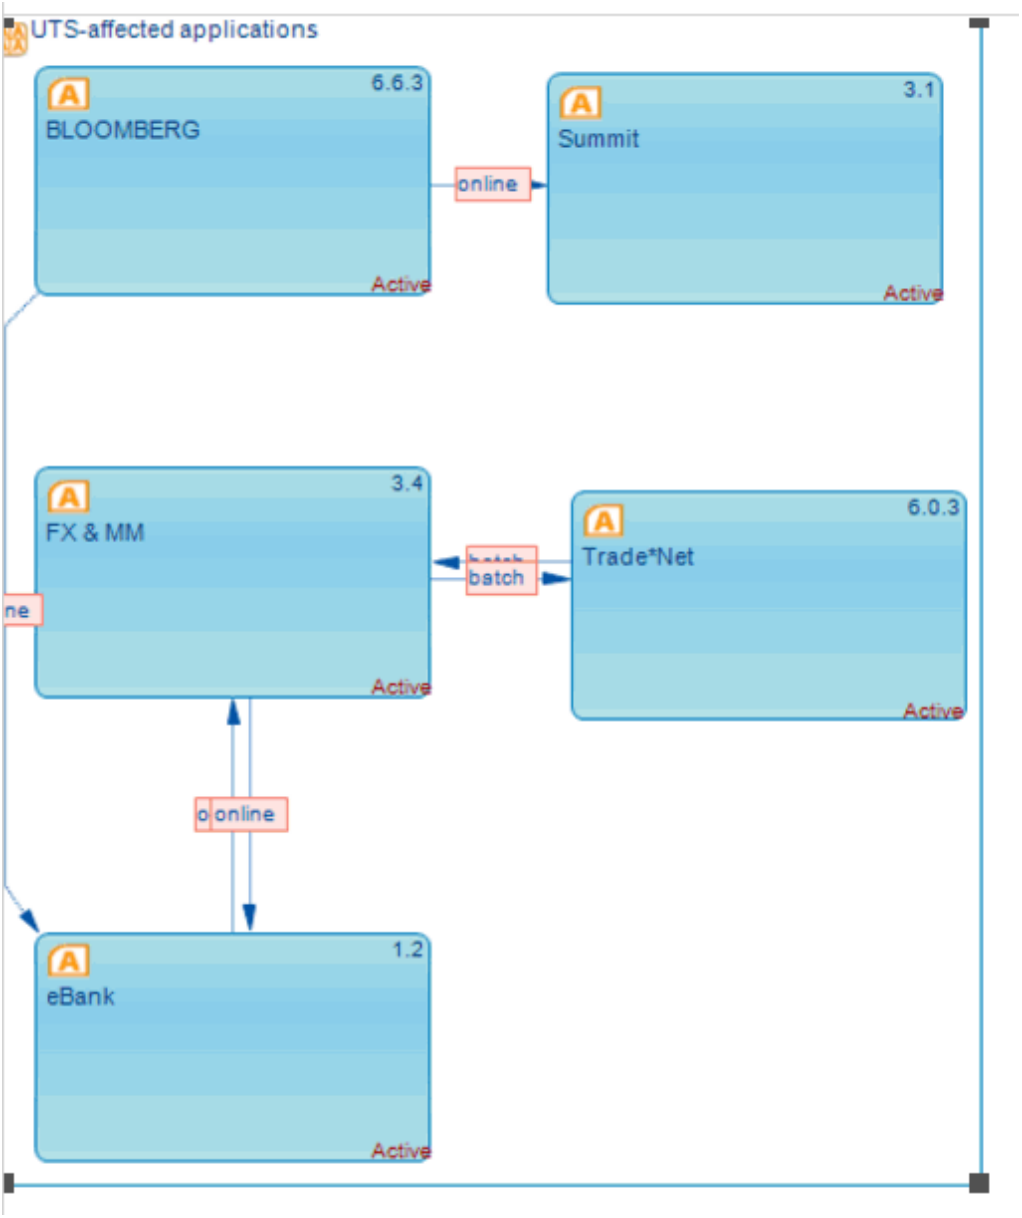


FIGURE: Information flows displaying Connection Type attributes in decoration boxes

The XML object ***DiagramInformationFlowDef*** allows you to specify which standard or custom attributes may be displayed on the connection items. Connection items in standard diagrams can be information flows, business process information flows, solution information flows, platform information flows, and migration rules. In diagram based on a custom diagram definition, other object classes may be used as connection items. In addition to the attributes to be selected, the back color and border color of the decoration boxes displaying the attributes in the diagram, and the maximum number of diagram items and connection items that may be displayed in a diagram.

The XML object ***DiagramInformationFlowDef*** also allows you to specify the sizes that can be selected for the diagram items in the **Diagram Item Size** field in diagrams. This is described in the section Configuring the Sizes of Diagram Items in Automatically Generated Diagrams.

The following image displays the configuration of the class Information Flow in the XML object ***DiagramInformationFlowDef***.

```
<DiagramInformationFlowDef LinkCountDecoration = "true"
NodeNumberThreshold = "10" LinkNumberThreshold = "30">

    <InformationFlowClassDef
        ClassName = "InformationFlow"
        Properties = "ID,Name,StartDate,EndDate,ObjectState,
                    Data.Name,InterfaceSystems.Name,
                    TargetService.Operations.Name,ConnectionType.Name,
                    ConnectionMethod.Name,ConnectionFrequency.Name"
        Position = "PureCenter"
        BackColor = "MistyRose"
        BorderColor = "Salmon"
    />
    />
    <InformationFlowClassDef
        ClassName = "PlatformInformationFlow"
        Properties = "Name,ConnectionType.Name,ConnectionMethod.Name,
                    ConnectionDataFormat.Name,ConnectionFrequency.Name,
                    Operation.Name"
        Position = "PureCenter"
        BackColor = "White"
    />
    />
    <UserItemSizeDef
        Name = "Small"
        Caption = "Small"
        Width = "30"
        Height = "13"
        Tiny = "true"
    />
</DiagramInformationFlowDef >
```

FIGURE: Configuration of XML elements DiagramInformationFlowDef and InformationFlowClassDef

To edit the XML object ***DiagramInformationFlowDef***:

1) Go to the **Presentation** tab and expand the **XML Objects** folder.
2) Right-click the XML object ***DiagramInformationFlowDef*** and select **Edit XML**. The XML editor is displayed in the center pane. For general information about editing XML objects in Alfabet Expand, see Working with XML Objects.
3) In the XML element ***DiagramInformationFlowDef***, configure the following XML attributes as needed:

- `LinkCountDecoration`: Enter "`true`" to specify that the number of connection items between the nodes (source/target objects) is displayed if the **Layout** attribute is set to **Condensed** and no attributes are displayed on the connection items. Enter "`false`" if no numbers should be displayed between connection items if the **Layout** attribute is set to **Condensed** and no attributes are displayed on the connection items
- `NodeNumberThreshold`: Enter a numerical value as the limit for the number of nodes (typically diagram items representing applications) for which connection items should be generated. Remaining nodes exceeding the threshold value will not be displayed. The reduction of the number of objects in the diagram will improve performance for diagrams with an excessive number of application interfaces. The default value is "500".
- `ChildNodeThreshhold`: Some objects displayed in the diagram have referenced objects that can be added to the diagram. The subordinate objects may be automatically added to the object it references via the **Add Subordinates for Object** or the **Update Subordinates...** functionalities. Enter a numerical value as the limit for the number of child objects that may be generated for a diagram. Remaining nodes exceeding the threshold value will not be displayed. The reduction of the number of objects in the diagram will improve performance for diagrams with an excessive number of application interfaces. The default value is -1 which equates to no limit in order to provide backward compatibility.

- `LinkNumberThreshold`: Enter a numerical value as the limit for the number of connection items that should be generated. Remaining connection items exceeding the threshold value will not be displayed. The default value is "500".

  The XML attributes `NodeNumberThreshold` and `NodeNumberThreshold` are relevant for the following views:*Information Flow Diagram Page View* (`APP_DiagramReport`, `APP_Connections_Diagram`, `DVC_DiagramReport`), *Business Data Usage Diagram* (`BO_DataUsageDiagram`, `ICTO_DataUsageDiagram`), and the *Interface System Diagram Page View*, (`COM_InterfaceSystemDiagram`).

4) Below the XML element ***DiagramInformationFlowDef***, create an XML element ***InformationFlowClassDef*** for each object class representing a connection item that you want to configure. Configure the following XML attributes for each XML element ***InformationFlowClassDef***, as needed:

- `ClassName`: Enter the name of the object class representing the connection items that you want to configure. Permissible values for Alfabet standard diagrams include `InformationFlow`, `BPInformationFlow`, `SolutionInformationFlow`, `PlatformInformationFlow`, `NetworkRoute`, and `MigrationLink`. For diagrams based on a custom diagram definition, all classes that are specified as a connecting class in **Connection** elements of the custom diagram definition can be defined. If no class is defined, then all possible object classes are included by default. Class names that are misspelled will be ignored. The value of the **Name** attribute of the object class must be used to specify the object class.

- `Properties`: Enter a comma-separated list of standard and custom object class properties of the relevant object classes that may be displayed for the connection item. These properties will be available in the attribute filter available in the relevant diagram page view. The user can select one or more of these properties to display its values on the connection item. If multiple properties are selected for a custom diagram, they will be separated by a linebreak in the decoration box. If no property is defined in the XML attribute `Properties`, then all possible properties will be included per default. The properties will be displayed lexicographically for the selected interface language. You can define any of the following:

  - To add a property of the object class defined with the XML attribute `ClassName`, enter the name of the object class property.

    For example, if `ClassName` is `InformationFlow` and you would like the object state of the information flow to be displayed in the filter field, enter `ObjectState`.

  - If the object class defined with the XML attribute `ClassName` has object class properties of the type `Reference` or `ReferenceArray`, you can add any custom or standard property of the object class or object classes that are the reference target to the list. Enter the name of the object class property of the type `Reference` or `ReferenceArray` that establishes the reference and the name of the object class property of the target class that shall be displayed separated with a dot.

    For example, if `ClassName` is `InformationFlow` and you would like to add the name of the target object referenced via the property `From` of the information flow to the filter field, enter `From.Name`.

Please note the following:

- The attribute **Type Info** of the object class property of the type Reference or ReferenceArray displays the allowed target classes for the reference. If `Artifact` is defined as **Type Info**, any object class that represents instances of the IT architecture can be referenced.

  For example, for the object class property `From` for the object class `InformationFlow`, the following object classes are referenced by means of the **Type Info** attribute: `Application`, `Component`, `LocalComponent`, `Peripheral`, `Device`. Any of the classes may be a source object of the class `InformationFlow`. To specify the attributes of the source applications of information flows, you would then list the standard and custom object class properties of the class `Application` in the XML attribute `Properties`. If you wanted to also include the attributes of the source peripherals, you would also include the standard and custom object class properties of the class `Peripheral` in the XML attribute `Properties`.

- If multiple target object classes have object class properties with the same name, like For example, the property `Name`, the definition is valid for all target object classes. If you add a target object class property specific for one of multiple target object classes to the list, the object class property will only be displayed if the connection references the relevant object class.

- `Position`: Define the position of the attribute on the connection items in the diagram. Permissible values include:
  - `PureCenter`: Attribute is placed on the middle segment of the information flow
  - `Start`: Attribute is placed along the first segment of the connection above or left to the line
  - `End`: Attribute is placed along the last segment of the connection above or left to the line
  - `Center`:Attribute is placed along the middle segment of the connection above or left to the line
- `BackColor`: Define the background color for the caption of the attribute on the connection items. The value entered should be a Windows, Web, hexadecimal, or RGB color value.
- `BorderColor`: The attribute information is displayed in a rectangle called a decoration. Define the border color for the decorations associated with connection items. If the diagram designer designs a line to connect the decoration box to the connection item, the connecting line will also have this color. The specified color will be applied to the decorations that are automatically generated as well as those defined by the user. If no color is specified, the border will be light grey per default. The value entered should be a Windows, Web, hexadecimal, or RGB color value. For more information about the specification of decoration boxes within the context of the Alfabet Diagram Designer, see the section *Modifying the Decoration Boxes Displayed for Connection Items* in the reference manual *Designing IT Landscape Diagrams in Alfabet*.

5) In the toolbar, click the **Save**  button to save the XML definition.

Configuring the Default Settings for the Alfabet Diagram Designer

The XML object ***DiagramOptions*** allows you to configure the default settings for the attribute window in the Alfabet Diagram Designer. The XML object ***DiagramOptions*** allows you to configure such aspects as the default display of connection items (straight or elbowed lines), ruler and grid settings, and the default settings for the print preview and print functionalities. A user working in the Alfabet Diagram Designer can change the default setting as needed via the menu option **Actions** > **Diagram Settings**. For more information about defining the diagram settings in the context of the Alfabet Diagram Designer, see the section *Setting Up the Diagram* in the reference manual *Designing IT Landscape Diagrams in Alfabet*.

Designing diagrams is an involved process and is described in detail in the reference manual *Designing IT Landscape Diagrams in Alfabet*.

To edit the XML object ***DiagramOptions***:

1) Go to the **Presentation** tab and expand the **XML Objects** folder.
2) Right-click the XML object ***DiagramOptions*** and select **Edit XML**. The XML editor is displayed in the center pane. For general information about editing XML objects in Alfabet Expand, see Working with XML Objects.
3) Define the XML attributes, as needed. The table below displays the XML elements and XML attributes that can be edited for the XML object ***DiagramOptions***:

XML Element (bold) / XML Attribute	Explanation
DiagramOptions	
`DrawGrid`	Enter "`true`" if a grid should be displayed in the Alfabet Diagram Designer. Enter "`false`" if a grid should not be displayed. The grid version can be defined in the XML attribute `GridMode`. This attribute is only applicable to the display in the Alfabet Diagram Designer and not to the resulting diagram in the diagram page view.
`Rulers`	Enter "`true`" if a rulers should be displayed in the Alfabet Diagram Designer. Enter "`false`" if rulers should not be displayed. This XML attribute is only applicable to the display in the Alfabet Diagram Designer and not to the resulting diagram in the diagram page view.
`HorGridSize`	Enter an integer to determine the horizontal grid size used in millimeters in the Alfabet Diagram Designer. This XML attribute is only applicable to the display in the Alfabet Diagram Designer and not to the resulting diagram in the diagram page view.
`VerGridSize`	Enter an integer to determine the vertical grid size used in millimeters in the Alfabet Diagram Designer. This XML attribute is only applicable to the

XML Element (bold) / XML Attribute	Explanation
	display in the Alfabet Diagram Designer and not to the resulting diagram in the diagram page view.
PhysicalMode	Enter "true" to apply the margin definition to the diagram in the Alfabet Diagram Designer. The printed image will include all areas that do not belong to the margin definition. Enter "false" if the margin definition should not be applied to the diagram. The layout is typically distributed to four pages, depending on the paper size and margin definition. The pages are printed individually.
ViewPrintLayout	Enter "true" to apply the print layout to the diagram. The margins as well as header/footer are greyed out. Enter "false" if the print layout should not be applied to the diagram.
LeftMargin	Enter an integer to determine the applicable left margin in millimeters in the Alfabet Diagram Designer. This XML attribute is only relevant when displaying the diagram in the Alfabet Diagram Designer in print layout or when printing the diagram.
RightMargin	Enter an integer to determine the applicable right margin in millimeters in the Alfabet Diagram Designer. This XML attribute is only relevant when displaying the diagram in the Alfabet Diagram Designer in print layout or when printing the diagram.
TopMargin	Enter an integer to determine the applicable top margin in millimeters in the Alfabet Diagram Designer. This XML attribute is only relevant when displaying the diagram in the Alfabet Diagram Designer in print layout or when printing the diagram.
BottomMargin	Enter an integer to determine the applicable bottom margin in millimeters in the Alfabet Diagram Designer. This XML attribute is only relevant when displaying the diagram in the Alfabet Diagram Designer in print layout or when printing the diagram.
HeaderMargin	Enter an integer to determine the applicable header margin (for example, the margin between the header and the main diagram) in millimeters in the Alfabet Diagram Designer. This XML attribute is only relevant when displaying the diagram in the Alfabet Diagram Designer in print layout or when printing the diagram.
FooterMargin	Enter an integer to determine the applicable footer margin (for example, the margin between the footer and the main diagram) in millimeters in the Alfabet Diagram Designer. This XML attribute is only relevant when

XML Element (bold) / XML Attribute	Explanation
	displaying the diagram in the Alfabet Diagram Designer in print layout or when printing the diagram.
`RepeatHeader`	Enter one of the following XML attributes to determine how the header should be applied to the various pages of the printed diagram. Options include: • `EveryPage`: Header is applied to every page of the printed output. • `ButFirstPage`: Header is applied to every but the first page of the printed output. • `FirstPage`: Header is only applied to the first page of the printed output. • `None`: Header does not apply to the printed output.
`RepeatFooter`	Enter one of the following XML attributes to determine how the footer should be applied to the various pages of the printed diagram. Options include: • `EveryPage`: Footer is applied to every page of the printed output. • `ButFirstPage`: Footer is applied to every but the first page of the printed output. • `FirstPage`: Footer is only applied to the first page of the printed output. • `None`: Footer does not apply to the printed output.
`ElbowedConnection`	Enter "`true`" if the connection items (information flows, migration rules, etc.) that are automatically added to the diagram should be drawn as an elbow line (with 90° angle). Enter "`false`" if the connection items should be created as a straight line.
`CenterConnection`	Enter "`true`" if the end points of connection items should be determined by the user via the drag-and-drop action. Enter "`false`" if the end points of connection items should always be drawn from the center of one diagram object to the center of the other diagram object.
`PrintScale`	Enter an integer to determine the scaling factor that should be applied to the diagram when printing.

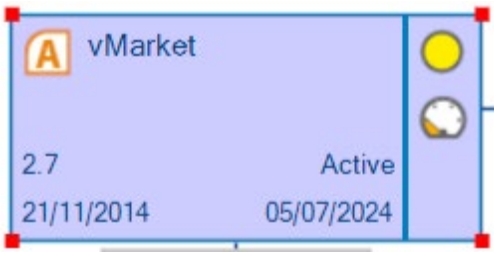
XML Element (bold) / XML Attribute	Explanation
`Landscape`	Enter "`true`" if the diagram should use the specified paper size in landscape mode. Enter "`false`" if the diagram should use the specified paper size in portrait mode.
`GridMode`	Enter "`true`" if the grid should be displayed as grid lines in the Alfabet Diagram Designer. Enter "`false`" if the grid should be displayed as grid points.
`LockToolBoxItem`	Enter "`true`" if the mouse pointer icon should continue to represent the item selected in the **Toolbox Items** pane in the Alfabet Diagram Designer (for example, Application) until a different item is selected in the **Toolbox Items** pane. Enter "`false`" if the mouse pointer icon should revert to the pointer tool upon completion of every interaction.
`Format`	Enter one of the following XML attributes to determine the paper format to be used as the default for diagrams. Permissible options are: • `A4 210x297`: Standard A4 paper size • `A3 297x420`: Standard A3 paper size • `A2 420x594`: Standard A2 paper size • `A1 594x840`: Standard A1 paper size • `A0 840x1186`: Standard A0 paper size • `Letter`: US Letter paper size (216x279 cm or 8.5x11 in) • `Legal`: US Legal paper size (216x356 cm or 8.5x14 in) • `11x17`: US 11x17 paper size (279x432 cm)
`WarnOnSemanticLayoutChange`	Enter "`true`" if a warning message should be displayed if changes made in a diagram result in a semantic change.
`AutomaticallyRescanDiagramOnLoad`	Enter "`true`" to automatically display semantic changes made to an object in a diagram when the diagram is reloaded in the Alfabet user interface or Alfabet Diagram Designer. Enter "`false`" if semantic changes shall only be updated to the diagram when the **Update** button is triggered in the diagram's view in the Alfabet user interface or when the **Refresh Diagram** option in the **Semantic Actions** menu is triggered in the Alfabet Diagram Designer. Please note that the XML attribute `AutomaticallyRescanDiagramOnLoad` i must be set to "`false`" if the **Automatically Rescan on Load** checkbox is selected in the **Diagram Settings** editor in the Alfabet Diagram Designer. If the XML attribute `AutomaticallyRescanDiagramOnLoad` is set

XML Element (bold) / XML Attribute	Explanation
	to "`true`", the semantic changes will not be explicitly updated to the diagram regardless of the definition of the **Automatically Rescan on Load** attribute.
`SaveWorkinProgress`	Enter "`true`" if the diagram shall be automatically saved even if a session time-out occurs. If a diagram is opened after a session has timed out, the user will be asked if the diagram that was in progress when the session expired should be opened and replace the most recently saved diagram. A standard message is displayed for semantic groupings defined in Alfabet standard diagrams.
`SaveFrequency`	Enter the number of minutes in order to define how frequently the diagram shall be automatically saved.

4) In the toolbar, click the **Save** button to save the XML definition.

Configuring the Color, Opacity, and Size of the Selection Handles of Diagram Items

The attributes available in the **Visual Selection Layout** section of the GUI scheme configuration allow the color, opacity, and size of the handles surrounding selected objects in diagrams and matrices to be specified.



To specify the handles, expand the **GUI Schemes** node in the **Presentation** tab and select the relevant GUI scheme you want to define. In the **Application** section of the attribute window, expand the **Visual Selection Layout** and specify the **Color**, **Opacity**, and **Size** attributes as needed. In the toolbar, click the **Save** button to save the definition.

For more information, see the section Configuring GUI Scheme Definitions for the Alfabet Interface in the chapter Configuring the Visualization of the Alfabet Interface as well as a detailed documentation of all GUI scheme attributes in the chapter *Overview of GUI Scheme Attributes* in reference manual *Configuring Alfabet with Alfabet Expand - Appendix*.

Configuring the Assignment Capability

Assignments allow users to collaborate with one another about objects in the enterprise architecture.

An assignment is a task that is defined for a selected object and assigned to a specific user. The assignee is expected to provide the required input for the object by a specified due date. Assignments can be defined to be optional or mandatory. Email notifications may be configured to be sent in the context of the assignment capability.

The assignment capability is available for all object classes that support the use of assignments.

- For an overview of the object classes for which assignments can be created, see the chapter *Overview of Configurable Features for Object Classes* in the reference manual *Configuring Alfabet with Alfabet Expand - Appendix*.
- For general information about the use of assignments in Alfabet, see the section *Sending and Receiving Assignments for Alfabet Objects* in the reference manual *Getting Started with Alfabet*.

A number of configurations are required in order to implement the full range of functionality available with the assignment capability. The following configurations must be completed by the solution designer. These configurations are carried out in the configuration tool Alfabet Expand and are explained in the section below:

- If emails are to be sent in the context of the assignment capability, the email capability must be activated and the content of the text templates used for the emails may need to be modified. For more information about the configuration required for email notifications in the context of the assignment capability, see the section Configuring Email Notifications in the Context of Assignments.
- The statuses to be used in the context of your enterprise's assignment workflow may be configured in the XML object ***ReleaseStatusDefs***.
- A **Notify Authorized User** button may be displayed in the toolbar of an object profile in order to allow an assignment to be quickly created and sent to the authorized user of a selected object. The implementation of this button must be configured for all relevant object classes for which it is to be implemented. For more information about configuring the display of the **Notify Authorized User** button, see the section Configuring the Display of the Notify Authorized User Button for Assignment Creation.
- The views needed for the assignment capability are available in the relevant user profiles. Please note the following regarding the relevant views required to work with the assignment capability:
  - The **My Assignments** functionality (`Home_Assignments`) allows a user to view all assignments that he/she is responsible for. The **Sent Assignments** functionality (`Home_SentAssignments`) allows the user who has created assignments to keep track of all assignments that he/she is the originator of. Both functionalities allow users to set reminders for themselves about upcoming assignment deadlines. As the solution designer, you must ensure that the functions **My Assignments** (`Home_Assignments`) and **Sent Assignments** (`Home_SentAssignments`) are available in the relevant user profiles you configure for your Alfabet community. For more information about configuring user profiles, see the section Making Functionalities Accessible to a User Profile in the chapter Configuring User Profiles for the User Community.
  - The **Assignments** page view (`ObjectAssignments`) allows users to create new assignments for a selected object. The view also features a notepad functionality that allows you to

communicate about the assignment or the object targeted by the assignment. The **Assignments** page view (`ObjectAssignments`) should be available in all object views for which assignments should be created in your enterprise. For more information about configuring object views, see the section Configuring Object Views.

The language displayed for a user's email notifications is specified by a user administrator in the **Email Notification Language** attribute for the relevant user in the **User Administration** functionality accessible via the `Admin` user profile. For more information, see the section *Defining and Managing Users* in the reference manual *User and Solution Administration*.

The following configuration requirements must be completed by the system administrator in the tool Alfabet Administrator:

- All Alfabet functionalities for which the email capability is to be implemented require the setup of a connection to an SMTP server for outgoing email. For more information, see the section *Activating the Dispatch of Email Notifications in Alfabet* in the reference manual *System Administration*.
- The user profile used to open the Alfabet views targeted by hyperlinks in the email is, by default, the user profile that the sender was logged in with when the view was sent/triggered. However, your system administrator may configure that Alfabet views in email notifications are to be opened using the recipient's user profile. For more information, see the section *Configuring the Setup To Open the Alfabet Interface via Links in Email Notifications* in the reference manual *System Administration*.

In order to trigger functionalities associated with target dates, a batch job must be configured and executed by your system administrator. For more information about configuring a batch job for the review of assignment target dates, see the section *Triggering Target Date Control for the Assignments Capability* in the reference manual *System Administration*.

The following information is available

Configuring Email Notifications in the Context of Assignments

The assignment capability allows for email notifications to be automatically sent in various contexts in the assignment workflow. Email notifications may be sent automatically in the following situations in the context of the assignment capability:

- to the assignee when a new assignment is created
- to a new assignee when an assignment is reassigned
- to the originator of the assignment when the assignment's status is changed

- to either the assignee and/or the originator when a notepad entry is made about the assignment
- to the assignee when the assignment nears its impending target date
- to the originator if the assignment is not completed by its target date

In order to send the email notifications in the contexts of assignments, the email capability must be explicitly activated for the assignments. Furthermore, default text templates that email notifications are based on are provided by Software AG. These text templates can be used as is or they can be edited according to the needs of your enterprise.

The following configuration requirements must be completed by the system administrator in the tool Alfabet Administrator:

- All Alfabet functionalities for which the email capability is to be implemented require the setup of a connection to an SMTP server for outgoing email. For more information, see the section *Activating the Dispatch of Email Notifications in Alfabet* in the reference manual *System Administration*.
- The user profile used to open the Alfabet views targeted by hyperlinks in the email is, by default, the user profile that the sender was logged in with when the view was sent/triggered. However, your system administrator may configure that Alfabet views in email notifications are to be opened using the recipient's user profile. For more information, see the section *Configuring the Setup To Open the Alfabet Interface via Links in Email Notifications* in the reference manual *System Administration*.

For more information about the configuration of email notifications in the context of the assignment capability, see the following sections below:

- Implementing the Email Capability for the Assignment Functionality
- Defining the Text Templates Used for the Assignment Capability

Implementing the Email Capability for the Assignment Functionality

The XML object ***SolutionOptions*** allows you to define whether email notifications should be sent in the context of assignments. Email notifications may be sent automatically in the following situations in the context of the assignment capability:

- to the assignee when a new assignment is created
- to a new assignee when an assignment is reassigned
- to the originator of the assignment when the assignment's status is changed
- to either the assignee and/or the originator when a notepad entry is made about the assignment
- to the originator if the assignment is not completed by its target date
- to the assignee when the assignment nears its impending target date

The configuration of the email capability via the XML attribute `SendAssignmentsMails` in the XML object ***SolutionOptions*** is a prerequisite for the implementation of the reminder email notifications. However, setting the XML attribute `SendAssignmentsMails` to "`true`" does not result

in reminder emails being automatically sent per default. Email notifications will only be sent to the assignee if he/she selects the **Send Reminder Notifications** option when defining assignment reminders in the **My Assignments** functionality.

The following configuration requirements must be completed by the system administrator in the tool Alfabet Administrator:

- All Alfabet functionalities for which the email capability is to be implemented require the setup of a connection to an SMTP server for outgoing email. For more information, see the section *Activating the Dispatch of Email Notifications in Alfabet* in the reference manual *System Administration*.
- The user profile used to open the Alfabet views targeted by hyperlinks in the email is, by default, the user profile that the sender was logged in with when the view was sent/triggered. However, your system administrator may configure that Alfabet views in email notifications are to be opened using the recipient's user profile. For more information, see the section *Configuring the Setup To Open the Alfabet Interface via Links in Email Notifications* in the reference manual *System Administration*.

To activate the email capability in the context of assignments in the XML object ***SolutionOptions***:

1) Go to the **Presentation** tab and expand the **XML Objects** folder.
2) Right-click the XML object ***SolutionOptions*** and select **Edit XML**. The XML editor is displayed in the center pane. For general information about editing XML objects in Alfabet Expand, see Working with XML Objects.
3) In the XML attribute `SendAssignmentsMails`, enter "`true`" if an email notification should be automatically sent when an assignment is created (email sent to assignee) and the assignment status is changed (email sent to assignment originator). Enter "`false`" if email notifications should not be automatically generated.

   Setting the XML attribute `SendAssignmentsMails` to "`true`" also enables the sending of emails when notepad entries are made in the context of the strategy planning and master planning capabilities.

4) In the toolbar, click the **Save**  button to save the XML definition.

Defining the Text Templates Used for the Assignment Capability

Software AG provides several default text templates that are used for the email notifications sent in the context of the assignments capability. All preconfigured text templates that are available for the assignments capability can be found in the ***ASMT*** folder  . To access the folder and available text templates, click the **Presentation** tab, expand the **Text Templates**  node in the explorer, and expand the ***ASMT*** folder  .

The text templates define the email text, relevant references to objects and their object class properties, and hyperlinks to the relevant objects in the solution interface. You can make the following changes to any text template available in Alfabet Expand:

- The **Subject** field of the email can be specified via the **Caption** attribute of the text template.
- The text template can be either formatted as ASCII or HTML. Please note that the HTML must be XML-conform HTML, compliant with HTML 5, and use standard HTML tags.
- There are three different types of variables that can be included in a text template:
    - Predefined standard variables: These are variables that are predefined by Software AG and serve the purpose of referencing the relevant data in the Alfabet database. For example, the variable `{Object:RefImage}` typically allows the base object referenced by the text template to be included in the text template. You can add, remove, or move the entire variable via copy and paste. If the expression in the curly brackets `{XXX}` is changed, the text template may fail to work correctly.
    - Object variables: A specified set of variables is available that allows information such as the object targeted by the notification or a user referenced by the object. The syntax of these references are {<ObjectClass>:<ObjectClassProperty>}, whereby the set of object classes that can be specified in <ObjectClass> are predefined. Any scalar property defined for the <ObjectClass> expression can be referenced in the <ObjectClassProperty>. For example, if an application is the base object referenced by the email, you would enter `{Object:ID}` to include the ID of an application or `{Object:Description}` to include the description of an application. You can add, remove, or move the entire variable via copy and paste.
    - Query variables: It is possible to specify an Alfabet query or SQL query to add more complex references to the text template that cannot be captured via scalar properties (for example, additional referenced information or a document link). If you plan to specify an Alfabet query or native SQL query to the text template, you must enter the variable {`Query:` <QueryName>} to the text template, whereby the <QueryName> expression is determined by the value of the **Name** attribute specified for the query text configuration object.
- The text displayed in the templates can be edited, as needed.
- Locale texts can be created for each text template in order to provide the email in the relevant secondary languages supported by your enterprise.

- For detailed information about the configuration of text templates as well as creating various language versions of the text templates for your enterprise, see the section Configuring Text Templates for Email Notifications.
- For an overview of all available text templates for the assignments capability and an explanation of the purpose of each variable, see the chapter *Overview of Preconfigured Text Templates and Their Variables* in the reference manual *Configuring Alfabet with Alfabet Expand - Appendix*.

Defining the Statuses Used for the Assignment Capability

The XML object ***ReleaseStatusDefs*** allows you to configure the statuses available for the assignment capability as well as the transition from one status to the next. A default configuration is available in the XML object. However, the status definitions can be edited and adapted to the needs of your enterprise.

This XML object should be defined as part of the initial configuration of the Alfabet solution. These definitions should not be changed once the Alfabet database is in use.

To edit the XML object ***ReleaseStatusDefs*** for assignments

1) Go to the **Presentation** tab and expand the **XML Objects** node.
2) Right-click the XML object ***ReleaseStatusDefs*** and select **Edit XML**. The XML editor is displayed in the center pane.

```
<ReleaseStatusDef
        ClassNames = "Assignment"

        StatusSet = "Created,Accepted,In Progress,Work Completed,Returned,
                Re-Assigned,Closed"
        RetiredStatusSet = "Created,Closed"
        EditableStatusSet = "Created,Accepted,In Progress,Returned,Re-Assigned,
                Work Completed"
        PrivateStatus = "Returned"
        RedefinedStatus = "Re-Assigned"
        ApprovedStatus = "Work Completed"
        ClosedStatus = "Closed"
        DefaultStatus = "Created">

        <StatusTransition ToStatus="Created" FromStatuses=""/>
        <StatusTransition ToStatus="Accepted" FromStatuses="Created,Re-Assigned"/>
        <StatusTransition ToStatus="In Progress"  FromStatuses="Created,Accepted,
                Work Completed,Re-Assigned"/>
        <StatusTransition ToStatus="Work Completed"  FromStatuses="Created,Accepted,
                In Progress,Re-Assigned"/>
        <StatusTransition ToStatus="Returned" FromStatuses=""/>
        <StatusTransition ToStatus="Re-Assigned" FromStatuses="Created,Accepted,
                In Progress,Returned"/>
        <StatusTransition ToStatus="Closed" FromStatuses=""/>

</ReleaseStatusDef>
```

3) Edit the XML attributes in the status definition for the object class `Assignment`. The table below explains the XML attributes that may be defined.

XML Element (bold) / XML Attribute	Description
ReleaseStatusDef	
`ClassNames`	Enter `Assignment`.
`StatusSet`	Enter a comma-separated list of all statuses that are to be implemented in the assignment workflow. `"Created,Accepted,In Progress,Work Completed,Returned,Re-Assigned,Closed"`

XML Element (bold) / XML Attribute	Description
	 Only ASCII characters made be used in the name of an enumeration item. Please note that NO error will be displayed if you use characters that are not conform to ASCII.
`RetiredStatusSet`	Enter a comma-separated list of statuses defined in the XML attribute `StatusSet` in order to indicate that an assignment is retired and may be deleted. If an object with the release status specified in the XML attribute `RetiredStatusSet` may not be edited by users, it should not be listed in the XML attribute `EditableStatusSet`. Users with relevant access permissions may delete an assignment with a status defined in the XML attribute `RetiredStatusSet`. If no status is defined in the XML attribute `RetiredStatusSet`, the deletion of assignments will be forbidden for all users other than a user with administrative permissions.
`EditableStatusSet`	Enter a comma-separated list of statuses defined in the XML attribute `StatusSet` that may be edited by users with relevant access permissions. If an object with the release status specified in the XML attribute `RetiredStatusSet` may not be edited by users, it should not be listed in the XML attribute `EditableStatusSet`.
`PrivateStatus`	Enter one status defined in the XML attribute `StatusSet` that should be assigned to expired mandatory assignments. If the XML attribute `PrivateStatus` is not included in the XML object ***ReleaseStatusDefs*** of it is left unspecified, the value will be defined as `Private` per default.  Expired mandatory assignments are automatically reassigned to the assignment's originator: Only the originator will have edit permissions for the reassigned assignment. In contrast, expired optional assignment will be automatically assigned the XML attribute `ClosedStatus`.
`RedefinedStatus`	Enter one status defined in the XML attribute `StatusSet` to indicate that an assignment has been reassigned to a different user. The status value of the assignment will automatically be changed to the valued specified in the XML attribute `RedefinedStatus` if the assignment is reassigned to another user. If the XML attribute `RedefinedStatus` is not included in the XML object ***ReleaseStatusDefs*** of it is left unspecified, the value will be defined as `Redefined` per default.

XML Element (bold) / XML Attribute	Description
`ApprovedStatus`	Enter one status defined in the XML attribute `StatusSet` that indicates that the assignment is complete. Once a user assigns the status specified in the XML attribute `ApprovedStatus` to the assignment, the assignment will no longer be automatically reassigned to the originator when the target date is reached. If the XML attribute `ApprovedStatus` is not included in the XML object ***ReleaseStatusDefs*** of it is left unspecified, the value will be defined as `Approved` per default.
`ClosedStatus`	Enter one status defined in the XML attribute `StatusSet` that should be assigned to an assignment that has been completed by the assignee and has been confirmed as completed by the originator. If the XML attribute `ClosedStatus` is not included in the XML object ***ReleaseStatusDefs*** of it is left unspecified, the value will be defined as `Closed` per default. Expired optional assignments will be automatically assigned the status specified in the XML attribute `ClosedStatus`. In contrast, expired mandatory assignments will automatically be assigned the status specified in the XML attribute `PrivateStatus`.
`DefaultStatus`	Enter one status that is the default status for assignments. The default status is automatically assigned to a new assignment upon its creation.

4) The XML element ***StatusTransition*** allows the sequence of statuses to be defined. You should create an XML element ***StatusTransition*** for each status listed in the XML attribute `StatusSet`. The definition for status transitions is determined by the configuration of the XML attributes `FromStatuses` and `ToStatus`. The status defined for the XML attribute `ToStatus` can be selected by the user subsequent to the status(es) defined in the XML attribute `FromStatuses`. The table below explains the XML attributes that may be defined.

For example, an object must have the statuses `Created` or `Re-Assigned` in order to allow a transition to the status `Accepted`.

```
<StatusTransition ToStatus="Accepted"
FromStatuses="Created,Re-Assigned"/>
```

If you do not enter a value in the quotation marks, no statuses can be selected in order to transition for a status by the user.

XML Element (bold) / XML Attribute	Description
StatusTransition	
`ToStatus`	Enter one status that may follow the statuses described in the XML attribute `FromStatuses`. An XML attribute `ToStatus` definition should be made for each status in the status set.
`FromStatuses`	Enter one or more statuses in a comma-separated list that may precede the status described in the XML attribute `ToStatus`. It is recommended that a XML attribute `FromStatuses` definition should be made for each XML attribute `ToStatus` definition in the status set. Enter the word "any" in the quotation marks if all statuses may be defined for either the XML attribute `ToStatus` or the XML attribute `FromStatuses`. For example: `<StatusTransition ToStatus="Planned" FromStatuses="any"/>`

5) The XML element `Status` definitions allow tooltip texts to be defined for the statuses available for assignments.

XML Element (bold) / XML Attribute	Description
Status	Allows you to provide custom tooltips for each status. Users will see the tooltips for the statuses in the relevant editor. The tooltip text you define in the context of the status configuration will be added to the tooltip hover box for the object class property `Status`. The text defined in the XML attribute `Hint` for the statuses will be line-separated and appended below the text for the standard tooltip.
`Name`	Enter the name of the status.
`Hint`	Enter a Help text that will help users to understand the meaning of the status. It is recommended that the text is not excessively long. The value defined in the XML attribute `Hint` will be displayed as custom Help in editors, filters, and legends. The texts for the individual statuses will be line-separated. The texts defined for custom Help can be translated in the **Translation Editor**. For more information about the translation of custom terminology, see the chapter Localization and Multi-Language Support for the Alfabet Interface.

6) In the toolbar, click the **Save** button to save the XML definition.

Configuring the Display of the Notify Authorized User Button for Assignment Creation

The XML object ***AssignmentConfigDef*** allows you to determine which object classes allow for the **Notify Authorized User** button to be displayed in the toolbar of the object profile.

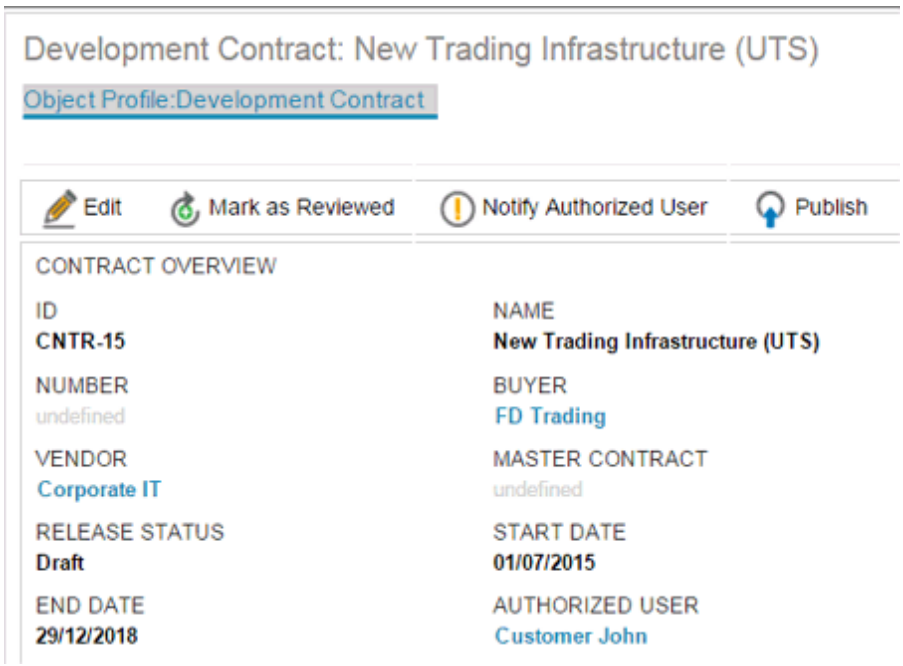


FIGURE: Notify Authorized User button in an object profile

By clicking the **Notify Authorized User** button, the user can quickly create an assignment that is assigned to the authorized user of the selected object. The assignment will be sent to the **My Assignments** functionality of the object's authorized user and, if the email capability has been configured, the authorized user will also receive an email informing him/her that a new assignment has been created.

- An assignment can be created via the **Notify Authorized User** button only for objects for which an authorized user has been defined.
- The email capability must be explicitly activated for assignments in order for email notifications to be sent when an assignment is created via the **Notify Authorized User** button. For more information, see the section Configuring Email Notifications in the Context of Assignments.
- Documents and Web links (URLs) can be attached to the assignment in the **Notification Assignment** editor available via the **Notify Authorized User** button. For more information about making documents available for attachment, see the section *Uploading Documents and Managing User Permissions to Document Folders in the Internal Document Selector* in the reference manual *User and Solution Administration*. For more

information about defining a default prefix for a Web link, see the section Configuring Default URL Prefixes for the Attachments Page View in this chapter.

To edit the XML object ***AssignmentConfigDef***:

1) Go to the **Presentation** tab and expand the **XML Objects** folder, and expand the **Administration** folder.

2) Right-click the XML object `AssignmentConfigDef` and select **Edit XML**. The XML editor is displayed in the center pane. For general information about editing XML objects in Alfabet Expand, see Working with XML Objects.

3) Define the XML attributes, as needed. The table below displays the XML elements and XML attributes that can be edited for the XML object ***AssignmentConfigDef***:

XML Element (bold) / XML Attribute	Explanation
AssignmentConfigDef	
`NotifyResponsibleClasses`	Enter a comma-separated list of object classes for which the **Notify Authorized User** button should be available. You must enter the value of the **Name** attribute of the object class. The **Notify Authorized User** button will be added to the toolbar of the object profiles for all cobject lasses defined in this XML attribute. If no class is specified in the XML attribute `NotifyResponsibleClasses`, the **Notify Authorized User** capability will be available for all object classes for which the concept of authorized user/user group is relevant.
`NotifyResponsiblePeriod`	Enter an integer to establish the default target date for the assignment. The target date is computed based on the date when the assignment is generated plus the value defined in the XML attribute `NotifyResponsiblePeriod`. The user creating the assignment can edit the target date, as needed. **EXAMPLE**: If the XML attribute `NotifyResponsiblePeriod` is defined as 30, the authorized user will have 30 days after the date that the assignment was generated to complete the assignment. An assignment generated on Jan. 1, 2008 will have a target date of Jan. 30, 2008.

4) In the toolbar, click the **Save**  button to save the XML definition.

Configuring Standard Business Support Matrices

The XML object ***ITMapDef*** allows you to configure the layout and behavior of the standard business support matrices in Alfabet. Configurable aspects of Alfabet 's standard business support matrices include:

- the visualization of matrix objects and axis objects including, for example, their color and caption information
- the default classes displayed on the X- and Y-axes of business support matrices as well as the order of the axis objects
- the visualization of blueprint map objects in the business support matrices
- the object classes that may be defined as providers of operational, strategic, and tactical business supports
- the object classes representing operational aspects that can be displayed on business supports in business support matrices
- relevance values that allow Alfabet users to filter information based on its relevance for the current analysis of the IT landscape
- the indicator displayed on business appraisal objects in the business support matrices

The specification of the XML object ***ITMapDef*** is relevant for the configuration of views displaying business support matrices available for the following object classes:

- `Application`
- `ICTObject`
- `BusinessFunction`
- `BusinessProcess`
- `Domain`
- `MarketProduct`
- `OrgaUnit`
- `SystemBuildingBlock`
- `ITStrategyMap`
- `MasterPlanMap`
- `MasterPlanMapView`
- `SolutionMap`

For a methodological overview of planning business supports in the context of master planning and conceptualizing the enterprise's target architecture, see the reference manual *IT Planning Basic*.

Business support matrices in Alfabet can convey a wealth of information about the enterprise's IT support. For information about functionalities common to most business support matrices, see the section *Appendix:Working with Business Support Maps* in the reference manual *IT Planning Basic*.

In addition to configuring the standard business support matrices in Alfabet, you can also define a configured report to display a customized matrix that allows business supports to be viewed and edited. For more information, see Configuring Matrices for Multi-Editing of Object Relations or Business Supports in the chapter Configuring Reports.

The attributes available in the **Visual Selection Layout** section of the GUI scheme configuration allow the color, opacity, and size of the handles surrounding selected objects in diagrams and

matrices to be specified. For more information, see the section Configuring GUI Scheme Definitions for the Alfabet Interface in the chapter Configuring the Visualization of the Alfabet Interface as well as a detailed documentation of all GUI scheme attributes in the chapter *Overview of GUI Scheme Attributes* in reference manual *Configuring Alfabet with Alfabet Expand - Appendix*.

To edit the XML object ***ITMapDef***:

1) Go to the **Presentation** tab and expand the **XML Objects** folder by clicking the + symbol. You will see all XML objects that can be edited.
2) Right-click the XML object ***ITMapDef*** and select **Edit XML**. The XML editoris displayed in the center pane. For general information about editing XML objects in Alfabet Expand, see Working with XML Objects.
3) Specify the following XML attributes below the root node ***ITMap*** to configure standard business support matrices, as needed.

- `XClass`: Enter the object class to display per default on the X-axis when a user accesses the matrix for the first time. Choices include either `Process` (for the object class `BusinessProcess`) or `Domain`. The default is "`Process`". Users can modify the X-axis in the context of a business support map.
- `YClass`: Enter the object class to display per default on the Y-axis when a user accesses the matrix for the first time. Choices include either `Organization` or `Product` (for the object class `MarketProduct`). The default is "`Organization`". Users can modify the Y-axis in the context of a business support map.
- `OBSProviders`: Enter the names of the object classes that are permissible to be the provider of operational business supports. Possible values are the object classes `Application` and `OrgaUnit`.The default value is `Application`.
- `TBSProviders`: Enter the names of the object classes that are permissible to be the provider of tactical business supports. Possible values are the object classes `ICTObjectVirtual`, `ICTObject`, `Application`, `SystemBuildingBlock`, and `OrgaUnit`.The default value is `ICTObjectVirtual`, `ICTObject`, and `Application`.
- `SBSProviders`: Enter the names of the object classes that are permissible to be the provider of strategic business supports. Possible values are the object classes `ICTObjectVirtual`, `ICTObject`, `SystemBuildingBlock`, and `OrgaUnit`.The default value is `ICTObjectVirtual` and `ICTObject`.
- `UseAxisClassColor`: Set to `True` to configure that the **Foreground Color** and **Background Color** attributes of the relevant class setting are displayed for the object classes that are displayed as axis objects in matrix views.
- `UseSupportClassColor`: Set to `True` to configure that the **Foreground Color** and **Background Color** attributes defined for the relevant class settings are displayed for the object classes that are displayed as matrix objects in matrix views.
- `ItemFont`: Specify the font to display for texts on the matrix objects. It is recommended that you enter "`Arial,12`" to correctly display the text. Font names with empty spaces may be defined (for example, `Times New Roman,6`).
- `AttributeFont`: Specify the font to display for texts in the attribute boxes available on the matrix objects. The attribute boxes display an abbreviate for the object states of the object providing the business support as well as the business support itself and the relevant operational aspects. It is recommended that you enter "`Arial,6`" to correctly display the

attribute information. Font names with empty spaces may be defined (for example, `Times New Roman,6`).

- `CopyResponsibilities`: Specify who the authorized user of a new operational business support based on an existing strategic or tactical business support will be. Enter "`true`" if the authorized user of the new operational business support is copied from the source business support. Enter "`false`" if the currently logged in user creating the new business support will be the authorized user. The default is set to "`false`".

  This attribute is relevant for the creation of operational business supports based on existing strategic or tactical business supports in the *Business Support Map Page View* for a master plan map.

- `ShowShortName`: Enter "`true`" if a concatenation of the short name and version of the object providing the business support should be displayed on the matrix objects. If no short name is defined, the full name will be displayed. Enter "`false`" if the full name of the business support should be displayed.

- `AspectClasses`: Enter the names of the object classes that can be defined as operational aspects for the object classes on the matrix axes as well as for operational business supports, tactical business supports, strategic business supports, and solution business supports. You can specify one or more of the standard operational aspect object classes (`Brand`, `CustomerSegment`, `Market`, and `SalesChannel`). However, any other object class or object class stereotype may be specified in the XML element `AspectClasses` as long as the object class property `ShortName` is available for the object class. The object classes `Brand`, `CustomerSegment`, `Market`, and `SalesChannel` are specified per default.

  Please note the following:

  - The object class property `ShortName` is required in order to visualize the operational aspects in a very small attributes box in cells in business support matrices. Please note that the short name should consist of only 2 or 3 letters.

  - Custom selectors may be configured for operational aspect classes that will be defined in the *Measure Types Page View*. For each <Class:Stereotype> defined in the XML element `AspectClasses` in the XML object ***ITMapDef***, a menu option will be generated in the **New** menu in the *Measure Types Page View*. The custom selector specified in the class setting of the respective object class or object class stereotype will open when the user clicks the menu option.

  - Depending on the object classes that may be specified as operational aspects, the following functionalities must be available to the relevant user profiles for which creating operational aspects shall be permissible:

    - *Capture Brands Functionality* (`BRND_CaptureBrands`)
    - *Capture Customer Segments Functionality* (`CSGM_CaptureCustomerSegments`)
    - *Capture Markets Functionality* (`MRKT_CaptureMarkets`)
    - *Capture Sales Channels Functionality* (`SCHNL_CaptureSalesChannels`)

- For a methodological overview of implementing operational aspects, see the section *Business Model Definition* in the reference manual *IT Planning Basic*.

- `BluePrintBColor`: Define the background color for the matrix objects in a blueprint map displayed on the business support matrices. The value entered should be a Windows, Web, hexadecimal, or RGB color value. The default value is "`Blue`".

- `BluePrintFColor`: Define the font color for the matrix objects in a blueprint map displayed on the business support matrices. The value entered should be a Windows, Web, hexadecimal, or RGB color value. The default value is "`Gold`".

4) Create an XML element `ClassEntry` for each object class that may be displayed on the X-axis or Y-axis (`Process`, `Domain`, `OrgaUnit`, or `MarketProduct`) of a business support matrix as well as for each object class that may be business support provider (`Application`, `OrgaUnit`, `ICTObject`, or `VirtualICTObject` displayed in a business support matrix. Please note that the class `OrgaUnit` should only be specified once. Specify the following XML attributes below the XML element `ClassEntry` as needed:

- `ClassName`: Mandatory: Specify the class name of the object class that shall be displayed in standard business support matrices. You may create an XML attribute `ClassName` for the following object classes: `Process`, `Domain`, `OrgaUnit`, `MarketProduct`, `Application`, `ICTObject`, or `VirtualICTObject`.

  The XML attribute `ClassName` may not be edited!

- `ShowProps`: This attribute can only be configured for the object classes `BusinessProcess`, `Domain`, `OrgaUnit`, and `MarketProduct`. Enter a comma-separated list of object class properties that should be displayed on the axis objects for the respective object class. The default settings for the object class properties for business processes or domains include the name (`Name`) of the object as well as the level ID number (`LevelIDNum`) that indicates its position in the respective process/domain hierarchy.

  The definition in the XML attribute `ShowProps` will also be applied to the *Business Process/Domain-Based Schedule Report Page View* (`ITMPM_Process-Based_ScheduleReport`) and *Organization/Market Product-Based Schedule Report Page View* (`ITMPM_OrganizationBased_ScheduleReport`).

- `SortProps`: This attribute can only be configured for the object classes `BusinessProcess`, `Domain`, `OrgaUnit`, and `MarketProduct`. Enter a comma-separated list of one or more object class properties that should be used to order the axis objects in the matrix. The default settings for the object class properties orders organizations and market products by name and orders business processes or domains by the level ID number (`LevelIDNum`).

  Please note that if the XML attribute `SortProps` is defined for an object class, the sorting will occur automatically, and manual sorting by the user will not be possible. If users shall be allowed to manually reorder the axis objects for an object class via the **Axes Quick Editor** available in the **Business Support Map** page views, you must ensure that NO values have been defined for the XML attribute `SortProps` for the relevant object class. If the XML attribute `SortProps` is defined for all matrix object classes, the **Axes Quick Editor** will be disabled in all relevant views.

- `Picture`: Specify the icon to display on the matrix objects for the object class specified in the XML attribute `ClassName`. Please note the order of priority for determining the icon displayed on matrix objects:

  1) Object class definition
  2) Class setting definition
  3) XML object ***ITMapDef*** definition
  4) Default specification of presentation object.

5) Create an XML element `Relevance` to define the values available for selection in the **Relevance Group** filter available in the **Business Support Map Options** editor in the business support matrices. The relevance values serve to filter out information that does not have enough relevance to be included in the business support maps. Alfabet users can select the minimum value that should be displayed in the business support matrix. All elements with a relevance value equal to or higher than the selected value will be displayed in the matrix. Specify the following XML attributes below the XML element `Relevance` as needed:

   - `Values`: In a comma-separated list, enter the possible values that can be selected in the **Relevance Group** filter.
   - `IsActive`: Enter "`true`" if the **Relevance Group** filter should be enabled. Enter "`false`" if the **Relevance Group** filter should NOT be enabled. If the filter is not enabled, a relevance group cannot be defined standard business support matrices. The default is "`true`".

6) Create an XML element `BusinessAppraisalDef` to define an indicator to visualize on the business appraisal object in business support matrices. Specify the following XML attributes below the XML element `BusinessAppraisalDef` as needed:

   - Enter the name of one indicator type that shall be visualized on the business appraisal matrix object.

     The indicator type must be assigned to the object class **Business Appraisal** in the **Class Configuration** functionality. An icon gallery must be assigned to the indicator type in order to visualize a value. For more information, see the section *Configuring Evaluation Types* in the reference manual *Configuring Evaluation and Reference Data in Alfabet*.

7) In the toolbar, click the **Save** button to save the XML definition.

Configuring Gantt Charts

The XML object ***SolutionOptions*** allows you to define whether the current date is considered in Gantt charts when the view is opened.

To edit the XML object ***SolutionOptions***:

1) Go to the **Presentation** tab and expand the **XML Objects** folder.
2) Right-click the XML object ***SolutionOptions*** and select **Edit XML**. The XML editor is displayed in the center pane. For general information about editing XML objects in Alfabet Expand, see Working with XML Objects.
3) In the XML attribute `GanttTodayScroll`, enter "`true`" the current date should be positioned so that it is quite visible in the Gantt chart when the view is opened.). Enter "`false`" if the Gantt chart should be displayed with no consideration to the current date. For the sake of backward capability, the default value "`false`" will be set for the XML attribute `GanttTodayScroll`.
4) In the XML attribute `UseFiscalYearCalendarInGantt`, specify "`true`" to display the quarters and years based on the configured fiscal calendar.
5) In the toolbar, click the **Save** button to save the XML definition.

Configuring Cost Management Capabilities

The XML object ***CostManagerDef*** allows you to define the visibility and editability of cost definition types associated with cost centers, projects, and architecture objects. Furthermore, you can specify parameters for the fiscal year for your enterprise. The XML object ***CostManagerDef*** must be configured in order to work with costs in the following Alfabet page views:

Object Class	Page View
Application	*Consolidated Operational Expenses Page View* *Operational Expenses Page View*
Deployment	*Operational Expenses Page View*
ICT Object	*Operational Expenses Page View*
ICT Object Group	*Operational Expenses Page View* *Cost Aggregation Page View*
ICT Object Category	*Operational Expenses Page View* *Cost Aggregation Page View*

Object Class	Page View
Organization	*Operating Expenses Page View* *Business Support Costs Hierarchy Page View*
Business Process	*Business Support Costs Hierarchy Page View* *Business Support Costs Page View* *Business Service Costs Page View* *Cost Benchmarking Page View*
Business Support	*Cost Benchmarking Page View*
Business Capability Map	*Business Capability ICT Cost Report Page View*
Project	*Cost Report Page View* *Cost Accrual Page View* *Business Case Page View* *Business Case Comparison Page View* *Project, Skill Request and Resource Request Time Schedule Page View* *Cash Out Planning Page View*
Bucket	*Cost Accrual Page View*
Cost Center	*Cost Accruel Page View*
Cost Center Group	*Cost Aggregation Page View*

For an overview of various methodologies to manage costs for architecture objects in Alfabet, see the sections *OPEX Optimization* and *Cost Driver Analysis* in the reference manual *Portfolio Management Advanced*.

The currency and currency units displayed on all page views and editors in which costs are captured and visualized is configured in the **Reference Data** functionality. For more information about the configuration of currencies, see the chapter *Configuring Currencies and Currency Exchange Rates for Cost Management Capabilities* in the reference manual *Configuring Evaluation and Reference Data in Alfabet*. The cost types required for the capture and analysis of costs are configured in the **Configuration** functionality. For more information, see the chapter

Configuring Cost Types and Income Types for Cost Management Capabilities reference manual *Configuring Evaluation and Reference Data in Alfabet*.

For more information about defining various cost aspects in the XML object ***CostManagerDef***:

- Configuring the Calculation of Business Support Costs
- Configuring the Editability of Costs in Cost Centers
- Configuring the Editability of Costs for Architecture Objects
- Specifying Quarterly or Monthly Budgeting for Cashout Planning
- Configuring the Default Values for Business Case Definitions
- Configuring the Fiscal Year for Cost Reporting in Your Enterprise

Configuring the Calculation of Business Support Costs

In the XML object ***CostManagerDef***, you can specify the means to calculate business support costs for a business process. You can specify whether the cost calculation includes the costs of the business services that the business support uses or if the calculation of the business support costs for a business process is based only on the costs of the business support.

To edit the XML object ***CostManagerDef***:

1) Go to the **Presentation** tab and expand the **XML Objects** folder.
2) Right-click the XML object ***CostManagerDef*** and select **Edit XML**. The XML editor is displayed in the center pane. For general information about editing XML objects in Alfabet Expand, see Working with XML Objects.
3) Specify the XML attribute `BusinessSupportServiceCosts`. Enter "`true`" if the calculation of business support costs for a business process includes the costs of the business services that the business support uses. Enter "`false`" if the calculation of the business support costs for a business process is based only on the costs of the business support.
4) In the toolbar, click the **Save**  button to save the XML definition.

Configuring the Editability of Costs in Cost Centers

Cost centers allow costs for applications, deployments, ICT objects, networks, service products, and projects to be grouped and the costs assigned to the cost center to be distributed to the objects in the group according to a defined allocation scheme. The costs are then visible in the standard Alfabet views for viewing or editing the object's costs.

In Alfabet, cost planning is based on user-defined cost types (for example, maintenance costs, license fees, man hours). Cost centers and cost types are configured in the **Configuration** functionality. For more information about configuring cost centers and cost types, see sections *Configuring Cost Centers for Cost Management Capabilities* and *Configuring Cost Types and Income Types for Cost Management Capabilities* in the reference manual *Configuring Evaluation and Reference Data in Alfabet*.

Costs are definable for each cost type per year. For cost planning within a time period, different cost definition types can be specified. The possible cost definition types available in Alfabet are:

- `Request`: The amount of money foreseen to be spent on the project or architecture object for the given cost type and time period. This information is relevant for budget planning to evaluate demand.
- `Budget`: The amount of money assigned to the project or architecture object for the given cost type and time period in budget planning. Please note that the value `Commited` is written to the `MonetaryID` column in the `BudgetValue` database table for the `Budget` cost definition type. This is particularly relevant for the import of costs via the data capture template functionality. For more information, see the section *Configuring a Cost-Based Data Capture Template* in the reference manual *User and Solution Administration*.
- `Current`: The costs already spent on the project or architecture object for the given cost type and time period.
- `Obligation`: The costs that are committed for the object (for example, money to be spent on contracts already signed or bills received but not paid for yet). This cost definition type is only relevant if the cash-out planning capability (*Cash Out Planning Page View*) is implemented for projects.
- `Forecast`: Costs that are not yet committed for the period but are already known to be due at the time period. This cost definition type is only relevant if the cash-out planning capability (*Cash Out Planning Page View*) is implemented for projects.

By default, only the current costs will be editable in a cost center. Cost requests and budgeting is done outside of cost centers. The default setting can be altered in the XML object ***CostManagerDef***. The visibility and editability of the different cost definition types can be defined separately. You can define, for example, that cost requests cannot be edited on the **Cost Accrual** page view of a cost center but that they are nevertheless visible in the view.

If you change the settings for cost center costs in the XML object ***CostManagerDef***, you should also adapt the settings for the editability and visibility of cost definition types in the cost views available for the architecture objects. Please note that if you define a cost definition type as editable in a cost center, it should NOT be editable in the cost views available for the architecture objects. **Any values that are edited in the cost views available for the architecture objects will overwrite the values assigned to the architecture object via the cost allocation defined for the cost center.**

To edit the XML object ***CostManagerDef***:

1) Go to the **Presentation** tab and expand the **XML Objects** folder.
2) Right-click the XML object ***CostManagerDef*** and select **Edit XML**. The XML editor is displayed in the center pane. For general information about editing XML objects in Alfabet Expand, see Working with XML Objects.
3) The default settings of the XML object ***CostManagerDef*** are displayed in the XML editor. The definition of costs for cost centers is defined in the XML element ***CostCentreCosts***, which contains one XML element ***CostColumn*** for each kind of cost definition (`Request`, `Budget`, `Current`, and `Obligation`).

   Define the visibility and editability of the cost definition types, as needed. The table below displays the attributes that can be edited for the XML element ***CostColumn***:

XML Element	Explanation
CostColumn	Specify one XML element `CostColumn` for each kind of cost definition (`Request`, `Budget`, `Current`, and `Obligation`) that should be available for cost centers. The cost definition `Forecast` is only relevant if the cash-out planning capability (*Cash Out Planning Page View*) is implemented for projects.
Type	The cost column types that are available for cost centers are `Request`, `Budget`, `Current`, and `Obligation`. The XML attribute `Type` defines which cost column type is configured with the XML element ***CostColumn***.
Visible	Enter "`true`" for a cost definition type that should be displayed in Alfabet views for cost centers. Enter "`false`" if the cost definition type should not be displayed in the views.
Editable	Enter "`true`" if the costs for a cost definition type should be editable in the *Cost Accrual Page View* of cost centers. Enter "`false`" if the costs in the column should not be editable in the relevant Alfabet page views.

4) In the toolbar, click the **Save** button to save the XML definition.

Configuring the Editability of Costs for Architecture Objects

In Alfabet, cost planning is based on user-defined cost types (for example, maintenance costs, license fees, man hours). Costs can be captured for applications, deployments, ICT objects, networks, service products, and projects per year. In the case of projects and buckets, costs can be captured on a monthly or quarterly basis via the *Cash Out Planning Page View* (`PRJ_Cashout`).

Cost types are configured in the **Configuration** functionality. For more information about configuring cost types, see chapter *Configuring Cost Types and Income Types for Cost Management Capabilities* in the reference manual *Configuring Evaluation and Reference Data in Alfabet*.

Costs are definable for each cost type per year. For cost planning within a time period, different types of cost definitions can be specified. The visibility and editability can be defined for the following cost definitions:

- `Request`: The amount of money foreseen to be spent on the project or architecture object for the given cost type and time period. This information is relevant for budget planning to evaluate demand.
- `Budget`: The amount of money assigned to the project or architecture object for the given cost type and time period in budget planning. Please note that the value `Commited` is written to the `MonetaryID` column in the `BudgetValue` database table for the `Budget` cost definition type. This is particularly relevant for the import of costs via the data capture template functionality. For more information, see the section *Configuring a Cost-Based Data Capture Template* in the reference manual *User and Solution Administration*

- `Current`: The costs already spent on the project or architecture object for the given cost type and time period.
- `Obligation`: The costs that are committed for the object (for example, money to be spent on contracts already signed or bills received but not payed for yet. This cost definition type is only relevant if the cash-out planning capability (*Cash Out Planning Page View*) is implemented for projects.

  Please note that the `Obligation` cost definition is a core concept for cash-out planning in projects. Therefore, the `Obligation` cost definition will be displayed in the context of the *Cash Out Planning Page View* regardless of whether it is configured in the XML object ***CostManagerDef***. In other words, if you specify that the `Obligation` cost definition should not be visible in the XML object ***CostManagerDef***, it will nevertheless be visible in the *Cash Out Planning Page View*.

- `Forecast`: Costs that are not yet committed for the period but are already known to be due at the time period. This cost definition type is only relevant if the cash-out planning capability (*Cash Out Planning Page View*) is implemented for projects.

By default, cost requests and budget costs are editable directly in the Alfabet views available for object costs. However, please note that per default, the current costs are not editable for object costs but are allocated to the object via a cost center. This default setting can be altered in the XML object ***CostManagerDef***.

If you change the settings for costs for architecture objects in the XML object ***CostManagerDef***, you should also adapt the settings for the editability and visibility of cost definition types in the Alfabet views available for cost centers.

Please note that if you define a cost definition type as editable in a cost center, it should NOT be editable in the cost views of the architecture objects. **Values edited in the cost views of the architecture objects overwrite the values assigned to the architecture object via the cost center cost allocation.**

You can explicitly configure the visibility and the editability of the different cost definition types in the XML object ***CostManagerDef***. For example, the current costs assigned to the object via cost center cost allocation might be configured to be visible in the Alfabet views available for object costs, but to not be editable in those views.

Please note that individual menu options (**Edit Current**, **Edit Budget**, **Edit Request**, etc) will be available for each visible cost definition type in the **Costs** menu in the *Operational Expenses Page View* (`ObjectOperatingCosts`) available in the object profiles for the object class **Application**, **Deployment**, **ICT Object**, **Network**, and **Service Product** as well as the *Cost Accrual Page View* (`PRJ_Costs`), *Cash Out Planning Page View* (`PRJ_Cashout`) available in the object profile for the class **Project**.

These menu options can be hidden for a user profile, thus allowing you to specify which user profiles may edit current costs, request costs, etc. Please note that if the XML attribute `Forecast` is set to `true` for the XML element `Editable`, for example, you should ensure that the menu option **Edit Forecast** is not visible in the *Operational Expenses Page View* (`ObjectOperatingCosts`) available in the object profiles for the object class **Application**, **Deployment**, **ICT Object**, **Network**, and **Service Product** or the *Cost Accrual Page View* (`PRJ_Costs`). For more information about hiding functionalities for a user profile, see the section Hiding Functionalities in a Page View or Configured Report.

To edit the XML object cost column type:

1) Go to the **Presentation** tab and expand the **XML Objects** folder.
2) Right-click the XML object ***CostManagerDef*** and select **Edit XML**. The XML editor is displayed in the center pane. For general information about editing XML objects in Alfabet Expand, see Working with XML Objects.
3) The default settings of the ***CostManagerDef*** XML object are displayed in the XML editor.
4) Cashout planning may be executed on a quarterly or monthly basis. To specify quarterly or monthly planning for cashout planning, add the XML attribute `DetailedFinancialPlanningPeriod` as a child of the root element ***CostManagerDef***. Enter "`Month`" if the cashout planning shall occur on a monthly basis. Enter "`Quarter`" if the cashout planning shall occur on a quarterly basis.
5) The definition of costs for applications, deployments, ICT objects, networks, service products, and projects is defined in the XML element ***ArchitectureCosts***, which contains one element ***CostColumn*** for each kind of cost definition (`Request`, `Budget`, `Current`, `Obligation`, and `Forecast`).

   Define the visibility and editability of the cost definition types, as needed. The table below displays the attributes that can be edited for the elements ***CostColumn***:

XML Element	Explanation
`Type`	Specify one XML element `CostColumn` for each kind of cost definition (`Request`, `Budget`, `Current`, `Obligation` and `Forecast`) that should be available for architecture objects. The cost definition `Forecast` is only relevant if the cash-out planning capability (*Cash Out Planning Page View*) is implemented for projects.
`Visible`	Enter "`true`" for a cost definition type that should be displayed in the relevant Alfabet views for architecture object costs. Enter "`false`" if the cost definition type should not be displayed in the relevant Alfabet views for architecture object costs.
`Editable`	Enter "`true`" if the costs for a cost definition type should be editable in the relevant Alfabet views for architecture object costs. Enter "`false`" if the costs in the column should not be editable in the relevant Alfabet views for architecture object costs. **NOTE**: If you enter "`true`" for a cost definition, the relevant menu option (**Edit Current**, **Edit Budget**, **Edit Request**, etc) will be available for each visible cost definition type in the **Costs** menu in the *Operational Expenses Page View* (`ObjectOperatingCosts`) available in the object profiles for the object class **Application**, **Deployment**, **ICT Object**, **Network**, and **Service Product** as well as the *Cost Accrual Page View* (`PRJ_Costs`), *Cash Out Planning Page View* (`PRJ_Cashout`) available in the object profile for the class **Project**. This can be hidden for relevant user profiles. For more information about hiding functionalities for a user profile, see the section Hiding Functionalities in a Page View or Configured Report. **NOTE**: If cost accrual is to be captured in the object class `CostCentre`, the current costs for architecture objects should not be editable. In this case, enter "`false`" for the cost column type representing current costs.

6) In the toolbar, click the **Save** button to save the XML definition.

Specifying Quarterly or Monthly Budgeting for Cashout Planning

n the case of projects and buckets, cashout planning may be executed on a quarterly or monthly basis *Cash Out Planning Page View* (`PRJ_Cashout`). Cashout planning may be executed on a quarterly or monthly basis.

Please note that the decision about whether to specify the values `Month` or `Quarter` must occur before cashout planning is carried out in the Alfabet user interface. It is not possible to switch between monthly and quarterly planning and aggregate or divide existing costs.

Please note the following configuration requirements:

- Cost types must be configured in the **Reference Data** functionality. For more information, see the chapter *Configuring Cost Types and Income Types for Cost Management Capabilities* in the reference manual *Configuring Evaluation and Reference Data in Alfabet*.
- Currencies must be configured in the **Reference Data** functionality. For more information, see the section *Configuring Currencies and Currency Exchange Rates for Cost Management Capabilities* in the reference manual *Configuring Evaluation and Reference Data in Alfabet*.
- The relevant cost definition types (**Request**, **Budget**, **Current**, etc), default values for business cases, and the specification of the fiscal year must be configured by your solution designer in the configuration tool Alfabet Expand. For more information, see the section Configuring the Editability of Costs for Architecture Objects in the reference manual *Configuring Alfabet with Alfabet Expand*.
- The start and end of the fiscal year. Thus, if the fiscal year specified for an enterprise starts on April 1st, the monthly calendar for 2015 will start with April 2015 and finish with March 2016. For more information about configuring the fiscal year, see the section Configuring the Fiscal Year for Cost Reporting in Your Enterprise in the reference manual *Configuring Alfabet with Alfabet Expand*.

To edit the XML object ***CostManagerDef***:

1) Go to the **Presentation** tab and expand the **XML Objects** folder.
2) Right-click the XML object ***CostManagerDef*** and select **Edit XML**. The XML editor is displayed in the center pane. For general information about editing XML objects in Alfabet Expand, see Working with XML Objects.
3) Add the XML attribute `DetailedFinancialPlanningPeriod` as a child of the root element ***CostManagerDef***. Enter "`Month`" if the cashout planning shall occur on a monthly basis. Enter "`Quarter`" if the cashout planning shall occur on a quarterly basis.
4) In the toolbar, click the **Save** button to save the XML definition.

Configuring the Default Values for Business Case Definitions

The following formulas are used to calculate business cases in Alfabet:

Formula for Net Cash Flow for year i (NCFi)

$$NCF_i = (INCOME_i - COST_i) * (1 - TaxRate)$$

Formula for Discounted Cash Flow (DCF), whereby i = year and COC = Cost of Capital

$$DCF = \sum_{i=0}^{n} \frac{NCF_i}{(1+COC)^i}$$

Formula for Overall Budget (OB)

$$OB = \sum_{i=0}^{n} COST_i$$

Formula for Relative Discounted Cash Flow (RDCF)

$$RDCF = \frac{DCF * 100}{OB}$$

The XML object ***CostManagerDef*** allows the default values in business cases to be defined. The default values defined here are displayed in the *Business Case Page View* (`PRJ_BusinessCase`) available for all project stereotypes configured for the project planning capability as well as for example, the **Spend Limit** editor available for buckets.

A **Business Case** page view (`PRJ_BusinessCaseSimple`) is available as an alternative to the standard **Business Case** page view (`PRJ_BusinessCase`) that allows project costs and income to be calculated without the inclusion of a tax rate, interest rate, discounted cash flow, or amortization time.

Please not that the period of the business case should not only focus on the cost incurred during the project execution, but should also factor in cost incurred for operation, maintenance and management of forthcoming projects/project scenarios or changes to existing projects/project scenarios. Typically the business case period should be at least 3 years, although more mature organizations might define a period of 5 or 7 years. Please note that individual projects can still define business cases with a shorter period. In this case, users would simply leave the periods beyond the project scope undefined.

For more information about configuring the project planning capability, see the section Configuring the Project Management Capability.

To edit the XML object ***CostManagerDef***:

1) Go to the **Presentation** tab and expand the **XML Objects** folder.
2) Right-click the XML object ***CostManagerDef*** and select **Edit XML**. The XML editor is displayed in the center pane. For general information about editing XML objects in Alfabet Expand, see Working with XML Objects.
3) Define the XML attributes, as needed. The table below displays the XML elements and XML attributes that can be edited for the XML object ***CostManagerDef***:

XML Element (bold) / XML Attribute	Explanation
BusinessCaseDef	
`Period`	**NOTE**: Changes made to the `Period` attribute will only be applied to business cases created after the modification to the `Period` attribute. Existing business cases will retain their definitions. Starting with the current year, enter an integer to define the number of years for which the cost types and income types are to be calculated in the business case.
`TaxRate`	Enter an integer as the default value for the tax rate. The value is a percentage. For example, enter 10.5 for 10.5%.
`CostOfCapital`	Enter an integer as the default value for the capital interest rate. The value is a percentage. For example, enter 30 for 30%.

4) In the toolbar, click the **Save**  button to save the XML definition.

Configuring the Fiscal Year for Cost Reporting in Your Enterprise

The XML object ***CostManagerDef*** allows you to define the fiscal year as determined by your enterprise. The fiscal year is based on the start year of the project.

To edit the XML object ***CostManagerDef***:

1) Go to the **Presentation** tab and expand the **XML Objects** folder.
2) Right-click the XML object ***CostManagerDef*** and select **Edit XML**. The XML editor is displayed in the center pane. For general information about editing XML objects in Alfabet Expand, see Working with XML Objects.
3) Define the XML attributes, as needed. The table below displays the XML elements and XML attributes that can be edited for the XML object ***CostManagerDef***:

XML Element (bold) / XML Attribute	Explanation
FiscalYearDef	
`Day`	Enter an integer for the first day of your company's fiscal year. For example, if the first day is the first day of a specific month, enter 1.

XML Element (bold) / XML Attribute	Explanation
`Month`	Enter an integer for the first month of your company's fiscal year. For example, if the first month is September, enter 9.
`YearOffset`	You must enter either `0` or `1` to define the year for the fiscal year. The fiscal year is based on the start year of the project. For example, If the start year of the project is `2020`, the XML attribute `Day` is 1, and the XML attribute `Month` is 9: • If you define `0` for the XML attribute `YearOffset`, the fiscal year `2020` begins in September `2020` and concludes by the end of August `2021`. • If you define `1` for the XML attribute `YearOffset`, the fiscal year `2020` begins in September `2019` and concludes by the end of August `2020`.  For example, if the project start date is 05.06.2018 and end date is 07.10.2019: • If `Day` = "1", `Month` = "9" and `YearOffset` = "0", then the years 2017, 2018 and 2019 will be listed in the **Fiscal Year** filter field in the **Cash Out Planning** page view for the project. • If `Day` = "1", `Month` = "9" and `YearOffset` = "1", then the years 2018, 2019 and 2020 will be listed in the **Fiscal Year** filter field in the **Cash Out Planning** page view for the project.

4) In the toolbar, click the **Save**  button to save the XML definition.

Configuring the Permissibility of Files and Web Links in Alfabet

You can specify the file extensions that may be uploaded and downloaded from the **Internal Document Selector** as well as the linkage of documents stored in an external file system as well as specify the default prefix for URLs can be specified in order to direct the navigation. Documents can be downloaded and attached from the **Internal Document Selector** as well as an external file system by users via the *Attachments Page View*. Web links (URLs) can also be attached to an object in the *Attachments Page View*.

Apart from the configured permissability, there is a general file content size restriction for ZIP file upload. ZIP files are checked during update for the size of content after decompression. The file will not be uploaded if the decompressed size is more than 100 percent of the compressed size or if storing the file content on the local drive would result in less than 1 GByte free space remaining or if any deviations from normal compression mechanisms are detected.

The following information is available:

- Specifying the Permissible File Extensions for Uploading/Downloading Files
- Configuring Default URL Prefixes for the Attachments Page View
- Configuring Files on a Network Drive as Attachments

Specifying the Permissible File Extensions for Uploading/Downloading Files

For security reasons, a blacklist and whitelist concept is available to restrict the uploading and downloading of files with permissible file extensions. This is relevant for the **Internal Document Selector** as well as the linkage of documents stored in an external file system. File extensions can be specified in a blacklist as not permissible for uploading and downloading. Alternatively, a whitelist can be configured that explicitly and exclusively allows specified file extensions for upload and download. The whitelist is optional and will be disabled per default. A file extension specified in the blacklist will supersede the same file extension specified in the whitelist so that if a file extension is listed in both the whitelist and in the blacklist, it will not be possible to upload or download files with the specified file extension.

A default blacklist is specified in the XML attribute `Blacklist` in the XML object ***FileExtensionLists***. For example, the default blacklist includes the file formats SVG, HTML, and WSDL. It is recommended that SVG files are available only if they have been generated in the Alfabet Web application. If your enterprise should prefer to use any of these file formats, you should remove them from the XML attribute `Blacklist`.

Please note that

Please note that the following file types cannot be opened directly in Alfabet and will be automatically saved and downloaded as a ZIP file even if not defined in the blacklist or additionally defined in the whitelist: .com, .bat, .exe,.ad, .adprototype, .asax, .ascx,.ashx, .asmx, .asp, .aspx, .axd, .browser, .cd, .compiled, .config, .cs, .csproj, .dd, .exclude, .java, .jsl, .ldb, .ldd, .lddprototype, .ldf, .licx, .master, .mdb, .mdf, .msgx, .refresh, .rem, .resources, .resx, .sd, .sdm, .sdmDocument, .sitemap, .skin, .soap, .svc, .vb, .vbproj, .vjsproj, .vsdisco, and .webinfo.

The file extensions for the blacklist and the whitelist are configured in the XML object ***FileExtensionLists*** that is available both in Alfabet Expand and in the Alfabet Administrator. The XML object has the following XML structure:

```
<FileExtensionLists>
```

```
<ExtensionLists>
    <WhiteList IsEnabled="false">
        <Extension>.xls</Extension>
        <Extension>.xlsx</Extension>
        [...]
    </WhiteList>
    <BlackList>
        <Extension>.exe</Extension>
        <Extension>.bat</Extension>
        [...]
    </BlackList>
</ExtensionLists>
</FileExtensionLists>
```

To configure the XML object ***FileExtensionLists***:

1) Go to the **Presentation** tab and expand the **XML Objects** folder and the **Administration** folder.
2) Right-click the XML object ***FileExtensionLists*** and select **Edit XML**. The XML editor is displayed in the center pane. For general information about editing XML objects in Alfabet Expand, see Working with XML Objects. The following is possible:
   - To enable the whitelist, the XML attribute `IsEnabled` of the XML element `WhiteList` must be set to `true`.
   - To add a file extension to the whitelist, a new child XML element `Extension` with the definition of the file extension starting with a period (.) has to be added to the `WhiteList` or `BlackList` element respectively.
   - To add a file extension to the blacklist or to the whitelist, a new child XML element `Extension` with the definition of the file extension starting with a period (.) has to be added to the `WhiteList` or `BlackList` element respectively.
3) Click the **Save** button to save the definition.

Configuring Default URL Prefixes for the Attachments Page View

The *Attachments Page View* as well as the **Notification Assignment** editor available via the **Notify Authorized User** button allows users to attach documents or Web links (URLs) to an object. When users define a Web link, an editor opens in which users can enter the link address in a **URL** field. Per default, the prefix displayed in this field is: `http://www.`

For more information about the general configuration required to implement the **Notify Authorized User** button, see the section Configuring the Display of the Notify Authorized User Button for Assignment Creation.

The default prefix can be changed in Alfabet Expand if, for example, you want the URLs to navigate to a corporate content management solution such as Microsoft® SharePoint®. The prefix will be automatically

displayed in the field and users can enter the remaining Web address. The prefix can be changed in the **URL** field by the user, if necessary.

To define a prefix for the URL editor:

1) Go to the **Meta-Model** tab, expand the **Class Model** node, expand the **Classes** node, and click the `ALFA_URI` class node.
2) Expand the `PROPERTIES` node and click the object class property `LINK`. In the **Default Value** attribute in the attribute window, enter the URL prefix
3) Click the **Save** button to save the definition.

Configuring Files on a Network Drive as Attachments

The file selector `ALFA_URI_OLD` may be configured for the *Attachments Page View* that allows the target file to be selected from the network drive. The file selector `ALFA_URI_OLD` must be specified for the **Edit View** attribute of the class setting `ALFA_URI`. The local directory path must be enabled as a trusted site for the relevant browser and must run under HTTPS protocol.

The following browsers support opening the files via the Web link definition in Alfabet: Microsoft® Internet Explorer® 11.0 and Microsoft® Edge® in conjunction with Windows® 10. Mozilla® Firefox® 24.0 or higher including Mozilla® Firefox® Quantum are also supported but require additional configuration in the browser settings.

Configuring Dynamic Web Links That Users Can Access

The XML object ***WebViewManager*** allows you to configure dynamic web links that users can access in the *Dynamic Web Links Page View* of the relevant object classes.

Dynamic web links reference applications that are accessible via a URL. The dynamic web link references a specific location in the application, allowing you to access information in the application that is relevant to the object that the user is currently working with in Alfabet.

For example, a dynamic web link could be used in the following instances:

- To retrieve information about a selected organization in a human resources management tool.
- To retrieve cost information about a selected ICT object in an application like SAP Business Warehouse that documents cost information about the selected object.
- To retrieve information about a selected application in your enterprises's central help desk system.
- To retrieve data about a selected information flow in a document describing interface contacts in a document management system.

Next to being available in the *Dynamic Web Links Page View* page view of the relevant object class, dynamic web links can also be added to the following views:

- Dynamic web links can also be specified in value controls in object cockpits. To embed the dynamic web link in the object cockpit, a value control must be created, whereby the

Subtype attribute is set to the new `DynamicWebLink` option. All dynamic web links defined for the object class or object class stereotype of the object cockpit that have been configured in the XML object ***WebViewManager*** will be available for selection in the **Web Link** attribute of the object cockpit. At runtime, the dynamic web link will only be displayed if the object class and object class stereotype match the definition in the XML object ***WebViewManager***. For more information about configuring dynamic web links in object cockpits, see the section Adding a Dynamic Web Link to the Object Cockpit.

- Dynamic web links can be added to configured reports via an Alfabet instruction. The instruction will add an **Open Web Link** button to the report that opens the dynamic web link for the object selected in the configured report via a sub-menu option. In addition to the button interaction, the link can be opened via the **Operations** button in the object preview window. For more information about configuring dynamic web links in configured reports, see the section Adding Dynamic Web Links to a Configured Report.

To edit the XML object ***WebViewManager***:

1) Go to the **Presentation** tab and expand the **XML Objects** folder.
2) Right-click the XML object ***WebViewManager*** and select **Edit XML**. The XML editor is displayed in the center pane. For general information about editing XML objects in Alfabet Expand, see Working with XML Objects.
3) Define the XML attributes, as needed. The table below displays the XML elements and XML attributes that can be edited for the XML object ***WebViewManager***:

XML Element (bold) / XML Attribute	Explanation
WebViewDef	
`Caption`	Enter text to define the caption to be displayed as a header for the group of dynamic web links. For example, Business Intelligence Reports. The values defined for the XML elements `Caption` in the XML object ***WebViewManager*** will be extracted to the vocabularies so that dynamic web links can be rendered in the language specified for the Alfabet user interface.
`Class Names`	Enter a comma-separated list of object class names for which the dynamic web link(s) should be available. Each dynamic web link defined in the XML element ***WebViewDef*** will be available in the *Dynamic Web Links Page View* for all objects belonging to the object classes defined here. You must enter the technical name of the object class.

XML Element (bold) / XML Attribute	Explanation
	Dynamic web links can be limited to a specific object class stereotype. To this end, object class stereotypes can be specified in the XML element `ClassNames` in the XML object ***WebViewManager***. (For example: `ClassNames="Device:Cumulocity Device`).
WebLinkDef	
`Caption`	Enter text to define the caption to be displayed for the dynamic web link.

`HRef`	Enter the URL that should be invoked when a user clicks the dynamic web link. The construction rule for the URL is:
	`http://(AddressToApplication)/[NameOfReport]?Target={PropertyNames}`
	where `{PropertyName}` is a placeholder for the current object's value of the object class property with the defined name. Please note that this object class property must be defined in the XML attribute PropNames of the dynamic web link to use it as a placeholder in the XML attribute `HRef`. Each placeholder can only return one object class property. Multiple placeholders can be used in the URL definition.
	The dynamic web link will not be displayed in the *Dynamic Web Links Page View* of objects if the object class property specified for the placeholder `{PropertyNames}` has no value defined.
	f the Web link contains a special character according to XML standards (for example: &, %, ;,<,>), these characters must be replaced by their XML conformant variant (for example: & for &)
	Below is an example of a typical URL for a dynamic web link in Alfabet. In the `HRef` attribute, the placeholders {`Name`} and {`Version`} are used. When a user will open the dynamic web link for an object, the placeholders will be replaced with the name and version of the current object that the dynamic web link is associated with.
	`HRef=http://localhost/Reports/ApplicationsReport.aspx?Target={Name}&Version={Version}`
	It is possible to specify part or all of the `HRef` definition in the server alias configuration as a server variable and reference the appropriate server variable in the `HRef` definition.

XML Element (bold) / XML Attribute	Explanation
PropNames	Enter a comma-separated list of object class properties used in the specification of the reference URL defined above. You must enter the name of the object class property. In the example HRef=http://localhost/Reports/OrganizationReport.aspx?Target={Name}&Version={Version}, you would enter Name,Version for the XML attribute PropNames.
Target	Enter text to define the target browser window that is opened when the URL is invoked. If the Target attribute is left empty, then each dynamic web link will open in a new window.

4) In the toolbar, click the **Save** button to save the XML definition.

Using Server Variables in Dynamic Web Links

In the definition of the dynamic Web link in the XML object ***WebViewManager***, you can include the server variable definitions in the definition of the XML attribute HRef.

For example, a dynamic Web link to a report that is to be hosted on the company Web server is first tested on a test Web server. Therefore, the following Web server variables would be defined in the alias configuration of the Alfabet Server:

- WEBSERVER, specifying the Web server used
- APPLICATION, specifying the virtual directory for the referenced report functionality on the Web server

The URL definition in the configuration of the dynamic Web link contains the variables instead of the current Web server name and virtual directory:

```
HRef=http://$WEBSERVER/$APPLICATION/OrganizationReport.aspx?Target={
REFSTR}
```

The definition is automatically converted to a valid link containing the values of the server variables. For example:

```
HRef=http://localhost/Reports/OrganizationReport.aspx?Target={REFSTR
}
```

The definition of server variables allows you to store information about the targets of dynamic Web links in the alias configuration of the Alfabet Server. Storing the information about the URL in the alias

configuration of the Alfabet Server instead of directly defining it in the external source configuration eases the propagation of changes.

For example, if the configuration of Alfabet is done first in a test environment and the test environment is an exact copy of the production environment except that the components are installed on different servers, then all URLs defined will be identical in the test and the production environment except for the Web server name. When migrating to the production environment, the Web server name must be changed in all URL definitions in Alfabet Expand. But if the Web server name is defined as a server variable in the alias configuration of the Alfabet Server, the configurations specified in Alfabet Expand reference the Web server name as variable in the `HRef` definitions and can be reused without changes in the production environment. Only the variable definition in the alias configuration of the Alfabet Server of the production environment must be set to the Web server definition for the production environment.

Either all or part of the URL definition for dynamic Web links can be defined in a server variable. It is also possible to build the URL from a number of concatenated server variables.

Server variables are defined in the Alfabet Administrator:

1) In the Alfabet Administrator, click the **Alfabet Aliases** node in the **Administrator** explorer.
2) In the table on the right, select the server alias that you want to define a server variable for and click the **Edit**  button. The alias editor opens.
3) Go to the **Variables** tab and click the **New** button. A dialog box opens.
4) In the **Variable Name** field, enter a unique name for the server variable.

   The server variable name may only contain letters (English alphabet), numbers, and the underscore symbol.

5) In the **Variable Value** field, enter all or part of the URL that should be the target of the Web link.

   If the Web link contains a special character according to XML standards (for example: &, %, ;,<,>), these characters must be replaced by their XML conformant variant (for example: `&` for &)

6) Click **OK** to save your changes. The server variable definition appears in the list of server variables.

   To edit or delete the server variable, select the server variable in the table and click the **Edit** or **Delete** button below the table.

7) Click **OK** to save your changes and close the editor. The server variable definition is now available in the server alias configuration and can be used for the URL definition specified in Alfabet Expand.

Configuring the Export of Views in the Alfabet Interface to HTML Files

In Alfabet Expand you can configure the styles that determine the layout of views as well as the header and footer text in the HTML files that are generated when a user exports a page view in Alfabet.

The export options available in Alfabet are described in the section *Exporting Data* in the reference manual *Getting Started with Alfabet*.

The following information is available:

- Specifying the Page Sizes Available to Export DOC and PDF Files
- Configuring the Style Sheet for the Export to HTML
- Configuring Header and Footer Text for Exported HTML Files

Specifying the Page Sizes Available to Export DOC and PDF Files

The XML object ***ExportDocumentPageSizeManager*** allows you to specify the paper size formats available in the **Export Page Setup** editor that opens when **Export** > **Microsoft Word** and **Export** > **Adobe PDF** is clicked in the toolbar available in object profiles/object cockpits and page views.

```
<ExportDocumentPageSizeManager>
   <AllPageSizes>
      <PageSizeDef Name="A4 210x297" PageWidth="210" PageHeight="297"
      Unit="Millimeter" Enabled="true" PaperKind="A4" />
      <PageSizeDef Name="A3 297x420" PageWidth="297" PageHeight="420"
      Unit="Millimeter" Enabled="true" PaperKind="A3" />
      <PageSizeDef Name="A2 420x594" PageWidth="420" PageHeight="594"
      Unit="Millimeter" Enabled="true" PaperKind="A2" />
   </AllPageSizes>
</ExportDocumentPageSizeManager>
```

To edit the XML object ***ExportDocumentPageSizeManager***:

1) Go to the **Presentation** tab and expand the **XML Objects** folder by clicking the + symbol. You will see all XML objects that can be edited.
2) Right-click the XML object ***ExportDocumentPageSizeManager*** and select **Edit XML**. The XML editor is displayed in the center pane. Edit the style sheet, as needed. For general information about editing XML objects in Alfabet Expand, see Working with XML Objects.
3) For each page size option that shall be available in the **Page Size** field in the **Export Page Setup** editor, create an XML element `PageSizeDef` as a child element of the XML element `AllPageSizes`. For each XML element, specify the following XML attributes:
   - `Name`: Specify the name for the page size. This XML attribute is mandatory. The value will be displayed in the **Page Size** field in the **Export Page Setup** editor.

- `PageWidth`: Specify an integer for the page width of the page size in the unit that you specify in the XML attribute `Unit`. This XML attribute is mandatory.
- `PageHeight`: Specify an integer for the page height of the page size in the unit that you specify in the XML attribute `Unit`. This XML attribute is mandatory.
- `Unit`:Enter either `Millimeter`, `Inch`, `Pixel`, or `Point`. This XML attribute is optional. If no value is defined, the default value `Millimeter` will be used.
- `Enabled`: Enter `True` if the page size shall be displayed in the **Page Size** field in the **Export Page Setup** editor. Enter `False` if the page size shall not be displayed in the **Page Size** field in the **Export Page Setup** editor. This XML attribute is optional. If no value is defined, the default value `True` will be used.
- `PaperKind`: Specify the kind of paper associated with the page size. For an overview of all possible values that may be specified for the XML attribute `PaperKind`, see the specification available via the **XML XSD** attribute. This XML attribute is optional. If no value is defined, the default value `Custom` will be used.

4) In the toolbar, click the **Save**  button to save the XML definition.

Configuring the Style Sheet for the Export to HTML

The XML object ***DataSetExportCss1*** allows you to configure the styles that determine the layout of views exported from Alfabet to HTML files. Standard style sheet definitions apply.

```
<style>
BODY
{
    border: none;
    background-color: White;
}

.DS_Caption
{
    font-family: "Tahoma";
    font-size: 12px;
    font-style: normal;
    line-height: 12px;
    color: Black;
    padding-left: 6px;
    height: 26px;
    background-color:White;
    border-top: "solid 1 white";
    width: 100%;
}

.DS_CaptionText
{
    text-align: left;
    vertical-align: middle;
    width: 98%;
}

.DS_Table
{
```

FIGURE: Example of a section of the styles definition in the XML object `DataSetExportCss1`

To edit the XML object ***DataSetExportCss1***:

1) Go to the **Presentation** tab and expand the **XML Objects** folder by clicking the + symbol. You will see all XML objects that can be edited.
2) Right-click the XML object ***DataSetExportCss1*** and select **Edit XML**. The XML editor is displayed in the center pane. Edit the style sheet, as needed. For general information about editing XML objects in Alfabet Expand, see Working with XML Objects.
3) Paste an existing style sheet in the <style> elements or edit the existing style sheet, as needed.
4) In the toolbar, click the **Save** button to save the XML definition.

Configuring Header and Footer Text for Exported HTML Files

The settings in the XML objects ***HTMLExportHeader*** and ***HTMLExportFooter*** allow you to determine the header and footer text in the HTML files that are generated when a user exports a page view in Alfabet.

To edit the XML object ***HTMLExportHeader*** and ***HTMLExportFooter***:

1) Go to the **Presentation** tab and expand the **XML Objects** folder.
2) Right-click the XML object ***HTMLExportHeader*** or ***HTMLExportFooter*** and select **Edit XML**. The XML editor is displayed in the center pane. In the ***HTMLExportHeader*** or ***HTMLExportFooter***, the text "powered by Alfabet" can be replaced as shown in the following example:`<p class='DS_Caption'>powered by Alfabet</p>`
3) In the toolbar, click the **Save** button to save the XML definition.

Configuring the Content Voting Capability via Object Associations

Alfabet provides a new content voting capability similar to that found in social media. The capability is configurable and can be implemented to allow users to rate, like, and identify expert users for all artifact object classes and the class **Report**. The button to vote or like an object or report will be available in the object profile toolbar for objects based on object classes or object class stereotypes for which the capability is configured. The new capability supports three different use cases:

- The `Rate` concept allows an object to be voted on based on a star-rating system. The rating can be expressed as an icon with a specified number of stars or via another type of icon gallery that supports rating an object. For example, users could specify their recommendation of an application based on a 3-star rating system.
- The `Like` concept allows an object to be endorsed based on a binary rating system. The rating can be expressed via a Like button or Heart icon or any other type of icon gallery that supports a true/false rating of an object. For example, users could click the Like button to specify their approval for a configured report. Please note that the Like button would be available in the object profile of that configured report and not in the configured report itself.
- The `Expert` concept allows a user to register him/herself as an expert of an object. For example, a user could specify him/herself to be an expert of a technology or technical component. The user could deregister him/herself at any time.

Each use case must be configured in the XML object ***ObjectAssociationsConfig***. Depending on the use case, the relevant value `Vote`, `Like`, or `Expert` must be specified in the XML attribute `Name`. For each use case, the solution designer can specify the object classes/object class stereotypes for which the content voting shall be implemented, the icon for the toolbar button as well as the icons for voting, and the text and tooltips to support the users to use the voting buttons. The use case may be enabled for read-only users as needed, thus allowing the enterprise to collect input from a large part of the user community.

The rating, like, and expert values capture for an object can be configured to be included in the **Attributes** section of the object profile or object cockpit or collected for a specified set of objects in a configured report.

The object class `ObjectAssociations` can be queried in configured reports to provide information about all object associations for a specific object or set of objects. To include the object association data for a specific object in the object cockpit, you could create a ValueControl interface element of the Sub-Type = ValueByQuery. The following displays a query to display the number of likes for the demand stereotype Idea in an object cockpit:

```
SELECT NULL, COUNT(p.REFSTR)AS 'Count'
FROM OBJECTASSOCIATIONS oa, DEMAND dem, PERSON p
WHERE dem.REFSTR = oa.A_OBJECT
AND dem.STEREOTYPE = 'Idea'
AND p.REFSTR = oa.A_USER
AND dem.REFSTR = @BASE
/* Alfabet Instructions */
PICTUREASSIGNMENT(Count, GreaterThan, 0, Small:LikeHeart, IconText,
"", "");
```

For more information about configuring object cockpits, see the section Configuring Object Cockpits for a Custom Object View. For more information about specifying configured reports, see the chapter Configuring Reports.

To configure the content voting capability:

1) Go to the **Presentation** tab and expand the **XML Objects** folder. The XML object ***ObjectAssociationsConfig*** opens.
2) Right-click ***ObjectAssociationsConfig*** and select **Edit XML**. The XML editor is displayed in the center pane.
3) Below the root XML element `ObjectAssociationsConfig`, specify an XML element `ObjectAssociationGroup` for the use case you will configure. The XML element `ObjectAssociationGroup` allows you to enable the read-only status for the object association as well as specify a top-level button with the subordinate object associations available as sub-buttons. This would be displayed on the user interface as a button (object association group) with options in a drop-down menu (object associations) and is useful if the captions for the object associations are too long for a toolbar button:

- Define the following XML attributes if you want to implement a toolbar button with a drop-down menu. If you do not plan to specify a toolbar button with a drop-down menu, then you can leave the following four XML attributes empty.
  - `Name`: Enter a technical name for the object association group. The name may not have empty spaces.
  - `Caption`: Enter the caption that shall be displayed on the object association group button in the object profile toolbar.
  - `Tooltip`: Specify the tooltip that shall be displayed on the object association group button in the object profile toolbar.
  - `Icon`: Specify the icon that shall be displayed on the object association group button in the object profile toolbar.

    All icons implemented in the XML object ***ObjectAssociationsConfig*** must be available in the icon gallery. For more information, see the section Adding and Maintaining Icons for the Alfabet Interface in the chapter Configuring the Visualization of the Alfabet Interface.

- If you want to enable read-only user profiles to access the object associations defined in the object association group, you must specify `"true"` for the XML attribute `EnableForReadOnly` for the XML element `ObjectAssociationGroup` as well as for the XML element `ObjectAssociation`.
- Create a child XML element `ObjectAssociation` for each use case you want to implement and define the following XML attributes. Please note that multiple object associations of the same use case (`Vote`, `Like`, or `Expert`) may be configured.
  - `Name`: Enter one of the following to specify the implementation of that use case for the object association.
    - `Vote` to allow an object to be voted on based on a rating system that supports rating an object (for example, via a star rating system)

- `Like` to allow an object to be endorsed based on a binary rating system (such as Like/Unlike)
- `Expert` to allow a user to register him/herself as an expert of an object

- To specify the object association for the use case where `Name` = `Vote`:
  - `ApplicationClasses`: Enter a comma-separated list of object classes and object class stereotypes where this object association may be implemented.
  - `ApplyToClasses`: Specify `"true"` if the object association should be available for the sub-classes specified in the `ApplicationClasses` attribute. For example, the class `TechicalService` has a sub-class `SolutionTechnicalService`. Users can rate the object of the parent class differently than the object of the sub-class.
  - `EnableForReadOnly`: Specify `"true"` if users with ReadOnly access permissions may define the object association. Specify `"false"` if users with ReadOnly access permissions may not define the object association. Please note that the XML attribute `EnableForReadOnly` must also be set to `"true"` for the XML element `ObjectAssociationGroup` if the XML attribute `EnableForReadOnly` is set to `"true"`.
  - `IconGallery`: Specify the icon group that shall be used for the voting. The icon group must contain multiple icons to represent the different values for rating (such as a 3-star or 5-star rating). Captions may be explicitly defined for the icons in an icon group. For more information, see the section Adding and Maintaining Icons for the Alfabet Interface in the chapter Configuring the Visualization of the Alfabet Interface.
  - `InteractionAddIcon`: Specify the name of the icon for the button that shall be displayed for the toolbar button.
  - `InteractionAddCaption`: Optionally, specify the caption that shall be displayed for the toolbar button.
  - `InteractionAddTooltip`: Optionally, specify the tooltip that shall be displayed for the toolbar button.
  - `EditAfterCreate`: Specify `"true"` if the user may modify the rating. Specify `"false"` if the user may not modify the rating
  - `Delete`: Specify `"true"` if the user may revoke the rating . Specify `"false"` if the user may not revoke the rating.
  - `InteractionDeleteIcon`: This XML attribute is typically not relevant for an object association of the type `Vote`.
  - `InteractionDeleteCaption`: This XML attribute is typically not relevant for an object association of the type `Vote`.
  - `InteractionDeleteTooltip`: You could provide a tooltip giving users instruction about how to revoke the rating. For example: "Click the rating to revoke your vote."
  - `ConfirmMessageDelete`: Specify a confirmation message that the user must confirm if the voting is revoked.

- To specify the object association for the use case where `Name` = `Like` or `Expert`:
  - `ApplicationClasses`: Enter a comma-separated list of object classes and object class stereotypes where this object association may be implemented.
  - `ApplyToClasses`: Specify `"true"` if the object association should be available for the sub-classes specified in the `ApplicationClasses` attribute. For example, the class `TechicalService` has a sub-class `SolutionTechnicalService`. Users can rate the object of the parent class differently than the object of the sub-class.
  - `EnableForReadOnly`: Specify `"true"` if users with ReadOnly access permissions may define the object association. Specify `"false"` if users with ReadOnly access permissions may not define the object association. Please note that the XML attribute `EnableForReadOnly` must also be set to `"true"` for the XML element `ObjectAssociationGroup` if the XML attribute `EnableForReadOnly` is set to `"true"`.
  - `InteractionAddIcon`: Specify the name of the icon for the button that shall be displayed for the toolbar button.
  - `InteractionAddCaption`: Optionally, specify the name of the icon for the button that shall be displayed for a positive vote.
  - `InteractionAddTooltip`: Optionally, specify the tooltip that shall be displayed for the button that shall be displayed for a positive vote.
  - `InteractionDeleteIcon`: Specify the name of the icon for the button that shall be displayed for a negative vote. For example, to unlike an object.
  - `InteractionDeleteCaption`: Optionally, specify the name of the icon for the button that shall be displayed for a negative vote.
  - `InteractionDeleteTooltip`: Optionally, specify the tooltip that shall be displayed for the button that shall be displayed for a negative vote.
  - `Delete`: Specify `"true"` if the user may revoke the rating . Specify `"false"` if the user may not revoke the rating.
  - `ConfirmMessageDelete`: Specify a confirmation message that the user must confirm if the voting is revoked.

4) In the toolbar, click the **Save**  button to save the XML definition.

Configuring the Questionnaire Functionality

The basic questionnaire functionality is provided via the standard functionalities. The creation, distribution, answering, and management of questionnaires provided by these functionalities is described in the reference manual *User and Solution Administration*.

The feature requires configuration in Alfabet Expand for the following:

- Defining configured reports to find the relevant objects and optionally the relevant users for the questionnaire.
- Creating questionnaire indicators for additional objects for an already activated questionnaire.
- Optional configuration of an environment for answering questionnaire indicators with advanced edit functionalities.
- Implementation of a review and approval process for the questionnaire.
- Providing an overview of questionnaire outcome via calculation of scores based on numeric values for each possible answer for the questions of the questionnaire.

The above-mentioned functionalities are mainly based on the definition of configured reports and events. In the following, a complete workflow is given for each feature including examples. Basic knowledge about the definition of configured reports and events is assumed. The descriptions link to the detailed information about configured reports and events where applicable.

The following information is available:

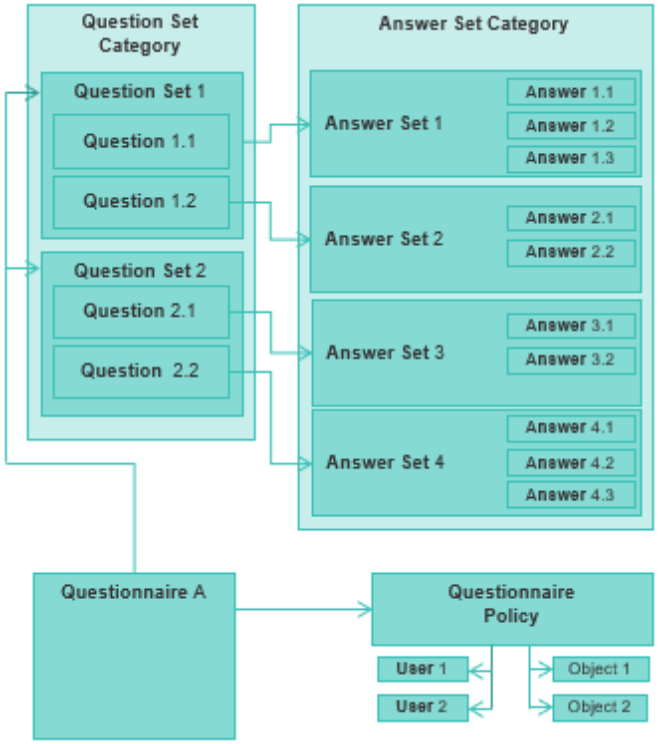
Overview of the Standard and customized Configuration of Questionnaires

A complete overview of the object classes involved in questionnaire creation, management, and answering is required to built configured reports for the feature and set the right parameters for event templates. This section provides an overview of the relevant classes for questionnaire creation. Details about the technical names of the classes and the object class properties involved are given in the following sections in the context of the individual configuration steps.

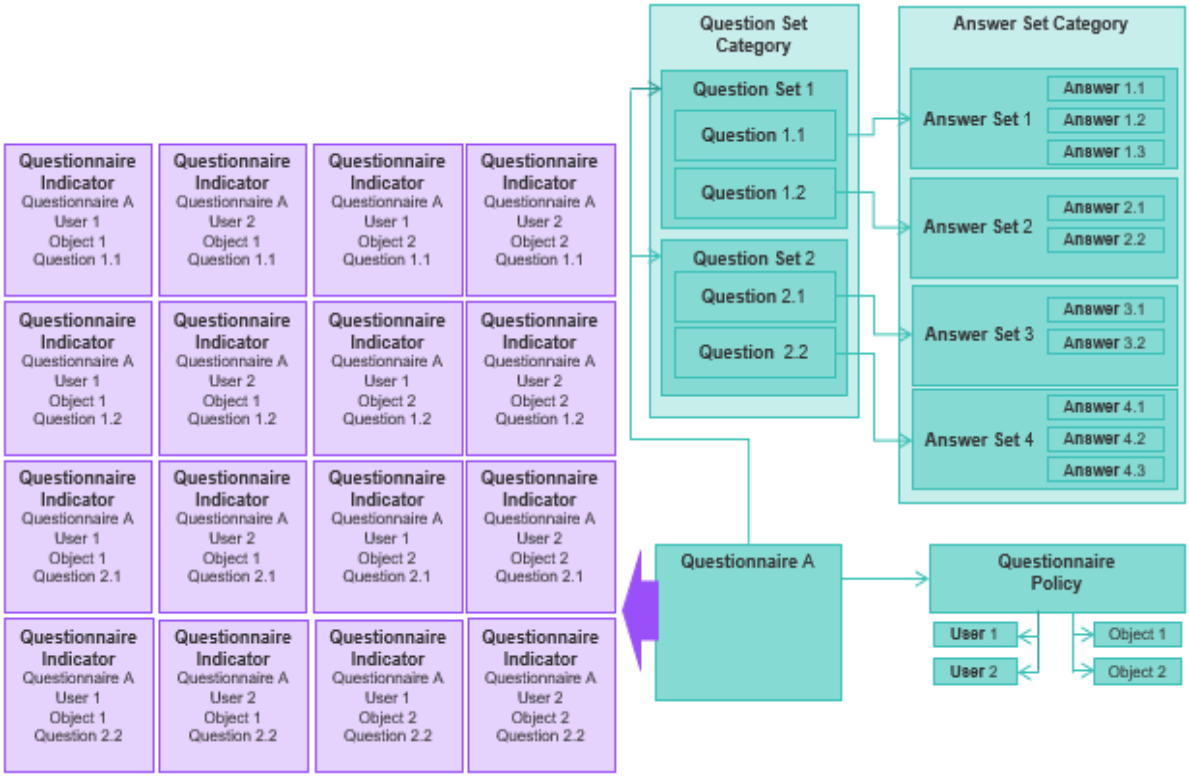
A questionnaire consists of question sets that contain the questions to be answered. Each question either links to an answer set which consists of a predefined set of possible answers that the user can select in a dropdown list, or it provides a free text field. For each question, the user can additionally provide a personal comment.

The question sets of the questionnaire are not defined directly in the questionnaire. Question sets and answer sets are created independent from the questionnaire as child elements of question set categories and answer set categories. this allows answer sets to be re-used in different questions and question ses to be added to multiple different questionnaires. Questions can only be added to questionnaires via question sets. Preconfigured answers can only be added to questions via answer sets.

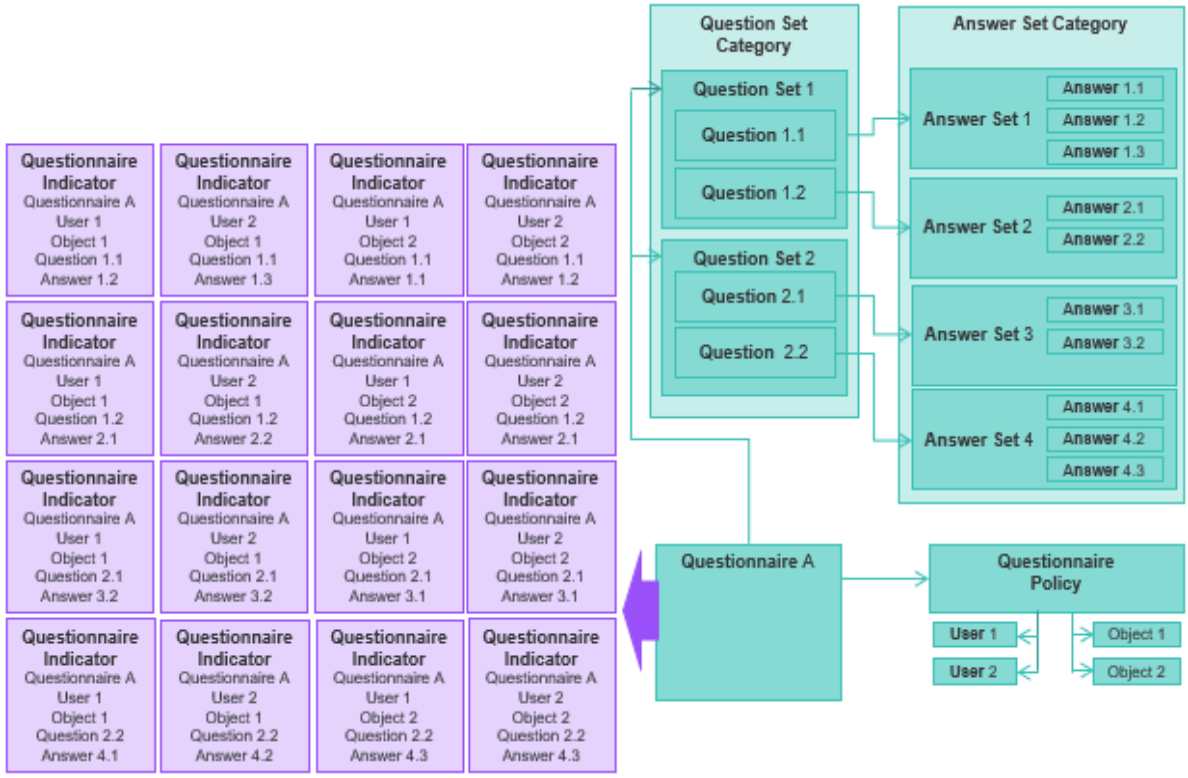
Questionnaires are defined to request information about objects in the Alfabet database from users that are responsible for the object. For example, a questionnaire can be defined to find out whether applications comply to the new company security standards. The questions shall be answered for all applications by all users with a role architect for the application. The relevant users and objects are determined via a questionnaire policy. Like question sets, the questionnaire policy is defined independent of the questionnaire and can be reused in multiple questionnaires. Questionnaire policies reference one or multiple configured reports that return the relevant objects. the relevant users can be the authorized user of each object, users with a defined role for the object, or any other users found via a configured report.



On starting the questionnaire aafter complete configuration, a questionnaire indicator is created for each question in the questionnaire for each combination of object and user derived from the questionnaire policy. questionnaire indicators reference the relevant questionnaire, question, user, and object.

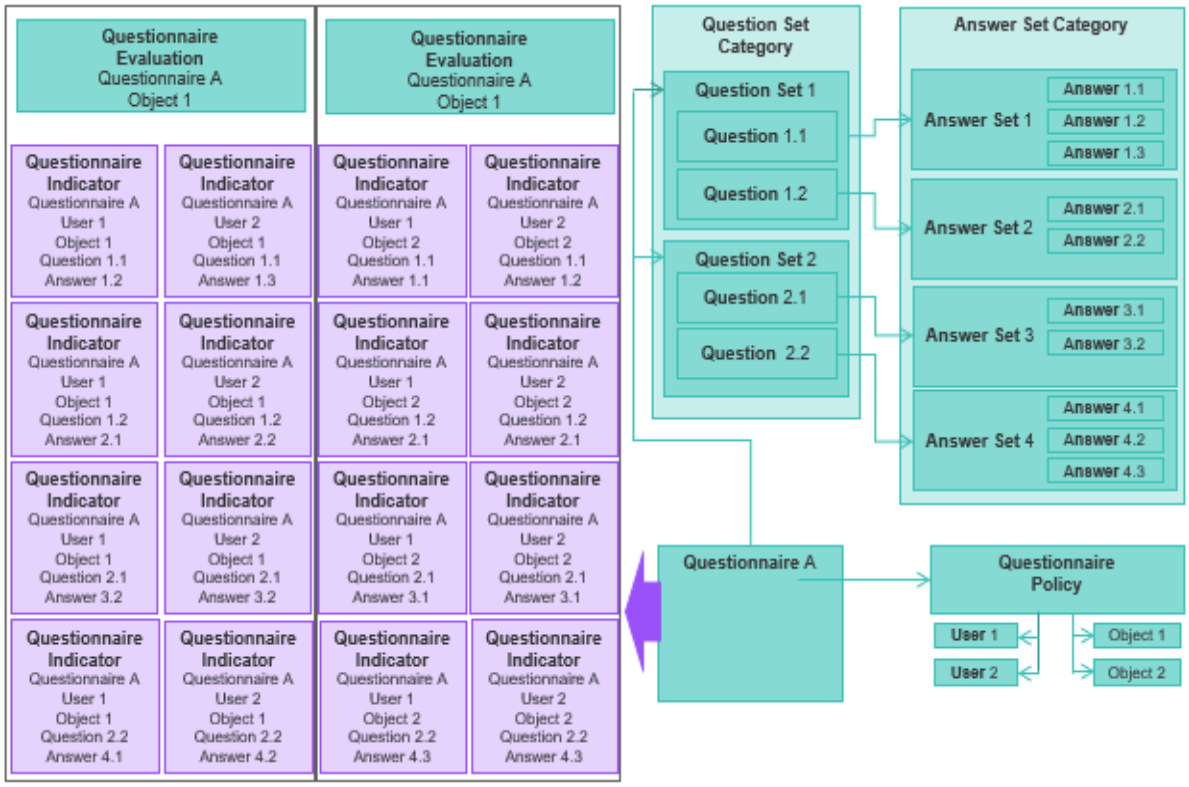


Users can edit questionnaire indicators assigned to them. The answer selected by the user or the user's free text answer will then be stored in the questionnaire indicator.



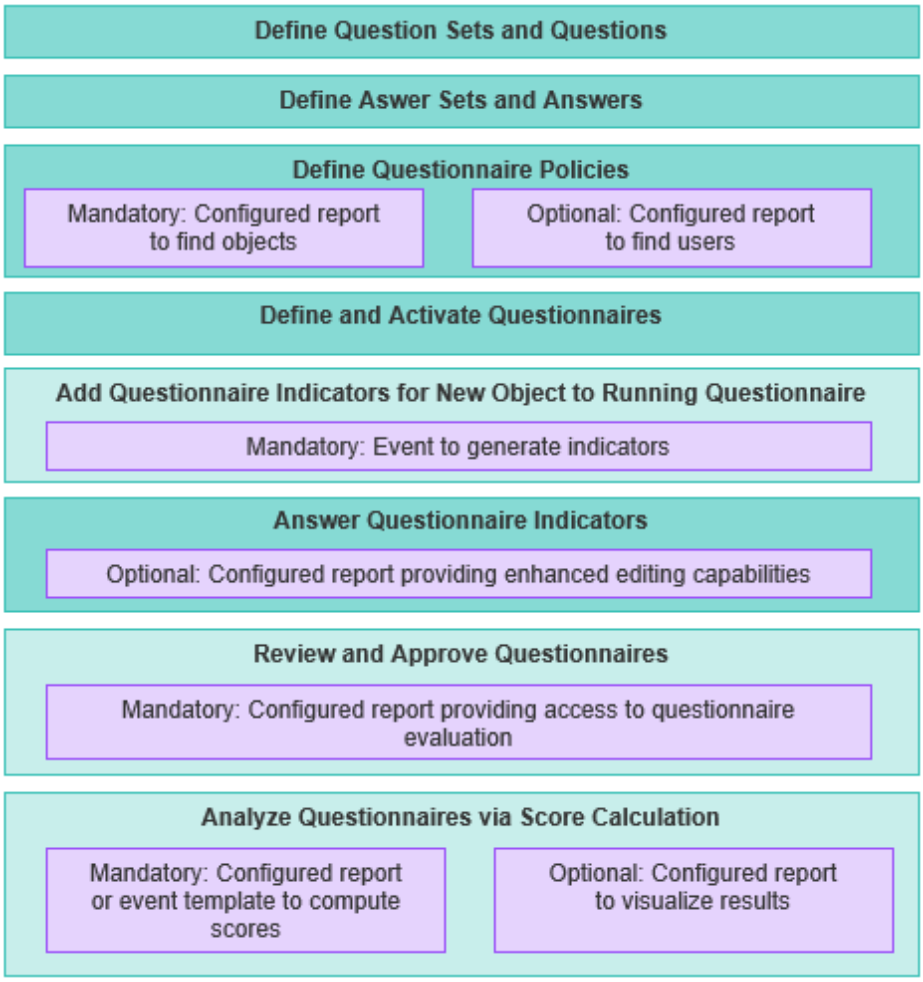
After the users have answered the questions in a questionnaire via the questionnaire indicators assigned to them, a review process can be implemented. Review of the answers can be done on the level of the individual questionnaire indicators, which can store a review comment and a status. Review can also be done on

the level of the questionnaire. For this purpose, questionnaire evaluation objects are created on activation of the questionnaire for each combination of questionnaire and object. Questionnaire evaluation objects provide the ability to review as well as to approve all answers from all involved users answering the questions in the questionnaire for the specific object. For this purpose, the questionnaire evaluation object can store a release status, a review comment and an approval comment.



In addition, the outcome of a questionnaire can be expressed by numbers assigned to each answer in the answer sets. Answers can be assigned numeric values according to their relevance for a given evaluation. For example, if the risk of applications shall be evaluated, a higher number can be given to answers indicating a high risk than to answers indicating a low risk. After the users answered the questions in the questionnaire, a score can be computed from the numeric values of the selected answers. Scores are providing information about the outcome of a questionnaire without detailed analysis the individual answers. In the example, a low overall score for the risk of applications means a low overall risk, while a high score indicators that actions might be required to reduce risk.

If you would like to use the questionnaire functionality, you can configure many of the relevant objects in the functionalities on the Alfabet user interface. Other parts of the questionnaire functionality require configurations in Alfabet Expand. The image below provides an overview of the activities that are involved in working with questionnaires. Optional features like score computation are displayed in a lighter color. If configurations in Alfabet Expand are involved or are optionally involved, this is displayed in lavender colored boxes within the feature boxes.



Configuring Reports Finding Objects Or Users for the Questionnaire Policy

A questionnaire policy defined the users that shall answer the questions in the questionnaire and which objects the users shall answer the question for.

The definition of a configured report is required to find the relevant objects.

For the specification of the relevant users, the definition of a configured report is optional and the authorized user of the object or users having a specific role assigned for the object can alternatively be specified to answer the questionnaire. The way questionnaire indicators are defined is different for the different methods.

- If the authorized user or users assigned to a role for object shall answer the questionnaire, the questionnaire indicators generated for an object are generated for the user that is authorized user of that object or assigned a role for that object. For example, if user 1 is the authorized user for object 1 and user 2 is the authorized user for object 2, only user one will have to answer questions about object 1 and only user 2 will have to answer questions about object 2.
- If users are defined via a query, a questionnaire indicator is defined for each combination of relevant object and user. For example, if the questionnaire policy finds user 1 and user 2 and finds object 1 and object 2, both user 1 and user 2 will have to answer the questions for both object 1 and object 2.

The following configuration steps are required:

- Defining a Report Category for Questionnaire Policies
- Defining a Configured Report for a Questionnaire Policy

Defining a Report Category for Questionnaire Policies

Only configured reports assigned to a report category for the use case `QuestionnairePolicies` can be used in questionnaire policies. You can define one category used for all reports, or you can define multiple categories, For example, to mark reports as relevant for finding objects or for finding users by assigning them to different categories for the use case `QuestionnairePolicies`.

To define a report category for the use case `QuestionnairePolicies`:

1) In the **Presentation** tab of Alfabet Expand, expand the explorer node **XML Objects**.
2) Right-click on the XML object ***UseCaseCategories*** in the explorer and select **Edit XML** from the context menu. The XML object opens in the middle pane.
3) Enter the following code as child element of the XML element ***UseCaseCategories***:

```
<UseCaseInfo UseCase="QuestionnairePolicies">
   <ScopeInfo Scope="Report"
   Categories="CommaSeparatedListOfCategoryNames" />
</UseCaseInfo>
```

   The XML attribute `Categories` must be set to either one category name or a comma separated list of category names. Please note that a category name is a technical name and should not contain special characters or whitespaces. All category names that are defined can be used in the **Category** attribute of a configured report to activate the report for the use in questionnaire policies.

4) In the toolbar, click the **Save**  button.

Defining a Configured Report for a Questionnaire Policy

To define a configured report for use in questionnaire policies:

1) In the **Reports** tab, right-click the **Reports** folder or a sub-folder thereof and select **Create New Report**. You will see the new configured report listed below the selected report folder.
2) In the property window, edit the following attributes of the configured report:
   - **Name**: Change the technical name of the configured report to a meaningful name. The technical name of the configured report will be displayed in the questionnaire policy editor.

     The technical name is used for identification of the configured report in the context of technical processes such as merging the report configuration with a report configuration saved as an XML file. Therefore, the following is required when defining the name of a configured report:

- The name must be unique. The name must be unique regardless of the report folder it is structured in.
- A validation mechanism checks for correct syntax when defining a technical name. Please note that names may not begin with an empty space nor include special characters. For a list of the special characters that are not allowed, see the section Defining Attributes for Configuration Objects in the chapter Getting Started with Alfabet Expand.

- **Category**: Select a category defined for the `QuestionnairePolicies` use case in the XML object ***UseCaseCategories***.
- **Type**: Select `Query`.
- **Alfabet Query/Query As Text**: Click the **Browse** button in the **Alfabet Query** attribute to open the **Alfabet Query Builder** or define the Alfabet query in a simple text editor in the **Query As Text** attribute. The following is required in the query definition:
  - The `FIND` class must be `Person` to find the users responsible for answering the questionnaire, or the object class of the objects for which the questionnaire shall be answered.
  - Show properties are ignored.
  - `FROM` clauses and `WHERE` clauses can be used to find the relevant objects or users.

Optionally you can set other report attributes, for example, to provide a caption and description and to exclude the configured report from being available for other functionalities. This section only describes the attributes technically required to execute the configured report in the questionnaire policy. For a complete description of available attributes, see Creating a Tabular Configured Report of the Type Query and Creating a Tabular Configured Report of the Type NativeSQL.

3) In the toolbar, click the **Save** button to save your changes.
4) Right-click the configured report and select **Set Report State to 'Active'** from the context menu.

Adding Questionnaire Indicators for New Objects to a Started Questionnaire

Starting a questionnaire will create the questionnaire indicators for all objects found by the query in the assigned questionnaire policy.

The number of relevant objects may change during the time period for answering the questionnaire. New objects may be created or the data for existing objects may be changed to match the search conditions in the questionnaire policy.

To add additional questionnaire indicators for a new object to a started questionnaire, an event can be added to a wizard or workflow. Events are based on a customer configured event template. They can be triggered via an on enter, on cancel, or on exit step action of a wizard step or via an on enter, on refuse, on expired, or on exit step action of a workflow step.

For example, an active questionnaire is currently answered by the authorized users of all applications with a criticality indicator set to 'High' or 'Very High'. The evaluation page view for the application is available as a wizard step in a wizard. If a user changes the criticality indicator and moves on to the next page of the wizard, the event will be triggered, and questionnaire indicators will be created for the application.

To trigger generation of questionnaire indicators on execution of a workflow or wizard creating or changing a relevant object, you must create an event template and add the event template to a wizard step action or a workflow step action. These steps are described below for the start of a questionnaire indicator.

Please note that the execution of event templates requires a basic configuration of event management. This basic configuration is described in the chapter Configuring Events and has to be available to perform the configurations described in the following.

- Configuring an Event Template for Generation of Questionnaire Indicators
- Adding the Event Template to a Workflow or Wizard

Configuring an Event Template for Generation of Questionnaire Indicators

This section is limited to a basic description of the settings in the event template. If you are not familiar with the definition of events, you should read the chapter Configuring Events first to understand the meaning of the different settings for event execution.

Event templates are defined in the **Events** tab of Alfabet Expand:

1) Go to the **Events** tab of Alfabet Expand.
2) Right click the node **Events** and select **Create New Questionnaire Add Indicators Event** from the context menu. The new event template is added on the root level of the event management tree.
3) Click on the new event template and edit the following attributes:
   - **Name**: Enter a unique name for the event template. The name is used to identify the event templates in configurations.
   - **Description**: Optionally enter a short text describing the functionality of the event. This information is only visible in the event template attributes in the **Events** tab to inform For example, other solution designer about the functionality implemented with the event template.
   - **Execute Immediately**: Setting this attribute to `True` will cause the Alfabet Web Application to execute the event immediately by triggering the REST API call for the event. The event is nevertheless written to the `ALFA_EVENT_BUS` table, but with the `STATE` set to `FINISHED` or, if execution was not successful, to `ERROR`. Setting this attribute to `False` will lead to standard scheduling of the event via the `ALFA_EVENT_BUS` table and execution via the Alfabet Server.
   - **Connection Type**: Select `SelfReflective`, if the event shall be executed for the same Alfabet database it is triggered from, or `Query`, if the event shall be executed on an Alfabet database that is defined via an **Alfabet Database Connection**.
   - **Connection via Query** / **Connection via Query as Text**: This attribute is only applicable and visible if the **Connection Type** is `Query`. Define a query that returns the `REFSTR` of the

Alfabet database connection to be used for execution of the event. The query must return a single `REFSTR`. It can either be defined as native SQL query or Alfabet query:

- Use the **Connection via Query** attribute to define an Alfabet query. Show properties are not required for the query.

```
ALFABET_QUERY_500
FIND Alfabet_DBConnection
WHERE Alfabet_DBConnection.Name = 'EventConnection'
```

- Use the **Connection via Query as Text** attribute to define a native SQL query with the `REFSTR` of the Alfabet database connection as only `SELECT` argument.

```
SELECT REFSTR
FROM ALFABET_DBCONNECTION
WHERE ALFABET_DBCONNECTION.NAME = 'EventConnection'
```

- **Group**: If you would like to structure your event templates in folders, enter the name of the event template folder the event template shall be located in. If event template folders have already been defined for other event templates, they will be displayed in a drop-down list and can be selected. If you want to define a new event template folder, enter a new name into the field. The folder is then created in the explorer. The event template is moved to the selected event template folder.

4) Expand the event's node in the explorer and expand the **Parameters** node. Three parameter nodes are displayed.

5) Click each of the parameter nodes and define the following in the attribute section:

- ***@Questionnaire***: This parameter is mandatory. Define a query finding the relevant questionnaire. The questionnaire must have the release status defined as `ApprovedStatus` for the object class `Questionary` in the XML object ***ReleaseStatusDef*** and the questionnaire target date must be in the future.

For more information about the definition of release status values, see Configuring Release Status Definitions for Object Classes.

You can either define an Alfabet query in the **Value for Parameter via Query** attribute or a native SQL query in the **Value for Parameter via Query as Text** attribute. The query must return the `REFSTR` of the relevant questionnaire in a dataset with one column and one row.

For example, a native SQL query to find the questionnaire may read:

```
SELECT NULL, QUESTIONARY.REFSTR
FROM QUESTIONARY
WHERE QUESTIONARY.NAME = 'Security Assessment for Cloud
Servers'
```

- ***@Object***: This parameter is mandatory. Define a query finding the relevant object only. Typically, this will be the base object of the wizard or workflow you are currently working with. You can either define an Alfabet query in the **Value for Parameter via Query** attribute or a native SQL query in the **Value for Parameter via Query as Text** attribute. The `FIND` class of

the Alfabet query must be the object class of the relevant object. The native SQL query must return the `REFSTR` of the object class of the relevant object as first `SELECT` argument. The query must contain conditions that limit the result to a single object.

For example, an Alfabet query to find the object may read:

```
ALFABET_QUERY_500
FIND Device
WHERE Device.REFSTR CONTAINS:BASE
AUTODSINFO
QUERY_XML
<QueryDef>
   <ShowProperty Type="Property" ClassName="Device"
   Name="REFSTR" />
</QueryDef>
```

- ***@UserName***: This parameter is optional. If specified, the string defined in the parameter will be written into the `CREATION_USER` object class property of the questionnaire indicators generated by the event. Please note that according to the setting of the **Update History User Name** in the server alias of the Alfabet Web Application, the `CREATION_USER` object class property stores either the user name or the technical name of users. The information returned for the parameter must match the setting in the server alias.

  For information about the setting in the server alias, see *Configuring User Information Displayed in History Tracking* in the reference manual *System Administration*.

You can either define an Alfabet query in the **Value for Parameter via Query** attribute or a native SQL query in the **Value for Parameter via Query as Text** attribute. The query must return the user name or the technical name of an Alfabet user in a tabular dataset with a single row and a single column. Instead of the defining the user via a query, a fixed user name or technical name can be defined in the **Default Value** attribute.

For example, a native SQL query to set the `CREATION_USER` to the user that is triggering the event may read:

```
SELECT PERSON.REFSTR, PERSON.USER_NAME
FROM PERSON
WHERE PERSON.REFSTR = @CURRENT_USER
```

6) Click the **Save**  button to save your changes.

7) Right-click the event template and select **Set Event State to Active** from the context menu.

Adding the Event Template to a Workflow or Wizard

Events can be triggered via an on enter, on cancel, or on exit step action of a wizard step or via an on enter, on refuse, on expired, or on exit step action of a workflow step. The implementation is the same for all wizard step actions and workflow step actions:

1) In Alfabet Expand, navigate to the wizard step or workflow step that you want the event to be triggered from.
2) Create a new wizard step action or workflow step action, as needed:
   - To create a new wizard step action for a wizard step, right-click the relevant **Action On Entered Step**, **Action On Exited Step**, or **Action On Cancelled Step** node and select the option to create the new wizard step action. For more information about configuring wizard step actions, see the section Configuring Wizard Step Actions for a Wizard Step.
   - To create a new workflow step action for a workflow step, right-click the relevant **Action On Entered Step**, **Action On Refused Step**, **Action On Expired Step**, or **Action On Exited Step** node of the workflow step and select the option to create the new workflow step action. For more information about configuring workflow step action to trigger an event, see the section Configuring Events to Be Triggered for a Workflow Step.
3) Click the new wizard step action/workflow step action in the explorer and edit the following attributes in the attribute window:
   - **Technical Name**: Enter a name for the wizard step action/workflow step action. This name is not displayed in the Alfabet interface.
   - **Action Type**: Select `TriggerEvent`.
   - **Technical Comment**: Enter any relevant information about the wizard step action/workflow step action.
   - **Event Template**: Select the relevant event template from the drop-down list.
4) Optionally, you can define a condition to execute the event depending on the availability of specific data returned by a query. For example, you could specify that the event may only be executed if a property of the base object of the wizard is set to a specific value. Edit the following attributes in the attribute window to define the condition:
   - **Check Query** / **Check Query as Text**: Define a query that will return a result only if a condition is met. The query can be defined either as an Alfabet query in the **Check Query** attribute or as a native SQL query in the **Check Query as Text** attribute.
   - **Result Type**: Select `Positive` if the event shall only be executed if the query returns a result. Select `Negative` if the event shall only be executed if the query does not return a result.

For example, an event to update an application's indicators when a wizard step is exited shall be triggered if the application's release status is set to the value "Approved". The following query will only return a result if the application that is the base application of the wizard step has the correct release status:

```
SELECT REFSTR
FROM APPLICATION
WHERE APPLICATION.STATUS = 'Approved'
```

```
AND APPLICATION.REFSTR = @WIZARDBASE
```

The **Result Type** is set to `Positive` so that that the event is only executed if the query returns a result.

5) Click the **Save**  button to save your definitions.

Configuring the AI-Enabled Data Quality Analysis Functionality

Analysis of IT infrastructure and any IT planning activity relies on up-to-date and complete data. Alfabet offers an **AI-Enabled Data Quality Analysis** functionality that scans the data about objects of an object class for similarity in attribute settings, forming clusters of objects that are structurally related based on a selected set of class properties, roles and indicators. Within these clusters, objects will only deviate in the availability of a low percentage of attributes and have high similarity in other settings. Therefore, identification of attributes that are only missing for a few of the objects in the cluster is a good way to check data completeness in a context that takes data structure into account.

The **AI-Enabled Data Quality Analysis** functionality is available for all object classes that can be structured in groups such as application groups, project groups, etc.

This feature requires configuration in Alfabet Expand for the following:

- Configuring Group Object Class for Storing Report Reference in Alfabet Expand
- Creating Parent Group Object for Cluster Storage in Alfabet User Interface
- Creating a Configured Report with AI-Enabled Data Quality Analysis functionality
  - Configuring a Report with AI-enabled Data Quality Analysis using the Report Assistant
- Enabling user access for standard functionality

Configuring Group Object Class for Storing Report Reference in Alfabet Expand

The **AI-Enabled Data Quality Analysis** functionality is available for all object classes that can be structured in groups such as application groups, project groups, etc. The results of the analysis are stored using already existing group infrastructure.

The analysis stores the results in a hierarchy of groups with a specific object class stereotype. If object class stereotypes are already configured for the group object class, it is recommended to define a separate object class stereotype for the analysis to clearly distinguish between groups created for the analysis and groups to structure objects. If object class stereotypes are not defined for the group class, you must define at least one object class stereotype for the definition of groups structuring objects in addition to the object class stereotype used to store analysis results.

A custom object class property for storing a reference to the object class `ALFA_REPORT` must also be defined for the group object class. This property is crucial in storing information about the configured report used to trigger the analysis.

Do the following to configure the group object class in Alfabet Expand:

1) Go to the **Meta-Model** tab, expand the **Classes** node and click on the relevant group object class to be configured.
2) In the attribute window, click the **Browse** button available for the **Stereotypes** attribute to open the XML text editor.
3) Define a stereotype as child elements of the XML element `ClassStereotypes`. The stereotypes are defined with the following XML syntax: `<Stereotype Name="" Caption="" CaptionPlural="" Description="" Comments="" HasMandates="" IDPrefix="" />`.

   For each object class stereotype, define the following XML attributes:

An error message will be displayed upon closing the text editor if syntax errors are written in the XML definition of the **Stereotypes** attribute.

- `Stereotype Name`: Enter the technical name for each object class stereotype. You may define a name of up to 64 characters. This name should not be changed once the object class stereotypes are implemented.

  Changing the technical name after objects have been created based on the object class stereotype requires such objects to be updated by means of an ADIF scheme. For more information, see the reference manual *Alfabet Data Integration Framework*.

- `Caption`: Enter the caption for the object class stereotype. This is the name that users will see in the Alfabet user interface.

  The caption of the object class stereotype should be different than the caption of its object class. This is particularly important for the implementation of the search functionality for the object class stereotype. For more information, see the section Configuring Class Settings for Object Classes and Object Class Stereotypes in the chapter Configuring User Profiles for the User Community.

- `CaptionPlural`: Enter a plural form for the caption. This is the name in plural that users will see in the Alfabet user interface.
- `Description`: Provide a brief description about the object class stereotype that will be displayed to users in the **Stereotype Selector** when defining a new object of the group class. The description should inform the user that this stereotype is used for technical processes and shall not be used to create groups manually.
- `Comments`: Optionally enter text in order to provide information about the object class stereotype. This information is only for the purposes of configuration. It is not displayed in the Alfabet user interface but explains the meaning of the stereotype for solution designers. The comment can for example, inform about the role of the stereotype in data quality analysis.
- `HasMandates`: Enter "`true`" if the mandate capability should be available for the object class stereotype. Enter "`false`" if the mandate capability should not be available for the object class stereotype. If the XML attribute `HasMandates` is defined as "`false`" for an object class stereotype, objects based on the object class stereotype will be visible to users with any mandate implemented in your enterprise. For information about additional configuration requirements necessary to implement the mandate capability, see the section *Implementing the Mandate Capability for a Federated Architecture* in the chapter Configuring Access Permissions for Alfabet

Additional attributes can be set for stereotypes. However, these are not relevant for this usecase and are described in detail in the section Configuring Object Class Stereotypes for Object Classesof chapter *Configuring the Class Model*.

Example of the XML definition in the **Stereotypes** attribute for the object class `ComponentGroup`:

```
<ClassStereotypes>
   <Stereotype Name="ComponentGroup" Caption="Component
   Group" Description="This stereotype is for all ordinary
```

```
component groups." CaptionPlural="Component Groups"
Comments="" HasMandates="true" IDPrefix="" />

<Stereotype Name="ComponentDQAG" Caption="Component Data
Quality Analysis Group" Description="This stereotype is
for Component groups used to conduct data quality cluster
analysis." CaptionPlural="Component Data Quality Analysis
Groups" Comments="" HasMandates="true" IDPrefix="" />

</ClassStereotypes>
```

4) Click the **Save** button to save your changes.

5) Right-click the relevant object class node and select **Add New Property**. The **Create New Property** editor opens. Define the following fields:

   - **Property Name**: Enter a unique name for the custom object class property.
   - **Technical Name**: Enter a unique technical name for the custom object class property that will be used in the Alfabet database table as a column header.

     Please note that the `Technical Name` may not begin with an empty space nor include special characters. It should consist of upper-case letters only and must not be longer than 30 characters. For information about additional configuration requirements necessary to create a new custom property, see the section Creating a New Custom Property in the chapter Configuring the Class Model.

6) Click **OK** to save the definition.

7) In the attribute window of the custom object class, define the following attributes:

   - **Property Type**: Select `Reference`.
   - **Type Info**: Enter `ALFA_REPORT`.
   - **Caption**: Specify a caption to be displayed for the property in the Alfabet user interface.
   - **Comments**: Provide information relevant to solution designers regarding the maintenance of the custom object class property. For example: "This property is used for data quality cluster analysis and will be filled automatically."
   - **Hint**: Enter informational text about the custom object class property to be displayed in the Alfabet interface.

8) In the toolbar, click the **Save** button to save your changes.

Creating Parent Group Object for Cluster Storage in Alfabet User Interface

It is necessary to create a parent group instance specifically to store each analysis as a group with the clusters as sub-groups that contain the objects that belong to that cluster. This is done in the Alfabet User Interface for the relevant object group.

When an analysis is triggered, sub-groups representing the clusters are created and stored under this parent group. If the analysis is triggered again later, the sub-groups and the content therein will be re-created.

To create an analysis-specific parent group, navigate to the relevant object group view on the user interface and create a new group instance. A context sensitive help file is available in the standard Alfabet online help that explains the creation of object groups to end users.

Creating a Configured Report with AI-Enabled Data Quality Analysis functionality

On the Alfabet user interface, the user triggers the analysis via a configured report. Each analysis is triggered by a different configured report, therefore, one configured report must be defined for each analysis that shall be performed. The report also defined parameters changing the display of the standard views for data analysis.

When the group object class and the parent group have been configured, a configured report used for triggering the data quality analysis can then be created.

Do the following to configure the report in Alfabet Expand:

1) In the **Reports** tab, right-click the **Reports** folder or a sub-folder thereof and select **Create New Report**. You will see the new configured report listed below the selected folder.
2) In the attribute window, select `Custom` in the **Type** field.
3) In the attribute window, define the following attributes for the configured report:

- **Name**: Optionally, change the technical name of the configured report. The technical name of the configured report must be unique.

  The technical name is used for identification of the configured report in the context of technical processes such as merging the report configuration with a report configuration saved as an XML file. Therefore, the following is required when defining the name of a configured report:

  - The name must be unique. The name must be unique regardless of the report folder it is structured in.
  - The name may not be changed once a configured report has been created.
  - A validation mechanism checks for correct syntax when defining a technical name. Please note that names may not begin with an empty space nor include special characters. For a list of the special characters that are not allowed, see the section Defining Attributes for Configuration Objects in the chapter Getting Started with Alfabet Expand.

- **Template**: Select `DataQualityAIReport` to create a configured report that triggers the AI-enabled data quality analysis.
- **Caption**: Enter a caption for the configured report. The caption you define here will be displayed in the **Reports Administration** functionality in the **Administration** module and on top of the **Configured Reports** in the Alfabet user interface.
- **Description**: Provide short information about the configured report that is useful to Alfabet users. This comment will be displayed on the Alfabet user interface in the header of the configured report in a single line under the report caption and in the **Description** field for the configured report in the table of all views listing configured reports, like the **Configured Reports** views of the **Search** functionalities.

In the configured report, the description will be truncated if it is longer than one line on the screen. Therefore, the description should be short to ensure complete display in the configured report header.

Additional attributes are available to configure visibility, search parameter helping the user to find the configured report, and parameters relevant for filters. These advanced attribute settings are described in the section Creating a New Report for Multi-Editing of Objects in the chapter Configuring Reports.

4) In the explorer, right-click the configured report and select **Create Custom Report View** to build a view for the report.
5) In the explorer, right-click the configured report and select **Start Alfabet Report Assistant**. The **Report Assistant** opens.
6) Reports triggering data quality analysis are designed in the **Report Assistant**. Configure the report as described below in the section Configuring a Report with AI-enabled Data Quality Analysis using the Report Assistant.
7) Click **OK** to locally save the configuration.
8) In the toolbar, click the **Save** button to save your changes.

Configuring a Report with AI-enabled Data Quality Analysis using the Report Assistant

Explorer Tab Element	Required to Configure:
Data Source Definition	Definition of a query that selects the range of data from the Alfabet database to be analysed.
Default Layout	Selection of features to be included in the analysis and definition of the structural information provided for the relevant object class.
Options	Further definition of attributes for relevant properties available for the object class. Only properties of the data type `Reference` and role types are displayed here.

In the **Data Source Definition** tab, define either a native SQL query or Alfabet query that finds the objects that shall be analyzed:

An Alfabet Query can be defined in the **Alfabet Query** attribute via the Alfabet Query builder. The selection of classes as `FIND` class is limited to the object classes that can be analyzed. `FROM` and `WHERE` clauses can be used to limit the analysis to a subset of the objects available for the `FIND` class. Show Properties are not required.

A native SQL Query can be defined in the **Native SQL** attribute. The first argument of the `SELECT` statement must return the `REFSTR` of the objects that shall be analyzed. Other arguments for the `SELECT` statement are not required. `Joins` and `WHERE` clauses can be used to limit the analysis to

a subset of the objects available for the selected object class. For information about defining queries, see the chapter Defining Queries.

In the **Default Layout** tab, the table on the left displays all object class properties of the data types `string`, `Integer`, `Real`, `Boolean`, and `Reference` of the selected object class as well as indicators and role types assigned to the selected object class. These are the analyzable features. The column headers give information about the data in the column while also allowing easy editability of the features.

Clicking a column header sorts the table rows according to the values in the column. The technical name is displayed in the **Feature** column, the date type is displayed in the **Type** column, and the caption displayed in the column headers of the analysis views is displayed in the **Caption** column. The **Exclude** column allows one to set a checkmark to exclude the feature from the analysis, the **Show in Editor** column allows one to set the checkmark if the property is to be included into the editor and the **View Only** column allows one to set a checkmark if the property is only to be displayed non editable in the editor and is only considered if **Show in Editor** is also checked for the property.

The buttons above the table apply settings to all the features in the table. The **Exclude All** and **Include All** buttons set and remove checkmarks in the exclude column of the table for all the features, **Refresh Available Features** button simply refreshes the features available for analysis as generated by the query and **Number of Fixed Columns** defines which feature column should be fixed in the editor.

For the general structure of the report, the following attributes are required to be defined in the **Default Layout** tab:

Attribute	Description
Data Completion Recommendation Marker	Define a string that will be displayed in all cells of the cluster analysis views that are identified as missing information for the combination of a feature and object.
Max column Header Length	Define the maximum length of the column headers in the cluster analysis views. The name of a feature will be truncated if it is longer than the defined maximum and should be adapted to the screen size of the users performing the analysis for better readability.
Parent Group	Select the object class stereotype of the group object class that shall be used to generate the analysis group that is the parent group for the cluster groups.
Stereotype	Select the object class stereotype of the group object class that shall be used to generate the cluster groups.
Prefix	Define a prefix to be used in naming the cluster results from the data quality analysis.
Report Reference Property	Select the custom property of the group object class that shall store the reference to this configured report.

Attribute	Description
Property Completion Threshold	Define the threshold percentage of objects in a cluster that should have data filled into the object class property for the clustering analysis to regard as complete. Properties with less than this percentage across the objects in the cluster will not be considered in the analysis.
Minimum Cluster Size for Gap Detection	Define a minimum number of objects a cluster should have to be included in data quality analysis. Clusters generated with a number of objects less than the number defined in this property will not be analyzed for data gaps. The default is 10.
Max String Complexity	Define a threshold percentage of distinct string values. Object Class Properties of type String with percentage of distinct values less than or equal to this value will be included in the clustering analysis along with their values.
Background Color	Define the background color for the cells of the cluster analysis views that are identified as missing information for the combination of a feature and object.
Foreground Color	Define the text color for the cells of the cluster analysis views that are identified as missing information for the combination of a feature and object.

The **Options** tab of the **Report Assistant** offers configuration capabilities for fields in the multi-editor of the standard cluster view that take over values from a list of available results, for example, object class properties based on an enumeration or storing a reference to another object.

Only object class properties of the data type String or Reference are displayed. Object class properties of other data types and indicator types are not available in the explorer, because no attributes can be set for them.

In the attribute window of the root node, define the following for the processing of changes to the metamodel and for the behavior of the editing capabilities in the configured report:

- **Automatically Add New Class Properties**: If set to `True`, a new object class property created for the object class in Alfabet Expand is automatically added to the bottom of the dataset in the tab **Default Layout** of the configured report. If set to `False`, the new role type must be added explicitly to the dataset in the configured report by clicking the button **Refresh Available Properties** in the **Default Layout** tab. For both methods, the object class property added to the dataset will be configured to be both visible and editable in the configured report. The default is `False`.
- **Automatically Add New Indicator Types**: If set to `True`, and a new evaluation type is assigned to the object class, the indicator(s) of the evaluation type are automatically added to the bottom of the dataset in the tab **Default Layout** of the configured report. If set to `False`, the new indicator(s) must be added explicitly to the dataset in the configured report by clicking the button **Refresh Available Properties** in the **Default Layout** tab. For both methods, the indicator added to the dataset will be configured to be both visible and editable in the configured report. The default is `True`.

- **Automatically Add New Role Types**: If set to `True`, a role type that is newly assigned to the object class is automatically added to the bottom of the dataset in the tab **Default Layout** of the configured report. If set to `False`, the new role type must be added explicitly to the dataset in the configured report by clicking the button **Refresh Available Properties** in the **Default Layout** tab. For both methods, the role type added to the dataset will be configured to be both visible and editable in the configured report. The default is `True`.
- **Enable 'Set All' for Class Properties**: If set to `True`, the user can select multiple objects in the table of the configured report, select **Properties** from the drop-down list of the button **Set all** and open an editor to set identical values for properties of all selected objects. The user first selects the properties to be reset. Then he/she assigns one value to each selected property and these values are then set for all selected objects when the user closes the editor. If set to `False`, the option **Properties** is not visible in the dropdown list of the **Set all** button.
- **Enable 'Set All' for Indicators**: If set to `True`, the user can select multiple objects in the table of the configured report, select **Indicators** from the drop-down list of the button **Set all** and open an editor to set identical values for indicators of all selected objects. The user first selects the indicators to be reset. Then he/she assigns one value to each selected indicator and these values are then set for all selected objects when the user closes the editor. If set to `False`, the option **Indicators** is not visible in the dropdown list of the **Set all** button.
- **Enable 'Set All' for Role Types**: If set to `True`, the user can select multiple objects in the table of the configured report, select **Role types** from the drop-down list of the button **Set all** and open an editor to set identical values for roles of all selected objects. The user first selects the role types to be reset. Then he/she assigns one value to each selected role type and these values are then set for all selected objects when the user closes the editor. If set to `False`, the option **Role types** is not visible in the dropdown list of the **Set all** button.
- **Validate Edit Permissions**: If set to `True`, access permissions of the user are evaluated when the user opens the editor. If objects selected by the user are not editable for the user because of any of the implemented access permission concepts, the objects are not displayed in the editor. If none of the objects is editable, an empty editor might open. Therefore, it is recommended to define the query of the configured report to take access permission concepts of the user into account and display only editable objects in the dataset. If **Validate edit permissions** is set to `False`, the user can edit any object in the editor even if the access permission concepts implemented would not allow him/her to edit the object. The default is `True`.
- **Enforce Property Editability Rules**: If set to `True`, the editability of the properties in the editor will depend on the editability of the property in the editor or wizard for the base object class used in the class settings for the object profile:
  - If the **Read-Only** attribute of the editor interface control is set to `True`, the property will not be editable for all objects, even if explicitly defined as editable in the configured report.
  - If a condition defined in the **Read-Only Condition** attribute of the editor inhibits editing for a specific object, the property will not be editable for the specific object. The default is `False`.
  - If a validator is defined with the attribute Validator of an object class property, the validation is also performed in the editor of the configured report.
  - If the editor for the base object class checks whether start dates are set to a date prior to end dates, the validation of start and end dates is also performed in the editor of the configured report.

Please note the following:

- Evaluation of conditions requires a lot of computing capacity. Therefore, the number of objects that are simultaneously editable should be set to a small number with the attribute **Max Number of Records** if **Enforce Property Editability Rules** is set to `True`.
- The restrictions based on editability in editors and wizards are not applied to editing in the **Set All** functionality.
- Wizard Step conditions are not evaluated for the editor in the configured report.

- **Max Number of Records**: Defines the maximum number of objects that can be edited simultaneously in the editor. If the user selects more objects for editing, some of the selected objects are not displayed for editing and the user will be informed about that via a message on top of the editor.
- **Restrict Properties to Editor/Wizard Definition**: If set to `True`, properties not editable to the user via an editor or wizard will also be automatically set to view only in the editor of the configured report. This is independent of the editability setting in the **Default Layout** tab.

Information about additional configuration requirements for behavior of editing capabilities in a configured report is available in the section Defining Tabular Configured Reports for Multi-Editing of Object Class Properties in the chapter Configuring Reports.

Enabling user access for standard functionality

Define user access permissions for the configured report in the Reports Administration functionality of Alfabet. By default, access is possible for all users. For more information on how to assign user access rights, see the chapter *Defining and Managing User Access to Configured Reports* in the reference manual *User and Solution Administration*.

Configuring the Feedback Bot

A Feedback Bot capability is available in the slide-in toolbar that allows end users to provide feedback about any view, configured report, object cockpit, guide view, etc. implemented in their Alfabet solution. Two different concepts are configurable for the Feedback Bot:

- The Feedback Bot may provide a 5-star rating concept whereby the user rates the current view based on 1-5 stars and may optionally provide a comment but does not expect a response to the feedback.
- The Feedback Bot may provide for a more elaborate contact form concept. This feedback concept functions similar to first-level support, whereby the user provides feedback or asks a question and expects a response from a user responsible for the feedback.

The Feedback Bot may be configured to implement only one or both concepts. The start page of the Feedback Bot will only be displayed if both feedback concepts are implemented. The start page will provide the user with buttons to open the relevant Feedback Bot. When a user provides feedback, an email may be automatically sent to a person configured as the recipient of the feedback.

Please note the following configuration requirements:

- The XML object ***AlfaFeedbackBotConfig*** must be configured to implement the Feedback Bot capability. The solution designer must specify the XML element `SpecificFeedbackPage` to implement the 5- star rating system and/or the XML element `ContactUsPage` to implement a contact form for a first-level support concept for which a response from a responsible user is expected. Please note the following:
  - The texts to display in Feedback Bot in the Alfabet user interface can be configured.
  - The email address of the user responsible for the feedback as well as the email template to use for the notifications to the responsible user can be configured.
  - Screenshots may be made in association with a feedback entry. The screenshot capability may be implemented for the 5-star rating system and/or the first-level support concept. The screenshot will be made of the p of the screen where the user has the mouse pointer focused at the time that the feedback entry was made. No user information displayed in the masthead will be included in the screenshot.
  - Event templates may be configured for both Feedback Bot contexts. For example, this could be implemented to trigger events to create a ticket in a ticketing system or to consolidate feedback from all users across all instances in a single place.
- Email notifications are configurable via a text template and may contain information about the user sending the feedback, the comments they have entered in the Feedback Bot, and an express view link to the view for which the feedback was entered. Private email templates `FeedbackBot_ContactForm` and `FeedbackBot_SpecificFeedback` are available per default. Public text templates can be created to customize the email notifications. For more information about the variables that may be configured in custom text templates, see the section *Text Templates for the Feedback Bot* in the reference manual *Configuring Alfabet with Alfabet Expand - Appendix*.
- The types of feedback (such as Complaint, Suggestion, etc.) listed in the contact type field in the Feedback Bot may be modified in the protected enumeration ***Feedback_ContactUs_Type***. For more information about configuring the protected

enumeration ***Feedback_ContactUs_Type***, see the section *Protected Enumeration: Feedback_ContactUs_Type* in the reference manual *Configuring Alfabet with Alfabet Expand - Appendix*.

- The following is required to enable the Feedback Bot capability:
  - The XML attribute `IsActive` must be set to "`true`" in the XML object ***AlfaFeedbackBotConfig***.
  - The **Enable Feedback Bot** attribute must be set to `True` for the relevant user profiles to use the Feedback Bot capability. For more information, see the section *Creating a User Profile* in the reference manual *User and Solution Administration*.
  - The **Enable Feedback for View** attribute must be set to `True` for the relevant user profiles to activate the **Feedback for Current View** functionality. This is relevant for user profiles responsible for reviewing and responding to feedback provided via the Feedback Bot.
  - Each user must select the **Enable Feedback Bot** checkbox in the **User Settings** editor. For more information, see the section *Defining Your User Settings in Alfabet* in the reference manual *Getting Started with Alfabet*.
- The visualization of the Feedback Bot can be specified in the GUI scheme associated with the relevant user profile. For more information about configuring the visualization of the Feedback Bot, see the section Configuring GUI Scheme Definitions for the Alfabet Interface as well as the section *Attributes Displayed in the Grid Section: Secondary Window Skins* in the reference manual *Configuring Alfabet with Alfabet Expand - Appendix*.
- All feedback created will be displayed in the **Feedback Review** functionality (`ADMIN_Feedback`) that must be made available to an administrative user profile. The feedback can be systematically analyzed based on various filters such as feedback types, views type, base object, user profile, etc. in order to understand areas of improvement in the configuration of the Alfabet solution. Additionally, feedback that has been provided for a view or report via the Feedback Bot can be displayed in the Alfabet user interface in a seconday view for those users responsible for reviewing and responding to the feedback. This allows the responsible users to navigate the Alfabet user interface and see the feedback for the relevant view where they currently are. A secondary view with the caption **Feedback for Current View** will be displayed with a link if feedback has been provided for the view, configured report, object cockpit, guide view, etc. Clicking the link will open the *Feedback Review Functionality* in a new browser tab which displays all feedback in detail for the view. The following is required to implement the **Feedback for Current View** capability:
  - The **Enable Feedback for View** must be set to `True` for the user profiles responsible for reviewing and responding to feedback provided via the Feedback Bot.
  - The **Enable Check Feedback for View** checkbox must be selected in the **User Settings** editor for the relevant users responsible for reviewing and responding to feedback. For more information, see the section *Reviewing the Feedback Provided by the User Community* in the reference manual *User and Solution Administration*.

To configure the Feedback Bot capability:

1) Go to the **Presentation** tab and expand the **XML Objects** folder. The XML object ***AlfaFeedbackBotConfig*** opens.

2) Right-click ***AlfaFeedbackBotConfig*** and select **Edit XML**. The XML editor is displayed in the center pane.

3) Specify the following XML attributes below the root XML element `FeedbackBotInfo`:

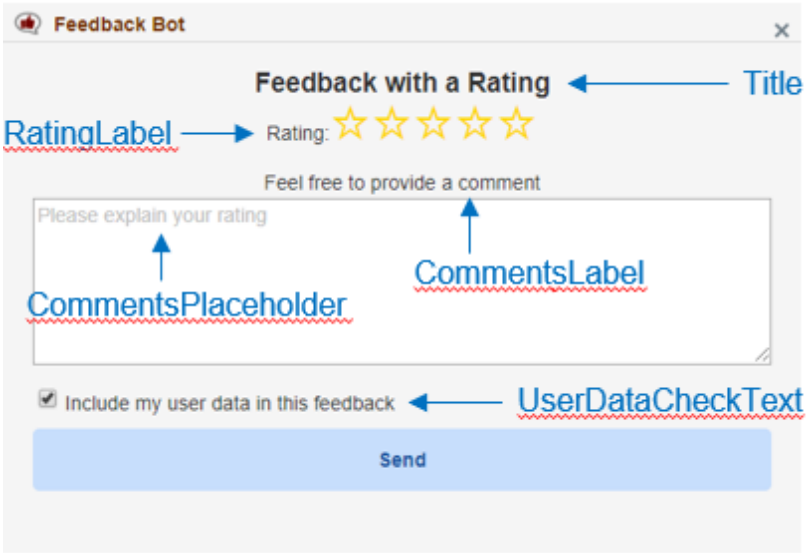
   - `IsActive`: Enter "`true`" to activate the Feedback Bot capability.
   - `UserPropertiesToSave`: Specify the properties for the object class `Person` that are stored in the `ALFA_FEEDBACK_INFO` class table in the Alfabet database.
   - `UserProfilePropertiesToSave`: Specify the properties for the object class `UserProfile` that are stored in the `ALFA_FEEDBACK_INFO` class table in the Alfabet database.
   - `Forecolor`: Specify the foreground color for the **Send** button in the Feedback Bot.
   - `Backcolor`: Specify the background color for the **Send** button in the Feedback Bot.
   - `MouseoverForecolor`: Specify the foreground color when the user mouses over the **Send** button in the Feedback Bot.
   - `MouseoverBackcolor`: Specify the background color when the user mouses over the **Send** button in the Feedback Bot.

4) The XML element `FeedbackHomePage` allows you to specify the start page of the Feedback Bot if both Feedback Bot concepts are implemented (i `ShowSpecificFeedbackOption`: = "`true`" and `ShowContactOption` = "`true`" . In the start page, you can define the visibility and the text on the buttons that provide users access to the star-rating Feedback Bot and/or the contact-form Feedback Bot. If only one feedback concept is implemented, then the start page will not be displayed. Add a child XML element `FeedbackHomePage` to the root XML element `FeedbackBotInfo` and specify the following XML attributes:

   - `ShowLogo`: Specify "`true`" to display the Alfabet logo.
   - `ShowIntroText`: Specify "`true`" to display the texts defined in the XML attributes `IntroTitle` and `IntroDescription`.
   - `IntroTitle`: Specify the text to display as the title to the introduction.
   - `IntroDescription`: Specify the text to display as an introductory description to the Feedback Bot.

- `ShowSpecificFeedbackOption`: Specify "`true`" to display the button for the star-rating Feedback Bot. If set to "`false`", the values defined for the XML attributes `SpecificFeedbackTitle` and `SpecificFeedbackDescription` will not be displayed.
- `SpecificFeedbackTitle`: Specify the text to display as the title of the button for the star-rating Feedback Bot.
- `SpecificFeedbackDescription`: Specify the text to display as the explanation for the star-rating Feedback Bot.
- `ShowContactOption`: Specify "`true`" to display the button for the contact form Feedback Bot. If set to "`false`", the values defined for the XML attributes `ContactOptionTitle` and `ContactOptionDescription` will not be displayed.
- `ContactOptionTitle`: Specify the text to display as the title of the button for the contact form Feedback Bot.
- `ContactOptionDescription`: Specify the text to display as the explanation for the contact form Feedback Bot.
- `SpecificFeedbackIcon`: Specify the icon to display for the star-rating Feedback Bot.
- `ContactOptionIcon`: Specify the icon to display for the contact form Feedback Bot.

5) The XML element `SpecificFeedbackPage` allows you to implement and configure the 5- star rating system with no response is implemented. Add a child XML element `SpecificFeedbackPage` to the root XML element `FeedbackBotInfo` and specify the following XML attributes:



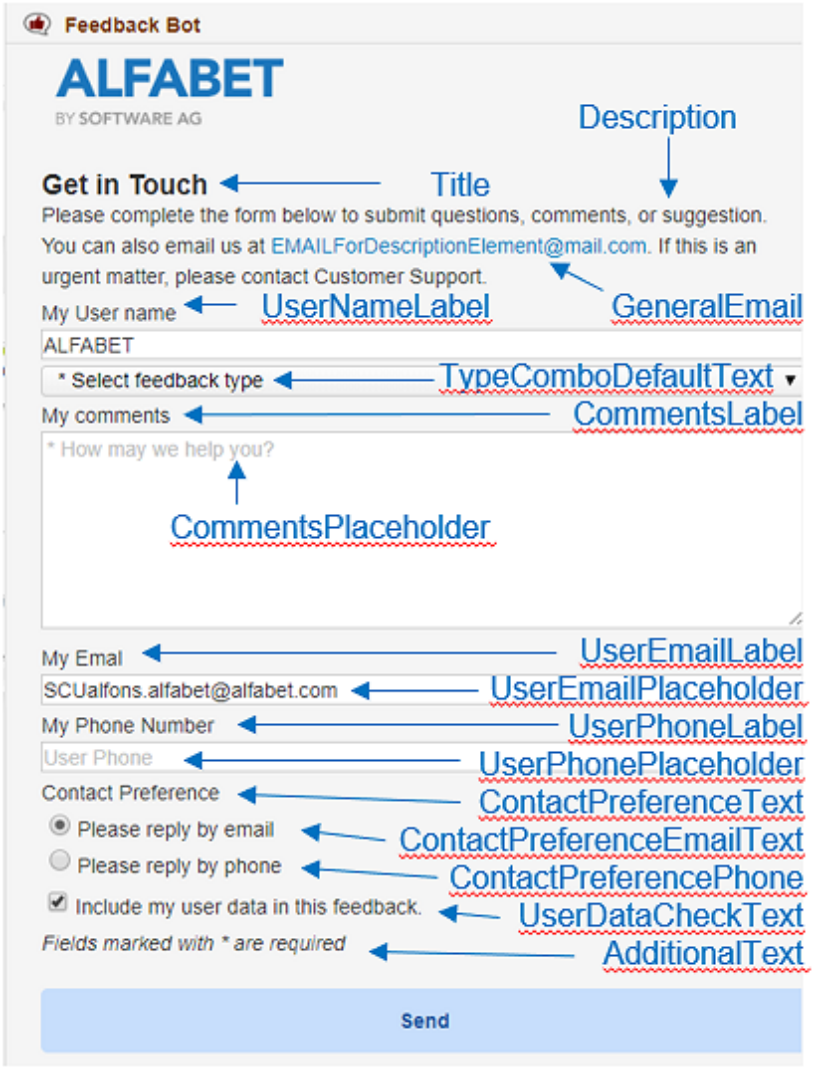
- `Title`: Specify the text to display as the title of the Feedback Bot based on the star-rating concept. The title will also be displayed in the **Feedback Type** field in the **Feedback Review** functionality.
- `ShowStars`: Enter "`true`" to display the 5 stars in the Feedback Bot. If set to "`false`", the 5 stars and the value specified in the XML attribute `RatingLabel` will not be displayed.
- `RatingLabel`: Specify the text next to the 5 stars.

- `ShowComments`: Enter "`true`" to display the comments field in the Feedback Bot. If set to "`false`", the comments field and the values defined for the XML attributes `CommentsLabel` and `CommentsPlaceHolder` will not be displayed.
- `CommentsLabel`: Specify the caption of the comments field.
- `CommentsPlaceHolder`: Specify the placeholder text displayed in the comments field.
- `ShowUserDataCheck`: Enter "`true`" to display the user data checkbox in the Feedback Bot. If set to "`false`", the checkbox and the value specified in the XML attribute `UserDataCheckText` will not be displayed.
- `UserDataCheckText`: Specify the text next to the user data checkbox.
- `SendMail`: Enter "`true`" if an email should be sent about the feedback to the email address defined in the XML attribute `ToEmail` when the **Send** button is clicked.
- `ToEmail`: Enter the email address that the email should be sent to.
- `EmailTemplate`: Specify the email template to use for the email. The private email template `FeedbackBot_SpecificFeedback` is available per default and will be used if no email template is defined. Public text templates can be created to customize the email notifications. For more information about the variables that may be configured in custom text templates, see the section *Text Templates for the Feedback Bot* in the reference manual *Configuring Alfabet with Alfabet Expand - Appendix*.
- `EventTemplate`: Specify an event template if needed. For example, this could be implemented to trigger events to create a ticket for the feedback in a ticketing system or to consolidate feedback from all users across all instances in a single place. For more information about implementing events, see the section Configuring Events.
- `ShowFeedbackThanks`: Enter "`true`" if the thanks page shall be displayed after the **Send** button has been clicked. The text for the thanks page can be configured in the XML element `ThanksPage` .
- `AttachmentsFolder`: Screenshots may be made in association with a feedback entry. The screenshot will be made of the aspect of the screen where the user has the mouse pointer focused at the time that the feedback entry was made. No user information displayed in the masthead will be included in the screenshot. Specify the folder in the **Internal Document Selector** to save images captured by the user of their current screen when creating the feedback entry. (For example: `AttachmentsFolder="SYSTEM\Screenshots_SpecificFeedbackPage"`). If no value is defined for the XML attribute `AttachmentsFolder`, then the screen capture capability will not be available.

  Please note that the screenshots will be saved as JPEG files. Therefore, you must ensure that the file extension.jpeg is not listed in the blacklist defined in the XML object ***FileExtensionLists***. If a whitelist is specified the XML object ***FileExtensionLists***, then the file extension.jpeg must be included as a permissible file extension. For more information, see the section Configuring the Permissibility of Files and Web Links in Alfabet .

6) The XML element `ContactUsPage` allows you to implement and configure a first-level support concept whereby a response is expected by the creator of the feedback. Add a child XML element `ContactUsPage` to the root XML element `FeedbackBotInfo` and specify the following XML attributes:



- `ShowLogo`: Specify "`true`" to display the Alfabet logo.
- `GeneralEmail`: Enter an email address that shall be displayed in the {0} variable that can be used in the XML attribute `Description`.
- `SendMail`: Enter "`true`" if an email should be sent about the feedback to the email address defined in the XML attribute `ToEmail` when the **Send** button is clicked.
- `ToEmail`: Enter the email address that the email should be sent to.
- `EmailTemplate`: Specify the email template to use for the email. The private email template `FeedbackBot_ContactForm` is available per default and will be used if no email template is defined. Public text templates can be created to customize the email notifications. For more information about the variables that may be configured in custom text templates, see the section *Text Templates for the Feedback Bot* in the reference manual *Configuring Alfabet with Alfabet Expand - Appendix*.
- `Title`: Specify the text to display as the title of the Feedback Bot based on the contact form concept. The title will also be displayed in the **Feedback Type** field in the **Feedback Review** functionality.
- `Description`: Specify the text to display as an introductory description to the contact form.

- `ShowUserName`: Enter "`true`" to display the current user name field in the Feedback Bot. If set to "`false`", the checkbox and the value specified in the XML attribute `UserNameLabel` will not be displayed.
- `UserNameLabel`: Specify the text to display as a caption for the current use name field.
- `ShowTypeCombo`: Enter "`true`" to display the feedback type field in the Feedback Bot. If set to "`false`", the feedback type field and the values defined for the XML attributes `TypeLabel` and `TypeComboDefaultText` will not be displayed.
- `TypeLabel`: Specify the caption of the feedback type field.
- `TypeComboDefaultText`: Enter the default placeholder text to display in the feedback type field.
- `TypeMandatory`: Enter "`true`" if the definition of the feedback type is required for the feedback. The types of feedback (such as Complaint, Suggestion, etc.) listed in the contact type field in the Feedback Bot may be modified in the protected enumeration `Feedback_ContactUs_Type`.
- `ShowComments`: Enter "`true`" to display the comments field in the Feedback Bot. If set to "`false`", the comments field and the values defined for the XML attributes `CommentsLabel` and `CommentsPlaceHolder` will not be displayed.
- `CommentsLabel`: Specify the caption of the comments field.
- `CommentsPlaceHolder`: Specify the placeholder text displayed in the comments field.
- `CommentsMandatory`: Enter "`true`" if the definition of the comments field is required for the feedback.
- `ShowUserEmail`: Enter "`true`" to display the user email field in the Feedback Bot. If set to "`false`", the user email field and the values defined for the XML attributes `UserEmailLabel` and `UserEmailPlaceHolder` will not be displayed.
- `UserEmailMandatory`: Enter "`true`" if the definition of the user email is required for the feedback.
- `UserEmailLabel`: Specify the caption of the user email field.
- `UserEmailPlaceHolder`: Specify the placeholder text displayed in the user email field.
- `ShowUserPhone`: Enter "`true`" to display the user phone number field in the Feedback Bot. If set to "`false`", the user email field and the values defined for the XML attributes `UserPhoneLabel` and `UserPhonePlaceHolder` will not be displayed.
- `UserPhoneMandatory`: Enter "`true`" if the definition of the user phone number is required for the feedback.
- `UserPhoneLabel`: Specify the caption of the user phone number field.
- `UserPhonePlaceHolder`: Specify the placeholder text displayed in the user phone number field.
- `ShowContactPreference`: Enter "`true`" to display the contact preference information in the Feedback Bot The contact preference allows the user to specify whether he/she prefers to be contacted per email or phone. If set to "`false`", the user email field and the values defined for the XML attributes `UserPhoneLabel` and `UserPhonePlaceHolder` will not be displayed.

- `ContactPreferenceText`: Specify the caption of the contact preference section of the Feedback Bot.
- `ContactPreferenceEmailText`: Specify the text for the button available for the option to be contacted per email.
- `ContactPreferencePhoneText`: Specify the text for the button available for the option to be contacted per phone.
- `ShowUserDataCheck`: Enter "`true`" to display the current user name field in the Feedback Bot. If set to "`false`", the checkbox and the value specified in the XML attribute `UserDataCheckText` will not be displayed.
- `UserDataCheckText`: Enter the text to display for the checkbox that allows the user to provide permission that his/her first and last name is included in the email sent to the user responsible for the user feedback information. (For example: Include my user data with this feedback.)
- `AdditionalText`: Enter any additional text that shall be displayed at the bottom of the Feedback Bot above the **Send** button.
- `ShowFeedbackThanks`: Enter "`true`" if the thanks page shall be displayed after the **Send** button has been clicked. The text for the thanks page can be configured in the XML element `ThanksPage` .
- `EventTemplate`: Specify an event template if needed. For example, this could be implemented to trigger events to create a ticket for the feedback in a ticketing system or to consolidate feedback from all users across all instances in a single place. For more information about implementing events, see the section Configuring Events.
- `AttachmentsFolder`: Screenshots may be made in association with a feedback entry. The screenshot will be made of the aspect of the screen where the user has the mouse pointer focused at the time that the feedback entry was made. No user information displayed in the masthead will be included in the screenshot. Specify the folder in the **Internal Document Selector** to save images captured by the user of their current screen when creating the feedback entry. (For example: `AttachmentsFolder="SYSTEM\Screenshots_ContactUsPage"`). If no value is defined for the XML attribute `AttachmentsFolder`, then the screen capture capability will not be available.

  Please note that the screenshots will be saved as JPEG files. Therefore, you must ensure that the file extension.jpeg is not listed in the blacklist defined in the XML object ***FileExtensionLists***. If a whitelist is specified the XML object ***FileExtensionLists***, then the file extension.jpeg must be included as a permissible file extension. For more information, see the section Configuring the Permissibility of Files and Web Links in Alfabet .

7) The XML element `ThanksPage` allows you to implement a thank you page after the user has hit the **Send** button.. Add a child XML element `ThanksPage` to the root XML element `FeedbackBotInfo` and specify the following XML attributes:

- `ShowLogo`: Specify "`true`" to display the Alfabet logo.
- `Title`: Enter the text that shall be displayed as the title of the thank you page.
- `Text`: Enter the text that shall be displayed for the thank you page.

8) In the toolbar, click the **Save**  button to save the XML definition.

Configuring Onboarding Emails for New Users

Alfabet can be configured to automatically send onboarding emails with an automatically generated login password and login link to new users created by a user administrator in the **Users Administration** `(ADMIN_UsersOverview)` functionality. To enable this functionality, the XML attribute `SendUserOnboardingMail` in the XML object `SolutionOptions` must be set to `"true"`. The specification of a valid email address for new users will be mandatory if the XML attribute `SendUserOnboardingMail`is set to `"true"`

For more information about creating a new user, see the chapter *Defining and Managing Users* in the reference manual *User and Solution Administration*.

To edit the XML object ***SolutionOptions***:

1) Go to the **Presentation** tab and expand the **XML Objects** folder.
2) Right-click the XML object ***SolutionOptions*** and select **Edit XML**. The XML editor is displayed in the center pane. For general information about editing XML objects in Alfabet Expand, see Working with XML Objects.
3) In the XML attribute `SendUserOnboardingMail`, enter `"true"` to automatically send onboarding emails with an automatically generated login password and login link to new users. Set to `"false"` if .
4) In the toolbar, click the **Save**  button to save the XML definition.

Enabling the User Assistance Functionality

Users can request assistance about a standard or configured view in Alfabet via a **Request User Assistance** option in the Help menu available in the main toolbar in Alfabet. If triggered, an email with a link to the view will be sent to the user in the enterprise who has been specified as responsible for user assistance.

To implement this capability, the XML attribute `EnableRequestSuperUserAssistance` in the XML object ***SolutionOptions*** must be set to `True`.

Additionally, the **Is User Assistant** checkbox in the **User** editor must be selected for the user who is responsible for answering user questions about the Alfabet solution. For more information about specifying a user as responsible for user assistance, see the section *Defining and Managing Users* in the reference manual *User and Solution Administration*.

To edit the XML object ***SolutionOptions***:

1) Go to the **Presentation** tab and expand the **XML Objects** folder.
2) Right-click the XML object ***SolutionOptions*** and select **Edit XML**. The XML editor is displayed in the center pane. For general information about editing XML objects in Alfabet Expand, see Working with XML Objects.

3) In the XML attribute `EnableRequestSuperUserAssistance`, enter "`true`" if the **Request User Assistance** option in the Help menu shall be available in the main toolbar. Set to "`false`" if it should not be available.

4) In the toolbar, click the **Save**  button to save the XML definition.

Configuring Translation of Secondary and Statutory Languages to the Enterprise's Primary Language

The XML object ***SolutionOptions*** allows you to define whether data captured in a secondary language or in a statutory language shall be translated to the primary language via the automatic translation capability. The XML attribute `EnableTranslationToPrimaryLanguage` must be set to "`true`" for any of the following situations:

- If object data shall be captured in a non-primary language, the XML attribute `EnableTranslationToPrimaryLanguage` must be set to "`true`" to ensure that the object data may be automatically translated to the primary language. For more information about the configuration requirements to capture data in a non-primary language, see the section Allowing Data To Be Captured in a Non-Primary Language.
- If object data shall be captured in a statutory language, the XML attribute `EnableTranslationToPrimaryLanguage` must be set to "`true`" to ensure that the object data may be automatically translated to the primary language. For more information about the configuration requirements to capture data in a non-primary language, see the section Specifying a Statutory Language for the Enterprise.

Implementing Proposed Local Components and Proposed Information Flows

The concept of proposed local components can be implemented to perform simple technology changes that don't require extensive planning and investment. Local components discovered from other systems (such as Dynatrace© or AppDynamics©) and imported to Alfabet may be created as proposed local components and only added as real local components to the organization's IT inventory after they have been explicitly included in an approval process. Proposed local components can also be manually created in the context of the application or component they are relevant for. Application/component owners can then assess whether or not a proposed local component shall be included in the platform architecture of the application or component. Proposed local components can be approved and added as "real" local components to the inventory or dismissed and deleted from the Alfabet database. The local components will inherit the values specified for the proposed local components and can be further defined, as needed.

For an overview of the methodology of working with proposed information flows, see the section `ATO: Implementing Proposed Local Components to Manage Technolog..` and X in the reference manual *Portfolio Management Basic*.

- The class `ProposedLocalComponent` inherits the standard and custom properties of the class `LocalComponent` and the class `ProposedInformationFlow` inherits the standard and custom properties of the class `InformationFlow`. Please note that values captured

for any additional custom properties created for either `ProposedLocalComponent` or `ProposedInformationFlow` will be lost when the proposed objects are approved as "real" local components or information flows. Therefore, it is recommended that additional custom properties are not configured for the classes `ProposedLocalComponent` or `ProposedInformationFlow`.

- Components and information flows discovered in external systems (such as Dynatrace© or AppDynamics©) can be imported as objects of the classes `ProposedLocalComponent` or `ProposedInformationFlow` and mapped to the applications or components for which they are proposed. For more information about configuring an ADIF import scheme to import discovered local components and information flows from another system, see the reference manual *Alfabet Data Integration Framework*.
- Class settings (`ProposedLocalComponent` or `ProposedInformationFlow`), custom object views and object cockpits (`COMLP_ObjectView` and `IFP_ObjectView`), and custom editors (`COMLP_Editor` and `IFP_Editor`), may be configured for proposed local components and proposed information flows. Furthermore, wizards and workflows can be implemented to ease data capture.
- Imported proposed local components will be visualized in the *Platform Architecture Page View* (`PLATCOM_Matrix`) and *Components Page View* (`COM_LocalComponents`) views available for an application or component. Proposed local components can also be manually created in these views.
- Imported proposed information flows will be visualized in the *Information Flows Page View* (`APP_InformationFlows`) and (`COM_InformationFlows`) views. Proposed information flows can also be manually created in these views.
- For more information about the methodology of proposed local components, see the section `ATO: Implementing Proposed Local Components to Manage the Techn..` in the reference manual *Portfolio Management Basic*.

In order to implement the concept of proposed local components or proposed information flows in your solution configuration, the XML attribute `EnableProposedObjectHandling` must be set to "`true`" in the XML object ***SolutionOptions***. This setting ensures that imported and manually created proposed local components and proposed information flows will be visualized in the relevant views and the menu options to create, include, and edit them will be available in the Alfabet user interface.

To enable the proposed local components and proposed information flows concept in the Alfabet user interface:

1) Go to the **Presentation** tab and expand the **XML Objects** folder.
2) Right-click the XML object ***SolutionOptions*** and select **Edit XML**. The XML editor is displayed in the center pane. For general information about editing XML objects in Alfabet Expand, see Working with XML Objects.
3) In the XML attribute `EnableProposedObjectHandling`, enter "`true`" if proposed local components or proposed information flows may be created and visualized in the relevant Alfabet views. In this case, existing proposed local components/proposed information flows will be displayed and relevant menu options to create and edit will be available in the Alfabet user interface. Set to "`false`" if proposed local components and proposed information flows shall not be displayed and the options to create and edit them shall not be available.
4) In the toolbar, click the **Save** button to save the XML definition.

Configuring the Creation of Business Services for Business Functions

The XML object ***SolutionOptions*** allows you to define whether each business function may have only one unique business service defined for it or whether a business function may have multiple business services defined for it.

1) Go to the **Presentation** tab and expand the **XML Objects** folder.
2) Right-click the XML object ***SolutionOptions*** and select **Edit XML**. The XML editor is displayed in the center pane. For general information about editing XML objects in Alfabet Expand, see Working with XML Objects.
3) In the XML attribute `BusinessServiceUniqueness`, enter "`true`" if applications/components may provide only one business service for a specific business function. Set to "`false`" if applications/components may provide multiple business services for the same business function.

   If multiple business services may be defined, users will be able to define a unique name for each business service in the **Caption** field in the **Business Service** editor.

4) In the toolbar, click the **Save** button to save the XML definition.

Configuring the Context for the Creation of Business Data

The XML object ***SolutionOptions*** allows you to define whether business data may be created in the context of business objects and the objects that are using the business data (applications, components, etc.) or whether business data may only be created in the context of business objects.

To edit the XML object ***SolutionOptions***:

1) Go to the **Presentation** tab and expand the **XML Objects** folder.
2) Right-click the XML object ***SolutionOptions*** and select **Edit XML**. The XML editor is displayed in the center pane. For general information about editing XML objects in Alfabet Expand, see Working with XML Objects.
3) In the XML attribute `CreateBusinessDataOutsideBO`, enter "`true`" if business data may be created in the context of business objects and the objects that are using the business data (applications, components, etc.). Enter "`false`" if business data may only be created in the context of business objects.
4) In the toolbar, click the **Save** button to save the XML definition.

Making the Bookmarks Menu Available to the User Community

Alfabet provides a bookmark capability that allows you to save links that allow you to quickly navigate to the relevant object or view that you want to work with. The bookmark can point to a page view, object profile (or object cockpit), report, or object selected in an explorer. Users may access their bookmarks in the **Bookmark** > **Bookmarks** menu as well as the **Bookmark Desktop** functionality. In order to make the **Bookmarks** menu accessible to the user community, you must set the GUI scheme attribute **Show Bookmark Tree in Menu** to `True`. For more information about specifying the GUI scheme, see the section Configuring GUI Scheme Definitions for the Alfabet Interface.

Please note that the solution designer may set the **Can Create Bookmark** attribute to `False` for specific custom object views, page views, and configured reports. If this is the case, these views may not be bookmarked. For more information, see the chapter Configuring Object Views.

Implementing the AlfaBot for Navigation via a Full-Text Command

Alfabet provides an AlfaBot window that the user can access via the slide-in toolbar on the right of the user interface. The user can enter text in the AlfaBot window to do any of the following:

- Create a new object of an object class or object class stereotype.
- Edit an existing object of an object class or object class stereotype.
- Navigate to the object view or a page view of an existing object of an object class or object class stereotype.
- Navigate to a diagram.
- Navigate to a configured report.
- Start a Workflow.
- Search for information in configured reports via a full text question about object data.

User interaction in the AlfaBot window is based on natural language processing. The user enters a simple sentence and the AlfaBot searches for given structures and placeholder values based on training phrases. The training phrases are analyzed primarily by the third-party NLP processing tool Dialogflow™. Dialogflow is a third-party component but is not embedded in Alfabet. A license must be purchased by the customer directly from Google LLC to be able to use the AlfaBot.

The `Analyze` intent which enables search within the content of configured reports does not require analysis of strings via an NLP provider. At the same time, all other intents can be deactivated. The `Analyze` intent can be implemented as an additional search capability without purchasing Dialogflow.

The sentences the users type in the AlfaBot window as well as the interpretations returned by Dialogflow are stored in the Alfabet database and Alfabet will try to interpret user sentences based on the already stored and analyzed user sentences if a user uses the same wording for a similar action. If the meaning of the request can be evaluated based on stored prior requests, the sentence will not be sent to Dialogflow again. The costs for language analysis by Dialogflow can be reduced over time via this mechanism.

The AlfaBot will only be displayed in the user interface if the feature is activated and configured by a solution designer and the user interface is rendered in English language.

For end user information about accessing the AlfaBot capability in the user interface, see the section *Using the AlfaBot User Assistance* in the reference manual *Getting Started with Alfabet*.

The following configurations are required to enable navigation via the AlfaBot:

- Creating a Dialogflow Account and Configuring the Connection to the Account in Alfabet
- Configure the Alfabet Class Model to Allow Access via the AlfaBot
- Define AlfaBot Search Capabilities for Configured Reports
  - Configuring the Reports
  - Enabling Semantic Search in the Attributes of Configured Reports
    - Defining a Search Index Directory
    - Defining a Search Group for the Object Class Report
    - Updating the Search Index in Regular Intervals
    - Configuring the AlfaBot to Use the Search Group
  - Activating Search in Reports via the Analyze Intent
    - Defining the Configured Reports Included in the Search
    - Creating a Search Index for the Intent
    - Creating a Popularity Score for Reports
    - Defining a Search Result Threshold for the Semantic Search
    - Managing Automatically Generated Reports
  - Excluding Configured Reports from Results for Defined Users or User Profiles
- Activating Workflow Start via the AlfaBot for a Workflow Template
- Activating the AlfaBot in the AlfaBot Configuration Functionality
- Configuring Training Phrases for the AlfaBot
- Deactivating Intents
- Updating Dialogflow Entities With Information About Customization of the Meta-Model
- Running the AlfaBot in Offline Mode

Creating a Dialogflow Account and Configuring the Connection to the Account in Alfabet

The third-party component Dialogflow™ is not embedded in Alfabet. A license must be purchased by the customer directly from Google LLC.

Prior to setting up the connection, make sure that the web server hosting the Alfabet Web Application can access the following servers via HTTPS:

- www.googleapis.com, port 443
- dialogflow.googleapis.com, port 443

If the connection to Dialogflow fails, the error message "Name Resolution Failure" will be displayed to users trying to use the AlfaBot. The cause for this error could be connection problems with the above mentioned servers, name resolution failure, or proxy name resolution failure for the connection.

The connection to the customer's agent in the Dialogflow API must then be defined in Alfabet Expand in the XML object ***AlfaChatBotConfig***.

The description below includes information about general configuration requirements in Dialogflow to ease understanding of the required Alfabet configuration. Dialogflow handling is not described in detail. For information about how to perform the configuration steps mentioned below, consult the Dialogflow documentation.

1) Log in to Dialogflow and select **Create new agent** in the drop-down menu on the upper left of the interface. Define a name and the basic settings of the new agent and click **Create**.

   Note the following about the configuration of the new agent:

   - The default language of the agent must be English. The AlfaBot currently does not accept any other language.
   - Do not edit the intents. Intents are managed via the Alfabet user interface and will be updated in Dialogflow via the connection defined in this configuration step.
   - Do not change any settings not mentioned in the following procedure description.
   - Do not import or restore the agent from a ZIP file.
   - Do not export the agent.

2) Click on the **gear** icon next to the agent.
3) You will see the information about the **Google Project** for the account. The **Project ID** and **Service Account** properties are required as information for the configuration of access to the agent when configuring the AlfaBot in Alfabet Expand.
4) Go to the **ML Settings** tab and check the following settings:

   - Make sure that the **Match Mode** is Hybrid (**Rule-based and ML**).
   - Make sure that the **ML Classification Threshold** is 0.6.
   - It is recommended to turn the **Automatic Spell Correction** on.

5) In Dialogflow, Click on the **Service Account** . This will look like `dialogflow-xxx@<project id>.iam.gserviceaccount.com`.
6) Click **IAM** in the menu and then click the pencil shaped edit button on the right of the service account information. An editor opens on the right.
7) Add the following roles to the service account:
   - Editor
   - Dialog Flow API Admin
   - Dialog Flow API Client
8) Click **Service Accounts** in the menu to create a P12-key for your service account.
9) Click on the **Edit** icon on the top and select **Create Key**.
10) Select the **P12** checkbox and click **Create**.
11) A window opens providing a password and a file for download.
12) The password is required as information for the configuration of access to the agent when configuring the AlfaBot in Alfabet Expand.
13) Store the downloaded file in a folder that the Alfabet Web Application has access permission to.
14) Log in to Alfabet Expand.
15) and expand the nodes **XML Objects** > ***IntegrationSolutions***.
16) Double-click ***AlfaChatBotConfig***. The XML object opens in the middle pane.
17) The XML object has the following structure:

```
<AlfaChatBotConfig>
   <Proxy url="" user="" psw="" domain=""></Proxy>
   <ChatBotInfo
      Type="Dialogflow"
      IsActive="true"
      ProjectId="project id"
      AccountId="account id"
      CertificateFile="path to P12 certificate file"
      CertificateSecret="password for P12 certificate">
      <Settings MaxSelectionOptions="5" />
   </ChatBotInfo>
</AlfaChatBotConfig>
```

18) Set the XML attributes of the XML element ***ChatBotInfo*** to the following values:
   - `Type`: Enter `Dialogflow`.
   - `IsActive`: Enter `true` to activate the connection. If the XML attribute is set to `false`, the Alfabet Web Application will not connect to Dialogflow and the AlfaBot is not displayed to the users on the Alfabet user interface.
   - `ProjectId`: Enter the value of the **Project ID** property of your Dialogflow agent.
   - `AccountId`: Enter the value of the **Service Account** property of your Dialogflow agent.

- `CertificatePath`: Enter the absolute path to the location of the downloaded Dialogflow certificate file.
- `CertificateSecret`: Enter the password provided by Dialogflow for the certificate file.

Server variables can be used instead of the current values in the XML attributes `ProjectId`, `AccountId`, `CertificatePath` and `CertificateSecret`. A server variable is defined in the XML attribute as $<server variable name>. The server variables are substituted at runtime with the current value defined for the server variable in the server alias of the Alfabet Web Application. For information about the definition and use of server variables, see *Configuring Server Variables for Integration and Interoperability Solutions* in the reference manual *API Integration with Third-Party Components*.

19) Add the XML child element ***Settings*** to the XML element ***ChatBotInfo*** and define the following XML attributes, if applicable for your AlfaBot usage:

- `MaxSelectionOptions`: If multiple results are available for a user input, the AlfaBot answers with a list of available matching results. The number of matching results displayed to the user is limited. By default, the AlfaBot will provide five options, even if more results are available. To change the maximum number of results displayed in the AlfaBot, enter the number of maximum returned results in this XML attribute.

The font color and font style of the link list can be changed via the GUI scheme configuration with the attributes in the new attribute section **Application** > **AlfaBot Option Styles** > **Intent Style** attribute section of GUI schemes. For more information about the configuration of GUI schemes, see Configuring GUI Scheme Definitions for the Alfabet Interface.

- `AnalyzeIntentResultThreshold`: This XML attribute is only applicable if the `Analyze` intent for semantic analysis in configured reports shall be implemented. Optionally, you can change the maximum number of results per search. The default value is 100. The implementation of the semantic analysis is described in the section Enabling Semantic Search in the Attributes of Configured Reports below.
- `ReportSearchGroup`: This XML attribute is only applicable if the `Analyze` intent for semantic analysis in configured reports shall be implemented. A search group must be created for configured reports and the name of the search index must be entered in this attribute. The implementation of the semantic analysis is described in the section Enabling Semantic Search in the Attributes of Configured Reports below.
- `AnalyzeIntentReport`: This XML attribute is only applicable if the `Analyze` intent for semantic analysis in configured reports shall be implemented. The standard, private report `AlfabetDefaultAnalysisIntentReport` defines which reports are applicable to be added to the result dataset of the semantic analysis intent. This configuration can be overwritten. You can define a configured report returning objects of the object class `ALFA_REPORT` and enter the report name in this XML attribute to change the number and kind of configured reports considered in the semantic analysis. The implementation of the semantic analysis is described in the section Enabling Semantic Search in the Attributes of Configured Reports below.
- `AnalyzeIntentUserPermissionReport`: This XML attribute is only applicable if the `Analyze` intent for semantic analysis in configured reports shall be implemented. Optionally, you can define a configured report filtering the overall number of configured reports available for the semantic analysis on basis of user or user profile access permissions. The

implementation of the semantic analysis is described in the section Enabling Semantic Search in the Attributes of Configured Reports below.

20) Optionally, you can configure the Alfabet Web Application to direct requests to a proxy server. If you are using a proxy server, set the following XML attributes of the ***Proxy*** XML element:

- `url`: Enter the URL of the proxy server.
- `user`: If required, enter the user name for access to the proxy server. The domain name for authentication is defined separately with the domain XML attribute and must not be specified as part of the user name.
- `psw`: If required, enter the password for access to the proxy server.
- `domain`: If required, define the domain name that shall be used as part of the user name for authentication at the proxy server.

21) In the toolbar, click the **Save** button.

Configure the Alfabet Class Model to Allow Access via the AlfaBot

The ability to navigate to objects and/or to create and edit objects is restricted in the configuration of the object class and the class settings for the object class.

The following configuration is relevant on the level of the object class model:

For basic information about the configuration of the object class model, see Configuring the Class Model.

- Each object class in the meta-model has an **AlfaBot Support** attribute section with four attributes. For standard private and protected object classes, the attributes are visible but not editable. The attributes can only be set for public, customer-defined object classes. The **Creation Mode**, **Editing Mode**, and **Navigation Mode** attributes specify whether and how creation of object, editing of objects or navigation to objects is supported for the object class. The **Analysis Intent Mode** attribute specifies whether the object class is included into the search in configured reports that can be performed via the `Analyze` intent of the AlfaBot. The attributes can be set to one of the following:
  - `None`: The functionality is not supported for the AlfaBot.
  - `ContextDependent`: The functionality is supported by the AlfaBot and will take a required context into account. For example, information flows can only meaningfully be created in the context of a source or target object. If the user wants to create an information flow via the AlfaBot, the relevant view for creation of the information flow will open, like For example, the **Information Flows** page view of an application. This option is not relevant for the **Analysis Intent Mode** attribute.
  - `Full`: The functionality is supported by the AlfaBot context free. For the creation of objects with the **Creation Mode** attribute set to `Full`, the relevant editor or wizard will open.
- If the **Analysis Intent Mode** attribute of the object class is set to `Full`, a list of synonyms for the object class can be defined in the **Alias** attribute for both the object class and all object class properties thereof. If a user searches for one of the synonyms in the `Analyze` intent of the AlfaBot,

the AlfaBot will provide search results for the object class or object class property that the synonym is defined for.

The following configuration is relevant on the level of the class settings:

For information about the configuration of user profiles via view schemes and class settings, see Configuring User Profiles for the User Community.

- If at least one of the attributes **Creation Mode**, **Editing Mode**, and **Navigation Mode** in the **AlfaBot Support** attribute section of an object class is set to `Full` or `ContextDependent`, a section **Support in AlfaBot** will be visible in the class settings for the object class and all stereotypes thereof. The attributes **Support Creation**, **Support Editing**, and **Support Navigation** are displayed in the section only if the respective functionality is allowed on the class level. For example, if the **Creation Mode** is set to **ContextDependent** for an object class while the **Editing Mode** and **Navigation Mode** are set to `None`, only the **Support Creation** attribute will be displayed in the class settings.

The attributes **Support Creation**, **Support Editing**, and **Support Navigation** in the **Support in AlfaBot** section of the relevant class settings must be set to `True` in order to allow the user to navigate to, create, or edit objects of the relevant object class via the AlfaBot. By default, the attributes are set to `False`.

If the AlfaBot is implemented to automatically generate reports for the ***Analyze*** intent of the AlfaBot, ad-hoc reports will not be generated if the user is searching for information about an object class for which the **Navigation Mode** attribute is set to `False` in the relevant class settings.

The object classes `ALFA_MM_CLASS_INFO` and `ALFA_PM_CLASS_SETTING_INFO` provide information about the current configuration of the object class model and the current configuration of the class settings defined for object classes. This includes information about the settings for the AlfaBot support. To find out which object classes support the AlfaBot, you can create a configured report with a query targeting these object classes.

Define AlfaBot Search Capabilities for Configured Reports

Configured reports are by default accessible via the AlfaBot functionality. Optionally, configured reports can be excluded from accessibility via the AlfaBot.

There are two ways to access reports via the AlfaBot:

- Users can search for a configured report by entering the name of the report into the AlfaBot. If the report caption entered by the user in the AlfaBot for a request to open a configured report does not match the caption of one of the available configured reports, the AlfaBot will split the caption entered by the user into keywords and will perform a keyword search on the **Caption**, **Description** and the **Business Problem Statement** attributes of the configured reports that are accessible via the AlfaBot. In addition to a keyword search, a synonym search is performed on the text provided in the **Business Problem Statement** attribute.
- Users can search for content in configured reports by selecting the `Analyze` intent from the list of intents displayed on opening the AlfaBot. The `Analyze` intent opens a search view in the Alfabet user interface. The user can enter a description of the information he/she is looking for. The `Analyze` intent includes synonyms and related words into the search in addition to the search terms

entered by the user. Further, the intent offers advanced analysis capabilities with regard to the configured reports. In addition to the **Caption**, **Description**, and **Business Problem Statement** attributes of a configured report, the search will also use the **Apply To** attribute and the information from the **Semantic Analysis** sub-node of the configured report to find relevant reports. Strings in the **Alias** attribute of object classes and object class properties are taken into account to identify object classes.

The `Analyze` intent can be used without a connection to an NLP provider.

The following configuration is required to make full use of the search capabilities of the AlfaBot in the context of configured reports:

- Configuring the Reports
- Enabling Semantic Search in the Attributes of Configured Reports
  - Defining a Search Index Directory
  - Defining a Search Group for the Object Class Report
  - Updating the Search Index in Regular Intervals
  - Configuring the AlfaBot to Use the Search Group
- Activating Search in Reports via the Analyze Intent
  - Defining the Configured Reports Included in the Search
  - Creating a Search Index for the Intent
  - Creating a Popularity Score for Reports
  - Defining a Search Result Threshold for the Semantic Search
  - Managing Automatically Generated Reports
    - Activating the Automatic Generation of reports
    - Configuring the Information to be Displayed in the Automatically Generated Reports
    - Deleting Unused Automatically Generated Reports from the Database
- Excluding Configured Reports from Results for Defined Users or User Profiles

Configuring the Reports

1) In Alfabet Expand, go to the **Reports** tab.
2) In the explorer, click the configured report for which you want to change the AlfaBot configuration.
3) In the attribute window, set the following AlfaBot specific attributes according to demand:
   - **Applicable for AlfaBot**: Specify whether the configured report is accessible via the AlfaBot. By default, the attribute will be set to `True` for new reports. Set the attribute to `False` if the configured report should not be opened outside of a specific context. For example, this may be relevant for reports that are specifically designed to be embedded in an object cockpit.

An additional method to further restrict access to configured reports marked as applicable for AlfaBot per user profile or user is available and described below in the section Excluding Configured Reports from Results for Defined Users or User Profiles. The restrictions configured with this method will be applied to both the navigation to configured reports via the ***Navigate to Report*** intent and the semantic search in reports via the ***Analyze*** intent.

- **Business Problem Statement**: Optionally enter a description that will help users to search for the configured report in the AlfaBot. The text is not displayed in the user interface, but it is of special relevance for the search mechanisms implemented for the AlfaBot.

  You must create a search index to enable the semantic search including synonym search on text entered as business problem statement. This configuration step is described below in the section Enabling Semantic Search in the Attributes of Configured Reports.

4) Click the **Save**button to save your changes.

Enabling Semantic Search in the Attributes of Configured Reports

A semantic or synonym search can be performed based on the user input in the **Business Problem Statement** attribute of the configured reports that are accessible via the AlfaBot. In addition to a keyword search, a synonym search queries the text. This search mechanism requires that a search index is available for the content of the **Business Problem Statement** attribute. It should be activated to make full use of the search capabilities available for the AlfaBot.

The semantic search does not require natural language processing via an NLP provider and can be implemented without a connection to DialogFlow. Nevertheless, it requires general activation of the AlfaBot and activation of the `Analyze` intent. If you want to implement it as a search functionality while not providing a connection to DialogFlow required for the other intents of the AlfaBot, you can de-activate all other intents as described in the section.

The following configuration is required

- Defining a Search Index Directory
- Defining a Search Group for the Object Class Report
- Updating the Search Index in Regular Intervals
- Configuring the AlfaBot to Use the Search Group

Defining a Search Index Directory

A search index directory must be defined for storage of the search indexes on the local file system. This is done by a system administrator in the server alias of the Alfabet Web Application and the Alfabet Server. The absolute path to the relevant directory must be defined in the **Search Index Directory** attribute on the **Overview** tab of the server alias editor. In most cases, the search index directory will already be specified because it is also used for the full text search and for the online help search.

For more information, see the section *Creating a Server Alias for the Alfabet Web Application* in the reference manual *System Administration*.

Defining a Search Group for the Object Class Report

An object centric search group must be defined in the XML object `SearchManager`:

1) In the **Presentation** tab in Alfabet Expand, expand the **XML Objects** folder.
2) Right-click the XML object ***SearchManager*** and select **Edit XML**.

   The XML editor is displayed in the center pane. For general information about editing XML objects in Alfabet Expand, see Working with XML Objects

3) Enter the following XML element `SearchGroup` as child element of the XML object ***SearchManager***:

```
<SearchGroup Name="SemanticSearchInReportAttributes">
   <Query Name="SemanticSearchInReports" ClassName="ALFA_REPORT"
   ImageProps="CAPTION" ShowProps="CAPTION"
   ExportProps="NAME,CAPTION,DESCRIPTION,BUSINESS_COMMENT" />
</SearchGroup>
```

   you can optionally change the XML attributes `Name` of the configuration displayed above. The `Name` of the search group is the name of the search group folder in the search index directory. It is also to be used in command lines or editors of the mechanism available for search index update to identify the search group.

   For an explanation of the meaning of the XML attributes in a search group, see Configuring a Global Search Group in the chapter Configuring Custom Selectors and Search Functionalities.

4) In the toolbar, click the **Save** button to save the XML definition.

Updating the Search Index in Regular Intervals

The search index must be updated in regular intervals. This can be done using one of the following options:

- An administrative user can create and update the full-text search indexes for globally-defined search groups in the administrative **Full-Text Search** functionality on the Alfabet user interface. The functionality allows creation and update of indexes for all supported languages to be performed.

The view `ADMIN_FullTextSearch` must be added to the user profile of the administrative user to enable manual creation and update of the globally-defined full-text search. For information about how to manually create and update search indexes, see the section *Creating an Index for the Full-Text Search* in the reference manual *User and Solution Administration*.

- Via the **Job Schedule** functionality on the Alfabet user interface, administrative users can create job schedules for the automatic creation and update of search indexes for globally-defined full-text search groups in defined time intervals. A job schedule triggers the creation and update of the

search index of a single full-text search group. Please note that the job schedule functionality currently supports only definition of full-text search indexes for the language English (United States).

For information about how to implement and configure the **Job Schedule** functionality, see the section Activating the Job Schedule Functionality. For information about how to schedule full-text search index update via a job schedule, see the section *Creating a Job Schedule for the Generation of a Full-Text Search Index* in the reference manual *User and Solution Administration*.

- Via the executable `FullTextSearchUtil.exe`, system administrators can configure a batch process to regularly create and update search indexes for globally-defined full-text search groups. The command line tool can create and update indexes for all supported languages. It can either update an index for a defined search group or for all globally-defined full-text search groups.

For more information about the configuration of the batch process, see the section *Updating Indexes with the FullTextSearchUtil.exe* in the reference manual *System Administration*.

Configuring the AlfaBot to Use the Search Group

The AlfaBot must be configured to use the search group:

1) Go to the **Presentation** tab in Alfabet Expand.
2) Navigate to **XML Objects** > `IntegrationSolutions` > ***AlfaChatBotConfig***.
3) Right-click the XML object ***AlfaChatBotConfig*** and select **Edit XML**.
4) In the editor in the middle pane, enter the name of the new report in the XML attribute `AnalyzeIntentReport` of the child XML element `Settings` of the XML element `ChatBotInfo`:

```
<AlfaChatBotConfig>
    <Proxy url="" user="" psw="" domain=""></Proxy>
    <ChatBotInfo
        Type="Dialogflow"
        IsActive="true"
        ProjectId="project id"
        AccountId="account id"
        CertificateFile="path to P12 certificate file"
        CertificateSecret="password for P12 certificate">
        <Settings MaxSelectionOptions="5"
        AnalyzeIntentReport="CustomizedReportName"ReportSearchGroup="Seman
        ticSearchInReportAttributes" />
    </ChatBotInfo>
</AlfaChatBotConfig>
```

5) In the toolbar, click the **Save** button to save the XML definition.

Activating Search in Reports via the Analyze Intent

Users can search for content in configured reports by selecting the `Analyze` intent from the list of intents displayed on opening the AlfaBot. The `Analyze` intent opens a search view in the Alfabet user interface. The user can enter a description of the information he/she is looking for. The `Analyze` intent includes synonyms and related words into the search in addition to the search terms entered by the user. Further, the intent offers advanced analysis capabilities with regard to the configured reports. In addition to the **Caption**, **Description**, and **Business Problem Statement** attributes of a configured report, the search will also use the **Apply To** attribute and the information from the **Semantic Analysis** sub-node of the configured report to find relevant reports. Strings in the **Alias** attribute of object classes and object class properties are taken into account to identify object classes.

The following configurations and regular maintenance steps are required for implementation of the `Analyze` intent of the AlfaBot in addition to the general configuration of the AlfaBot functionality:

- Defining the Configured Reports Included in the Search
- Creating a Search Index for the Intent
- Creating a Popularity Score for Reports
- Defining a Search Result Threshold for the Semantic Search
- Managing Automatically Generated Reports
  - Activating the Automatic Generation of reports
  - Configuring the Information to be Displayed in the Automatically Generated Reports
  - Deleting Unused Automatically Generated Reports from the Database

Defining the Configured Reports Included in the Search

In the **Reports** explorer in Alfabet Expand, the private `AlfabetDefaultAnalysisIntentReport` report is available in a private `AlfaBotReports` report folder. The reports find configured reports relevant for the new ***Analyze*** intent via a query targeting the object class `ALFA_REPORT`. Only configured reports that are returned by this report are included in the search for the intent.

The configured report limits the search to configured reports that have the **Applicable for AlfaBot** attribute set to `True`. Furthermore, the **Apply to Class** attribute must either be not set, set to an artifact class in the IT landscape, or set to an object class involved in risk management, project management, or contract management. Configured reports are excluded if they provide editing capabilities for object classes or are configured in the scope of Alfabet functionalities (such as in the questionnaire or data capture template functionalities).

The standard ***AlfabetDefaultAnalysisIntentReport*** report can optionally be substituted by a configured report with a customized set of reports to be included. The following description of the configuration uses the existing private report as a template for creating an own report. The query finding the reports can also be defined from scratch, but working with the predefined query enhances configuration speed and ensures that relevant properties of the reports are taken into account for selection.

1) In the **Reports** explorer in Alfabet Expand, right-click the report folder that the report shall be created in and select **Create New Report**.

For information about structuring configured reports in report folders, see Managing and Structuring Your Configured Reports in Folders.

2) Click the new report and change the **Name** attribute of the configured report in the attribute window to a meaningful, unique name. the name should not contain special characters or whitespaces.
3) In the explorer, navigate to ***AlfaBotReports*** > ***AlfabetDefaultAnalysisIntentReport***.
4) Right-click the ***AlfabetDefaultAnalysisIntentReport*** report and select **Copy**.
5) Navigate back to your new report.
6) Right-click the new report and select **Paste**.
7) In the menu of Alfabet Expand click **Save** to save the new report definition.
8) Click the **Browse** button in the **Native SQL Query** attribute of the configured report.
9) In the editor, change the native SQL query according to demand and click **OK** to save your changes.
10) In the menu of Alfabet Expand click **Save** to save the new report definition.
11) Go to the **Presentation** tab in Alfabet Expand.
12) Navigate to **XML Objects** > ***IntegrationSolutions*** > ***AlfaChatBotConfig***.
13) Right-click the XML object ***AlfaChatBotConfig*** and select **Edit XML**.
14) In the editor in the middle pane, enter the name of the new report in the XML attribute `AnalyzeIntentReport`of the child XML element `Settings` of the XML element `ChatBotInfo`:

```
<AlfaChatBotConfig>
    <Proxy url="" user="" psw="" domain=""></Proxy>
    <ChatBotInfo
        Type="Dialogflow"
        IsActive="true"
        ProjectId="project id"
        AccountId="account id"
        CertificateFile="path to P12 certificate file"
        CertificateSecret="password for P12 certificate">
        <Settings MaxSelectionOptions="5"
        AnalyzeIntentReport="CustomizedReportName" />
    </ChatBotInfo>
</AlfaChatBotConfig>
```

15) In the toolbar, click the **Save** button to save the XML definition.

An additional method to further restrict access to configured reports marked as applicable for AlfaBot per user profile or user is available and described below in the section Excluding Configured Reports from Results for Defined Users or User Profiles. The restrictions configured with this method will be applied to both the navigation to configured reports via the ***Navigate to Report*** intent and the semantic search in reports via the ***Analyze*** intent.

Creating a Search Index for the Intent

The `Analyze` intent requires regular generation of a search index. This requires the following configuration:

- A search index directory must be defined for storage of the search indexes on the local file system. This is done by a system administrator in the server alias of the Alfabet Web Application and the Alfabet Server. The absolute path to the relevant directory must be defined in the **Search Index Directory** attribute on the **Overview** tab of the server alias editor. In most cases, the search index directory will already be specified because it is also used for the full text search and for the online help search.

For more information, see the section *Creating a Server Alias for the Alfabet Web Application* in the reference manual *System Administration*.

- The `Analyze` intent requires regular generation of a search index via the standard `SemanticSearch` ADIF import scheme available in the **Alfabet Standard Jobs** folder of the ADIF explorer in Alfabet Expand. It is recommended to run this ADIF job regularly (For example, daily) to include changes to configured reports, indicator types, and evaluation types. The ADIF job can be scheduled for automatic execution via the **Job Schedule** functionality.

The ADIF job must be executed without definition of a file to export to. The ADIF job will add a directory ***AnalyzeReports*** to the search index directory defined in the server alias configuration and add a complete search index file infrastructure to this directory.

For information about how to execute ADIF jobs, see *Configuring ADIF Schemes* in the reference manual *Alfabet Data Integration Framework*.

Please note:

- Execution of the ADIF job will fail if the configured report defined with the XML attribute `AnalyzeIntentReport` of the XML object **AlfaChatBotConfig** does not exist, does not return any results, or does not return results for the object class `ALFA_REPORT` only.
- The ADIF job for update of the search index will be run automatically on update of the meta-model via AMM file and after re-store of a database from ADBZ file to adapt the search results to changes in the meta-model configuration.

Creating a Popularity Score for Reports

The popularity score for configured reports included in the search results for the `Analyze` intent provides information to the user about whether the report is often or seldom visited by users. The popularity score will only be displayed if it is calculated in the background in regular intervals. The following is required to calculate the score:

- The **Presentation Usage Tracking** functionality needs to be activated in the server alias configuration of the Alfabet Web Application. Set the **Track Presentation Usage** attribute in the **Server Settings** > **Tracking** tab to **Local Database** to activate **Presentation Usage Tracking**. For information about the complete configuration options for **Presentation Usage Tracking**, see *Activating Presentation Usage Tracking* in the reference manual *System Administration*.

- An ADIF job based on the standard `UpdateReportsPopularity` ADIF import scheme available in the **Alfabet Standard Jobs** folder of the ADIF explorer in Alfabet Expand must be executed in regular intervals to generate and update the popularity score. The ADIF job can be scheduled for automatic execution via the **Job Schedule** functionality. It will enter the number of times the `POPULARITY` object class property of the `ALFA_REPORT` object class.

  The ADIF job for update of the popularity score will be run automatically on update of the meta-model via AMM file to adapt the search results to changes in the meta-model configuration.

Defining a Search Result Threshold for the Semantic Search

User input into the search field of the faceted semantic search is preprocessed prior to sending it to the search engine. Substrings consisting of multiple words are compared to entities like For example, object class names or indicator type name. If strings are matching an entity name, they are emphasized in the search string sent to the search engine. Emphasizing of search sub-strings is fine tuned if either no search results are returned with the current syntax or if too many results are found. The maximum number of results is 100 per default and can be changed in the XML object ***AlfaChatBotConfig***: that may be returned is configurable with the new XML attribute `AnalyzeIntentResultThreshold` which has been added to the XML element `ChatBotInfo` of the XML object . The default value for the XML attribute `AnalyzeIntentResultThreshold` is 100.

1) Go to the **Presentation** tab in Alfabet Expand.
2) Navigate to **XML Objects** > `IntegrationSolutions` > ***AlfaChatBotConfig***.
3) Right-click the XML object ***AlfaChatBotConfig*** and select **Edit XML**.
4) In the editor in the middle pane, add an XML attribute Anal`AnalyzeIntentResultThreshold` to the child XML element `Settings` of the XML element `ChatBotInfo` and set it to the maximum number of search results:

```
<AlfaChatBotConfig>
    <ChatBotInfo
        ...
        >
        <Settings MaxSelectionOptions="5"
            AnalyzeIntentResultThreshold="100"
            AnalyzeIntentReport="CustomizedReportName" />
    </ChatBotInfo>
</AlfaChatBotConfig>
```

5) In the toolbar, click the **Save** button to save the XML definition.

Managing Automatically Generated Reports

Automatically generated reports are simple tabular datasets that are generated on the fly if the user looks for objects of a defined object class or object class stereotype and the information about the object that

the user wants to know is either the setting of a defined indicator, a defined role for a user, or the value setting for an object class property based on an enumeration.

The automatically generated reports are simple tabular datasets listing all objects that match the search.

Reports will not be generated automatically if the user is searching for information about an object class for which the **Navigation Mode** attribute is set to `False` in the relevant class settings. The user profile permissions to access object class property, indicator, and role information is also considered for automatic generation of reports.

Automatically generated reports are stored persistently after creation. In the **Reports** explorer in Alfabet Expand, they are located in the private folder **Analysis Intent Ad-Hoc Reports** . The name and caption of the automatically generated reports is concatenated from the name or caption of the object class or object class stereotype the information in the automatically generated report is about and the hits from the user question that the information was generated from amended with a random number. For example, a report which is automatically generated for a user query to search components with a high usability, the name would be `ComponentIndicatorNameUsabilityIndicatorSemanticValueHigh_<number>` and the report caption would be `Component - Indicator Name - Usability - Indicator Semantic Value - High`.

Configured reports are stored in the object class `ALFA_REPORT`. The object class `ALFA_REPORT` has a boolean object class property `ADHOC` that is set to `True` for automatically generated configured reports only.

Automatically generated reports are assigned to the user profile the user posting the request that led to the generation of the report was logged in with. The report will be available to other users logged in with the same user profile. If a user logged in with the same user profile uses the faceted semantic search with a request matching the results in the already existing automatically generated report, the existing report will be re-used instead of generating a new report. In addition, the automatically generated report will automatically be visible in the **Configured Reports** functionality of all users with the same user profile. At the same time, it will be excluded from the functionality for all other user profiles and the **Selector Behavior** attribute of the configured report is set to 'Not Visible', which means that the automatically generated reports cannot be selected by a user via a reports selector.

The automatically managed reports will be available to report administrators in the **Report Administration** functionality and the availability for user profiles can be changed by the administrator.

The automatic generation of reports requires activation and maintenance:

- Activating the Automatic Generation of reports
- Configuring the Information to be Displayed in the Automatically Generated Reports
- Deleting Unused Automatically Generated Reports from the Database

Activating the Automatic Generation of reports

To activate automatic generation of reports:

1) Go to the **Presentation** tab in Alfabet Expand.
2) Navigate to **XML Objects** > `IntegrationSolutions` > ***AlfaChatBotConfig***.
3) Right-click the XML object ***AlfaChatBotConfig*** and select **Edit XML**.

4) In the editor in the middle pane, add the XML attribute `AnalyzeIntentType` to the XML element `ChatBotInfo` and set it to one of the following values:

   - `Search`: Automatic generation of reports is deactivated and only existing configured reports will be searched for results. This is the default.
   - `GenerateReports`: Automatic generation of reports is activated and existing configured reports are not searched for results.
   - `Both`: Search results will both include automatically generated reports and results from existing configured reports.

5) In the toolbar, click the **Save**  button to save the XML definition.

A clean-up mechanism for removing un-used automatically generated reports is available. This mechanism deletes all ad-hoc reports that have never been opened by any user. Whether an ad-hoc report has been opened will be read from the presentation usage table. Activation of presentation usage tracking is Therefore, a precondition for clean-up of un-used ad-hoc reports. It is Therefore, highly recommended to activate presentation usage tracking in the server alias of the Alfabet Web Application at the time generation of ad-hoc reports is activated. For information about activation of presentation usage tracking, see the section *Presentation Usage Tracking* in the reference manual *System Administration*.

Configuring the Information to be Displayed in the Automatically Generated Reports

By default, automatically generated reports are simple tabular datasets that provide a list of objects of an object class or object class stereotype that has been identified to match the search condition. Without any additional configuration, the automatically generated reports display all object class properties of the data types String, Text, Date, Integer, and Real which are defined in the **Properties in Preview** and **Image Properties** attributes of the relevant class settings for the object class or object class stereotype. In addition, all object class properties used to filter the ad-hoc report results are displayed. This includes information about the role type or about the indicator type and indicator semantic value, if applicable.

You can change the output of the automatically generated reports to show additional information with the following configurations:

- You can change the **Properties in Preview** section attribute of the class settings of the object class to provide other information. Please note however that this will also change the information displayed in object preview windows.

For information about changing the class setting attributes, see Creating a Custom Class Setting for a Protected Object Class or Object Class Stereotype in the chapter Configuring User Profiles for the User Community.

- Define database views which return the required information. The automatically generated reports are generated from both database tables and database views. If a report is automatically generated from a database view, it will display the dataset of the database view instead of the preview properties from the class settings of the object class.

Only information from database views with the **Applicable for AlfaBot** attribute set to `True` are considered for automatic generation of reports. The search will use the **Base Class** attribute of the database view and the information from the **Semantic Analysis** sub-node of the database view to find relevant database views for automatic generation of reports.

For information about defining database views, see Creating Database Views To Enhance Performance And Support Search Functionalities.

- Define report collections for object classes to provide additional information about the listed objects to the user. If report collections are defined for the object class or object class stereotype the automatically generated report is about, the user will see a number of tabs to open configured reports with additional information such as gantt charts or diagrams about all objects in the tabular dataset. Report collections defined for an object class or object class stereotype are displayed on both standard configured tabular reports and automatically generated reports finding objects of that object class.

For information about the configuration of report collections, see Integration of Configured Reports as Report Collection Into Tabular Configured Reports in the chapter Configuring Reports.

Deleting Unused Automatically Generated Reports from the Database

Automatically generated reports are stored persistently and are re-used, which means that they are added to the result dataset of similar matching user requests, if applicable. Multiple automatically generated reports might be generated per user request, and users might navigate only to one of the ad-hoc reports to find an answer to the current request or they might navigate to a customer configured report instead. Therefore, many ad-hoc reports will never be opened by any user. A mechanism is available to clean the database from un-used ad-hoc reports. This mechanism will delete all automatically generated reports that have not been used by any user and that are not generated on the current date according to the **Creation Date** object class property of the report.

The following configuration is required for the clean-up procedure:

- To clean the database from un-used automatically generated reports, presentation usage tracking needs to be activated when activating ad-hoc report generation. The presentation usage tracking will be read by the clean-up job to evaluate which ad-hoc reports have been opened by users. For information about activation of presentation usage tracking, see the section *Presentation Usage Tracking* in the reference manual *System Administration*.
- An ADIF job based on the standard `AdHocReportsCleanup` ADIF import scheme available in the **Alfabet Standard Jobs** folder of the ADIF explorer in Alfabet Expand must be executed in regular intervals to clean the database from automatically generated reports that have never been opened by any user. The ADIF job can be scheduled for automatic execution via the **Job Schedule** functionality. For information about how to execute ADIF jobs, see *Configuring ADIF Schemes* in the reference manual *Alfabet Data Integration Framework*

During update of the meta-model via an AMM file replacing the configuration in the target database, automatically generated reports are not deleted from the target database.

Excluding Configured Reports from Results for Defined Users or User Profiles

The availability of configured reports via the AlfaBot is controlled by the following mechanisms:

- ***Navigate to Report*** intent: Users have access to all configured reports with the **Applicable for AlfaBot** attribute set to `True`. For more information about the required configuration, see Configuring the Reports.

- ***Analyze*** intent: Users have access to all configured reports found by the private standard ***AlfabetDefaultAnalysisIntentReport*** report or a customer configured substitution of this report defined in the XML object ***AlfaChatBotConfig***. For more information about the required configuration, see Defining the Configured Reports Included in the Search.

In addition, access to configured reports via the AlfaBot can be restrict per user profile or per user. The restrictions configured with this method will be applied to both the navigation to configured reports via the ***Navigate to Report*** and the semantic search in reports via the ***Analyze*** intent.

1) In the **Reports** explorer in Alfabet Expand, right-click the report folder that the report shall be created in and select **Create New Report**.

   For information about structuring configured reports in report folders, see Managing and Structuring Your Configured Reports in Folders.

2) Click the new report and set the following attributes: the

   - **Name**: Change the default name to a meaningful, unique name. The name should not contain special characters or whitespaces.
   - **Type**: Select either `NativeSQL` to define a native SQL query to generate the result dataset, or `Query` to define an Alfabet query.
   - **Applicable for AlfaBot**: Select `True`.
   - **Caption**: Optionally, change the default caption to a meaningful caption.
   - **Description**: Optionally enter a description explaining the purpose of the configured report.
   - **Native SQL Query** / **Alfabet Query**: Click the **Browse** button to open the query editor and define a query as follows:
     - The query must find objects of the object class `ALFA_REPORT`. For an Alfabet query, the `FIND` class must be `ALFA_REPORT`. For a native SQL query, the first argument in the `SELECT` statement must return the `REFSTR` of objects of the object class `ALFA_REPORT`. All other arguments of the `SELECT` statement or show properties defined for Alfabet queries are not relevant for the functionality to restrict access to configured report.
     - Use the Alfabet query parameters `CURRENT_USER` and `CURRENT_PROFILE` to refer to the current working environment.

     The following example is a native SQL query using the parameter `CURRENT_PROFILE` to exclude the configured reports from access via the AlfaBot if they have been excluded for the user profile the user is currently logged in with via the **Reports Administration** functionality. The object class `ALFA_REPORT_USAGE` stores the setting done in the **Reports Administration** functionality. This object class includes all configured reports that have been excluded or included explicitly for a user profile or a user.

     The example query is based on a copy of the query defined in the standard, private configured ***AlfabetDefaultAnalysisIntentReport*** report to ensure that only reports available in general for the ***Analyze*** intent are included in the list of configured reports a user might access when working with a specific user profile:

```
SELECT rep.REFSTR, rep.NAME
FROM ALFA_REPORT rep
```

```
LEFT JOIN ALFA_REPORTUSAGE ru ON ru.REPORT = rep.REFSTR AND
ru.OWNER = @CURRENT_PROFILE

WHERE (rep.TEMPLATE IS NULL

OR (rep.TEMPLATE NOT IN
('ITMAP_TableReport','Relationships_TableReport','Relationshi
ps_EditableTableReport','EvaluationReport','MatrixMapReport_E
x','CustomPivotTable','GaugeReport','RefApiObjectReport','Wid
getReport','UserManagementReport','ContactManagementReport','
EditableClassViewReport','AugmentedAIReport','DiagramListRepo
rt','PercentageDistributionReport','DataCaptureTemplateStatus
Report','QuestionnaireEvaluationReport','DataQualityAIReport'
,'JobScheduleAdministrationReport')

AND rep.TEMPLATE NOT LIKE 'Capture%'))

AND (rep.APPLYTOCLASS IS NULL OR rep.APPLYTOCLASS IN (SELECT
A_NAME FROM ALFA_MM_CLASS_INFO WHERE PARENT IN
('Artifact','ArtifactAuthorized','ContractBase','ProjectClass
es','RiskManagement')))

AND rep.APPLICABLE_ALFABOT=1

AND (ru.A_TYPE = 'Excluded' or ru.A_TYPE IS NULL)
```

3) In the menu of Alfabet Expand click **Save** to save the new report definition.
4) Go to the **Presentation** tab in Alfabet Expand.
5) Navigate to **XML Objects** > `IntegrationSolutions` > ***AlfaChatBotConfig***.
6) Right-click the XML object ***AlfaChatBotConfig*** and select **Edit XML**.
7) In the editor in the middle pane, enter the name of the new report in the XML attribute `AnalyzeIntentUserPermissionReport`of the child XML element `Settings` of the XML element `ChatBotInfo`:

```
<AlfaChatBotConfig>
    <Proxy url="" user="" psw="" domain=""></Proxy>
    <ChatBotInfo
        Type="Dialogflow"
        ...>
        <Settings MaxSelectionOptions="5"
            AnalyzeIntentUserPermissionReport="PermissionReportName" />
    </ChatBotInfo>
</AlfaChatBotConfig>
```

8) In the toolbar, click the **Save**  button to save the XML definition.
9) Restart the web server hosting the Alfabet Web Application. The permissions will only be applied after a web server restart.

A web server restart is also required after changes have been made to the query of the already existing user permission report.

Activating Workflow Start via the AlfaBot for a Workflow Template

Workflows can only be started via the AlfaBot for workflow templates that are configured to accept workflow start via the AlfaBot:

1) In the Workflow tab in Alfabet Expand select the workflow template that shall be started via the AlfaBot.
2) In the attribute window define the following attributes:
   - **Allow AlfaBot to Create New Workflows for Existing Objects**: Set to `True` to allow workflows to be started for processing of existing objects.
   - **Allow AlfaBot to Create New Workflows for New Objects**: Set to `True` to allow workflows to be started for creation of new objects.

Activating the AlfaBot in the AlfaBot Configuration Functionality

The AlfaBot must be initialized in the **AlfaBot Configuration** (`CONF_AlfaBot`) functionality.

The functionality must be made available to an administrative user via the user profile configuration. For information about how to provide access to a functionality for a user, see Making Functionalities Accessible to a User Profile.

When the functionality opens without the AlfaBot being initialized, the explorer will be empty and a **Setup AlfaBot** button will be displayed. Click the button to initialize the AlfaBot. The explorer will be filled with the available intents and the button will no longer be displayed.

Configuring Training Phrases for the AlfaBot

Training phrases are configured in the **AlfaBot Configuration** (ChatBot_Config) functionality in the Alfabet user interface.

The functionality of the AlfaBot is based on intents. An intent is a defined functionality (such as the creation of a new object or the navigation to a configured report) that triggers a predefined response of the AlfaBot. Training phrases are defined for each intent. A training phrase is a phrase that might be entered by a user to trigger the intent. It can contain placeholders for all variables that may occur in the phrase. For example, if a user wants to create an object for an object class or object class stereotype, the placeholder can be entered in the training phrase at the position where the name of the object class or object class stereotype is expected. Placeholders have a predefined name starting with @. For example, a training phrase for the creation of an object could be:

```
I want to create a @classOrStereotype
```

Please note that the AlfaBot only understands English phrases.

If a user enters a phrase in the AlfaBot, the phrase will be sent to Dialogflow. Dialogflow analyzes the result and sends information about the identified intent and the placeholder values back to the AlfaBot. The AlfaBot will execute the intent if both the intent and the placeholders are meaningfully identified in a phrase. Otherwise, it will try to execute one of the intents that request additional information from the user.

The sentences the users type in the AlfaBot window as well as the interpretations returned by Dialogflow are stored in the Alfabet database and Alfabet will try to interpret user sentences based on the already stored and analyzed user sentences if a user uses the same wording for a similar action. If the meaning of the request can be evaluated based on stored prior requests, the sentence will not be sent to Dialogflow again. The costs for language analysis by Dialogflow can be reduced over time via this mechanism.

Internal processing of user input can be deactivated via the **Turn Config Mode On** button in the workspace of the root node of the explorer of the **AlfaBot Configuration** functionality.

For both internal processing and processing via Dialogflow, user input will be processed in different consecutive steps which are all executed with a fuzzy search mechanism to cope with misspellings:

- The user input is first compared to all available training phrases to identify the intent. If the training phrase matches an intent and placeholders are included in the training phrase, the words entered in the location of the placeholders will be identified.
- The captions of relevant configuration objects in the current configuration of the meta-model are provided to Dialogflow as a list of allowed values for the respective placeholders. For example, a value for the placeholder @classOrStereotype will only be resolved successfully if it is identical to the caption of an existing object class or object class stereotype in the current configuration. If user input cannot be mapped to one of the intents via the training phrases, it will be compared with the lists of allowed values for the entity definitions. If it matches an entity definition, the AlfaBot will process it as information about the content provided by the entity. For example, if the AlfaBot asks the user for which object class he/she would like to create an object, the user can enter the object class caption without any additional text. The entry will correspond to an allowed value for object class caption and will be processed as such. Fuzzy search within entity definitions is used to cope with typos in the requests.

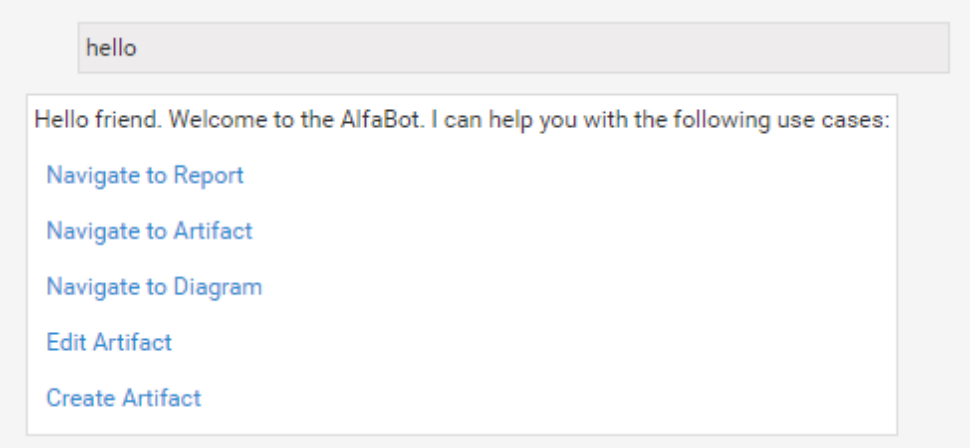
  The entities must be updated if the meta-model configuration changes. Details are provided below.

- If no matching results are found and the user input consists of more than one word, the user input will be split into separate words and a keyword search will be performed. For configured reports, the search mechanisms perform a synonym search on the text provided in the **Business Problem Statement** attribute in addition to a keyword search on caption and description of the configured report.

The font color and font style of the link lists in the AlfaBot are configurable. The styling of intents and options is carried out via the **Alfabot Options Styles** section of the GUI scheme. For more information, see the section Configuring GUI Scheme Definitions for the Alfabet Interface in the chapter Configuring the Visualization of the Alfabet Interface as well as a detailed documentation of all GUI scheme attributes in the chapter *Overview of GUI Scheme Attributes* in reference manual *Configuring Alfabet with Alfabet Expand - Appendix*.

All intents that can be processed by the AlfaBot are listed in the explorer of the **AlfaBot Configuration** functionality. The following intents are available:

- **Welcome**: Phrases that the user might enter as a welcome text with no additional intention, like "Hello" or "Good Morning". The AlfaBot will answer with any of the configured responses followed by a list of the activities that are supported by the AlfaBot. The user can click any of the activities and will then be asked immediately to provide the required information about the object, class or view names relevant for the intent of the selected use case without needing to type a phrase that identifies the intent.



The font color and font style of the link list can be changed via the GUI scheme configuration by means of the attributes in the attribute section **Application** > **AlfaBot Option Styles** > **Intent Style**. For more information about the configuration of GUI schemes, see Configuring GUI Scheme Definitions for the Alfabet Interface.

- **Create Artifact**: If the user wants to create a new object, he/she can use any of the configured training phrases. Object creation can be supported either context-free or context-dependent: The AlfaBot needs the caption of the object class or object class stereotype to process the intent. If the object class or object class stereotype is configured to allow creation via the AlfaBot, the AlfaBot will open the editor or wizard for creation of a new object. After the user has created the object, the object profile or object cockpit of the new object will open in the Alfabet user interface. If the object class or object class stereotype is configured to deny creation via the AlfaBot, the AlfaBot will inform the user.
  - Context-free object creation: Any object that can be created without knowing the defined context (such as an application) can be created context-free. The AlfaBot requires the caption of the object class or object class stereotype to process the intent. If the object class or object class stereotype is configured to allow creation via the AlfaBot, the AlfaBot will open the editor or wizard to create the new object. After the user has created the object, the object profile or object cockpit of the new object will open in the user interface.
  - Context-dependent object creation: Any object that requires a specific context (such as a business service which can only be created in the context of a providing application) is created context-dependent. The AlfaBot needs the caption of the object class or object class stereotype to process the intent. If the object class or object class stereotype is configured to allow creation via the AlfaBot, the AlfaBot will scan the configuration of the current user profile for the ability to create the object via the buttons in page views. If the object can be created in multiple views, the user will be asked for more details. The AlfaBot will also ask the user for the name of the object he/she wants to create a dependent object for. The AlfaBot will open the relevant view for the object that the user specifies as the context object.

If the object class or object class stereotype is configured to deny creation via the AlfaBot, the AlfaBot will inform the user.

- **Navigate to Artifact**: If the user wants to open a standard page view for an existing object or the object profile or object cockpit of an existing object, he/she can use any of the configured training phrases. The AlfaBot needs the caption of the object class or object class stereotype, the name of the object, and optionally the caption of a standard page view or object cockpit to process the intent. If the object class or object class stereotype is configured to allow navigation via the AlfaBot

and the user profile configuration the user is currently logged in with provides access to the view, the AlfaBot will open the defined view. If the user does not provide information about a standard page view or object cockpit to open, the object profile or first defined object cockpit will open. If the object class or object class stereotype is configured to deny navigation via the AlfaBot, the AlfaBot will inform the user.

- **Edit Artifact**: If the user wants to edit an existing object, he/she can use any of the configured training phrases. The AlfaBot needs the caption of the object class or object class stereotype and the name of the object to process the intent. If the object class or object class stereotype is configured to allow editing via the AlfaBot, the AlfaBot will open the editor or wizard for the object. If the user profile of the user is configured to open a wizard for editing the object, the user can add the caption of the wizard view he/she would like to edit to the request. The wizard will then open displaying the requested wizard step. After the user has edited the object, the object profile or object cockpit of the edited object will open in the Alfabet user interface. If the object class or object class stereotype is configured to deny editing via the AlfaBot, the AlfaBot will inform the user.
- **Navigate to Diagram**: If the user wants to open a configured report, he/she can use any of the configured training phrases. The AlfaBot identifies the diagram via a combination of diagram name, diagram type, and the name of the object that the diagram was created for. The AlfaBot will open the requested diagram.
- **Navigate to Report**: If the user wants to open a configured report, he/she can use any of the configured training phrases. The AlfaBot needs the caption of the report to process the intent. The AlfaBot will open the requested configured report.
- **Start Workflow**: If the user wants to start a workflow, he/she can use any of the configured training phrases. Workflows can be started via the AlfaBot for all workflow templates that have been enabled to start via the AlfaBot. In the AlfaBot, a user can ask to start a workflow for an existing object by entering the object class stereotype and object name. If multiple workflows can be started for the object, these will be listed in the AlfaBot and the user can start the relevant workflow. Alternatively, the user can ask to start a workflow by entering the workflow caption. Multiple captions defined to start a workflow with new objects or with existing objects will be taken into account. In this case, the AlfaBot will request information about the object that the workflow shall be started with. The caption of the workflow started via the AlfaBot is a concatenation of the caption configured for the workflow and the name of the object that the workflow has been started for.
- **Analyze**: If a user searches for specific information in reports that may not have relevant information in the title or description, he/she can use any of the configured training phrases. For example, a user searching for information about the usability of the enterprise's applications could find the report "Market Readiness of Applications" which includes an indicator for usability even though the term "usability" is neither in the title or description of the report.
- **Provide Keywords**: If the AlfaBot is not able to identify a configured report in the **Navigate to Report** request, for example, the user will be asked to provide keywords to identify the report. The user can answer this request with any of the configured training phrases for this request or provide the keywords without additional text. If multiple keywords are provided, they can be separated with either a comma, the word "`and`", or an ampersand (&).
- **Provide Class or Stereotype Name**: If the AlfaBot is not able to map the value of a placeholder that should return an object class caption or object class stereotype caption to any of the available object classes or object class stereotypes, the user will be asked to provide a correct caption. The user can answer this request with any of the configured training phrases for this request or provide the object class or object class stereotype caption without additional text.

- **Provide Object Name**: If the AlfaBot is not able to map the value of a placeholder that should return an object name to any of the available objects, the user will be asked to provide a correct object name. The user can answer this request with any of the configured training phrases for this request or provide the object name without additional text.
- **Fallback**: This intent will be executed if the phrase that the user enters in the AlfaBot cannot be mapped to any of the other intents. The AlfaBot will answer with any of the configured responses.
- **Provide Positive Confirmation**: If the AlfaBot requests a confirmation from the user that the interpretation of the user request is correct, the user can answer with any of the configured training phrases for this intent to confirm.
- **Provide Negative Confirmation**: If the AlfaBot requests a confirmation from the user that the interpretation of the user request is correct, the user can answer with any of the configured training phrases for this intent to confirm.
- **Cancel Conversation**: Phrases that the user might enter to indicate that he/she would like to end the conversation in the AlfaBot window. By default, no response is returned and the AlfaBot will close without a prior response. Optionally, responses can be configured. The AlfaBot will answer with any of the configured responses prior to ending the conversation.
- **Ask for Help**: Phrases that the user might enter if he/she does not know how to work with the AlfaBot. The AlfaBot will answer with any of the configured responses.

If you click an intent in the explorer, a workspace opens that lists all training phrases and, if applicable, responses that are available in a table. All training phrases are listed by default in ascending alphanumerical order. You can change the sort order by clicking the header of a column in the table. The table provides the following information:

- **Training Phrases** / **Responses**: The text of the training phrase or response is listed in the column. If an intent can have both training phrases and responses, the table will be an expandable dataset with a separate section for training phrases and responses.
- **Synchronized**: The column displays a selected checkbox for all training phrases and responses that have been sent to Dialogflow. If the selected checkbox is not displayed, the training phrase can currently not be used for the intent. Click the **Synchronize** button in the toolbar to send the phrases to Dialogflow.
- **Reserved**: If the column displays a selected checkbox, the training phrase or response is a standard phrase that cannot be edited or deleted.

The AlfaBot is preconfigured to understand standard training phrases. Some of these are reserved to ensure a basic functionality of the AlfaBot and cannot be changed or deleted. If the training phrases provided by default do not match the wording that is typically used by your users, you can add typical phrases that you expect to be entered in the AlfaBot for the selected intent.

It is recommended to use the **AlfaBot Interaction Analysis** functionality to analyze the outcome of user input in the AlfaBot and to decide about new training phrases based on actual user input. For more information, see the section *Training the AlfaBot to User Input* in the reference manual *User and Solution Administration*.

To create a new training phrase or a new response for the **Welcome**, **Fallback**, **Cancel Conversation**, and **Ask for Help** intents:

1) Click the **Intents** root node of the explorer.
2) Click the **Turn Configuration Mode On** button.

If the button is called **Turn Configuration Mode Off**, the configuration mode is already turned on. In configuration mode, training phrases can be edited and user input is exclusively processed via Dialogflow. Internal pre-processing based on existing intents is deactivated.

3) In the explorer, click the intent for which you want to add training phrases.

4) In the toolbar of the intent's workspace, click **New** > **Training Phrase** to enter a training phrase or **New** > **Response** to enter a response. An editor opens.

5) Enter text in the **Training Phrase** field for the training phrase or the **Response** field for the response. For a training phrase, enter a phrase that the user can enter to execute the intent. The training phrase must fulfill the following criteria:

- The training phrase must be written in English.
- The training phrase must not contain special characters and punctuation. A mechanism is implemented that strips the following characters from the training phrase or response on synchronization: comma (,) dot (.), semicolon (;), question mark (?), exclamation mark (!), slash (/), backslashes followed by quotation mark or single quotation mark (\', \"), curly brackets ({,}), parenthesis ((,)), square brackets ([,]), angle brackets (<,>), plus sign (+), equal sign (=), asterisk (*), underscore (_), dollar sign ($), hash (#), circumflex (^), percent sign (%).
- The guidelines for the intent provide information about the placeholders that can be used in the training phrase. A training phrase can only include each placeholder once. It can include only a subset or none of the placeholders listed in the guidelines. The AlfaBot will then ask the user to provide the missing information.

  Typically a placeholder is used for names of For example, objects, object classes, or configured reports. An exception of this rule is the `Analyze` intent where the placeholder `@report` is not standing for the name of a configured report but the complete information the user is looking for. Standard training phrases for this intent are For example, "What are `@report`" or "Where are `@report`". This ensures that most of the user input is analyzed via the search mechanism.

- The training phrase must not consist of only placeholders. The identification of a placeholder without text is managed by a separate mechanism that does not require training phrases and will not work properly if a training phrase consists of only placeholders.

  The identification of only placeholder values as input requires additional configuration described below.

For a response, enter a phrase that the AlfaBot can return to the user as a result of the intent. The phrase must not include placeholders and it must be written in English language.

6) Click **OK**. The training phrase or response is added to the table. The **Synchronized** column is empty.

7) In the toolbar, click **Synchronize**. The training phrase or response is sent to Dialogflow. The **Synchronized** column now displays a checkmark.

8) Click the **Intents** root node of the explorer.

9) Click the **Turn Config Mode Off** button.

Existing training phrases or responses that are not reserved can be edited via the **Edit** button or deleted via the **Delete** button. Both actions require that the changes to the training phrases for the intent are synchronized with Dialogflow via the **Synchronize** button afterwards.

Each time a customer-defined training phrase is changed or added in the AlfaBot configuration functionality or a standard training phrase is added or changed via an update of the meta-model (for example, on upgrade to a new Alfabet release), an example question will be added to the internal list of stored user input in the AlfaBot. This reduces the number of requests send to Dialogflow®. If a user enters a request corresponding to the new training phrase in the AlfaBot, the internal pre-processing can interpret the request based on the example phrase and does need to send this request to Dialogflow®. The example phrases are not visible in the **AlfaBot Interaction Analysis** functionality.

Deactivating Intents

Intents can be deactivated in the **AlfaBot Configuration** (`ChatBot_Config`) functionality in the Alfabet user interface.

If an intent is deactivated, it is not taken into account by the AlfaBot when trying to match the user input to an intent. In addition, it is removed from the list of intents displayed to the user on first opening of the AlfaBot in a user session. For example, for companies that have not implemented workflows, it would be confusing for the users to see the intent about start of a workflow in the intent list of the AlfaBot and the workflow intent should Therefore, be deactivated. Only intents listed on start of the AlfaBot can be deactivated.

1) Click the root node of the explorer. A view with a table listing relevant intents and the information about activation or deactivation is displayed. By default, all intents are activated and show a hook in the column **Active**.
2) In the table listing the intents, select one or multiple intents that you would like to deactivate.
3) In the toolbar above the table, select **Deactivate**.
4) End the user session and re-start the Alfabet Web Application to apply the changes.

To re-activate a deactivated intent, select the intent in the table and click **Activate** in the toolbar. Re-activation also requires a re-start of the Alfabet Web Application to apply the changes.

Updating Dialogflow Entities With Information About Customization of the Meta-Model

For some intents, the user may enter a placeholder value only. For example, if the AlfaBot asks the user to provide the name of an object class, it is highly probable that a user will not enter "The name is application", but "application" only.

Placeholders in training phrases correspond to entities in Dialogflow. Some of the entities for the intents that are preconfigured for Alfabet not only provide a name for the placeholder in the training phrase, but also provide a range of allowed content values. For example, for object classes, a list of object class captions is stored directly in Dialogflow. Captions of standard page views, wizard steps, and configured reports are also stored in the respective entities.

If a user enters text in the AlfaBot, Dialogflow first compares the text with the available training phrases. If no matches are found, the text is compared with the list of values defined for each entity. If the entry matches an entity value, the information is processed accordingly.

On update of the meta-model via AMM files, new entity values based on the changes applied to the meta-model are directly sent to Dialogflow if the connection to Dialogflow is configured and active while updating the meta-model. Customer configuration of the current database directly performed in Alfabet Expand must be updated manually. This includes stereotype definition, configured reports, and re-naming of standard page view captions and object class names via the vocabulary or via view customization.

Click the **Update AlfaBot Entities** button in the workspace of the root node of the explorer to update entity values for Alfabet -specific intents with strings resulting from configuration of the meta-model.

Running the AlfaBot in Offline Mode

The connection of the AlfaBot to Dialogflow can be deactivated temporarily or permanently if the high number of already processed intents enable the AlfaBot to handle user requests on basis of pre-processed intents only. The connection can be deactivated permanently or until the next web server restart only.

To deactivate the connection until the next web server restart:

- In the **AlfaBot Configuration** functionality on the Alfabet user interface, click the button **Use AlfaBot Offline**.

The Alfabet Web Application will check on each Web Server restart whether DialogFlow is accessible and will return to online mode if the check is positive.

To deactivate the connection to Dialogflow permanently:

- In Alfabet Expand, go to the **Presentation** tab.
- Expand the explorer nodes **XML Objects** > ***IntegrationSolutions***.
- Right click the node ***AlfaChatBotConfig*** and select **Edit XML**.
- In the editor, add the XML attribute `IsOffline` to the XML element `ChatBotInfo` and set it to `true`.

```
<AlfaChatBotConfig>
    <ChatBotInfo
        Type="Dialogflow"
        IsActive="true"
        IsOffline="true"
        [...]>
        <Settings [...]>
    </ChatBotInfo>
    </AlfaChatBotConfig>
```

Configuring the Extended Data Capture Functionality

The **Extended Data Capture Templates** functionality provides a sophisticated and comprehensive means to collect large sets of data for object classes as well as reference information for properties of the type `ReferenceArray` in the context of XLSX files. One or more data capture templates can be configured for a permissible object class in order to address multiple data capture approaches for different regional units, customer segments, products, etc. Data may be captured in any of the languages supported by your enterprise.

For more information about data collection via data capture templates, see the section *Capturing Data with Data Capture Templates* in the reference manual *User and Solution Administration*.

The following configuration is required to implement the **Extended Data Capture Templates** functionality:

- **Enable for Data Capture Templates**: Select `True` if the object class may be captured via data capture templates. Select `False` if the object class may not be captured via data capture templates. For each object class for which the **Enable for Data Capture Templates** attribute is set to `True`, you must enable the individual properties that shall be captured for the object class by setting the **Enable for Data Capture Templates** attribute for each object class property to `True`. For information about specifying the **Enable for Data Capture Templates** attribute for an object class property, see the section Editing a Protected Property.
- Specify the object class and object class properties for which data shall be captured:
  - Set the **Enable for Data Capture Templates** attribute to `True` for the object class for which a data capture template is to be configured. Data capture is limited to `Artifact` object classes only and the **Enable for Data Capture Templates** attribute may only be specified for those classes for which data capture is permissible. If data capture is not permissible for a class, the attribute will be greyed out.
  - Set the **Enable for Data Capture Templates** attribute to `True` for each public or protected object class property that shall be exported to the data capture template for the object class. If the protected property is inherited from the parent object class `Artifact` or `ArtifactAuthorized`, then the **Enable for Data Capture Templates** attribute will be greyed out. In this case, you must specify a local setting for the property that will apply to the property only in the context of this object class. To do so, expand the **Local Settings** section and set the **Enable for Data Capture Templates** attribute to `True` to override the inherited setting from the parent object class.

    Properties of the type `BinData`, `Picture`, `DateArray`, `POSIX`, `ByteArray`, `DateArray`, `DateTimeArray`, `BindataArray`, `IntegerArray`, `TimeArray`, `PropertySet`, `StringArray`, and `URLArray` are not suitable for data capture templates.

    For more information about configuring object classes and object class properties, see the chapter Configuring the Class Model in the reference manual *Configuring Alfabet with Alfabet Expand*.

- Specify the release statuses for class-based and reference-based date capture templates. Release status definitions must be configured in the XML object ***ReleaseStatusDefs*** for the classes `ALFA_DATACAPTURETEMPLATE:Class` and `ALFA_DATACAPTURETEMPLATE:Reference`. For more information about specifying release statuses, see the section Configuring Release Status Definitions for Object Classes in the reference manual *Configuring Alfabet with Alfabet Expand*.

- If necessary, create configured reports that shall be assigned to data capture templates. The configured report should be of the type `Query` or `NativeSQL` and should return the set of objects to be reviewed, updated, or deleted as well as the sort order of the returned objects. For each configured report, the **Category** attribute of the configured report must be set to ADIF or the relevant category specified for the use case `DataCaptureTemplates` in the XML object `UseCaseCategory`. The reports assigned the relevant category for data capture templates will be available in the Export Record Provider field in the **Data Capture Template** editor. For more information about specifying the XML object `UseCaseCategory`, see the section Assigning a Category for Specific Functional Use to a Configured Report For more information about how to create a configured report, see the chapter Configuring Reports in the reference manual *Configuring Alfabet with Alfabet Expand*. Configured reports may need to be created for the following:

  Please note that instead of specifying a configured report to limit the set of objects available in the XLSX file, it is also possible to specify that either all available objects or only objects based on a specified stereotype may be exported.

  - Configured reports may be configured to find the objects for the relevant object class targeted by the data collection activity that shall be exported to the XLSX file.
  - Configured reports may be configured to find the referenced objects for properties of the type `Reference`.
  - Configured reports may be configured to find the relevant objects for properties of type `ReferenceArray`. A configured report may be specified to find objects of the base class of the reference and another configured report may be configured to find the objects that the base class objects may reference.
  - Configured reports may be configured to find the relevant persons or organizations referenced by a role type.
  - Optional for either class-based or reference-based data capture templates: A configured report may be configured to find the objects to export as sample data to the XLSX file. Sample data may be exported to the XLSX file to provide examples of existing data for users to understand how to create or modify the data in the XLSX file. The sample data is exported to a **Sample Data** tab in the XLSX file where users can experiment with the data. The sample data will not be reimported to Alfabet and Therefore, the Alfabet database will not be impacted by changes made to the sample data.

- Ensure that the **Extended Data Capture** (`ADMIN_CaptureDataNextGen`) functionality is available to the user profile of the users that will be responsible for configuring data capture templates and importing and exporting the data. For more information about adding functionalities to a user profile, see Making Functionalities Accessible to a User Profile in the chapter Configuring User Profiles for the User Community.
- If necessary, configure the asynchronous import and export for large amounts of data. If asynchronous execution is configured, the user defining the data capture template may activate asynchronous import/export of data. If asynchronous import/export of data is not activated, the data will be imported and exported synchronously. To make asynchronous execution available for data capture.
  - The asynchronous import and export of data requires a running Alfabet Server to be connected to the same database as the Alfabet Web Application providing the **Extended Data Capture** functionality in the Alfabet user interface.

- A remote alias must be configured and the **Use Server to Execute ADIF Jobs** checkbox must be selected for the remote alias. For more information, see the section *Creating a Remote Alias* in the reference manual *User and Solution Administration*.
- The Alfabet Web Application must be configured to connect to the Alfabet Server via the remote alias and to use the Alfabet Server for the execution of ADIF jobs. The **Use Server to Execute ADIF Jobs** attribute in the **Application Server** tab of the server alias of the Alfabet Web Application must be selected.
- The RESTful services must be activated for the Alfabet Web Application as defined in the reference manual *Alfabet RESTful API*. The configuration of the RESTful services must grant at least the following access:
  - A user for execution of self-reflective events must be defined.
  - Both the access permissions for the RESTful services in the server alias of the Alfabet Web Application and for the user for execution of self-reflective events must grant the permissions **Has Batch Utilities API Access**.
- Specify the document folder in the **Internal Document Selector** where the XLSX files generated during asynchronous import/export shall be stored in. This is specified in the XML object ***IDocManagerConfiguration*** and is described in detail in the section Configuring Access Permissions to Folders in the Internal Document Selector for the Job Schedule. Please note that the configuration of the folder for data capture templates is included in the XML specification `<UseCase Name="JobSchedule">`. The caption specified in the XML attribute `Folder Name` will be displayed for the folder in the **Import/Export Asynchronously** tab of the **Data Capture Template - Class** editors. This caption may differ from the technical folder name in the XML attribute `Path`.
- In the **Import/Export Asynchronously** tab of the **Data Capture Template - Class** editor available in the **Extended Data Capture** functionality, ensure that the **Import/Export Asynchronously** checkbox is selected and select the relevant document folder in the **Internal Document Selector** where the export file shall be created. For more information about the required configuration of extended data capture templates, see the section *Capturing Data with Data Capture Templates* in the reference manual *Configuring Alfabet with Alfabet Expand*.

Activating the Job Schedule Functionality

With the **Job Schedule** functionality, users can schedule execution of the following functionalities in regular intervals.

- ADIF import and ADIF export.
- Removal of old information about ADIF session execution from the Alfabet database.
- Update and creation of full text search indexes.
- Re-computation of automatically calculated indicators.
- Assignment of coloring defined by color rules.
- Starting workflows configured to be started automatically, for closing workflow steps configured to be closed automatically, for automatic deletion of finished workflows, and for rescanning and updating roles and responsibilities for workflows and workflow steps.

In the **Job Schedule** functionality, users can create objects of the object class Job Schedule that provide information about the functionality to execute and the time table for execution. Directly after creation of a job schedule, a wakeup event is added to a job scheduler event queue with the information about the job schedule and the next execution time.

The Alfabet Server checks the event queue in regular intervals for job schedules that need to be executed. At execution time, the following is done:

- A RESTful service call to the Alfabet RESTful services schedules an ADIF job for immediate execution in the queue for ADIF execution. All job schedule functionalities are executed via ADIF.

  For the execution of ADIF import and ADIF export, the defined ADIF job is scheduled for execution. For all other functionalities, standard private ADIF jobs are available to execute the functionalities. The ADIF jobs are visible in the ADIF explorer in Alfabet Expand in the folder ***StandardJobs***. They cannot be edited.

- A new wakeup event for the next execution in the job schedule's time table is added to the job scheduler queue.

The following preconditions must be met to enable the **Job Schedule** functionality:

- The job scheduler requires a running Alfabet Server to be connected to the same database as the Alfabet Web Application providing the **Job Schedule** functionality on the user interface.
- The Alfabet Web Application must be configured to to use the Alfabet Server for execution of ADIF jobs. The **Use Server to Execute ADIF Jobs** attribute in the **Application Server** tab of the server alias of the Alfabet Web Application must be selected.
- The RESTful services of the Alfabet Web Application must be activated and configured as described in the chapter *Activating the Alfabet RESTful API on Server Side* of the reference manual *Alfabet RESTful API*.
- A user must be configured for execution of RESTful service calls via self-reflective events. For more information, see Configuring a User to Execute Self-Reflective Events below.
- The **Job Schedule** (`JobSchedule`) functionality must be added to the user profile of the user that will be responsible for scheduling the jobs. For more information about adding functionalities to a

user profile, see Making Functionalities Accessible to a User Profile in the chapter Configuring User Profiles for the User Community.

- Optionally, the interval that the Alfabet Server checks the queues for scheduled wakeup events and ADIF jobs can be adapted to your demands. The default intervals are optimized for the functionality and usually do not need to be changed. For more information, see Changing the Interval for Checking the Queues of Scheduled Events and ADIF Jobs below.
- For the execution of ADIF export and import, a number of additional configurations are required that are described below in the section Configuration Required for Scheduling ADIF Jobs.
- For the rescan of indicators, a number of additional configurations are required that are described below in the section Configurations for Scheduling Rescan of Indicators.
- For each functionality to execute, the required configuration for activation and execution of the functionality in Alfabet has to be available. For information about the configuration of the basic functionalities provided by the job schedules, see one of the following:
  - For the configuration of ADIF export schemes, see *Configuring Data Export with ADIF* in the reference manual *Alfabet Data Integration Framework*.
  - For the configuration of ADIF import schemes, see *Configuring Data Import with ADIF* in the reference manual *Alfabet Data Integration Framework*.
  - For the configuration of the full-text search functionality, see Configuring the Full-Text Search Capability.
  - For the configuration of color rules, see *Configuring Color Rules for Map Views and Diagram Views* in the reference manual *Configuring Evaluation and Reference Data in Alfabet*.
  - For the definition of automatically calculated indicators for evaluation types, see *Configuring Evaluation Types* in the reference manual *Configuring Evaluation and Reference Data in Alfabet*.
  - For the configuration of workflows, see Configuring Workflows

The following information is available:

- Configuring a User to Execute Self-Reflective Events
- Changing the Interval for Checking the Queues of Scheduled Events and ADIF Jobs
- Defining Maintenance Windows
- Configuration Required for Scheduling ADIF Jobs
  - Creating Categories for the Job Schedule Use Case
  - Configuring the ADIF Scheme to be Executable via the Job Schedule Functionality
  - Configuring Access Permissions to Folders in the Internal Document Selector for the Job Schedule
- Configurations for Scheduling Rescan of Indicators
  - Creating Report Categories for the Job Schedule Use Case
  - Defining the Query in a Configured Report

Configuring a User to Execute Self-Reflective Events

The user selected for execution of events of the type `SelfReflective` will be used for authentication of RESTful service calls to the RESTful API of the Alfabet Web Application for both wakeup events involved in job scheduling and for all other event based activities that involve execution via the RESTful API.

For more information about triggering actions via event templates, see the chapter Configuring Events.

It is recommended to create a user that is exclusively used for executing events via the RESTful services. The user can be excluded from access to any objects except for executing job schedules, asynchronously starting ADIF jobs via the user interface, and start of workflows, RESTful service calls and/or execution of ADIF jobs via events based on event templates, but it is also possible to use an existing user.

The user must be a named user with at least one user profile assigned. The user profile is not used for evaluation of access permissions. A ReadOnly user profile is sufficient to execute the RESTful services in the context of events.

Only one user can be selected for execution of events of the type `SelfReflective`. If you assign this functionality to a user while another user has already been selected to execute self-reflective events, the setting is removed from that user when it is set for the user you are currently assigning it to. Therefore, if a user has already been defined in the context of the activation of any other functionality, you should add the required access permissions described below to this user instead of creating another user to make sure that the permissions for the functionality the user was created for is maintained.

To create a user for execution of self-reflective events in the **User Administration** functionality on the Alfabet user interface:

The same functionality is also available via the Alfabet Administrator. For information about accessing the user management functionalities of the Alfabet Administrator see *Functionalities Available via the Expanded Explorer of the Connected Alias* in the reference manual *System Administration*.

1) In the toolbar of the **User Administration** view, select **New** > **Create New User**. An editor opens.
2) In the editor, define the following:

   Basic Data tab:

   - **Name**: Enter a meaningful name for the user. The user is a technical user. You can either assign the name of an existing person to it or give it a name that indicates that this is a virtual person defined to execute a functionality.
   - **User Name**: Enter a user name. The user name is used by the RESTful services to identify the user.
   - **Type**: Select `NamedUser`.

   API Permissions tab:

   - **Has API V2 Access**: Select the checkbox.
   - **API Access Options**: Make sure that the following permission are selected:
     - **Has ADIFAPIInvocation Access** for the execution of ADIF schemes via the **ADIF Import Job Schedule** and the **ADIF Export Job Schedule**.

- **Has Batch Utilities API Access** for the execution of all other job schedules.

- **Generate API Password**: Click the button. The API Password field is filled. For events of the type `Query`, copy the **API User Name** and the **API Password** . These have to be entered into the specification in the XML object `AlfabetIntegrationConfig` described below in the section Configuring the Connection Parameters in the XML Object AlfabetIntegrationConfig.

3) Click **OK** to close the editor. The new user is added to the table in the **User Administration** view.
4) Select the user in the table and select **Action** > **Set as Executes Self-Reflective Events User** in the toolbar.
5) Select the user in the table and click the **Navigate**  button.
6) In the object profile of the user, click **Assigned User Profiles**.
7) In the toolbar of the **Assigned User Profiles** view, click **New** > **Assign User Profiles**.
8) In the selector, select a user profile and click **OK** to assign it to the user. For a user that is exclusively used for events, it is recommended to use a ReadOnly user profile.

The configuration described above is the configuration required for the **Job Schedule** functionality only. In addition, you can set any other properties of the user. For security reasons you might also consider to assign a login password to the user although the user password is not required for the **Job Schedule** functionality. For information about the available configuration options for users, see *Defining and Managing Users* in the reference manual *User and Solution Administration*.

Changing the Interval for Checking the Queues of Scheduled Events and ADIF Jobs

This configuration is optional. The default interval of the Alfabet Server for checking the wakeup events created for execution of job schedules for ADIF jobs due for execution is 500 milliseconds and the default interval of the Alfabet Server for checking the ADIF jobs queue and execute the next ADIF job is 3000 milliseconds. Optionally, you can adapt these values to your demands.

The configuration has to be performed in the tool Alfabet Administrator:

1) In the explorer of the Alfabet Administrator, click the **Alfabet Aliases** node.
2) In the table, select the server alias configuration that is used for starting the Alfabet Server.
3) In the toolbar, click the Edit  button. The server alias editor opens.
4) Go to the **Server Settings** > **General** tab and edit the following attributes:
   - **ADIF Job Server Sleep Time (milliseconds)**: Enter the time between checking of the queue of ADIF jobs to be executed.
   - **Event Server Sleep Time (milliseconds)**: Enter the time between checking the event queue for scheduled wakeup events to be executed.
5) Click **OK** to save your changes.

Defining Maintenance Windows

This configuration is optional. Maintenance work on the Alfabet components, like For example, update of the meta-model, conflicts with the execution of scheduled jobs. To ensure that no scheduled jobs are executed during maintenance, maintenance windows can be defined in Alfabet. Job schedules can then be configured to read the current maintenance window specification and schedule any job that is due during a maintenance window to start 1 minute after the end time of the maintenance window instead.

Maintenance windows can either be configured to be recurring once a week or once a month or they can be scheduled for a specified date. All specifications refer to the time of the server host.

Maintenance windows are configured in the XML object ***MaintenanceWindows*** in Alfabet Expand:

1) In the Presentations tab, expand the explorer nodes **XML Objects** > **Administration**.
2) Double-click the ***MaintenanceWindows*** node. The XML editor opens in the middle pane with an empty root XML element:

   ```
   <MaintenanceWindows></MaintenanceWindows>
   ```

3) For each maintenance window that you want to define, add a child XML element `MaintenanceWindow` to the XML element `MaintenanceWindows`.
4) The definition of the XML attributes for the XML element `MaintenanceWindow` depends on the scheduling options:

   To define a recurring maintenance window, add the following XML attributes:

   - `DayOfWeek`: If the maintenance window occurs once a week, define the day of the week that the maintenance window shall occur. Allowed values are the English names of the days of the week starting with a capital letter.
   - `DayOfMonth`: If the maintenance window occurs once a month, define the day of the month that the maintenance window shall occur as integer.
   - `StartTime`: Define the start time of the maintenance window in the twenty-four hour time in the format hh:mm.
   - `EndTime`: Define the end time of the maintenance window in the twenty-four hour time in the format hh:mm.

   Example for maintenance windows recurring once a week and once a month:

   ```
   <MaintenanceWindows>
      <MaintenanceWindow DayOfWeek="Friday" StartTime="20:30"
      EndTime="23:00"/>
      <MaintenanceWindow DayOfMonth="12" StartTime="08:00"
      EndTime="12:00"/>
   </MaintenanceWindows>
   ```

   To define a maintenance window for a defined date, add the following XML attributes:

   - `Format`: Define the date format that you will use for definition of the date for the maintenance window. the XML attribute is optional. If it is not defined, the date format defined in the culture settings that are configured to be the primary culture are used.Allowed formats are:

- MM/dd/yyyy
- dd/MM/yyyy
- M/d/yyyy
- d/M/yyyy

- `Date`: Define the date the maintenance window will occur in the format defined with the XML attribute `Format`.
- `StartTime`: Define the start time of the maintenance window in the twenty-four hour time in the format hh:mm.
- `EndTime`: Define the start time of the maintenance window in the twenty-four hour time in the format hh:mm.

Example for a one time maintenance window:

```
<MaintenanceWindows>
   <MaintenanceWindow Date="12/13/2019" Format="MM/dd/yyyy"
   StartTime="08:00" EndTime="12:00"/>
</MaintenanceWindows>
```

5) In the toolbar, click the **Save**  button.

Maintenance work is usually scheduled by system administrators with no access to Alfabet Expand. The XML object ***MaintenanceWindows*** can Therefore, also be defined in the Alfabet Administrator or in an XML file located on the local file system and imported into the XML object in the Alfabet database via a command line tool.

To provide access to the XML object ***MaintenanceWindows*** via the Alfabet Administrator, set the attribute **Visible In Administrator** of the XML object to `True`.

For more information about the methods for defining maintenance windows that are available for system administrators, see *Defining Maintenance Windows for Scheduled Jobs* in the reference manual *System Administration*.

Configuration Required for Scheduling ADIF Jobs

The following configuration is required for the execution of ADIF import or ADIF export via the **Job Schedule** functionality. These configuration steps are not required for other job schedules.

The following information is available:

- Creating Categories for the Job Schedule Use Case
- Configuring the ADIF Scheme to be Executable via the Job Schedule Functionality
- Configuring Access Permissions to Folders in the Internal Document Selector for the Job Schedule

Creating Categories for the Job Schedule Use Case

ADIF schemes can only be scheduled via the **Job Schedule** functionality if they are assigned to a category defined for the functionality in the XML object ***UseCaseCategories***.

To set the categories for the **Job Schedule** functionality in the XML object ***UseCaseCategories***:

1) In the **Presentation** tab of Alfabet Expand, expand the explorer node **XML Objects**.
2) Right-click on the XML object ***UseCaseCategories*** in the explorer and select **Edit XML** from the context menu. The XML object opens in the middle pane.
3) Enter the following code as child element of the XML element ***UseCaseCategories***:

```
<UseCaseInfo UseCase="JobScheduler">
   <ScopeInfo Scope="ADIF" Categories="CommaSeparatedListOfCategories" />
</UseCaseInfo>
```

   The XML attribute `Categories` must be set to either one category name or a comma separated list of category names. Please note that a category name is a technical name and should not contain special characters or whitespaces. All category names that are defined can be used in the **Category** attribute of an ADIF scheme to activate scheduling for the ADIF scheme.

   Private ADIF schemes are delivered with Alfabet to trigger For example, automated translation or import or export in the scope of an integration interface. If you would like to schedule execution of these private ADIF schemes, the list of categories must include the respective category that is preset for the ADIF scheme. The following category names are set for private ADIF schemes:

   - `Translation` for all ADIF jobs for batch processing associated with automated translation.
   - `Technopedia` for the ADIF import scheme `ALFABET_TECHNOPEDIA_UPDATE`.
   - `CentraSite` for all ADIF jobs that are associated with CentraSite.
   - `APIGateway` for the ADIF import scheme `Alfabet_APIGateway_Synchronization`.
   - `Apigee` for the ADIF import scheme `Alfabet_Apigee_Synchronization`.
   - `APIPortal` for the ADIF import scheme `Alfabet_APIPortal_Synchronization`.

4) In the toolbar, click the **Save**  button.

Configuring the ADIF Scheme to be Executable via the Job Schedule Functionality

The ADIF Job must meet the following preconditions to be scheduled via the **Job Schedule** functionality:

- It must be assigned to one of the categories defined for the use case `JobScheduler` and the scope `ADIF` in the XML object ***UseCaseCategories***.

  For information about defining category names in the XML object ***UseCaseCategories***, see Creating Categories for the Job Schedule Use Case.

- The ADIF scheme must not include parameters defined in compatibility mode or with the data type `StringArray` or `ReferenceArray`.

To activate job scheduling for an ADIF import scheme:

1) In the **ADIF** tab of Alfabet Expand, click the ADIF scheme.
2) In the attribute window, select one of the categories defined for the use case `JobScheduler` and the scope `ADIF` in the XML object ***UseCaseCategories***.

Configuring Access Permissions to Folders in the Internal Document Selector for the Job Schedule

ADIF import scheduled via the job scheduler can be performed from a file located in the **Internal Document Selector** of the Alfabet database. This method is optional. Import can also be performed from a file on the local file system. ADIF export to file via the job scheduler can exclusively target the **Internal Document Selector**. Export of data to the local file system is not available for scheduled jobs.

The job scheduler can only access folders of the **Internal Document Selector** with explicit access permissions for the job scheduler.

To define the IDOC folders that are accessible via scheduled ADIF jobs:

1) In the **Presentation** tab of Alfabet Expand, expand the explorer node **XML Objects** > **Administration**.
2) Right-click on the XML object ***IDocManagerConfiguration*** in the explorer and select **Edit XML** from the context menu. The XML object opens in the middle pane.
3) Enter the following code:

```
<IDocManager>
   <UseCase Name="JobSchedule" >
      <Folder Name="FolderShowName" Path="IDOC:\Path" />
   </UseCase>
</IDocManager>
```

   The XML element `UseCase` can have multiple child elements `Folder`, each defining one folder that shall be accessible via the job scheduler. Define the folder with the following XML attributes of the XML element `Folder`:

   - `Name`: Define a caption that shall be displayed for the folder in the editor for scheduling ADIF jobs. The name does not have to be identical to the name of the folder in the **Internal Document Selector**.
   - `Path`: Define the path to the folder in the **Internal Document Selector** . The path must start with `IDOC:\` and end with the name of the selected folder. Backslashes must be used between folder names. The job scheduler can read and write in the defined folder and all subordinate folders of the defined folder.

4) In the toolbar, click the **Save**  button.

Configurations for Scheduling Rescan of Indicators

The following configuration is used for the rescan of indicators via the **Job Schedule** functionality. These configuration steps are not required for other job schedules.

Rescanning of indicators can optionally be limited to a subset of objects of a defined object class found by a query. The query must be provided via a configured report. This section describes the required configurations for using a configured report for the rescan of indicators via the job schedule functionality.

The following information is available:

- Creating Report Categories for the Job Schedule Use Case
- Defining the Query in a Configured Report

Creating Report Categories for the Job Schedule Use Case

Configured reports can only be used to restrict rescan of indicators via the **Job Schedule** functionality if they are assigned to a category defined for the functionality in the XML object ***UseCaseCategories***.

To set the categories in the **Job Schedule** functionality in the XML object ***UseCaseCategories***:

1) In the **Presentation** tab of Alfabet Expand, expand the explorer node **XML Objects**.
2) Right-click on the XML object ***UseCaseCategories*** in the explorer and select **Edit XML** from the context menu. The XML object opens in the middle pane.
3) Enter the following code as child element of the XML element ***UseCaseCategories***:

```
<UseCaseInfo UseCase="JobScheduler">
    <ScopeInfo Scope="Report" Categories="CommaSeparatedListOfCategories"
    />
</UseCaseInfo>
```

   The XML attribute `Categories` must be set to either one category name or a comma separated list of category names. Please note that a category name is a technical name and should not contain special characters or whitespaces. All category names that are defined can be used in the **Category** attribute of a configured report to activate it for the use in job schedule definitions for rescan of indicators.

4) In the toolbar, click the **Save**  button.

Defining the Query in a Configured Report

If only a subset of objects of a class shall be scanned for re-calculation of indicators, the information about which objects shall be included must be defined in a configured report.

The following configuration is required for the configured report:

For general information about configured reports, see Configuring Reports. For general information about defining queries for Alfabet configurations, see Defining Queries.

- The **Type** attribute of the configured report must be `Query` or `NativeSQL`.
- The **Category** attribute of the configured report must be set to one of the categories defined for the use case `JobScheduler` and the scope `Report` in the XML object ***UseCaseCategories***.
- The rescan mechanism reads the information about which objects are found from the query. For Alfabet queries, these are the objects defined as `FIND` class. For native SQL queries, the first argument in the `SELECT` statement must return the `REFSTR` of the objects to be included into the rescan process. All other data returned via the `SELECT` statement of native SQL queries or the **Show Properties** of Alfabet Queries will be ignored.
- The configured report must have the **State** set to `Active` to be used for a job schedule.

Configuring the Web Polling Mechanism

The XML object `SolutionOptions` allows you to specify the Web polling mechanism that allows the user interface to poll the server for the completion status of background processes for which completion shall be announced via an **Event Feedback** message.

Each user who wants to implement the Web polling mechanism must activate Web polling in their user interface by selecting the **Enable User Interface to Poll Web Server** checkbox in the **User Settings** editor. For more information about defining user settings, see the section *Defining Your User Settings in Alfabet* in the reference manual *Getting Started with Alfabet*.

To edit the XML object `SolutionOptions`:

1) Go to the **Presentation** tab and expand the **XML Objects** folder.
2) Right-click the XML object `SolutionOptions` and select **Edit XML**. The XML editor is displayed in the center pane. For general information about editing XML objects in Alfabet Expand, see Working with XML Objects.
3) Specify the following XML attributes:
   - `WebUIPollingInterval`: Specify an integer for the interval of the polling in milliseconds. The default value is 30000 milliseconds.
   - `AsynchronousPublication`: Set to `True` to enable Web polling.
4) In the toolbar, click the **Save**  button.

Configuring the Propagation of Organizational Changes

The XML object ***OrganizationalChanges*** allows you to define settings for the propagation of changes to the organizational structure defined in the Alfabet solution. Users may view and potentially process organizational changes in the **Organizational Changes** page view available on the root node in the **Organizations** explorer as well as for an organization.

In the Alfabet solution, users can document changes to the enterprise's organizations and their dependent objects when a change is made to the organizational structure. For example, if an organization is merged with another organization, the objects dependent on that organization such as subordinate organizations or applications that provide support to the merged organization may need to be assigned to another organization.

Possible changes to the organizational structure include, for example:

- merging an organization with another organization
- absorbing an organization by another organization
- creating a new spin-off organization
- changing an organization's parent organization
- deleting an organization

Whenever a change occurs in the organizational structure, an automatic assignment will be generated for the authorized user(s) of the objects dependent on the organizational change. This allows the authorized user(s) to assess whether the organizational change impacts the object and what action should be taken.

If a changed organization is defined in a business support map, an automatic assignment will be generated for the authorized user(s) of the associated master plan map, IT strategy map, or solution map, unless specified otherwise. Additionally, an automatic assignment will be generated for the authorized user(s) of objects belonging to the following object classes, unless otherwise specified:

- `Application`
- `BusinessProcess`
- `Component`
- `Demand`
- `OrgaUnit`
- `BusinessSupport`
- `Project`
- `StrategicBusinessSupport`
- `TacticalBusinessSupport`

The batch processing tool `AlfaBatchExecutor.exe` must be executed in order for assignments to be generated for the authorized user(s) of the objects dependent to the organizational change. For more information about executing the batch job, see the section *Batch Processing for Monitors and Change Management with AlfaBatchExecutor.exe* in the reference manual *System Administration*.

Changes to the organizational structure can be carried out in two ways in Alfabet. Changes can either be made manually through the Alfabet interface, or automatically via an input file from an external application. Typically, changes to the organizational structure are committed by means of an external system such as a human resources management solution. In this case, you may want to configure the functionality so that

changes to the organizational structure may only be incorporated in Alfabet via an update from the external system.

The XML object ***OrganizationalChanges*** allows you to configure such aspects in the change propagation process including:

- for whom assignments should be generated if there is no authorized user defined for a dependent object
- the default target date for when such assignments should be closed
- whether automatic emails should be sent to the authorized users of dependent objects
- whether organizational changes may be manually defined by users
- whether organizational changes may be automatically defined via an external application
- exclusion rules that define which dependent objects are not considered in an organizational change (for example, all applications with the object state Retired or all demands with the release status Completed, etc.)

The following configuration requirements must be completed by the system administrator in the tool Alfabet Administrator:

- All Alfabet functionalities for which the email capability is to be implemented require the setup of a connection to an SMTP server for outgoing email. For more information, see the section *Activating the Dispatch of Email Notifications in Alfabet* in the reference manual *System Administration*.
- The user profile used to open the Alfabet views targeted by hyperlinks in the email is, by default, the user profile that the sender was logged in with when the view was sent/triggered. However, your system administrator may configure that Alfabet views in email notifications are to be opened using the recipient's user profile. For more information, see the section *Configuring the Setup To Open the Alfabet Interface via Links in Email Notifications* in the reference manual *System Administration*.

The text displayed in automatically-generated email notifications is also configured in Alfabet Expand. For an overview of all text templates available for organizational changes, see *Text Templates for Organizational Changes* in the reference manual *Configuring Alfabet with Alfabet Expand - Appendix*. Please note that you should not set the **Is HTML** attribute to `True` in the context of the text templates available for organization changes. For more information, see the section Configuring Text Templates for Email Notifications in the reference manual *Configuring Alfabet with Alfabet Expand*.

To access the XML object ***OrganizationalChanges***:

1) Go to the **Presentation** tab and expand the **XML Objects** folder, and expand the **ObjectChanges** folder.
2) Right-click the XML object ***OrganizationalChanges*** and select **Edit XML**. The XML editor is displayed in the center pane. For general information about editing XML objects in Alfabet Expand, see Working with XML Objects.
3) Define the XML attributes, as needed. The table below describes the XML elements and XML attributes that can be edited for the XML object ***OrganizationalChanges***:

XML Element (bold) / XML Attribute	Explanation
ObjectChangesDef	
`DefaultResponsible`	Enter the name of the default user that should receive assignments associated with the propagation of changes if the impacted object has no authorized user defined or if the relevant organization does not have a parent organization. The name should be written as follows: [USERNAME]. The text template `TextTemp_ObjectChangeDefaultResponsible` will be sent to the user specified in this attribute if no authorized user is defined for the object impacted by the change. For more information, see *Text Templates for Organizational Changes* in the reference manual *Configuring Alfabet with Alfabet Expand - Appendix*.
`DefaultTargetSpanInDays`	Enter an integer to establish the target date when an assignment generated due to an organization change should be completed. The target date is computed based on the date when the assignment is generated plus the value defined in the XML attribute `DefaultTargetSpanInDays`.  If thd XML attribute `DefaultTargetSpanInDays` is defined as 30, every assignment that is generated in the context of an organizational change will have a target date that is 30 days after the date that the assignment was generated. An assignment generated on Jan. 1, 2008 will have a target date of Jan. 30, 2008.
`Profile`	Enter the name of the user profile required to access the Alfabet interface via the hyperlink displayed in the email notification that is generated for the assignment triggered by an organizational change.
`SendEmails`	Enter "`true`" if notification via email should be sent in addition to the assignment to the authorized user(s) of the dependent object informing them about the organizational change. Enter "`false`" if no email notification should be sent.
`AllowObjectChangeOnUI`	Enter "`true`" if organizational changes may be manually defined by users in the **Organizational Changes** page view. Enter "`false`" if users may not manually define organizational changes. The respective functionalities will be disabled in the **Organizational Changes** page view and thus hidden in the user interface.

XML Element (bold) / XML Attribute	Explanation
`ProcessExternal-Changes`	Enter "`true`" if organizational changes are defined via the input of data via an external application. Enter "`false`" if organizational changes should not be triggered via the input of data from an external application. Depending on the value you define, only the relevant functionalities will be displayed in the **Organizational Changes** page view.
ExclusionRule	
`ClassNames`	Enter the values of the **Name** attribute of the object classes for which you want to define an exclusion rule. Multiple classes should be separated by a comma. Enter the symbol * (asterisk) if all classes relevant for the organizational changes capability should be included. Object class names that are misspelled are ignored.
ExclusionRuleDetail	Define criteria that determines which dependent objects should be ignored in the organizational change functionality.
`PropertyName`	Enter the technical name of the public and/or custom object class property (for example, Status) that determines which dependent objects should be ignored in the organizational change functionality. The object class property is relevant for all object classes listed in the XML attribute `ClassNames`.
`ExcludedValues`	Enter one or more values (for example, Discarded, Closed) relevant to the object class property that determine its exclusion.

4) In the toolbar, click the **Save**  button to save the XML definition.

Configuring the Propagation of Business Process Changes

The XML object ***BusinessProcessChanges*** allows you to define settings for the propagation of changes to the business process hierarchy defined in the Alfabet solution. In Alfabet, users may view and potentially process business process changes in the **Process Changes** page view available on the root node in the **Business Processes** explorer as well as for a business process.

In the Alfabet solution, users can document changes to the enterprise's business processes and their dependent objects when a change is made to the business process model. For example, if a business process is merged with another business process, the objects dependent on that business process such as subordinate business processes or applications that provide support to the merged business process may need to be assigned to another business process.

Possible changes to the business process hierarchy include, for example:

- merging a business process with another business process
- absorbing a business process by another business process
- creating a new spin-off business process
- changing a business process's parent business process
- deleting a business process

Whenever a change occurs in the business process hierarchy, an automatic assignment will be generated for the authorized user(s) of the objects dependent to the business process change so that he/she can consider whether the business process change impacts the object and what action should be taken.

If a changed business process is defined in a business support map, an automatic assignment will be generated for the authorized user(s) of the associated master plan map, IT strategy map, or solution map, unless specified otherwise. Additionally, an automatic assignment will be generated for the authorized user(s) of objects belonging to the following object classes, unless otherwise specified:

- `Application`
- `BusinessProcess`
- `Component`
- `Demand`
- `OrgaUnit`
- `BusinessSupport`
- `Project`
- `StrategicBusinessSupport`
- `TacticalBusiness` Support

The batch processing tool `AlfaBatchExecutor.exe` must be executed in order for assignments to be generated for the authorized user(s) of the objects dependent to the process change. For more information about executing the batch job, see the section *Batch Processing for Monitors and Change Management with AlfaBatchExecutor.exe* in the reference manual *System Administration*.

Changes to the business process hierarchy can be carried out in two ways in Alfabet. Changes can either be made manually through the Alfabet interface, or automatically via an input file from an external application. Typically, changes to the business process hierarchy are committed by means of an external system such as a human resources management solution. In this case, you may want to configure the functionality so that changes to the business process hierarchy may only be incorporated in Alfabet via an update from the external system.

The XML object ***BusinessProcessChanges*** allows you to configure such aspects in the change propagation process including:

- for whom assignments should be generated if there is no authorized user defined for a dependent object
- the default target date for when such assignments should be closed
- whether automatic emails should be sent to the authorized users of dependent objects
- whether business process changes may be manually defined by users
- whether business process changes may be automatically defined via an external application

- exclusion rules that define which dependent objects are not considered in a business process change (for example, all applications with the object state Retired or all demands with the release status Completed, etc.)

The following configuration requirements must be completed by the system administrator in the tool Alfabet Administrator:

- All Alfabet functionalities for which the email capability is to be implemented require the setup of a connection to an SMTP server for outgoing email. For more information, see the section *Activating the Dispatch of Email Notifications in Alfabet* in the reference manual *System Administration*.
- The user profile used to open the Alfabet views targeted by hyperlinks in the email is, by default, the user profile that the sender was logged in with when the view was sent/triggered. However, your system administrator may configure that Alfabet views in email notifications are to be opened using the recipient's user profile. For more information, see the section *Configuring the Setup To Open the Alfabet Interface via Links in Email Notifications* in the reference manual *System Administration*.

The text displayed in automatically-generated email notifications is also configured in Alfabet Expand. Please note that you should not set the **Is HTML** attribute to `True` in the context of the text templates available for process changes. For an overview of all text templates available for business process changes, see *Text Templates for Organizational Changes* in the reference manual *Configuring Alfabet with Alfabet Expand - Appendix*. For more information, see the section Configuring Text Templates for Email Notifications in the reference manual *Configuring Alfabet with Alfabet Expand*.

To access the XML object ***BusinessProcessChanges***:

1) Go to the **Presentation** tab and expand the **XML Objects** folder and expand the **ObjectChanges** folder.
2) Right-click the XML object ***BusinessProcessChanges*** and select **Edit XML**. The XML editor is displayed in the center pane. For general information about editing XML objects in Alfabet Expand, see Working with XML Objects.
3) The table below describes the XML elements and XML attributes that can be edited for the XML object ***BusinessProcessChanges***:

XML Element (bold) / XML Attribute	Explanation
ObjectChangesDef	
`DefaultResponsible`	Enter the name of the default user that should receive assignments associated with the propagation of changes if the impacted object has no authorized user defined or if the relevant business process does not have a parent business process. The name should be written as follows: [USERNAME].

XML Element (bold) / XML Attribute	Explanation
	The text template `TextTemp_ObjectChangeDefaultResponsible` will be sent to the user specified in this attribute if no authorized user is defined for the object impacted by the change. For more information, see *Text Templates for Organizational Changes* in the reference manual *Configuring Alfabet with Alfabet Expand - Appendix*.
`DefaultTargetSpanInDays`	Enter an integer to establish the target date when an assignment generated due to a business process change should be completed. The target date is computed based on the date when the assignment is generated plus the value defined in the XML attribute `DefaultTargetSpanInDays`.  If the XML attribute `DefaultTargetSpanInDays` is defined as 30, every assignment that is generated in the context of a business process change will have a target date that is 30 days after the date that the assignment was generated. An assignment generated on Jan. 1, 2008 will have a target date of Jan. 30, 2008.
`Profile`	Enter the name of the user profile required to access the Alfabet interface via the hyperlink displayed in the email notification that is generated for the assignment triggered by a process change.
`SendEmails`	Enter "`true`" if notification via email should be sent in addition to the assignment to the authorized user(s) of the dependent object informing them about the business process change. Enter "`false`" if no email notification should be sent.
`AllowObjectChangeOnUI`	Enter "`true`" if business process changes may be manually defined by users in the **Process Changes** page view. Enter "`false`" if users may not manually define business process changes. The respective functionalities will be disabled in the **Process Changes** page view and thus hidden in the user interface.
`ProcessExternalChanges`	Enter "`true`" if business process changes are defined via the input of data via an external application. Enter "`false`" if business process changes should not be triggered via the input of data from an external application. Depending on the value you define, only the relevant functionalities will be displayed in the **Process Changes** page view.
ExclusionRule	
`ClassNames`	Enter the values of the **Name** attribute of the object classes (for example, `Project`, `ICTObject`) for which you want to define an exclusion rule. Multiple classes should be separated by a comma. Enter the symbol * (asterisk)

XML Element (bold) / XML Attribute	Explanation
	if all classes relevant to business process changes are included. Class names that are misspelled are ignored.
ExclusionRuleDetail	Define criteria that determines which dependent objects should be ignored in the business process change functionality.
`PropertyName`	Enter the technical name of the public and/or custom object class property (for example, Status) that determines which dependent objects should be ignored in the business process change functionality. The object class property is relevant for all object classes listed in the XML attribute `ClassNames`.
`ExcludedValues`	Enter one or more values (for example, Discarded, Closed) relevant to the object class property that determine its exclusion.

4) Click the **Save** button to save the XML definition.

Chapter 15: Configuring the Visualization of the Alfabet Interface

The visualization of the Alfabet interface can be specified in a variety of ways to align with your corporate guidelines. This includes, for example, the font family and colors used in the interface, the inclusion of the company logo in the header, the icons used to visualize indicators in object cockpits, configured reports, custom editors, the images used to visualize enterprise milestones as well as object classes in the interface.

The following information is available:

Configuring GUI Scheme Definitions for the Alfabet Interface

You can align the Alfabet interface according to your corporate design guidelines by specifying GUI scheme definition. Multiple GUI schemes can be created thus ensuring the styling requirements for different entities in a federated enterprise as well providing user profiles that support barrier-free accessibility. The GUI schemes can be assigned to the relevant user profile via the **GUI Scheme** attribute available on the user profile. For more information about assigning the GUI scheme to a user profile, see the section Making Functionalities Accessible to a User Profile.

The ***AlfaGuiScheme*** definition allows you to specify the font type, colors used for various aspects of the interface, line widths for the focus as well as the logos to display in the header of the Alfabet interface. The ***AlfaGuiScheme*** definition is applied to all aspects of the Alfabet interface including any configured guide pages. For more information about the configuration of guide pages, see the reference manual *Designing Guide Pages for Alfabet*.

Please note the following regarding the configuration of GUI schemes:

- The GUI scheme labelled `Default Scheme` will be automatically implemented if no further custom GUI schemes are defined or no GUI scheme is assigned to a user profile. This GUI scheme labelled `Default Scheme` cannot be deleted.
- The protected GUI scheme `SoftwareAG_103Styles` is available for reference and specifies all standard settings in the Alfabet user interface. Customers wishing to align their GUI scheme with the new standard Software AG styling can simply copy this scheme to their respective (default) GUI scheme.

- You can return to the default settings predefined for a GUI scheme at any time by right-clicking the ***AlfaGuiScheme*** object and selecting **Reset to Default Settings**.
- Several attributes are especially important in order to specify the ways that the focus is visualized in the user interface or the font color is displayed. For more information about configuring user profiles for users using screen readers and keyboard shortcuts, see the section Configuring Barrier-Free User Profiles.
- For an explanation and example of each attribute that can be defined for a GUI scheme, see the section *Overview of GUI Scheme Attributes* in the reference manual *Configuring Alfabet with Alfabet Expand - Appendix*.

To create an ***AlfaGuiScheme***:

1) Click the **Presentation** tab and expand the **GUI Schemes** folder by clicking the + symbol.
2) Right-click the **GUI Schemes** folder and select **Add New GUI Scheme** . The ***AlfaGuiScheme*** is added below the **GUI Schemes** folder.
3) To ease the definition of the GUI scheme attributes, ensure that the attributes are structured according to their purpose by clicking the **Categorized** button in the upper left corner of the attribute window.
4) In the **Common** section of the attribute window, specify a name for the GUI scheme in the **Name** field.
5) In the **Application** section of the attribute window, specify general aspects of the interface. Please note the following:
   - The **Application Font** attribute specifies the font to be used. The `Roboto` font is not a standard font available via the web browser, and Therefore, must be uploaded from the Alfabet Web Application at runtime. The upload of runtime fonts is not permitted per default in the configuration of the Alfabet Web Application. Therefore, if the `Roboto` font should be used for the user interface, the use of runtime fonts must be explicitly enabled via the server alias. If the `Roboto` font is not explicitly enabled via the server alias, the fonts defined for the **Application Font Fallback 1** and **Application Font Fallback 2** attributes of the GUI scheme will be used in the Alfabet user interface. For more information about enabling the `Roboto` font via the server alias, see the section *Activating Roboto as the Standard Font for the Alfabet Interface* in the reference manual *System Administration*.
   - When you define the font type that should be used in the interface, the font size/weight will be automatically adjusted based on where the font is used in the interface. For example, the font size/weight will differ for menu items, explorer nodes, toolbar buttons, column captions, data in datasets, etc.
   - Please note that if a font name with spaces (for example, `Arial Narrow`) is configured in the ***AlfaGuiScheme*** object, the font type `Times` will be displayed per default if the Alfabet interface is rendered using the Mozilla® Firefox® browser. This is a limitation of the Firefox browser.
   - You must specify the rendering style of the interface controls in the custom editor. Two options are possible and the method you choose will determine how you go about designing the custom editor. You can choose the traditional rendering style, which reflects the explicit layout of all interface controls in the custom editor as designed by the solution designer, or the stack rendering style which automatically positions the visible interface controls in a one- or two-column linear list. For an overview of configuring the rendering styles of standard and

custom editors, see the section Specifying the Rendering Definition of the Custom Editor. In the **Application** section of the attribute window, expand the **Editor Rendering Options** attribute and define the following:

- **Rendering Style**: Select either **Traditional** to display standard and custom editors as the have been explicitly designed or select **Stack** to display standard and custom editors as a one- or two-columnar linear list. If you select **Stack**, define the attributes listed below.

  Please note that if you change the Rendering Style attribute, you must delete the value in the **Editor Rendering Options** field and click the **Save** button to update the attributes in the **Editor Rendering Options** section of the attribute window.

- **Stack Layout Type**: If **Stack** has been selected for the **Rendering Style** attribute: Select **One Column** if the captions and interface controls shall be displayed as a single left-aligned column in the editor. Select **Two Columns** if the captions and interface controls shall be displayed as two left-aligned columns in the editor. Please note that the sequence of the interface controls is determined by the **Tab Index** attribute defined for each interface control.
- **Preserve Layout in Group Boxes**: Select `True` if the position of interface controls in a Group Box interface control should follow a traditional rendering style and not be changed to have a stack rendering style. Select `False` if the interface controls in a Group Box interface control should have a stack rendering style.
- **Show Hint In-Line**: Select `True` if the help texts defined via the **Hint** attribute of the interface controls shall be displayed in the editor below the editor field. The hint icon specified in the **Interface Control Hint Icon** attribute will not be displayed if the **Show Hint In-Line** attribute is set to `True`. Select `False` if the help texts should not be displayed below the editor field.
- **Interface Control Hint Icon**: Displays the icon displayed to show the help texts defined for the **Hint** attribute of interface controls. It is recommended that this attribute is not changed. The hint icon will only be displayed if the **Show Hint In-Line** attribute is set to `False`.

- For an explanation of each attribute in the **Application** section of the attribute window, see the section *Attributes Displayed in the Grid Section: Application* in the reference manual *Configuring Alfabet with Alfabet Expand - Appendix*.

6) In the **Application Header** section of the attribute window, specify the visualization of the main header in the Alfabet interface including the masthead, toolbar buttons, etc. For an explanation of each attribute in the **Application Header** section of the attribute window, see the section *Attributes Displayed in the Grid Section: Application Header* in the reference manual *Configuring Alfabet with Alfabet Expand - Appendix*.

7) In the **Automated Assistant Positions** section of the attribute window, specify the size and location of configured automated assistants for various configuration objects. For an explanation of each attribute in the **Automated Assistant Positions** section of the attribute window, see the section *Attributes Displayed in the Grid Section: AlfaBot and Automated Assistant Positions* in the reference manual *Configuring Alfabet with Alfabet Expand - Appendix*. For more information about configuring automated assistants, see the section Providing Custom Online Help to the User Community.

8) In the **Dataset Rows Highlighting** section of the attribute window, specify the visualization of datasets (page views with tables) in the Alfabet interface. For an explanation of each attribute in the **Dataset Rows Highlighting** section of the attribute window, see the section *Attributes Displayed in the Grid Section: Data Rows Highlighting* in the reference manual *Configuring Alfabet with Alfabet Expand - Appendix*.

9) In the **Explorer Tree** section of the attribute window, specify the visualization of explorers. For an explanation of each attribute in the **Explorer Tree** section of the attribute window, see the section *Attributes Displayed in the Grid Section: Explorer Tree* in the reference manual *Configuring Alfabet with Alfabet Expand - Appendix*.

10) In the **Floating Presentation Toolbar** section of the attribute window, specify the **Buttons Full Opacity** attribute. Select `True` to turn off the opacity for the floating menus. The default value is `False`.

For example, when set to `True`:

When set to `False`:

11) In the **Light-Weight Text Pop-Ups** section of the attribute window, specify the attributes to visualize the pop-up windows available for editor field help texts in editors. For an explanation of each attribute in the **Light-Weight Text Pop-Ups** section to of the attribute window, see the section *Attributes Displayed in the Grid Section: Light-Weight Text Pop-Ups* in the reference manual *Configuring Alfabet with Alfabet Expand - Appendix*.

12) In the **Login Form** section of the attribute window, specify the attributes to visualize the login window. For an explanation of each attribute in the **Login Form** section of the attribute window, see the section *Attributes Displayed in the Grid Section: Login Form* in the reference manual *Configuring Alfabet with Alfabet Expand - Appendix*.

13) In the **Logos** section of the attribute window, define the following, as needed:

- **Custom Logo**: Click the **Browse** button and select the relevant file type and file that you want to upload and click **OK**. It is recommended that only icons in PNG format are imported to Alfabet. The logo you plan to display in Alfabet may not be larger 36 x 400 pixels.
- **Custom Logo Location**: Specify the location of the header where the custom logo should be displayed.
- **Custom Logo Tooltip**: Enter a short sentence for the tooltip when the user points to the custom logo.
- **Custom Logo URL**: Enter a URL that shall open in the browser when the user clicks the custom logo.
- **Product Logo Image**: Select one of the predefined visualizations of the Alfabet product logo.

- **Product Logo Tooltip**: Enter a short sentence for the tooltip when the user points to the Alfabet product logo.
- **Product Logo URL**: Enter a URL that shall open in the browser when the user clicks the Alfabet product logo.

14) In the **Slide-In Toolbar** section of the attribute window, specify the visualization of the slide-in toolbar available on the right edge of the user interface which provides various forms of user assistance such as AlfaBot user assistance, automated assistants, and quality widgets. For an explanation of each attribute in the **Main Slide-In Bar** section to of the attribute window, see the section *Attributes Displayed in the Grid Section: Slide-In Toolbar* in the reference manual *Configuring Alfabet with Alfabet Expand - Appendix*.

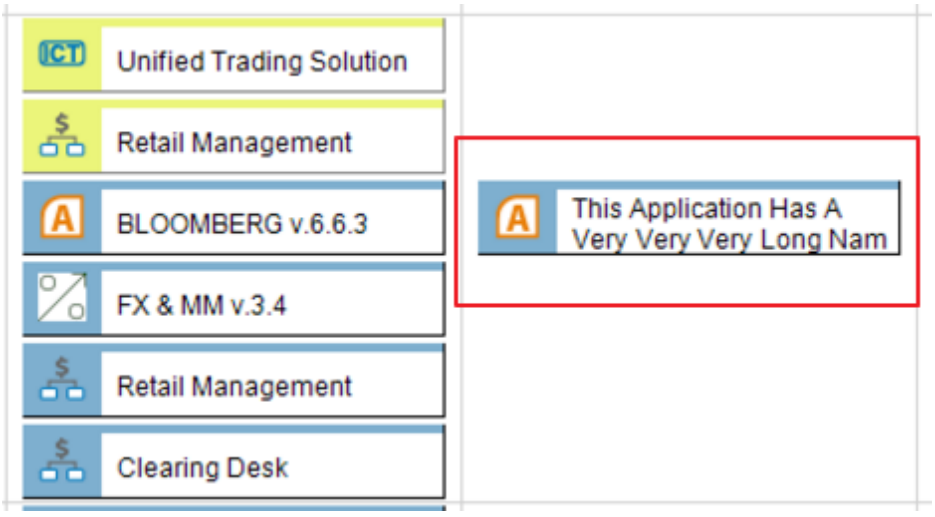
15) In the **Message Boxes** section of the attribute window, specify the attributes to visualize the error, info, question, and warning messages that may open in Alfabet. For an explanation of each attribute in the **Message Boxes** section of the attribute window, see the section *Attributes Displayed in the Grid Section: Message Boxes* in the reference manual *Configuring Alfabet with Alfabet Expand - Appendix*.

16) In the **Pop-Up Window** section of the attribute window, specify the colors used in the header of pop-up windows used to display wizards, for example. For an explanation of each attribute in the **Application Header** section of the attribute window, see the section *Attributes Displayed in the Grid Section: Popup Window* in the reference manual *Configuring Alfabet with Alfabet Expand - Appendix*.

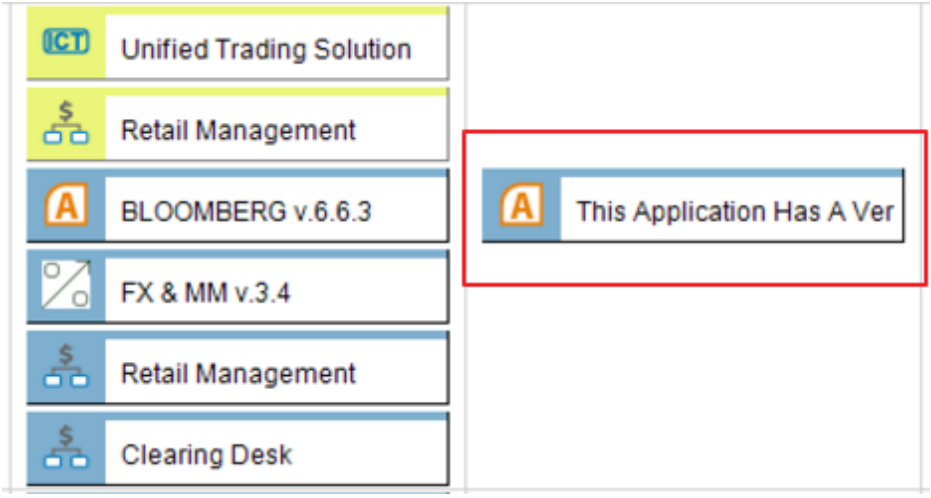
17) In the **Presentation Gantt** section of the attribute window, define the **Maximal Width of Gantt Dataset** attribute. Specify the maximum size in pixel of Gantt reports. This is may be particularly relevant for Gantt reports embedded in object cockpits or console reports. The value is applied if one of the rows in the dataset requires more space than what is defined. In this case, a scroll bar will be added to the dataset (potentially in addition to the scroll bar for the timeline section of the Gantt chart). It is recommended that the value is either -1 or no smaller than 300. The default value for Max Width Gantt Dataset is -1.

18) In the **Presentation Matrix** section of the attribute window, define the **Allow Multiline Matrix Item Caption** attribute. Select `True` if matrix captions should be distributed with a linebreak over two lines or select `False` if matrix captions should be truncated if longer than one line.

For example, when set to `True`:



When set to `False`:



19) In the **Secondary Window Skins** section of the attribute window, specify the visualization of the various forms of user assistance available in the slide-in toolbar displayed on the right edge of the user interface. These attributes allow you to specify the button icon, notch color, and colors of the pop-up windows used for AlfaBot user assistance, automated assistants, and quality widgets. For an explanation of the attributes available to specify the visualization of AlfaBot user assistance, automated assistants, and quality widgets in the **Secondary Window Skins** section of the attribute window, see the section *Attributes Displayed in the Grid Section: Secondary Window Skins* in the reference manual *Configuring Alfabet with Alfabet Expand - Appendix*.

20) In the **View Tabs** section of the attribute window, specify the visualization of tabs in editors, wizards, and guide views with tabbed pages. For an explanation of each attribute in the **View Tabs** section of the attribute window, see the section *Attributes Displayed in the Grid Section: View Tabs* in the reference manual *Configuring Alfabet with Alfabet Expand - Appendix*.

21) In the **Login Form** section of the attribute window, wxpand the **Usage Terms Acknowledgement Options** section to configure a login acknowledgement screen. If configured, users will be mandated to click the acknowledgement button before the actual content of the Alfabet application is shown. The acknowledgement timestamp will be logged in the database table `ALFA_USERLOGIN_DETAILS`. Define the following attributes:

- **Button Text**: Specify a text to be displayed for the acknowledgement button.
- **URL**: Specify a URL that opens automatically when the user has been authenticated successfully. Enter a valid URL starting with the prefix `https://www.` or `http://www.` The URL link may contain up to 511 characters.

22) In the toolbar, click the **Save** button to save the XML definition.

23) To assign the GUI scheme to the relevant user profile, go to the **Admin** tab, click the relevant user profile and select the GUI scheme in the **GUI Scheme** attribute. For more information about assigning the GUI scheme to a user profile, see the section Making Functionalities Accessible to a User Profile.

24) In the toolbar, click the **Save** button to save the user profile definition.

Specifying a Company Logo in the Alfabet Interface

You may specify a custom logo to display in the header of the Alfabet interface. You can also determine where the logo should be displayed in the header, a tooltip for the logo and a URL that shall open in the browser when the user clicks the custom logo. It is recommended that only icons in PNG format are imported to Alfabet. The logo you plan to display in Alfabet may not be larger 36 x 400 pixels.

Furthermore, you can select which predefined visualization of the Alfabet product logo should be displayed, where it should be displayed, and a URL that shall open in the browser when the user clicks the Alfabet product logo.

1) Click the **Presentation** tab in the tab bar and expand the **GUI Schemes** folder by clicking the + symbol.

2) Right-click the **GUI Schemes** folder and select either the `Default Scheme` or a custom GUI scheme created by your enterprise.

3) To ease the definition of the GUI scheme attributes, ensure that the attributes are structured according to their purpose by clicking the **Categorized** button in the upper left corner of the attribute window.

4) In the **Logos** section of the attribute window, define the following, as needed:

   - **Custom Logo**: Click the **Browse** button and select the relevant file type and file that you want to upload and click **OK**. It is recommended that only icons in PNG format are imported to Alfabet. The logo you plan to display in Alfabet may not be larger 36 x 400 pixels.

     The following special characters <,>,*,%,&,:,\,? may not be used in the names of icons available in Alfabet.

   - **Custom Logo Location**: Specify the location of the header where the custom logo should be displayed.
   - **Custom Logo Tooltip**: Enter a short sentence for the tooltip when the user points to the custom logo.
   - **Custom Logo URL**: Enter a URL that shall open in the browser when the user clicks the custom logo.
   - **Product Logo Location**: Select one of the predefined visualizations of the Alfabet product logo.
   - **Product Logo Tooltip**: Enter a short sentence for the tooltip when the user points to the Alfabet product logo.
   - **Product Logo URL**: Enter a URL that shall open in the browser when the user clicks the Alfabet product logo.

5) In the toolbar, click the **Save** button to save the XML definition.

6) To assign the GUI scheme to the relevant user profile, go to the **Admin** tab, click the relevant user profile and select the GUI scheme in the **GUI Scheme** attribute.

7) In the toolbar, click the **Save** button to save the user profile definition.

Adding and Maintaining Icons for the Alfabet Interface

A standard set of icons is provided with Alfabet Expand for use in the Alfabet interface. Software AG provides a number of icons stored in the **Icon Gallery** folder in Alfabet Expand that can be implemented in the solution configuration. These icons are bundled in icon groups. For example, the icon group Color Balls consists of the icons Green, Orange, Red that could be implemented to represent traffic light signals for indicators.

Customized icons may be displayed in a number of contexts in Alfabet. All icons that are to be implemented in Alfabet must first be added to the **Icon Gallery** folder in Alfabet Expand. Custom icons of varying sizes of varying sizes can be imported to Alfabet Expand for use in the Alfabet interface.

Please note the following:

- It is recommended that only icons in PNG format are imported to Alfabet with the exception of images used in guide view. In this case, any file format supported by the browser used to render Alfabet may be uploaded to the **Original Images** library:
- .NET technology requires that custom icons have a transparent background. The color of the bottom left pixel will be rendered transparent in the graphic. To ensure that the graphic can be properly rendered, you must ensure that the bottom left pixel of the graphic displays a color that is NOT used in the custom icon.
- The following special characters <,>,*,%,&,:,\,? may not be used in the names of icons available in Alfabet.
- A preconfigured set of icons are used to represent object classes in Alfabet. We recommend that you do not implement an icon that is already being used to represent an object class or relationship in the Alfabet solution. For example, it is recommended that you do not add the icon to an icon gallery because it represents an application in the Alfabet interface.
- The standard buttons **Delete**, **Detach**, **Edit**, **Export**, **Navigate**, and **Show** displayed in the toolbars in Alfabet views cannot be replaced with custom icons.
- The icon gallery `ENT_Milestones` is a protected icon gallery You may only add icons to or remove icons from this icon gallery. Attributes for the icon gallery cannot be modified.

The table below provides an overview of the various contexts in which custom icons may be used and where they are configured.

Custom Icon Can Be Implemented For:	Where Configured;	For More Information:
Company logo	**Custom Logo** attribute of the GUI scheme	Specifying a Company Logo in the Alfabet Interface
Evaluation types and indicator types	**Evaluations and Portfolios** functionality in Alfabet	*Configuring Evaluations, Prioritization Schemes, and Portfolios* in the reference manual *Configuring Evaluation and Reference Data in Alfabet*
Specified objects for preconfigured set of object classes. The custom ions will be displayed in diagrams, matrices, object profiles/object cockpits, previews, and standard and custom explorers.	**Icon** field of the editor for the relevant object class For example, `Application`, `Component`, `Domain`, `LocalComponent`, `ICTObject`, `Device`, `Location`, `OrgaUnit`, `SystemBuildingBlock`, and `StandardPlatform`.	See the relevant context-sensitive editor help.
Custom editors and object cockpits	Icon interface control in custom editors and object cockpits	Adding Icons to the Custom Editor and Adding Icons to the Object Cockpit
Configured reports	`PictureAssignment` instruction in queries	Using Instructions to Format the Results of an Alfabet or Native SQL Query
Class icon for an object class/object class stereotype. The custom ions will be displayed in diagrams, matrices, object profiles/object cockpits, previews, and standard and custom explorers.	**Icon** attribute of the class setting	Specifying the Icons Implemented for Object Classes and Object Class Stereotypes
Custom diagram item templates for diagrams	**Icon** attribute of the custom diagram item template	Configuring Custom Diagram Item Templates
Object classes displayed in views (such as matrices) and	XML object ***GeneralViewMap***	Specifying Icons for Object Classes in Presentation Objects and the

Custom Icon Can Be Implemented For:	Where Configured;	For More Information:
in the Alfabet Diagram Designer		Alfabet Diagram Designer
Guide View Picture interface controls in guide views	Guide Pages Designer ; Please note that the **Original Images** library is available only for images used in guide views. Any file format supported by the browser used to render Alfabet may be uploaded to the **Original Images** library: BMP files will be automatically converted to PNG since most browsers do not support the BMP format.	*Adding Guide View Pictures to the Guide View* in the reference manual *Designing Guide Pages for Alfabet*.
Content voting capability	XML object ***ObjectAssocationsConfig***	Configuring the Content Voting Capability via Object Associations

The following information is available:

- Uploading Custom Icons to the Icon Gallery
- Creating a New Icon Group and Adding Icons to the Icon Group
- Deleting an Icon or Icon Group

Uploading Custom Icons to the Icon Gallery

You can upload icons that are relevant for your company to Alfabet Expand, making them available for use in the solution interface. Custom icons can be structured in an icon group, if needed. Once an icon has been uploaded, it may be implemented in the solution interface to represent qualitative or performance information (such as indicators and evaluations) as well as associated with functionalities. It is recommended that only icons in PNG format are imported to Alfabet.

Icons of varying sizes can be uploaded to the **Icon Gallery** in Alfabet Expand. In addition to the library which contains the standard Alfabet icons that are 22x22 pixel in size, a **Large Icon** library allows you to add icons that are 30x30 pixel in size, and a **Free Icon** library allows you to add icons of an arbitrary size. The **Free Icon** library in particular allows icons of various sizes to be added to object cockpits, for example. The **Original Images** library is available only for images used in guide views. Any file format supported by the browser used to render Alfabet may be uploaded to the **Original Images** library:

The following special characters <,>,*,%,&,:,\,? may not be used in the names of icons available in Alfabet.

To upload custom icons to Alfabet Expand:

1) Go to the **Presentations** tab and right-click the **Icon Gallery**  folder and select one of the following libraries, depending on the icons you want to upload to Alfabet Expand:

- **Edit Icons (22x22)** to add PNG files with images that are 22x22 pixel in size
- **Edit Large Icons (30x30)** to add PNG files with images that are 30x30 pixel in size
- **Edit Free Icons (any size)** to add PNG files with images that are of an arbitrary size
- **Edit Original Images (any size)** to add any file format with an arbitrary size. Please note that the **Original Images** library is available only for images used in guide views. Any file format supported by the browser used to render Alfabet may be uploaded to the **Original Images** library: BMP files will be automatically converted to PNG since most browsers do not support the BMP format.

2) You will see the **Icons** editor in the center pane displaying any previously upload custom icons. In the toolbar, select **Icon Manager** > **Add New Icons**.
3) In the window that opens, select the file type and icon that you want to add and click **OK**. The icon is automatically displayed in the **Icon Manager** in the center pane of Alfabet Expand.
4) In the **Name** attribute, edit the name as needed. The following special characters <,>,*,%,&,:,\,? may not be used in the names of icons available in Alfabet.
5) Click the **Save** button in the toolbar to save your changes.

Creating a New Icon Group and Adding Icons to the Icon Group

An icon group allows custom and standard icons to be bundled and made available in an icon gallery.

You can create a new icon group and assign icons that you have added to Alfabet Expand as well as icons that exist in the predefined icon gallery provided by Software AG. To create an icon group in order to structure icons:

1) Go to the **Presentations** tab, and right-click the **Icon Gallery** node and select **New Icon Group**. A new icon group is displayed below the folder in the explorer.
2) Click the icon group to open the attribute window.
3) In the attribute window, enter a technical name for the icon group in the **Name** field. This is the icon group name that is visible in Alfabet Expand. In the **Caption** field, enter a caption for the icon group. This is the icon group name that users will see in Alfabet.
4) To add icons to the icon group, right-click the new icon group and select **Create Icon Definition**.
5) Expand the icon group to display the new icon definition and click the new icon definition.
6) Define the following in the attribute window:
   - **Name**: Enter a name for the icon
   - **Caption**: Specify a caption for the icon. This may be useful in the content voting capability, for example. For more information, see the section Configuring the Content Voting Capability via Object Associations.
   - **Icon**: Select the icon that you want assign to the icon definition.
7) Click the **Save** button in the toolbar to save your changes.

Deleting an Icon or Icon Group

You can delete an icon or icon group. To do so, right-click the icon or icon group and select Delete. If you delete an icon, the icon will be irrevocably deleted from the Alfabet database. If you delete an icon group, the icon group including all icons will be irrevocably deleted from the Alfabet database.

Specifying the Icons Implemented for Object Classes and Object Class Stereotypes

Any image that is to be configured as an icon for an object class or object class stereotype must first be uploaded to the icon gallery as described in the section Adding and Maintaining Icons for the Alfabet Interface. If custom icons have been defined for an object in the Alfabet interface, the custom icon defined for the object will have precedence over the icon configured for the object class/object class stereotype.

If you have configured a custom class setting for an object class or object class stereotype, you can replace the standard icon used for the object class in explorers, diagrams, matrices, etc. by defining the **Icon** attribute for that custom class setting. Please note that the images must first be uploaded to the icon gallery as described in the section Adding and Maintaining Icons for the Alfabet Interface. For general information about the configuration of class settings for a user profile, see the section Configuring Class Settings for Object Classes and Object Class Stereotypes.

To change the icon for a custom class setting:

1) Go to the **Presentation** tab and expand the **Class Settings** node.
2) In the **Class Settings** folder, navigate to the object class/object class stereotype folder that you want to define class settings for and expand the folder.
3) Right-click the public class setting template  that you want to specify for the relevant user profile.
4) In the **Icon** field, select the image that should replace the standard object class icon in the Alfabet interface.
5) In the toolbar, click the **Save**  button to save the class setting definition

Specifying Icons for Object Classes in Presentation Objects and the Alfabet Diagram Designer

It may be that a custom icon is specified for an object class via the class setting. In this case, the custom icon will be displayed in the object profile and explorer tree. However, if the class icon should be displayed in presentation objects such as matrix views (For example, the *Business Support Map Page View* or *Platform Architecture Page View*), you must explicitly define the replacement of the default standard class icon with the custom icon in the XML object ***GeneralViewMap***. The icon you specify in the XML object ***GeneralViewMap*** will replace the standard icon used for the object class in matrices and the **Toolbox Items** pane in the Alfabet Diagram Designer.

Please note that the images must first be uploaded to the icon gallery as described in the section Adding and Maintaining Icons for the Alfabet Interface.

An icon cannot be configured for an object class stereotype in the XML object ***GeneralViewMap***.

For more information about configuration possibilities for the XML object ***GeneralViewMap***, see the section Configuring the Alfabet User Interface to Map Standard Configuration Objects to Custom Configuration Objects in the chapter Executing Administrative Tasks in Alfabet Expand.

To change the default class icon for presentation objects:

1) Click the **Presentation** tab in the tab bar and expand the **XML Objects** folder by clicking the + symbol.
2) Right-click the XML object ***GeneralViewMap*** and select **Edit XML**. The **XML Editor** is displayed in the center pane.
3) Create an XML element `<MapEntry Type="Picture"/>` for each standard icon that you want to replace with a custom icon.
4) For each XML element `<MapEntry Type="Picture"/>`, enter the name of the standard Alfabet icon to be replaced in the `Source` XML attribute and enter the name of the custom icon to replace the standard Alfabet icon in the `Target` XML attribute. In order to enter the correct name of the standard Alfabet icon that you want to replace, see the class settings of the respective object class.

```
<AlfaViewMap Name="Map_WithExcludedElements">
    <MapEntry Type="Picture" Source="ICTObject"
    Target="Custom_MyICTObject"/>
    <MapEntry Type="Picture" Source="ICTObject_sbs"
    Target="Custom_MyStratBS"/>
    <MapEntry Type="Picture" Source="Application"
    Target="Custom_MyApplication"/>
</AlfaViewMap>
```

5) In the toolbar, click the **Save** button to save the XML definition.

Chapter 16: Configuring Events

Event management provides a means to automatically execute one of the following automatically as a consequence of a defined user action on the Alfabet user interface:

- Execution of an ADIF import or export job. The ADIF import or export can be executed either on the same or on a different Alfabet database.
- Start of workflows. A workflow can be started either on the same or on a different Alfabet database.
- Generation of a publication.
- Generation of questionnaire indicators for a defined object for an already running questionnaire.
- Score computation for questionnaire indicators.
- Sending of RESTful service calls to any RESTful service. The RESTful service call can target any third-party component or the Alfabet RESTful API.

The following user activities can be specified to trigger events:

- When a wizard step is entered, exited, or cancelled.
- When a workflow step is entered, refused, expired, or exited.
- When a rating or a contact request is submitted via the Feedback Bot.
- When an event template configured to send a RESTful service call is finished.

For the execution of an ADIF import or export job or the start of a workflow, execution of the event is performed via a RESTful service call to the RESTful API of the Alfabet Web Application. The service call triggers the ADIF scheme execution or starts the workflow as defined in the event. For events that send a RESTful service call to a third-party RESTful API, the defined service call is send on triggering the event.

There are two methods for executing the event:

- **Asynchronous execution**

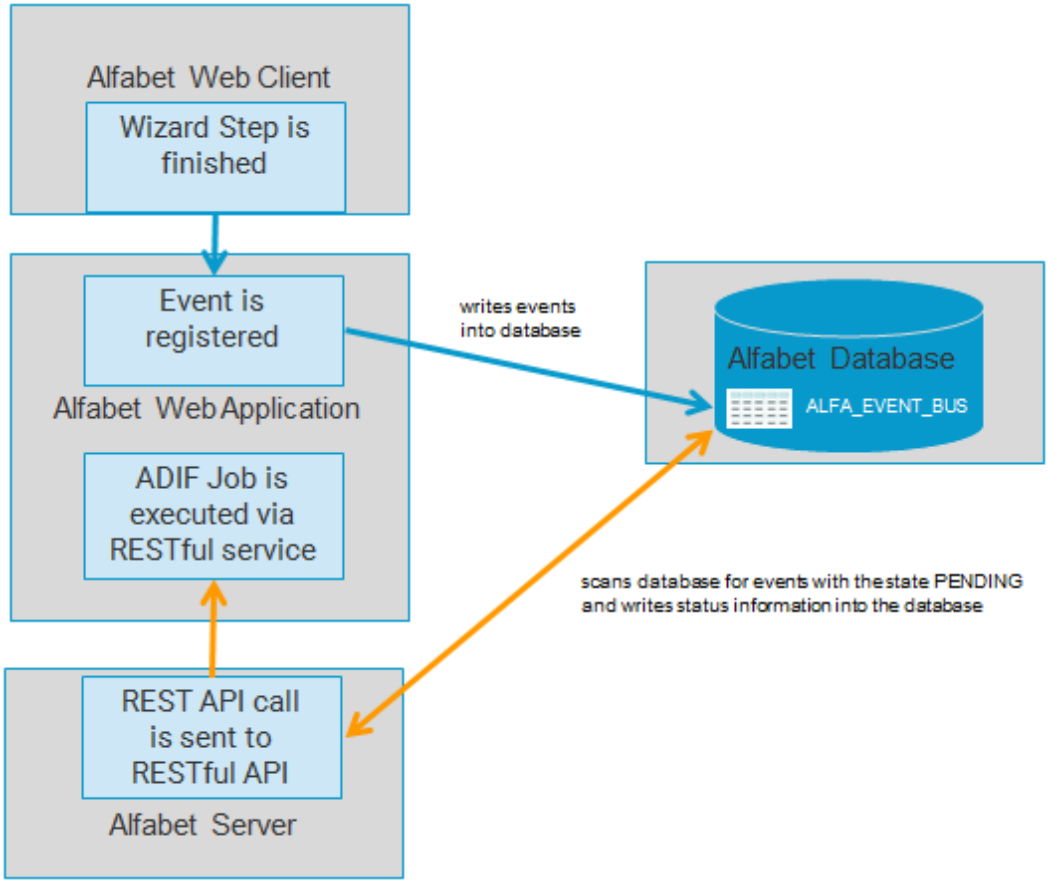
Asynchronous execution is available for all kinds of event.

The RESTful service call for the event is run in the background by an Alfabet Server connecting to the same Alfabet database. If a user triggers an event, the event will be registered. This means that the event is written to the database table of the object class `ALFA_EVENT_BUS` with the property `STATE` set to `PENDING`.

The Alfabet Server scans the database table of the object class `ALFA_EVENT_BUS` in regular intervals for events with the property `STATE` set to `PENDING`. Registered events are executed asynchronously in the order of registration. If multiple events are triggered at the same time, the events might be executed with a delay.

If queries are defined for the event with parameter settings (such as the referencing of a BASE object), the parameters will be substituted with the current values when the event is registered. The query is then executed with these settings when the event is executed.

The following figure shows an overview of the involved Alfabet components and event execution steps for the example of an asynchronous ADIF scheme execution based on an event triggered by a user leaving a wizard step:



- **Synchronous Execution**

Synchronous execution is available for events with the exception of events triggering execution of an ADIF export or an ADIF import.

Synchronously executed events are triggering immediate execution of the REST API call. The event is nevertheless written into the `ALFA_EVENT_BUS`, but with the `STATE` set to `FINISHED` or, if the execution of the event was not successful, to `ERROR`. This ensures that there is no gap between the triggering of the event and For example, the start of the workflow. The Alfabet Server is not required to execute synchronous events.

The following information is available:

- Configuring an Event Triggering Start of a Workflow, ADIF Execution, Publication, or Questionnaire
  - Related Functionalities
    - Configuring an ADIF Job or a Workflow Template To Be Executed via the Event
    - Enabling Execution of RESTful Service Calls
    - Configuring a User to Execute REST API Calls for Events
    - Defining the Event Template
      - Defining an Event Template to Start a Workflow

Configuring an Event Triggering Start of a Workflow, ADIF Execution, Publication, or Questionnaire Related Functionalities

A number of configuration objects must be configured for the event. The central configuration object is an event template that contains references to all components required for event execution. All other involved components are also used in other contexts.

Configuration depends on the connection type of event. There are two connection types of event:

- `SelfReflective`: The event is executed on the same Alfabet database it is triggered from. The REST API call is then directed to the same Alfabet Web Application and executed with a user configured to be used for self-reflective event executions.

- `Query`: The event is targeting either the same or another Alfabet database via an **Alfabet Database Connection** that specifies the connection to the RESTful service interface of a running Alfabet Web Application.

A complete event includes the following configurations depending on the connection type of event:

- If ADIF shall be activated or a workflow shall be started, the ADIF scheme or workflow template must be configured to be executable via the event.
- The RESTful services of the Alfabet Web Application must be activated.
- A call to the RESTful API of the Alfabet Web Application must be specified. The specification depends on the connection type of event:
  - For events of the connection type `Query`, the configuration is done in two steps:
    - First, the parameters for the service call are defined in the XML object `AlfabetIntegrationConfig`.
    - In a second step, an object of the object class **Alfabet Database Connection** must be defined that references the connection. The Alfabet database connection is an object in the Alfabet database, which means that it is subject to access permission concepts and that it can be found via a query.
  - For events of the connection type `SelfReflective`, a user must be configured for execution of the event.
- An event template must be defined that couples the information about which action shall be executed with the information about the target of the REST API call triggering the event.
- A workflow step action, a wizard step action or an ADIF scheme must be defined for the wizard step or workflow step which shall trigger the event.

The following figure shows the way an event is triggering the execution of an ADIF job when a user leaves a wizard step and the configurations that are required to trigger the event.

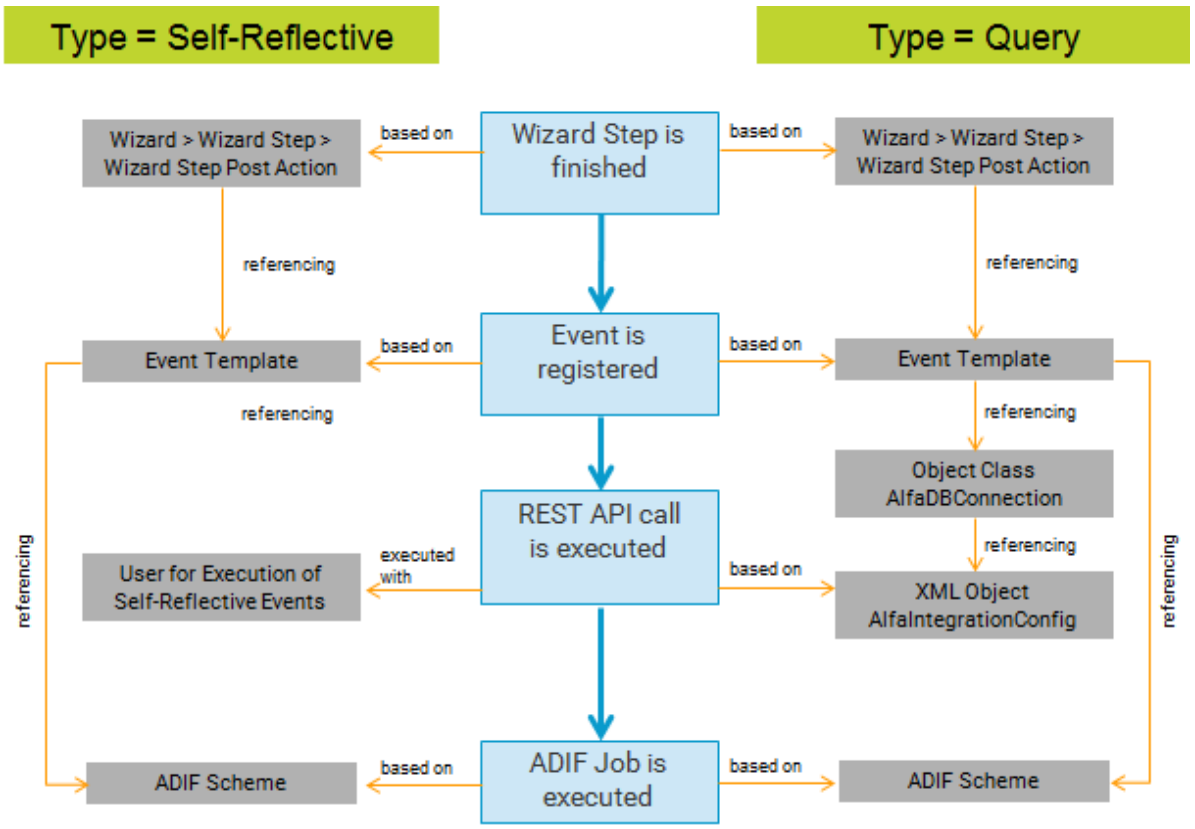


FIGURE: Execution of an ADIF Job triggered via an event and the necessary configuration

The RESTful service call is executed with the access permissions of the user defined to execute self-reflective events or the user specified in the XML Object ***AlfaIntegrationConfig***. Access permissions for the RESTful service call are Therefore, independent from the user triggering the event. Nevertheless, the user triggering the event as well as the user profile that the user is logged in with when triggering the event is stored as the executing user and user profile for the execution of the functionality triggered by the event. This mechanism enables asynchronous response for events and also ensures that workflows started for an existing object can be executed without access permission issues. This means that the user operating the Alfabet user interface and thereby triggering an event that in turn creates a workflow will be captured as the owner of the workflow.

The following information is available:

- Configuring an ADIF Job or a Workflow Template To Be Executed via the Event
- Enabling Execution of RESTful Service Calls
- Configuring a User to Execute REST API Calls for Events
- Defining the Event Template
  - Defining an Event Template to Start a Workflow
  - Defining an Event Template for the Execution of an ADIF Import Scheme
  - Defining an Event Template for the Execution of an ADIF Export Scheme
  - Defining an Event Template for Adding Questionnaire Indicators for an Object to a Questionnaire

Configuring an ADIF Job or a Workflow Template To Be Executed via the Event

An event can trigger the execution of any valid ADIF import scheme, ADIF export scheme or workflow template.

Please note the following preconditions for the configuration of ADIF schemes if they shall be executed via RESTful service calls:

- ADIF schemes that involve files located on the local network, either by exporting to files or importing from files cannot be executed via events. An exception for this rule is the execution of ADIF import events on completion of events triggering RESTful service calls. For more information about this exception, see the section Configuring an Event Template Sending a REST API Call to Trigger Another Event.

In addition to the configuration required for the ADIF scheme or workflow execution, the ADIF scheme or workflow template must be activated for execution via the REST API with the following setting:

1) In Alfabet Expand, click on the ADIF scheme or workflow template in the explorer.
2) Set the attribute **Applicable for REST API** to `True`.
3) In the toolbar, click the **Save** button.

Enabling Execution of RESTful Service Calls

The Alfabet database for which the ADIF scheme is executed or the workflow is started must be configured to allow access to the Alfabet RESTful services. This Alfabet database might be the same database as the one configured to trigger the event, but the event can also be executed on another Alfabet database. The required configuration is described below in a short overview. For a detailed description of the configuration required for the RESTful API, see the reference manual *Alfabet RESTful API*.

- A license for the Alfabet Data Integration Framework (ADIF) must be active.
- Configure the `web.config` file of the Alfabet Web Application to enable Alfabet RESTful services.
- Configure the Alfabet Web Application on the Web Server to enable access to the Alfabet RESTful services.
- Configure the server alias of the Alfabet Web Application to enable access to the Alfabet RESTful services.

Configuring a User to Execute REST API Calls for Events

It is recommended to create a new user that is exclusively used for triggering events via the RESTful services. The user can be excluded from access to any objects except for triggering workflows and/or ADIF jobs via RESTful service calls, but it is also possible to use an existing user. The user must be a named user with at least one user profile assigned. The user profile is not used for evaluation of access permissions. A ReadOnly user profile is sufficient to execute the RESTful services in the context of events.

The same user can be used for events of the type `Query` and `SelfReflective`. Please note however, that the user must be configured in the database that is the target of the REST API call. If the event is triggering

execution of an ADIF scheme or a workflow template in another Alfabet database, the user must be defined in the target database the REST API call is sent to by the event.

Only one user can be selected for execution of events of the type `SelfReflective`. If you assign this functionality to a user while another user has already been selected to execute self-reflective events, the setting is removed from that user when it is set for the user you are currently assigning it to.

The selected user will also be used for execution of events in the scope of the **Job Schedule** functionality.

To create a user for execution of events in the **User Administration** functionality on the Alfabet user interface:

The same functionality is also available via the Alfabet Administrator. For information about accessing the user management functionalities of the Alfabet Administrator see *Functionalities Available via the Expanded Explorer of the Connected Alias* in the reference manual *System Administration*.

1) In the toolbar of the **User Administration** view, select **New** > **Create New User**. An editor opens.
2) In the editor, define the following:

   Basic Data tab:

   - **Name**: Enter a meaningful name for the user. The user is a technical user. You can either assign the name of an existing person to it or give it a name that indicates that this is a virtual person defined to execute a functionality.
   - **User Name**: Enter a user name. The user name is used by the RESTful services to identify the user.
   - **Type**: Select `NamedUser`.

   API Permissions tab:

   - **Has API V2 Access**: Select the checkbox.
   - **API Access Options**: Make sure that the permissions **Has ADIFAPIInvocation Access** for the execution of ADIF schemes and/or **Has WorkflowADIFInvocation Access** for the execution of workflows are selected.
   - **Generate API Password**: Click the button. The API Password field is filled. For events of the type `Query`, copy the **API User Name** and the **API Password** . These have to be entered into the specification in the XML object `AlfabetIntegrationConfig` described below in the section Configuring the Connection Parameters in the XML Object AlfabetIntegrationConfig.
3) Click **OK** to close the editor. The new user is added to the table in the **User Administration** view.
4) If the user shall be used for execution of events of the type `SelfReflective`, select the user in the table and select **Action** > **Set as Executes Self-Reflective Events User** in the toolbar.
5) Select the user in the table and click the **Navigate** button.
6) In the object profile of the user, click **Assigned User Profiles**.
7) In the toolbar of the **Assigned User Profiles** view, click **New** > **Assign User Profiles**.

8) In the selector, select a user profile and click **OK** to assign it to the user. For a user that is exclusively used for events, it is recommended to use a ReadOnly user profile.

The configuration described above is the configuration required for the event management functionality only. In addition, you can set any other properties of the user. For security reasons you might also consider assigning a login password to the user although the user password is not required for the event management functionality. For information about the available configuration options for users, see *Defining and Managing Users* in the reference manual *User and Solution Administration*.

Configuring the Connection for Execution of an Event of the Connection Type Query

The following configuration is only applicable for events of the connection type `Query`.

The connection to the RESTful API of the Alfabet Web Application is done in two configuration steps:

- Configuring the Connection Parameters in the XML Object AlfabetIntegrationConfig
- Configuring the Alfabet Database Connection for Execution of the Event

Configuring the Connection Parameters in the XML Object AlfabetIntegrationConfig

The Alfabet Web Application acts as RESTful client that connects to the RESTful API of either itself or another Alfabet Web Application. The connection parameters must be configured in the XML object ***AlfabetIntegrationConfig*** in Alfabet Expand:

1) Go the **Presentation** tab of Alfabet Expand and expand the explorer node **XML Objects** > **Integration Solutions**.
2) Right click the XML object `AlfabetIntegrationConfig` and select **Edit XML** from the context menu. The XML object opens in the middle pane.
3) In the attribute window, edit the XML as described below.
4) Click the **Save**  button to save your changes.

The XML object must contain the following XML structure:

```
<AlfabetIntegrationConfig>
   <Connection
      name = "My Test Connection"
      service="http://localhost/ALFABET"
      active="true"
      user="DAME"
      psw="H7GLVUGZWQETKJFSX7HY6OK2CUB4WRGK"
      profile="MASTER"/>
</AlfabetIntegrationConfig>
```

The following XML elements and their attributes are part of the specification:

Element (Bold) / Attribute	Configuration Requirements
AlfabetIntegrationConfig	Root node of the configuration.
Connection	The configuration parameters for sending the RESTful service call and request the data from the source database. This XML element can be added multiple times to define multiple source databases.
`name`	Enter a unique name for the connection configuration. The name is used to identify the connection configuration For example, in editors on the Alfabet user interface. This attribute is mandatory.
`service`	Enter the URL of the Alfabet Web Application for access to the source database. This attribute is mandatory.
`active`	This attribute can be defined to deactivate (`false`) or activate (`true`) the connection. If the attribute is set to `false`, the connection will not be displayed in the drop-down list for the connection specification in the editor **Alfabet Database Connection** on the Alfabet user interface. The default value is `true`.
`user`	Enter the user name of the user configured to have access to the RESTful services of the Alfabet Web Application connected to the target database the ADIF scheme is executed on or the workflow is started for. For information about the required configuration of the user, see Configuring a User to Execute REST API Calls for Events. This attribute is mandatory.
`psw`	Enter the REST API password of the user defined in the `user` attribute. For more information about the configuration of the user, see the reference manual *Alfabet RESTful API*. This attribute is mandatory.
`profile`	Enter the user profile configured in the source database to grant the correct access permissions to the relevant object classes.

Configuring the Alfabet Database Connection for Execution of the Event

Configuration is done in the **Integration Solutions Configuration** functionality on the Alfabet user interface.

1) Go to the **Integration Solutions Configuration** functionality and click the **Alfabet Database Connection** node in the **Integration Solutions Configuration** explorer.

2) In the view, click **New** > **Create Alfabet Database Connection**.

> If you have already defined a similar connection and want to take over the settings of that connection for your new connection, you can alternatively click **New** > **Create Alfabet Connection as Copy** and select the existing connection the new connection should base on from the selector that opens. The editor for the new connection will then open with all settings identical to the copied connection and the name set to "Copy of <base connection name>".

3) In the **Alfabet Database Connection** editor, define the following fields as needed:

Basic Data tab:

- **ID**: Alfabet assigns a unique identification number to each Alfabet database connection. This number cannot be edited.
- **Name**: Enter a unique name for the Alfabet database connection.
- **Release Status**: Select the Alfabet database connection's current release status.

  The set of release statuses available for an object class are configured by your solution designer in the configuration tool Alfabet Expand. For more information, see the section Configuring Release Status Definitions for Object Classes in the reference manual *Configuring Alfabet with Alfabet Expand*. For general information about release statuses, see the section *Understanding Release Statuses* in the reference manual *Getting Started with Alfabet*.

- **Description**: Enter a meaningful description that will clarify the purpose of the Alfabet database connection.

Authorized Access tab:

- **Authorized User**: Click the **Search** icon to assign an authorized user to the selected Alfabet database connection. The authorized user will have Read/Write access permissions for the object and is responsible for the maintenance of the object.
- **Authorized User Groups**: Select one or more checkboxes to assign Read/Write access permissions to all users in the selected user group(s).

Connection tab:

- **Alfabet Connection**: Select the connection to the relevant Alfabet database that is configured in the XML element ***Connection*** in the XML object ***AlfabetIntegrationConfig*** in Alfabet Expand.
- **Allowed Classes**: This field is for implementation of the **Import Data Search** functionality only. No settings are required for event management.

4) Click **Test Alfabet Database Connection**. If your settings are correct, a message "The connection is valid" is displayed. Otherwise, an error message is displayed.

Defining the Event Template

An event template links to both the Alfabet database connection for execution of the event and to the ADIF scheme or workflow template to be executed. For each type of event a different type of event template must be defined:

- Defining an Event Template to Start a Workflow
- Defining an Event Template for the Execution of an ADIF Import Scheme
- Defining an Event Template for the Execution of an ADIF Export Scheme
- Defining an Event Template for Adding Questionnaire Indicators for an Object to a Questionnaire

Defining an Event Template to Start a Workflow

Event templates are defined in the **Reusable Elements** tab of Alfabet Expand:

1) Go to the **Reusable Elements** tab of Alfabet Expand.
2) Right click the node **Events** and select **Create New Workflow Event Template** from the context menu. The new workflow event template is added on the root level of the event management tree.
3) Click on the new event template and edit the following attributes:
   - **Name**: Enter a unique name for the event template. The name is used to identify the event templates in configurations.
   - **Description**: Optionally enter a short text describing the functionality of the event. This information is only visible in the event template attributes in the **Reusable Elements** tab to inform, For example, other solution designers about the functionality implemented with the event template.
   - **Workflow Template Name**: Select the workflow template from the drop-down list, to start a workflow based on that template via the event. The drop-down list displays all workflow templates that have the attribute **Applicable for REST API** set to `True` and the attribute **State** set to `Active`.
   - **Connection Type**: Select `SelfReflective`, if the event shall be executed for the same Alfabet database it is triggered from, or `Query`, if the event shall be executed on an Alfabet database that is defined via an **Alfabet Database Connection**.
   - **Connection via Query** / **Connection via Query as Text**: This attribute is only applicable and visible if the **Connection Type** is `Query`. Define a query that returns the `REFSTR` of the Alfabet database connection to be used for execution of the event. The query must return a single `REFSTR`. It can either be defined as native SQL query or Alfabet query:
     - Use the **Connection via Query** attribute to define an Alfabet query. Show properties are not required for the query.

```
ALFABET_QUERY_500
FIND Alfabet_DBConnection
WHERE Alfabet_DBConnection.Name = 'EventConnection'
```

- Use the **Connection via Query as Text** attribute to define a native SQL query with the `REFSTR` of the Alfabet database connection as the only `SELECT` argument.

```
SELECT REFSTR
FROM ALFABET_DBCONNECTION
WHEREALFABET_DBCONNECTION.NAME = 'EventConnection'
```

- **Execute Immediately**: Setting this attribute to `True` will cause the Alfabet Web Application to execute the event immediately by triggering the REST API call starting the workflow. The event is nevertheless written to the `ALFA_EVENT_BUS` table, but with the `STATE` set to `FINISHED` or, if execution was not successful, to `ERROR`. Setting this attribute to `False` will lead to standard scheduling of the event via the `ALFA_EVENT_BUS` table and execution via the Alfabet Server.
- **Base Objects via Query** / **Base Objects via Query as Text**: Optionally, a query can be defined to find the start objects for the workflow. This query is usually defined directly in the workflow template. If the workflow template does not contain a base object definition or if the event requires different search options for the base object (For example, to take parameters from the wizard or workflow it is triggered from into account), the query defined in the workflow template can be substituted with a query defined in the event. Use the **Base Objects via Query** attribute to define an Alfabet query. Use the **Base Objects via Query as Text** attribute to define a native SQL query. For information about how to define the start base class for an automatically started workflow, see Specifying the Objects Targeted by the Workflows
- **Source Objects via Query** / **Source Objects via Query as Text**: Optionally, a query can be defined to create new objects via the workflow on basis of a query defining which objects to create. This query is usually defined directly in the workflow template. If the event requires different search options for the base object (For example, to take parameters from the wizard or workflow it is triggered from into account), the query defined in the workflow template can be substituted with a query defined in the event. Use the **Source Objects via Query** attribute to define an Alfabet query. Use the **Source Objects via Query as Text** attribute to define a native SQL query. For information about how to define the start base class for an automatically started workflow, see Specifying the Objects Targeted by the Workflows.
- **Group**: If you would like to structure your event templates in folders, enter the name of the event template folder that the event template shall be located in. If event template folders have already been defined for other event templates, they will be displayed in a drop-down list and can be selected. If you want to define a new event template folder, enter a new name into the field. The folder is then created in the explorer. The event template is moved to the selected event template folder.

4) Click the **Save** button to save your changes.
5) Right-click the event template and select **Set Event State to Active** from the context menu.

Defining an Event Template for the Execution of an ADIF Import Scheme

Event templates are defined in the **Reusable Elements** tab of Alfabet Expand:

1) Go to the **Reusable Elements** tab of Alfabet Expand.

2) Right click the node **Events** and select **Create New ADIF Import Event Template** from the context menu. The new ADIF import event template is added on the root level of the event management tree.

3) Click on the new event template and edit the following attributes:

- **Name**: Enter a unique name for the event template. The name is used to identify the event templates in configurations.
- **Description**: Optionally enter a short text describing the functionality of the event. This information is only visible in the event template attributes in the **Reusable Elements** tab to inform, For example, other solution designers about the functionality implemented with the event template.
- **ADIF Scheme**: Select the ADIF import scheme that shall be executed from the drop-down list. The drop-down list displays all ADIF import schemes that have the attribute **Applicable for REST API** set to `True` and the attribute **State** set to `Active`.
- **Connection Type**: Select `SelfReflective`, if the event shall be executed for the same Alfabet database it is triggered from, or `Query`, if the event shall be executed on an Alfabet database that is defined via an **Alfabet Database Connection**.
- **Connection via Query** / **Connection via Query as Text**: This attribute is only applicable and visible if the **Connection Type** is `Query`. Define a query that returns the `REFSTR` of the Alfabet database connection to be used for execution of the event. The query must return a single `REFSTR`. It can either be defined as native SQL query or Alfabet query:
  - Use the **Connection via Query** attribute to define an Alfabet query. Show properties are not required for the query.

```
ALFABET_QUERY_500
FIND Alfabet_DBConnection
WHERE Alfabet_DBConnection.Name = 'EventConnection'
```

  - Use the **Connection via Query as Text** attribute to define a native SQL query with the `REFSTR` of the Alfabet database connection as only `SELECT` argument.

```
SELECT REFSTR
FROM ALFABET_DBCONNECTION
WHERE ALFABET_DBCONNECTION.NAME = 'EventConnection'
```

- **Variable Names**: If the ADIF scheme contain parameter definitions, the names of the parameters must be written as comma separated list into this attribute. The specification must be case sensitive. The values for the parameters must then be provided with the attribute **Values for Variables via Query** / **Values for Variables via Query as Text**.
- **Values for Variables via Query** / **Values for Variables via Query as Text**: The query must return the values for the variables defined in the attribute **Variable Names** in the same order. The query can be defined either via native SQL or via Alfabet query. Use the **Value for Variables via Query** attribute to define an Alfabet query. Use the **Values for Variables via Query as Text** attribute to define a native SQL query. Alfabet query language parameters can be used in the query. The base object returned via the Alfabet query language parameter `BASE` depends on the way an event has been triggered. For events triggered via a workflow or wizard, `BASE` returns the REFSTR of the object the user was working on in the wizard step or

workflow step triggering the event. For events triggered via an REST API call event, the `BASE` object is the same as the one for the event triggering the event.

The query must return a dataset with the column names identical to the parameter names defined with the attribute **Variable Names**.

For example, if **Variable Names** is defined as `@AppName,@AppVersion`, the query might be defined as:

```
SELECT REFSTR, NAME AS '@AppName', VERSION AS
'@AppVersion'
FROM APPLICATION
WHERE REFSTR = @BASE
```

- **Verbose Logging for ADIF Job**: Set the attribute to `True` if the ADIF job should be started with the command line parameter `-logverbose`, resulting in additional information about the running process to be logged. The default for this attribute is `False`. Verbose logging is in most cases not required and can lead to a decrease in performance.
- **Import File** If the event is triggered on completion of an event that has executed a RESTful service call, the return value from the REST API call can be handed over to the ADIF import event and from the ADIF import event to the ADIF import scheme for execution of the ADIF job. To enable this feature, a file name must be entered in the **Import File** attribute. The event template triggering this event will create the file and write the return value into it prior to triggering this event. Please note that the **Import File** attribute of the ADIF import scheme's JSON import set processing the return value must be set to the same file name as the **Import File** attribute of the event template. For more information about configuring the execution of an event on completion of an event sending a RESTful service call, see Configuring an Event Template Sending a REST API Call to Trigger Another Event.
- **Group**: If you would like to structure your event templates in folders, enter the name of the event template folder that the event template shall be located in. If event template folders have already been defined for other event templates, they will be displayed in a drop-down list and can be selected. If you want to define a new event template folder, enter a new name into the field. The folder is then created in the explorer. The event template is moved to the selected event template folder.

4) Click the **Save** button to save your changes.
5) Right-click the event template and select **Set Event State to Active** from the context menu.

Defining an Event Template for the Execution of an ADIF Export Scheme

Event templates are defined in the **Reusable Elements** tab of Alfabet Expand:

1) Go to the **Reusable Elements** tab of Alfabet Expand.
2) Right click the node **Events** and select **Create New ADIF Export Event Template** from the context menu. The new ADIF export event template is added on the root level of the event management tree.
3) Click on the new event template and edit the following attributes:

- **Name**: Enter a unique name for the event template. The name is used to identify the event templates in configurations.
- **Description**: Optionally enter a short text describing the functionality of the event. This information is only visible in the event template attributes in the **Reusable Elements** tab to inform, For example, other solution designers about the functionality implemented with the event template.
- **ADIF Scheme**: Select the ADIF export scheme that shall be executed from the drop-down list. The drop-down list displays all ADIF export schemes that have the attribute **Applicable for REST API** set to `True` and the attribute **State** set to `Active`.
- **Connection Type**: Select `SelfReflective`, if the event shall be executed for the same Alfabet database it is triggered from, or `Query`, if the event shall be executed on an Alfabet database that is defined via an **Alfabet Database Connection**.
- **Connection via Query** / **Connection via Query as Text**: This attribute is only applicable and visible if the **Connection Type** is `Query`.Define a query that returns the `REFSTR` of the Alfabet database connection to be used for execution of the event. The query must return a single `REFSTR`. It can either be defined as native SQL query or Alfabet query:
  - Use the **Connection via Query** attribute to define an Alfabet query. Show properties are not required for the query.

    

    ```
    ALFABET_QUERY_500
    FIND Alfabet_DBConnection
    WHERE Alfabet_DBConnection.Name = 'EventConnection'
    ```

  - Use the **Connection via Query as Text** attribute to define a native SQL query with the `REFSTR` of the Alfabet database connection as only `SELECT` argument.

    

    ```
    SELECT REFSTR
    FROM ALFABET_DBCONNECTION
    WHEREALFABET_DBCONNECTION.NAME = 'EventConnection'
    ```

- **Variable Names**: If the ADIF scheme contain parameter definitions, the parameters must be written as comma separated list into this attribute. The definition must be case sensitive.The values for the parameters must then be provided with the attribute **Values for Variables via Query** / **Values for Variables via Query as Text**.
- **Values for Variables via Query** / **Values for Variables via Query as Text**: The query must return the values for the variables defined in the attribute **Variable Names** in the same order. Use the **Value for Variables via Query** attribute to define an Alfabet query. Use the **Values for Variables via Query as Text** attribute to define a native SQL query. Please note that the first column of the native SQL query is ignored. Alfabet query language parameters can be used in the query. For events triggered via a workflow or wizard, `BASE` returns the REFSTR of the object the user was working on in the wizard step or workflow step triggering the event. For events triggered via a REST API call event, the `BASE` object is the same as the one for the event triggering the event.

The query must return a dataset with the column names identical to the parameter names defined with the attribute **Variable Names**.

For example, if **Variable Names** is defined as `@AppName,@AppVersion`, the query might be defined as:

```
SELECT REFSTR, NAME AS '@AppName', VERSION AS
'@AppVersion'
FROM APPLICATION
WHERE REFSTR = @BASE
```

- **Verbose Logging for ADIF Job**: Set the attribute to `True` if the ADIF job should be started with the command line parameter `-logverbose`, resulting in additional information about the running process to be logged. The default for this attribute is `False`. Verbose logging is in most cases not required and can lead to a decrease in performance.
- **Group**: If you would like to structure your event templates in folders, enter the name of the event template folder the event template shall be located in. If event template folders have already been defined for other event templates, they will be displayed in a drop-down list and can be selected. If you want to define a new event template folder, enter a new name into the field. The folder is then created in the explorer. The event template is moved to the selected event template folder.

4) Click the **Save** button to save your changes.
5) Right-click the event template and select **Set Event State to Active** from the context menu.

Defining an Event Template for Adding Questionnaire Indicators for an Object to a Questionnaire

Starting a questionnaire will create the questionnaire indicators for all objects found by the query in the assigned questionnaire policy.

The number of relevant objects may change during the time period for answering the questionnaire. New objects may be created or the data for existing objects may be changed to match the search conditions in the questionnaire policy.

To add additional questionnaire indicators for a new object to a started questionnaire, an event can be added to a wizard or workflow.

For example, an active questionnaire is currently answered by the authorized users of all applications with a criticality indicator set to 'High' or 'Very High'. The evaluation page view for the application is available as a wizard step in a wizard. If a user changes the criticality indicator and moves on to the next page of the wizard, the event will be triggered and questionnaire indicators will be created for the application.

Event templates are defined in the **Reusable Elements** tab of Alfabet Expand:

1) Go to the **Reusable Elements** tab of Alfabet Expand.
2) Right click the node **Events** and select **Create New Questionnaire Add Indicators Event** from the context menu. The new event template is added on the root level of the event management tree.
3) Click on the new event template and edit the following attributes:

- **Name**: Enter a unique name for the event template. The name is used to identify the event templates in configurations.
- **Description**: Optionally enter a short text describing the functionality of the event. This information is only visible in the event template attributes in the **Reusable Elements** tab to inform, For example, other solution designers about the functionality implemented with the event template.
- **Execute Immediately**: Setting this attribute to `True` will cause the Alfabet Web Application to execute the event immediately by triggering the REST API call for the event. The event is nevertheless written to the `ALFA_EVENT_BUS` table, but with the `STATE` set to `FINISHED` or, if execution was not successful, to `ERROR`. Setting this attribute to `False` will lead to standard scheduling of the event via the `ALFA_EVENT_BUS` table and execution via the Alfabet Server.
- **Connection Type**: Select `SelfReflective`, if the event shall be executed for the same Alfabet database it is triggered from, or `Query`, if the event shall be executed on an Alfabet database that is defined via an **Alfabet Database Connection**.
- **Connection via Query** / **Connection via Query as Text**: This attribute is only applicable and visible if the **Connection Type** is `Query`. Define a query that returns the `REFSTR` of the Alfabet database connection to be used for execution of the event. The query must return a single `REFSTR`. It can either be defined as native SQL query or Alfabet query:
  - Use the **Connection via Query** attribute to define an Alfabet query. Show properties are not required for the query.

    

    ```
    ALFABET_QUERY_500
    FIND Alfabet_DBConnection
    WHERE Alfabet_DBConnection.Name = 'EventConnection'
    ```

  - Use the **Connection via Query as Text** attribute to define a native SQL query with the `REFSTR` of the Alfabet database connection as only `SELECT` argument.

    

    ```
    SELECT REFSTR
    FROM ALFABET_DBCONNECTION
    WHERE ALFABET_DBCONNECTION.NAME = 'EventConnection'
    ```

- **Group**: If you would like to structure your event templates in folders, enter the name of the event template folder the event template shall be located in. If event template folders have already been defined for other event templates, they will be displayed in a drop-down list and can be selected. If you want to define a new event template folder, enter a new name into the field. The folder is then created in the explorer. The event template is moved to the selected event template folder.

4) Expand the event's node in the explorer and expand the **Parameters** node. Three parameter nodes are displayed.
5) Click each of the parameter nodes and define the following in the attribute section:
   - ***@Questionnaire***: This parameter is mandatory. Define a query finding the relevant questionnaire. The questionnaire must have the release status defined as `ApprovedStatus` for the object class `Questionary` in the XML object ***ReleaseStatusDef*** and the questionnaire target date must be in the future.

For more information about the definition of release status values, see Configuring Release Status Definitions for Object Classes.

You can either define an Alfabet query in the **Value for Parameter via Query** attribute or a native SQL query in the **Value for Parameter via Query as Text** attribute. The query must return the `REFSTR` of the relevant questionnaire in a dataset with one column and one row.

For example, a native SQL query to find the questionnaire may read:

```
SELECT NULL, QUESTIONARY.REFSTR
FROM QUESTIONARY
WHERE QUESTIONARY.NAME = 'Security Assessment for Cloud
Servers'
```

- ***@Object***: This parameter is mandatory. Define a query finding the relevant object only. Typically, this will be the base object of the wizard or workflow you are currently working with. You can either define an Alfabet query in the **Value for Parameter via Query** attribute or a native SQL query in the **Value for Parameter via Query as Text** attribute. The `FIND` class of the Alfabet query must be the object class of the relevant object. The native SQL query must return the `REFSTR` of the object class of the relevant object as first `SELECT` argument. The query must contain conditions that limit the result to a single object.

For example, an Alfabet query to find the object may read:

```
ALFABET_QUERY_500
FIND Device
WHERE Device.REFSTR CONTAINS:BASE
AUTODSINFO
QUERY_XML
<QueryDef>
   <ShowProperty Type="Property" ClassName="Device"
   Name="REFSTR" />
</QueryDef>
```

- ***@UserName***: This parameter is optional. If specified, the string defined in the parameter will be written into the `CREATION_USER` object class property of the questionnaire indicators generated by the event. Please note that according to the setting of the **Update History User Name** in the server alias of the Alfabet Web Application, the `CREATION_USER` object class property stores either the user name or the technical name of users. The information returned for the parameter must match the setting in the server alias.

For information about the setting in the server alias, see *Configuring User Information Displayed in History Tracking* in the reference manual *System Administration*.

You can either define an Alfabet query in the **Value for Parameter via Query** attribute or a native SQL query in the **Value for Parameter via Query as Text** attribute. The query must return the user name or the technical name of an Alfabet user in a tabular dataset with a single row and a single column. Instead of the

defining the user via a query, a fixed user name or technical name can be defined in the **Default Value** attribute.

For example, a native SQL query to set the `CREATION_USER` to the user that is triggering the event may read:

```
SELECT PERSON.REFSTR, PERSON.USER_NAME
FROM PERSON
WHERE PERSON.REFSTR = @CURRENT_USER
```

6) Click the **Save**  button to save your changes.

7) Right-click the event template and select **Set Event State to Active** from the context menu.

Configuring an Event for the Execution of a RESTful Service Call

A number of configuration objects must be configured for the event. The central configuration object is an event template that contains references to all components required for event execution. All other involved components are also used in other contexts.

A complete event triggering execution of a RESTful service call includes the following configurations:

- The parameters for the service call must be defined in the XML object `GenericRestConfig`.
- An object of the object class **REST API Connection** must be defined that references the connection. The REST API connection is an object in the Alfabet database, which means that it is subject to access permission concepts and that it can be found via a query.
- If the REST API call includes definition of a body, a configured report of the type `NativeSQL` must be created that returns the data to be included into the call in a format that can be converted to JSON by the Alfabet components.
- A REST API call event template must be defined that includes information about all required configuration objects.
- A workflow step action, a wizard step action or an ADIF scheme must be defined for the wizard step or workflow step which shall trigger the event.

The following figure shows how an event triggers the execution of a REST API call when a user leaves a wizard step and the configurations that are required to trigger the event:

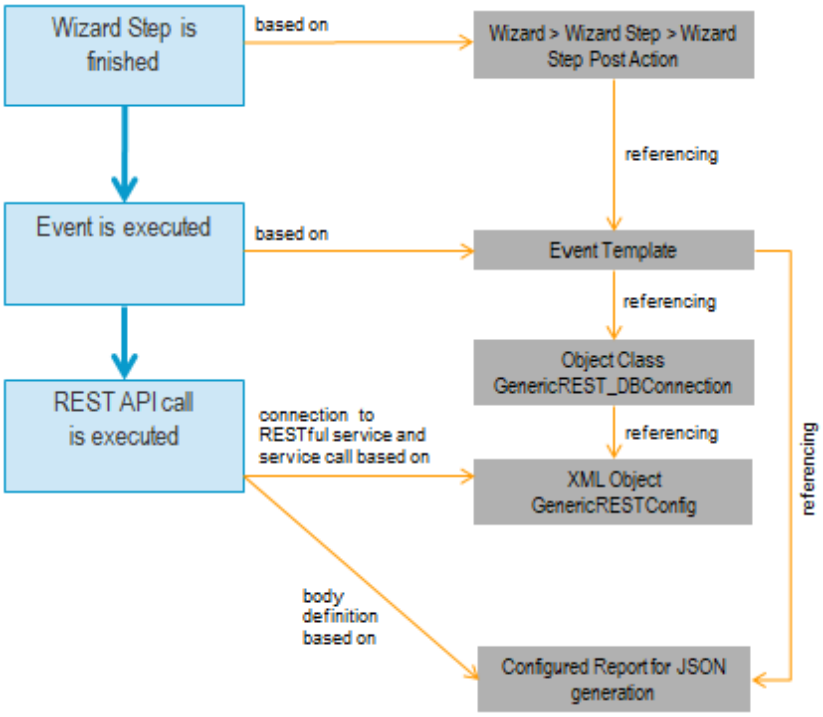

FIGURE: Execution of REST API call triggered via an event and the necessary configuration

The following information is available:

- Configuring the Connection Parameters in the XML Object GenericRestConfig
  - Defining a Dynamic Method Path for the RESTful Service Call
- Configuring the REST API Connection for Execution of the Event
- Defining the JSON Payload for the Body of the Service Call
  - Specifying Properties returning Text, String, Boolean, Date/Time Integer or Float
  - Specifying Properties returning an Array of Property Values
  - Specifying Properties Returning an Object
  - Specifying Properties Returning a List of Objects
- Creating an Event Template for Sending of a RESTful service call

Configuring the Connection Parameters in the XML Object GenericRestConfig

The Alfabet Web Application acts as RESTful client that connects to the RESTful API of any defined third-party component offering a RESTful service. The connection parameters must be configured in the XML object ***GenericRestConfig*** in Alfabet Expand:

1) of Alfabet Expand and expand the explorer node **XML Objects** > **Integration Solutions**.
2) Right click the XML object `GenericRestConfig` and select **Edit XML** from the context menu. The XML object opens in the middle pane.

3) Edit the XML as described below.

4) Click the **Save**button to save your changes.

The XML object must contain the following XML structure:

```
<GenericRestConfig>
    <Connection
        name = "ARIS Object Update"
        active="true"
        service="$ARIS_Service"
        authorization="tenant=default&amp;name=${ARIS_UserName}&amp;password=${ARIS_Password}&amp;key=${ARIS_Key}"
        auth_path = "/umc/api/tokens"
        auth_type = "token"
        auth_method_type = "POST"
        api="/abs/api"
        method_type = "PUT"
        method_content_type = "application/json"
        method_path = "/abs/api/objects/${dbname}/${objectGUID}"
        auth_release_type = "DELETE"
        auth_release_path = "/umc/api/tokens/${token}" />
</GenericRestConfig>
```

The following XML elements and their attributes are part of the specification:

Element (Bold) / Attribute	Configuration Requirements
GenericRestConfig	Root node of the configuration.
Connection	The configuration parameters for sending the RESTful service call. This XML element can be added multiple times to define multiple targets for RESTful service calls.
`name`	Enter a unique name for the connection configuration. The name is used to identify the connection configuration For example, in editors on the Alfabet user interface. This attribute is mandatory.
`active`	This XML attribute can be defined to deactivate (`false`) or activate (`true`) the connection. If the attribute is set to `false`, the connection will not be displayed in the drop-down list for the connection specification in the editor **Alfabet Database Connection** on the Alfabet user interface. The default value is `true`.

Element (Bold) / Attribute	Configuration Requirements
service	Enter the URL of the external application offering the RESTful service. This XML attribute is mandatory. The service XML attribute can be defined via a server variable to read the value of the XML attribute at runtime from the server alias configuration of the Alfabet Web Application for each service call. Only the complete value can be substituted with a server variable by specifying an $ sign followed by the server variable name. For information about how to define and use server variables, see Using Server Variables in Configurations.
auth_type	Enter the type of authentication at the external RESTful service. Supported values are: • basic for basic authentication with user name and password. The XML attributes authorization, auth_username and auth_password must also be defined for this authentication type. • token for request of a user token from the external RESTful service in a separate service call that is then valid for authentication during the actual service call. The XML attributes authorization, auth_path and auth_method_type must also be defined for this authentication type.
authorization	If auth_type is basic, enter Basic. Please note that Basic must start with a capital letter. If auth_type is token, enter the body definition for the authorization call. Please note that the specification must be compliant with definitions in XML. For example, ampersands must be written as & instead of &. The definition of the authorization XML attribute can include parts that are not directly defined in the authorization XML attribute but in the server alias of the Alfabet Web Application as server variable, to substitute the variable definition at runtime with the value from the server alias configuration of the Alfabet Web Application. Server variables can be included into the string with a $ sign followed by the server variable name in curly brackets. For example,: ${ServiceUserName} to include the server variable ServiceUserName. For information about how to define and use server variables, see Using Server Variables in Configurations.
auth_username	If auth_type is basic: Enter the user name for authentication at the external RESTful service.
auth_password	Enter the user password for authentication at the external RESTful service.

Element (Bold) / Attribute	Configuration Requirements
auth_path	If auth_type is token: Enter the path to the authentication end point of the external RESTful service relative to the URL defined with the attribute service.
auth_method_type	If auth_type is token: Enter the HTTP method used for the authentication call.
method_type	Enter the HTTP method used for the RESTful service call. The currently supported methods are GET, HEAD, POST, PUT, DELETE, and PATCH.
method_content_type	Enter the content type for the HTTP request. This attribute is optional. If not defined, the Content-Type header of the RESTful service call will be set to application/json.
method_path	Enter the path to the end point of the external RESTful service the service call should be made to, relative to the URL defined with the attribute service. The method_path specification can include dynamic parts that will be substituted at runtime from the values returned from a configured report. For more information, see Defining a Dynamic Method Path for the RESTful Service Call below.
auth_release_path	If auth_type is token, and the external RESTful service provides an endpoint to release tokens after use, the call to that endpoint to release the current token can be defined as part of the event execution. The path to the endpoint releasing the token including the required parameters for the service call must be defined in the auth_release_path XML attribute to activate the token release. The path definition should include the variable ${token}, that will be substituted at runtime with the token generated for the current RESTful service call. The attribute auth_release_type must also be defined to send the RESTful service call for releasing the token.
auth_release_type	If auth_type is token, and the external RESTful service provides an endpoint to release tokens after use, the call to that endpoint to release the current token can be defined as part of the event execution. Enter the HTTP method for the call to release the token into the auth_release_type XML attribute to activate the token release. The auth_release_path XML attribute must also be defined to send the RESTful service call for releasing the token.

Defining a Dynamic Method Path for the RESTful Service Call

The call to the endpoint of the external service defined with the `method_path` XML attribute in the `GenericRestConfig` XML object may contain parts that depend on the current call, like For example, adding the name of the object in the Alfabet database the user was working with in the wizard step that triggered the event as parameter handed over in the service call. Such parts can be filled dynamically via a configured report of the type `NativeSQL`.

For information about how to create a configured report of the type `NativeSQL`, see Creating a Tabular Configured Report of the Type NativeSQL.

The configured report definition must meet the following criteria:

- The **Category** attribute of the configured report must be set to the category specified for the use case `Events` in the XML object ***UseCaseCategories***.

  

  For information about the category definition in the XML object ***UseCaseCategories***, see Assigning a Category for Specific Functional Use to a Configured Report.

- The **Type** attribute of the configured report must be `NativeSQL`.
- The SQL query defined for the configured report must return a report with one row and a column for each variable to be used in the `method_path` XML attribute of the ***Connection*** XML element in the ***GenericRestConfig*** XML object.

  

  Please note that only visible columns in the result dataset of the query are taken into account. The first `SELECT` argument in the native SQL query is not visible in configured reports. In this context, it does not provide any functionality and can be set to NULL.

- Alfabet query language parameters can be used in the query. Please note that the parameter `BASE` returns the `REFSTR` of the object the user is currently working on in the wizard step or workflow step triggering the event. For events triggered via another REST API call event, the `BASE` object is the same as the one for the event triggering the event.

The column names from the result dataset of the configured report can then be used as variables in the definition of the method_path XML attribute. The required syntax is:

```
${ColumnName}
```

The variable will then be substituted with the value returned in the respective column at runtime.

Configuring the REST API Connection for Execution of the Event

Configuration is done in the **Integration Solutions Configuration** functionality on the Alfabet user interface.

1) Go to the **Integration Solutions Configuration** functionality and click the **REST APIConnection** node in the **Integration Solutions Configuration** explorer.
2) In the view, click **New** > **Create REST API Connection**.

If you have already defined a similar connection and want to take over the settings of that connection for your new connection, you can alternatively click **New** > **Create REST Connection as Copy** and select the existing connection the new connection should base on from the selector that opens. The editor for the new connection will then open with all settings identical to the copied connection and the name set to "Copy of <base connection name>".

3) In the **REST API Connection** editor, define the following fields as needed:

Basic Data tab:

- **ID**: Alfabet assigns a unique identification number to each REST API connection. This number cannot be edited.
- **Name**: Enter a unique name for the REST API connection.
- **Release Status**: Select the REST API connection's current release status.

  The set of release statuses available for an object class are configured by your solution designer in the configuration tool Alfabet Expand. For more information, see the section Configuring Release Status Definitions for Object Classes in the reference manual *Configuring Alfabet with Alfabet Expand*. For general information about release statuses, see the section *Understanding Release Statuses* in the reference manual *Getting Started with Alfabet*.

- **Description**: Enter a meaningful description that will clarify the purpose of the REST API connection.

Authorized Access tab:

- **Authorized User**: Click the **Search** icon to assign an authorized user to the selected Alfabet database connection. The authorized user will have Read/Write access permissions for the object and is responsible for the maintenance of the object.
- **Authorized User Groups**: Select one or more checkboxes to assign Read/Write access permissions to all users in the selected user group(s).

Connection tab:

- **REST Connection**: Select the connection to the relevant Alfabet database that is configured in the XML element ***Connection*** in the XML object ***GenericRestConfig*** in Alfabet Expand.

4) Click **Test REST API Connection**. If your settings are correct, a message "The connection is valid" is displayed. Otherwise, an error message is displayed.

Defining the JSON Payload for the Body of the Service Call

If the service call includes a body definition, the JSON object to be send as payload of the call has to be defined via a configured report. The configured report must be of the type `NativeSQL`.

For information about how to create a configured report of the type `NativeSQL`, see Creating a Tabular Configured Report of the Type NativeSQL.

The configured report definition must meet the following criteria:

- The **Category** attribute of the configured report must be set to the category specified for the use case `Events` in the ***UseCaseCategories*** XML object.

  

  For information about the category definition in the XML object ***UseCaseCategories***, see Assigning a Category for Specific Functional Use to a Configured Report.

- The **Type** attribute of the configured report must be `NativeSQL`.
- The SQL query defined for the configured report must return a report with a simple table that returns data of a given format in columns with given column names as described below.
- Alfabet query language parameters can be used in the query. For events triggered via a workflow or wizard, `BASE` returns the REFSTR of the object the user was working on in the wizard step or workflow step triggering the event. For events triggered via another REST API call event, the `BASE` object is the same as the one for the event triggering the event.

The `SELECT` statement of the configured report must return columns with a given name scheme returning specific parts of the JSON. Each row in the configured report corresponds to a row in the report.

In general, the following definition is required:

Column Name	Data to be returned in the column
`REFSTR`	The first `SELECT` argument in the native SQL query is not visible in configured reports. In this context, it does not provide any functionality and can be set to `NULL`.
`ObjID`	Each object in the JSON must have an identifier. The identifier is not visible in the JSON, but required to build the structure. The identifier can be any string and must be unique for the object within the report. Special characters are not allowed in identifier names. This column is mandatory. An identifier is required in each row of the report to assign the data defined in the row to the correct JSON object.
`ParentObjID`	If the data in a row belongs to a JSON object that is child of another JSON object, this column must return the identifier of the parent object. This column is not required for rows returning properties of the root object(s).
`ParentPropName`	If the data in a row belongs to a JSON object that is child of another JSON object, this column must return the name of the parent object's property containing the subordinate object. This column is not required for rows returning properties of the root object(s).
`PropName`	The name of the property that is defined with this row. This value is shown in the JSON output.

Column Name	Data to be returned in the column
	This column is mandatory.
PropIsList	The column defines whether the property values is a list of JSON objects. Allowed values are: • 1: the property value is a list of JSON objects. • 0: the property value in not a list of JSON objects. This column is mandatory.
ValueInteger	If the property value is an integer, this column must return the property value. Otherwise, the column must return NULL.
ValueFloat	If the property value is a float value, this column must return the property value. Otherwise, the column must return NULL. If non of the properties in the JSON output has a float value, the column can be left out in the report definition.
ValueText	If the property value is a text, this column must return the property value. Otherwise, the column must return NULL.
ValueBoolean	If the property value is a boolean, this column must return the string true or false. Otherwise, the column must return NULL. If non of the properties in the JSON output has a boolean value, the column can be left out in the report definition.
ValueDate	If the property value is a date in a valid date or date time type, this column must return the property value. Otherwise, the column must return NULL. In case a string type instead of a date type value is used, the data and time format must be ISO 8601 compliant, e.g. 2018-09-17 08:57:22.260. If non of the properties in the JSON output has a date value, the column can be left out in the report definition.

It is recommended to create the event template for the event prior to configuring the report and link the report to the event template in an early stage of configuring the report. The context menu of the event template provides a functionality for testing the JSON output of a configured report. It is not required to set the report state to **Active** for testing the JSON output via the event template. The functionality can be used to test intermediate stages of the JSON definition via the configured report. For more information, see Creating an Event Template for Sending of a RESTful service call.

The following sections provide details about the definition of different structures in the JSON:

- Specifying Properties returning Text, String, Boolean, Date/Time Integer or Float

- Specifying Properties returning an Array of Property Values
- Specifying Properties Returning an Object
- Specifying Properties Returning a List of Objects

Specifying Properties returning Text, String, Boolean, Date/Time Integer or Float

A JSON object consists of a number of properties that are a name/value pair. The JSON body of a RESTful service request can have either one single root JSON object or a list of JSON objects.

To define the properties of the type text, string, boolean, date/Time and number in a root JSON object, you must specify an internal object ID for the root object, like For example, the string `root`.

If the JSON contains a list of objects on the root level, each root level object must have a different internal object ID.

In addition, the attribute **Is List** of the event template must be set to `True` for processing of an object list on the root level.

For each property of a root JSON object, the configured report the JSON serialization is based on must contain a row that returns the following:

- The internal JSON object ID of the object in the column `ObjID`.
- The name of the property in the column `PropName`.
- The property value in either the column `ValueInteger`, `ValueFloat`, `ValueText`, `ValueBoolean`, or `ValueDate`, dependent on the data type of the value.
- The `PropIsList` column must be set to `0`.
- All remaining columns must be set to `NULL`.

For example, for creating a simple JSON object with the structure:

```
{
    "TextProperty": "This is a root property",
    "DateProperty": 2019-02-11 10:59:30.333,
    "IntegerProperty": 16,
    "BooleanProperty": true
}
```

The native SQL query of the configured report must result in the following dataset:

	ObjID	ParentObjID	ParentPropName	PropName	PropIsList	ValueInteger	ValueText	ValueDate	ValueBoolean
1	root			TextProperty	0		This is a root property		
2	root			DateProperty	0			2018-02-13 0...	
3	root			IntegerProperty	0	16			
4	root			BooleanProperty	0				1

The example is based on the following native SQL query:

```
SELECT NULL As REFSTR, 'root' As ObjID, NULL As ParentObjID, NULL As
ParentPropName, 'TextProperty' As PropName, 0 As PropIsList, NULL As
'ValueInteger', 'This is a root property' As 'ValueText', NULL As
'ValueDate', NULL As 'ValueBoolean'

UNION ALL

SELECT NULL As REFSTR, 'root' As ObjID, NULL As ParentObjID, NULL As
ParentPropName, 'DateProperty' As PropName, 0 As PropIsList, NULL As
'ValueInteger', NULL As 'ValueText', '2019-02-11 10:59:30.333' As
'ValueDate', NULL As 'ValueBoolean'

UNION ALL

SELECT NULL As REFSTR, 'root' As ObjID, NULL As ParentObjID, NULL As
ParentPropName, 'IntegerProperty' As PropName, 0 As PropIsList, 16
As 'ValueInteger', NULL As 'ValueText', NULL As 'ValueDate', NULL As
'ValueBoolean'

UNION ALL

SELECT NULL As REFSTR, 'root' As ObjID, NULL As ParentObjID, NULL As
ParentPropName, 'BooleanProperty' As PropName, 0 As PropIsList, NULL
As 'ValueInteger', NULL As 'ValueText', NULL As 'ValueDate', 1 As
'ValueBoolean'
```

If the property is not defined for the root XML object but a subordinate object included via a property returning a list of objects, the specification described above must be amended with the following:

- The JSON object ID of the parent JSON object in the column `ParentObjID`.
- The name of the property in the parent JSON object that returns the list of subordinate objects in the column `ParentPropName`.

The complete requirements for defining properties returning one JSON object is described in the section Specifying Properties Returning an Object, and for properties returning a list of JSON objects in the section Specifying Properties Returning a List of Objects.

Specifying Properties returning an Array of Property Values

For a property in a JSON object that shall contain an array of values, the configured report must return one row for each value in the array. Each row must be identical except for the defined value. The following must be returned:

- The JSON object ID of the JSON object containing the property with the array values in the column `ObjID`.
- The name of the property containing the array values in the column `PropName`.
- One of the values of the array in either the column `ValueInteger`, `ValueFloat`, `ValueText`, `ValueBoolean`, or `ValueDate`, dependent on the data type of the value. All rows defining values for the array should have the value defined in the same column.
- The `PropIsList` column must be set to `1`.

- The columns `ParentObjID` and `ParentPropName` must be set to `NULL` for a root node property or to the object ID and property name of the parent object and parent property if the array property is defined for a subordinate object.

  The complete requirements for defining properties returning one JSON object is described in the section Specifying Properties Returning an Object, and for properties returning a list of JSON objects in the section Specifying Properties Returning a List of Objects.

For example, for creating a property with an array in the root JSON object with the structure:

```
{
    "ArrayProperty": ["Value 1","Value2"]
}
```

The native SQL query of the configured report must result in the following dataset:

	ObjID	ParentObjID	ParentPropName	PropName	PropIsList	ValueInteger	ValueText	ValueDate	Valu
1	root			ArrayProperty	1		Value1		
2	root			ArrayProperty	1		Value 2		

Specifying Properties Returning an Object

For a property in a JSON object that shall contain a single JSON object, the configured report must return one row for the definition of the property as returning an object and an additional row for each property of the subordinate object.

For the definition of the property as a property containing an object, the following must be defined:

- The JSON object ID of the JSON object containing the property in the column `ObjID`.
- The name of the property in the column `PropName`.
- The columns `ParentObjID` and `ParentPropName` must be set to `NULL` for a root node property or to the object ID and property name of the parent object and parent property if the property is defined for a subordinate object.
- `NULL` in all of the columns `ValueInteger`, `ValueFloat`, `ValueText`, `ValueBoolean`, or `ValueDate`.
- The `PropIsList` column must be set to `0`.

For the definition of the properties of the subordinate object, the following must be defined:

- The JSON object ID of the subordinate JSON object containing the property defined with this row in the column `ObjID`.
- The name of the property defined with this row in the column `PropName`.
- The name of the property containing the subordinate object in the column `ParentPropName`.

- The object ID of the JSON object that the property containing the subordinate object belongs to in the column `ParentObjID`.
- The property value of the property defined with this row in either the column `ValueInteger`, `ValueFloat`, `ValueText`, `ValueBoolean`, or `ValueDate`, dependent on the data type of the value. All other of the property value columns must be set to `NULL`.
- The `PropIsList` column must be set to `0` if the property defined with this row specifies a simple value or to `1`, if the property defines an array.

For example, for creating a property with a subordinate object in the root JSON object with the structure:

```
{
    "ObjectProperty": {
        "SubTextProperty":"This is a subordinate object",
        "SubIntegerProperty": 1
        }
}
```

The native SQL query of the configured report must result in the following dataset:

	ObjID	ParentObjID	ParentPropName	PropName	PropIsList	ValueInteger	ValueText	ValueDate	ValueBoolean
1	root			ObjectProperty	0				
2	sin...	root	ObjectProperty	SubTextProperty	0		This is a s...		
3	sin...	root	ObjectProperty	SubIntegerPro...	0	1			

Specifying Properties Returning a List of Objects

For a property in a JSON object that shall contain a list of JSON objects, the configured report must return one row for the definition of the property as returning an object list and an additional row for each property of the subordinate objects.

For the definition of the property as a property containing a list of objects, the following must be defined:

- The JSON object ID of the JSON object containing the property in the column `ObjID`.
- The name of the property in the column `PropName`.
- The columns `ParentObjID` and `ParentPropName` must be set to `NULL` for a root node property or to the object ID and property name of the parent object and parent property if the property is defined for a subordinate object.
- `NULL` in all of the columns `ValueInteger`, `ValueFloat`, `ValueText`, `ValueBoolean`, or `ValueDate`.
- The `PropIsList` column must be set to `1`.

For the definition of the properties of the subordinate objects, the following must be defined:

- The JSON object ID of the subordinate JSON object containing the property defined with this row in the column `ObjID`. Please note that each object in the list of objects must have a different object ID.

- The name of the property defined with this row in the column `PropName`.
- The name of the property containing the list of subordinate objects in the column `ParentPropName`.
- The object ID of the JSON object that the property containing the list of subordinate objects belongs to in the column `ParentObjID`.
- The property value of the property defined with this row in the column `ValueInteger`, `ValueFloat`, `ValueText`, `ValueBoolean`, or `ValueDate` that corresponds to the data type of the value. All other of the property value columns must be set to `NULL`.
- The `PropIsList` column must be set to `0` if the property defined with this row specifies a simple value or to `1`, if the property defines an array.

For example, for creating a property with a list of two subordinate objects in the root JSON object with the structure:

```
{
   "ObjectProperty": [{
      "SubTextProperty":"This is the first object in a list",
      "SubIntegerProperty": 1
      },
      {"SubTextProperty":"This is the second object in a list",
      "SubIntegerProperty": 2
      }]
}
```

The native SQL query of the configured report must result in the following dataset:

	ObjID	ParentObjID	ParentPropName	PropName	PropIsList	ValueInteger	ValueText
1	root			ObjectListProp...	1		
2	firstinlist	root	ObjectListProperty	SubTextProperty	0		This is the first object in a list
3	firstinlist	root	ObjectListProperty	SubIntegerPro...	0	1	
4	secondinlist	root	ObjectListProperty	SubTextProperty	0		This is the second object in a l
5	secondinlist	root	ObjectListProperty	SubIntegerPro...	0	2	

Creating an Event Template for Sending of a RESTful service call

To define an event template for an event sending a RESTful service call:

1) Go to the **Reusable Elements** tab of Alfabet Expand.
2) The new RESTful service call event template is added on the root level of the event management tree.
3) Click the new event template and edit the following attributes in the attribute window:
   - **Name**: Enter a unique name for the event template. The name is used to identify the event templates in configurations.

- **Description**: Optionally enter a short text describing the functionality of the event. This information is only visible in the event template attributes in the **Reusable Elements** tab to inform, For example, other solution designers about the functionality implemented with the event template.
- **Connection via Query** / **Connection via Query as Text**: Define a query that returns the `REFSTR` of the REST API connection to be used for execution of the event. The query must return a single `REFSTR`. It can either be defined as native SQL query or Alfabet query:
  - Use the **Connection via Query** attribute to define an Alfabet query. Show properties are not required for the query.

    

    ```
    ALFABET_QUERY_500
    FIND GenericREST_DBConnection
    WHERE GenericREST_DBConnection.Name = 'EventConnection'
    ```

  - Use the **Connection via Query as Text** attribute to define a native SQL query with the `REFSTR` of the Alfabet database connection as only `SELECT` argument.

    

    ```
    SELECT REFSTR
    FROM GENERICREST_DBCONNECTION
    WHERE GENERICREST_DBCONNECTION.NAME = 'EventConnection'
    ```

    

    If the query returns no result, the event is not executed, but no error will be thrown. This behaviour can be used to define a query that couples the return value to a condition for executing the RESTful service call. For example, data about Alfabet objects to be exported to a third part application shall only be executed if the required external object ID is set for all objects included in the export.
- **Connection Report**: If the connection definition in the ***GenericRestConfig*** XML element includes dynamic parts in the specification of the `method_path` XML attribute, select the configured report returning the current values for the dynamic elements from the drop-down list.
- **Execute Immediately**: Setting this attribute to `True` will cause the Alfabet Web Application to execute the event immediately by triggering the REST API call starting the workflow. The event is nevertheless written to the `ALFA_EVENT_BUS` table, but with the `STATE` set to `FINISHED` or, if execution was not successful, to `ERROR`. Setting this attribute to `False` will lead to standard scheduling of the event via the `ALFA_EVENT_BUS` table and execution via the Alfabet Server.
- **Completion Event**: Select an existing event of any event type that shall be executed on completion of the REST API call event. The following is relevant for the execution of an event triggered on completion of an event sending a RESTful service call:
  - The base object of the current event is handed over as base object to the event triggered on completion. Queries defined for the completion event can reference this base object via the Alfabet query language parameter `BASE`.
  - If the completion event is triggering the execution of an ADIF import job, the return value from the REST API call executed via this event can be handed over to the completion event. The event template triggering the ADIF job must then include the definition of an import file with the **Import File** attribute of the event template for the

completion event. The file will be created and the return value written to it prior to triggering the completion event. Please note that the **Import File** attribute of the ADIF import scheme's JSON import set processing the return value must be set to the same file name as the **Import File** attribute of the event template.

- **Group**: If you would like to structure your event templates in folders, enter the name of the event template folder the event template shall be located in. If event template folders have already been defined for other event templates, they will be displayed in a drop-down list and can be selected. If you want to define a new event template folder, enter a new name into the field. The folder is then created in the explorer. The event template is moved to the selected event template folder.
- **Report**: If the service call should include a body, select the configured report defining the JSON object, which will be send as body, from the drop-down list.
- **Is List**: Set this attribute to `True` if the configure report specified with the attribute Report will result in a JSON having a list of JSON objects on the root level instead of a single root JSON object.

4) Click the **Save**button to save your changes.
5) A new window opens that displays the JSON request as generated from the data returned by the configured report defined with the **Report** attribute of the event template. Check the JSON request for correctness of structure and content. If the result is not as expected, the configured report has to be corrected.
6) Right-click the event template and select **Set Event State to Active** from the context menu.

Configuring Triggering of an Event

One of the following configurations can be used to configure execution of events on user interactions:

- Configuring a Wizard or Workflow to Trigger the Event
- Configuring an Event Template Sending a REST API Call to Trigger Another Event
- Configuring the Feedback Bot to Trigger an Event

Configuring a Wizard or Workflow to Trigger the Event

Events can be triggered via an on enter, on cancel, or on exit step action of a wizard step or via an on enter, on refuse, on expired, or on exit step action of a workflow step. The implementation is the same for all wizard step actions and workflow step actions:

1) In Alfabet Expand, navigate to the wizard step or workflow step that you want the event to be triggered from.
2) Create a new wizard step action or workflow step action, as needed:
   - To create a new wizard step action for a wizard step, right-click the relevant **Action On Entered Step**, **Action On Exited Step**, or **Action On Cancelled Step** node and select the option to create the new wizard step action. For more information about configuring wizard step actions, see the section Configuring Wizard Step Actions for a Wizard Step.

- To create a new workflow step action for a workflow step, right-click the relevant **Action On Entered Step**, **Action On Refused Step**, **Action On Expired Step**, or **Action On Exited Step** node of the workflow step and select the option to create the new workflow step action. For more information about configuring workflow step action to trigger an event, see the section Configuring Events to Be Triggered for a Workflow Step.

3) Click the new wizard step action/workflow step action in the explorer and edit the following attributes in the attribute window:

- **Technical Name**: Enter a name for the wizard step action/workflow step action. This name is not displayed in the Alfabet interface.
- **Action Type**: Select `TriggerEvent`.
- **Technical Comment**: Enter any relevant information about the wizard step action/workflow step action.
- **Event Template**: Select the relevant event template from the drop-down list.

4) Optionally, you can define a condition to execute the event depending on the availability of specific data returned by a query. For example, you could specify that the event may only be executed if a property of the base object of the wizard is set to a specific value. Edit the following attributes in the attribute window to define the condition:

- **Check Query** / **Check Query as Text**: Define a query that will return a result only if a condition is met. The query can be defined either as an Alfabet query in the **Check Query** attribute or as a native SQL query in the **Check Query as Text** attribute.
- **Result Type**: Select `Positive` if the event shall only be executed if the query returns a result. Select `Negative` if the event shall only be executed if the query does not return a result.

For example, an event to update an application's indicators when a wizard step is exited shall be triggered if the application's release status is set to the value "Approved". The following query will only return a result if the application that is the base application of the wizard step has the correct release status:

```
SELECT REFSTR
FROM APPLICATION
WHERE APPLICATION.STATUS = 'Approved'
AND APPLICATION.REFSTR = @WIZARDBASE
```

The **Result Type** is set to `Positive` sothat that the event is only executed if the query returns a result.

5) Click the **Save**  button to save your definitions.

Configuring an Event Template Sending a REST API Call to Trigger Another Event

Events can be triggered on completion of an event for sending of a RESTful service call.

On triggering of the event for sending a RESTful service call, the RESTful service call is executed, and if the event is configured to trigger another event on completion of the service call, the completion event is

triggered as soon as the return value from the external RESTful service has been received. The base object of the current event is handed over as base object to the event triggered on completion. Queries defined for the completion event can reference this base object via the Alfabet query language parameter `BASE`.

If the completion event is triggering the execution of an ADIF import job, the return value from the REST API call can be handed over to the completion event in JSON format. The event template triggering the ADIF job must then include the definition of an import file with the **Import File** attribute of the event template for the completion event. The file will be created and the return value written to it prior to triggering the completion event. Please note that the **Import File** attribute of the ADIF import scheme's JSON import set processing the return value must be set to the same file name as the **Import File** attribute of the event template.

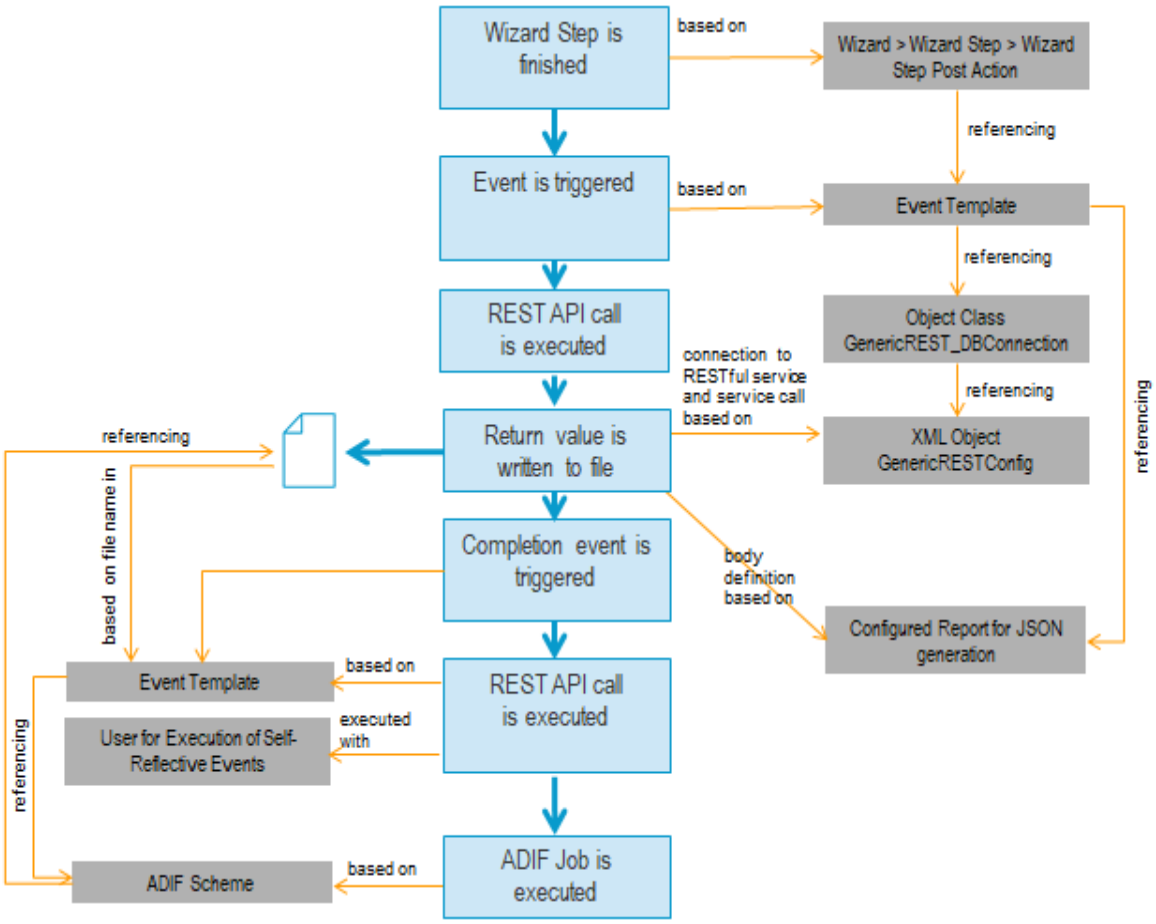

FIGURE: Triggering of an ADIF import job that processes the return value from an event template

To configure an event for execution of a RESTful service call to trigger another event on completion:

1) In Alfabet Expand, go to the **Reusable Elements** tab.
2) In the explorer, click the event template for execution of a RESTful service call that should trigger the event.
3) In the attribute window select the event template that shall be triggered on completion of this event in the drop-down list of the attribute **Completion Event**.
4) Click the **Save** button to save your definitions.

The following additional configuration is required to process the return value in an ADIF import triggered by the completion event:

- In the event template triggering the ADIF import, specify a file name with the extension JSON in the **Import File** attribute.
- In the ADIF scheme triggered by the completion event, create a JSON import set and set the **Import File** attribute of the JSON import set to the file name specified in the **Import File** attribute of the completion event template.

For information about creating and configuring an ADIF import scheme, see the reference manual *Alfabet Data Integration Framework*.

Configuring the Feedback Bot to Trigger an Event

Events can be triggered when a user sends a contact request or rating via the Feedback Bot, For example, to create a ticket for the feedback in a ticketing system via a RESTful service call.

1) Go to the **Presentation** tab and expand the **XML Objects** folder. The XML object ***AlfaFeedbackBotConfig*** opens.
2) Right-click ***AlfaFeedbackBotConfig*** and select **Edit XML**. The XML editor is displayed in the center pane.
3) To trigger an event when the user submits a rating, add an XML attribute `EventTemplate` to the XML element `SpecificFeedbackPage` and set it to the name of the event template:

   ```
   <SpecificFeedbackPage EventTemplate="NameofEventTemplate" [...]/>
   ```

4) To trigger an event when the user submits a contact form, add an XML attribute `EventTemplate` to the XML element `ContactUsPage` and set it to the name of the event template:

   ```
   <ContactUsPage EventTemplate="NameofEventTemplate" [...]/>
   ```

5) In the toolbar, click the **Save**  button to save the XML definition.

Checking the Execution of Events

Registered events are stored in the Alfabet database as objects of the object class `ALFA_EVENT_BUS` with the state `PENDING`. The state and other attributes of the event in the table are changed and amended during execution, informing about the success of execution. If errors occur, the error messages are also written to the database table of the object class `ALFA_EVENT_BUS`.

Two business functions are available that provide an overview over the execution of event as stored in the `ALFA_EVENT_BUS` table:

- The business function **Event Administration** (`ADMIN_Events`) provides information about all events that are triggered by any user.
- The business function **My Events** (`USER_Events`) provides information about all events that are triggered by the current user. The user triggering the event is the user that was using the wizard or workflow that triggered the event via one of its conditions.

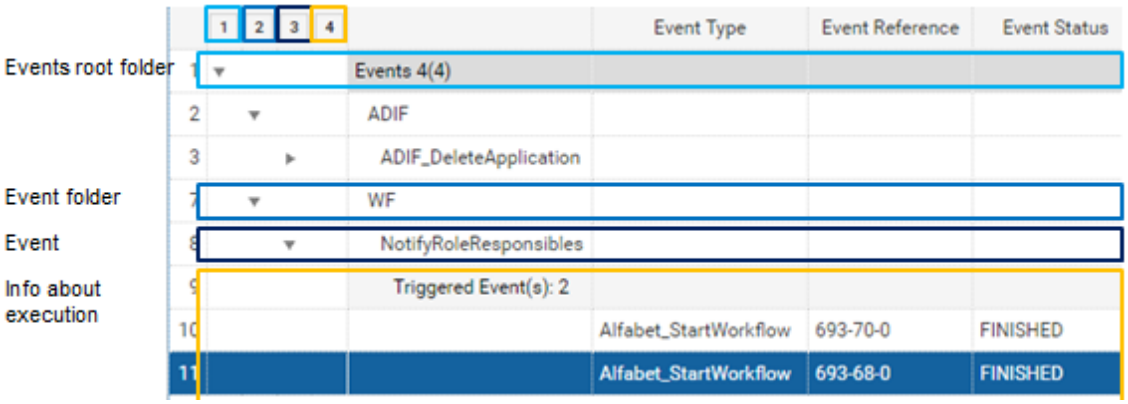
The views can be made available to the user via the user profile, guide page or guide view configuration.

For information about adding business functions directly to user profiles, see Making Functionalities Accessible to a User Profile. For information about adding business functions to user profiles via guide pages or guide views, see the reference manual *Designing Guide Pages for Alfabet*.

Both views show the same tabular view of the information about event execution.

The table is an expandable dataset that shows information about event execution in the structure that is defined for the event templates in Alfabet Expand:

- The first level displays the root node and informs about the number of executed events.
- The second level displays event folders and events that are located directly under the root node.
- The third level displays the events in the event folder, or, for events located directly under the root node, the list of triggered events.
- The fourth level displays the triggering for events located in event folders.



If an event has been triggered one or multiple times, each triggering of the event is listed as a separate row under the heading **Triggered Event(s)** with the following information about the event execution:

- **Event Type**: Displays whether the event triggers the start of a workflow (`Alfabet_StartWorkflow`), a RESTful service call (`RestCall`), execution of an ADIF import (`Alfabet_StartAdifImport`), or execution of an ADIF export (`Alfabet_StartAdifExport`). Monitoring events are reported as the event type `Task`.
- **Event Reference**: The `REFSTR` of the triggered event. This is a unique identifier for the scheduled or executed event.
- **Event Status**: The status can be one of the following:
  - **Pending**: The event has been triggered and is queued for execution.
  - **Executing**: The event is currently executed.
  - **Finished**: The event has been successfully executed.
  - **Canceled**: The event has been canceled.
  - **Error**: The event has been executed and an error occurred during execution of the event.

- **Execution Error**: The event has been executed and an error occurred during execution of the functionality triggered by the event.
- **Execution Forcefully Terminated**: The execution of the event has been terminated in the context of a server shutdown.

If monitoring events are scheduled for cyclic execution, regular executions will be managed via a single event. After the monitoring is triggered, the event will be immediately re-scheduled for execution ten minutes later. Therefore, the event status value of the event will remain **Pending** after monitoring has been triggered.

- **Event Callback Status**: This column is only filled for events triggering an ADIF import or export that are configured to wait for a callback from the triggered ADIF process. The event will have the status **Pending** as long as the ADIF process is executed. The status will then change to **Finished** or **Execution Error** depending on the success of the ADIF process execution.
- **Occurrence Time**: The date and time when the event was triggered.
- **Start Time**: This column is only filled for triggered cyclic monitoring events. Cyclic execution is based on a single event. After monitoring is executed, the event will not be terminated, but re-scheduled immediately for the next execution of monitoring. Therefore, the event status of the event will remain **Pending**. The next scheduled start time of monitoring will be displayed in the **Start Time** column.
- **Comment**: This field is currently not used.
- **Trigger Type**: Currently, the only trigger type is `ALFABET`. This means that the event is triggered from an Alfabet component.
- **Sender**: Currently, the only sender is `Alfabet`. This means that the event is triggered from an Alfabet component.

A filter is available to reduce the content of the view to a subset of the triggered events.

If the execution of an event failed, and the **Event Status** is set to **ERROR**, a detailed error message, including error messages that were thrown during execution of the RESTful service call for the event, can be downloaded for the failed event. Select the event in the table and click the **Show Event Message** button in the toolbar. The event message is written into a file that is then provided for download via the download mechanism of your browser.

Changing or Deleting an Event Template

Whether an event template can be executed, edited or deleted depends on the setting of the **Event State** of the event template:

- Event templates can only be edited if the **Event State** is set to **Plan**.
- Event templates can only be added to workflow or wizard step actions and executed by a user if the **Event State** is set to **Active**.
- Event templates can only be deleted if the **Event State** is set to **Plan** or **Retired**. Please note that event templates that are implemented to be executed via wizard or workflow step actions are ignored, if the **Event State** is set to **Retired**. That means that the event is not executed any longer without causing an error.

To edit an active event template:

1) In the explorer, right-click the event template and select **Show Usage**. A new window opens that lists all wizard and workflow steps triggering the execution of an event on basis of the selected event template.
2) On basis of the information, check whether re-configuration must be performed prior to altering the **Event State** of the event template. If a user executes a wizard or workflow that triggers the event and the **Event State** of the event template is not **Active**, an error message is displayed informing the user about the inactive **Event State** of the event template.
3) Right-click the event template and select **Set Event State to 'Plan'**.
4) Edit the event template.
5) Right-click the event template and select **Set Event State to 'Active'**.
6) If you changed the configuration of wizard or workflow step actions to prevent error messages caused by currently not active event template, revert the preliminary changes.

To delete an event template:

1) In the explorer, right-click the event template and select **Show Usage**. A new window opens that lists all wizard and workflow steps triggering the execution of an event on basis of the selected event template.
2) On basis of the information, remove the configuration using the event template from wizard and workflow configurations.
3) Right-click the event template and select **Set Event State to 'Retired'**.
4) Right-click the event template and select **Delete**.

Structuring Events in Event Folders

You can structure and organize event templates in group folders:

- To create an event folder for an existing event template, enter a name for the event folder in the **Group** attribute and press ENTER. The event folder appears ascendant to the selected event template.
- To create a new event template for an existing event folder, right-click the event folder and select **Create New Workflow Event Template**, **Create New ADIF Import Event Template**, or **Create New ADIF Export Event Template**.
- To add an event template to an existing event folder, click the **Group** attribute and select the relevant event template group. The event template is moved to the selected event folder.
- Any changes you make to the **Group** attribute of the event template must be saved by clicking the **Save**  button.

The context menu of the event folders includes options to alter the event state. If you select one of the options to alter the event state on an event folder, the event state of all events subordinate to the folder is changed.

Saving and Restoring the Configuration of Event Templates

It is recommended to configure events in a development environment and apply it to the production environment after complete testing only.

To take over the configuration done in a development environment to the Alfabet database of a test or production environment, the general mechanisms for merging or replacing solution configurations in one Alfabet database with the complete or partial solution configuration of another Alfabet database described in the section Applying Configuration Changes to Other Databases can be used.

Alternatively, the configuration can be saved to an XML file and merged from the XML file into the configuration of the target database:

1) Connect to the source database with Alfabet Expand.
2) In the **Reusable Elements** tab, do one of the following:
   - To store the complete event template configuration in an XML file, right-click the folder **Event Templates** and select **Save As**.
   - To store a single event template in an XML file, right-click the event template and select **Save As**.
3) In the explorer window that opens, select a location for the XML file that is accessible via Alfabet Expand in the target environment and click **Save** to save the file.
4) Connect to the target database using Alfabet Expand.
5) In the **Reusable Elements** tab, right-click the folder **Event Templates** and select one of the following:
   - **Replace from File** to overwrite the current configuration with the configuration in the XML file. The whole event template configuration is deleted and then the configuration stored in the XML file is applied. That means that all event templates in the XML file will overwrite corresponding event templates in the target database. Event templates in the target database that have no corresponding event template in the XML file will be deleted. Event templates that are only available in the XML file will be added.
   - **Merge from File** to merge the current configuration with the configuration in the XML file. All event templates in the XML file will overwrite corresponding event templates in the target database. Event templates that have no corresponding event template in the XML file will remain unchanged. Event templates that are only available in the XML file will be added.
6) In the explorer window that opens, select the XML file with your new event template configuration.
7) Confirm the warning message. The event template configuration in the target database is changed.

Chapter 17: Configuring Reports

Configured reports can be generated and configured in the **Reports** tab of Alfabet Expand for the following purposes:

- **Providing customer-specific information to the user community**

Standard Alfabet reports about objects in the Alfabet database are included in the standard Alfabet product. However, you can also configure and provide customized reports to the user community via the Alfabet interface.

- **Defining matrices or multi-editors for batch data capture**

The standard editors and views for the Alfabet interface allow the user to define data per object. In some special situations that require to change the data for a high number of objects, this can be a time consuming process. To ease data capture for multiple objects, a configured report can be defined that allows multiple business supports or relationships between objects to be defined for a customizable set of objects by clicking cells in a matrix. Another type of configured report provides editors for multi-editing of object class properties of selected objects either by defining individual values or by batch setting of a property to a defined value for all selected objects.

- **Defining compliance policies for the Compliance Management functionality**

For more information, see Configuring Queries for Compliance Policies in the section Configuring the Compliance Management Capability.

- **Defining datasets to export data via the Alfabet RESTful API**

For security reasons, the Alfabet RESTful service reads data from a query in a configured report that is executed at runtime instead of directly accessing the Alfabet database. For more information, see the reference manual *Alfabet RESTful API*.

- **Defining data export conditions for batch data export to HTML, XML or PDF files with the tool QueryExecutor.exe**

For more information, see the section *Exporting Data to XML, HTML, or Microsoft® Excel® Format with the QueryExecutor.exe* in the reference manual *System Administration*.

This chapter provides an overview of the types of configured reports that can be specified, explains how configured reports are implemented in the Alfabet interface, and describes in detail the necessary configuration steps.

The following information is available regarding reports:

Types and Features of Configured Reports

Alfabet offers a wealth of standard reports in the standard Alfabet solution. In addition to the standard reports that are available, customers can create configured reports required by the enterprise and display them in the Alfabet interface.

The following overview provides information about the different mechanisms to display the information in configured reports and about how configured reports can be integrated in the Alfabet interface.

Software AG provides mechanisms to create five types of configured reports:

Report Type	Description
`Query`	Configured report based on an Alfabet query that displays the query results as a tabular report. You can either allow the user to simply execute the configured report based on the configured Alfabet query, or you can allow the user to limit the Alfabet query results to a subset of the data by setting filters before the configured report is executed. For more information, see Query-Based Tabular Reports.
`NativeSQL`	Configured report based on a native SQL query that displays the query results as a tabular report. You can either allow the user to simply execute the configured report based on the configured native SQL query, or you can allow the user to limit the search results to a subset of the data by setting filters before the configured report is executed. For more information, see Query-Based Tabular Reports.
`Custom`	This type of configured report can result in any of the following report types: • Configured reports that display results as a graphic report, For example, as portfolio, treemap or chart report. The configured reports are based on a template and are defined in the **Report Assistant**. For more information, see Query Based Graphic Representations of Configured Reports. • A template-based matrix for multi-editing of objects. Three templates are available for the creation of a matrix for multi-editing of business supports, object relationships, and indicators. For more information, see Configured Reports Providing Ability for Mass Data Changes. • Console reports that display an object cockpit with a filter area. An object cockpit is a collection of subordinate configured reports displayed in a tabular grid. The filter settings of the console report are applied to all subordinate configured reports assigned to the object cockpit. For more information, see Configuring Console Reports. • Cascading report that displays at least one master report and one subordinate report. When the user selects an object in the master report, the content of the subordinate report changes and displays data related to the subordinate object. For more information, see Combining Multiple, Cascading Reports in One View. • Configured reports that display a geographic map with relevant data displayed by color of region or color and size of markers and connectors between markers.

Report Type	Description
ObjectView	Configured report displaying an object view or object cockpit configured for objects in a selected object class. For more information, see Configured Reports opening Existing Object Views or Object Cockpits.
Extern	Configured report opening a URL specified by the customer. This type of configured report allows for the display of reports showing data in the Alfabet database or external data generated by third-party reporting tools. For more information, see Integration of External Reports.

The following information is available about the features that are provided by the different kind of reports:

- Features Shared by All Types of Configured Reports
  - Providing Custom Online Help Files for a Configured Report
  - Publishing Current Report Results
  - Navigating to Objects Displayed in a Configured Report
  - Navigating to an URL From a Configured Report
  - Assigning Configured Reports to an Object Class
  - Specifying Base Classes Required for the Configured Report
  - Configuring Filters to Define Search Criteria
  - Invoking Start of a Workflow
  - Providing Additional Information in a Quality Widget
  - Hiding Toolbar Buttons
  - Restricting Access to the Alfabet database Via Configured Reports
- Query-Based Tabular Reports
  - Expandable Result Table
  - Definition of Frozen Columns
  - Adding Data to the Clipboard
  - User Specific Table Layout
    - Allowing the User to Hide Columns and Change the Column Order
    - Allowing the User to Alter the Structure and Design of the Report
  - Display of Results in Standard Alfabet Report Formats
  - Display of Results in Customer Configured Views
  - Configuring User Workspaces to Edit Objects in the Configured Report

Features Shared by All Types of Configured Reports

The following features are available for all of the types of configured reports that can be configured for your enterprise:

Providing Custom Online Help Files for a Configured Report

You can create context-sensitive online Help files that provide information about the configured report to the user community and add them to the standard Alfabet online Help. The help file is stored externally and the URL of the help file is defined in the configured report. When the user views the configured report in the Alfabet interface, he/she can click the **Help** button to open a dialog providing hyperlinks to the Help available for the current view. The user will not be able to distinguish between links to external help files and links to the standard Alfabet online Help. When the user clicks a link leading to an external custom help file, the URL specified in the configured report will open in a new window.

For more information about the structure and use of the Alfabet online Help, see the section *Using the Help in Alfabet* in the reference manual *Getting Started with Alfabet*.

Publishing Current Report Results

Alfabet allows for the export of views via an **Export** button in the toolbar. Tables can be exported to HTML or Microsoft® Excel® files and graphics can be exported to Microsoft® PowerPoint® files, Adobe® PDF files and HTML files with embedded graphics in a variety of graphic formats. This functionality is also available by default for all configured reports except for configured reports of the type `Extern`. Template-based matrix reports that support the simultaneously editing of multiple objects can only be exported to Microsoft® Excel® files.

The filter area of a configured report can be defined as included or excluded from export when configuring the report.

Please note the following:

- Gauge reports and geo map reports embedded in an object cockpit cannot be published to DOC or PDF format.
- Reports that return object class properties of the Property Type Text can only be exported to Microsoft® Excel® files if the content of the text fields does not contain more than 32768 characters, which is the length restriction for Microsoft® Excel® data sheet cells.
- For the following configured reports, the export functionality is only available if the third-party component Essential Objects is activated in the web.config file of the Alfabet Web Application.
  - Gallery reports
  - Branching diagram reports
  - Gauge reports
  - Circular roadmap reports
  - Map Charts

  For more information about the activation of the component, see *Prerequisits for Using Essential Objects®* in the reference manual *Technical Requirements*.

For more information about the export of views in Alfabet, see the section *Exporting Data* in the reference manual *Getting Started with Alfabet*.

For graphic reports, a printing functionality is additionally available via the floating toolbar. Clicking the **Print** button in the floating toolbar opens a view that allows to fine-tune the output of the graphic. Confirming the layout by clicking **OK** in the new window will open a new browser tab containing the graphic without the surrounding interface elements, like header and toolbar. The image can then be printed via the print functionality of the browser. This feature is not available for branching diagram reports.

For more information about the printing of graphic views in Alfabet, see the section *Printing a View in Alfabet* in the reference manual *Getting Started with Alfabet*.

Navigating to Objects Displayed in a Configured Report

The user can navigate to the object view of an object displayed in any type of configured report. Please note the following:

- In configured reports of the type `Query`, `NativeSQL`, or `Custom`, the user can access the object view of the object either by double-clicking the object in the results or by selecting the object in the results and clicking the **Navigate** button in the toolbar. Navigation to a base class without further configuration of the report is only possible for a preconfigured subset of object classes.

  - For configured reports based on an Alfabet query, navigation to the preconfigured subset of base classes is available by default. For configured reports based on a native SQL query, a special configuration is required. For more information see Definition of the SELECT Clause in the section Defining Native SQL Queries.
  - For an overview of the navigable object classes for that navigation is activated by default, see *Overview of Configurable Features for Object Classes* in the reference manual *Configuring Alfabet with Alfabet Expand - Appendix*.
  - For information about how to activate navigation for base object classes that do not offer navigation by default, see Activating Navigation From Reports to Object Classes Not Automatically Offering Navigation.
  - For configured reports of the type `Custom` that display a chart report, like For example, a bar or line chart, navigation is not available by default. The required configuration is described in the section Configuring Navigation from a Chart Report.
  - For configured reports of the type `Custom` that display a custom pivot table for analysis of cube data, navigation is not available by default. The required configuration is described in the section Activating Navigation From Reports to Object Classes Not Automatically Offering Navigation.

- For configured reports of the type `Extern` with a URL that access reports generated with external reporting tools, Software AG provides a link syntax that can be used to open Alfabet views via the external report. For information about the implementation of links to the Alfabet interface in external reports, see *Links to Alfabet Views from External Applications* in the reference manual *System Administration*.
- Configured reports of the type `ObjectView` already display the object view or object cockpit of an object as the report result.
- Alternatively, most configured reports can be configured to provide navigation directly to a page view of the selected object instead of the object's profile. For example, the configuration can specify that if the user double-clicks on an application group in a configured report, the application's portfolio view for the application group will open instead of the application group's object view. For

tabular configured reports, configuration is done by adding an Alfabet instruction. The configuration is described in the section Providing a Link to Alfabet Views, Editors or Wizards from Cells in a Report of the chapter Defining Queries. For most types of graphic representations of report results, the configuration can be done via the report assistant. The required setting in the report assistant is described in the section Defining Navigation from the Report to Alfabet Views.

- Reports can be configured to provide navigation to a related object class that is included in the result dataset instead of navigation to the base object class. This feature requires configuration of the query the report is based on by adding an Alfabet instruction. The configuration is described in the section Changing the Navigation Behavior of the Base Object Class in a Configured Report of the chapter Defining Queries.

Navigating to an URL From a Configured Report

If a cell in a dataset returns a valid URL without any other content, the URL is rendered as a link. If the user clicks the link, the URL opens in a new browser tab.

Assigning Configured Reports to an Object Class

Configured reports can be assigned to an object class by means of the **Apply to Class** attribute or the **Base Object Query** attribute, which are defined in the attribute window for the configured report. A configured report can only be assigned to one object class.

When a configured report of the type `Query`, `NativeSQL`, or `Custom` is assigned to an object class, the configured report automatically refers to a single object of the assigned object class with the Alfabet parameter `BASE` in the configured report's Alfabet query or native SQL query. The parameter `BASE` can be used in the query of the configured report to refer to a selected object of the assigned object class.

When the **Apply to Class** attribute is set, a selector field is automatically displayed on top of the configured report that allows an object in the assigned object class to be selected. If the configured report is displayed in the **Reports** page view of an object view or is assigned to an object view, the object specified with the Alfabet parameter `BASE` is by default the object the user is currently working with. The user can then change to another object by means of the selector.

For configured reports of the type `Query`, `NativeSQL`, `Extern` and `Custom`, the **Apply to Class** attribute also determines the display of the configured report in the **Configured Reports** page view. Configured reports are only available in the **Configured Reports** page view of the object view of an object class that has been defined in the **Apply to Class** attribute. If the **Apply to Class** attribute is not specified, the configured report will not be available in the **Configured Reports** page view for any object class.

The **Apply To Class** attribute is mandatory for configured reports of the type `ObjectView` and for configured reports of the type `Custom` displaying an HTML report about indicators. It is optional for all other configured reports

If the **Apply to Class** attribute is defined, the configured report will only be executed if a base object is defined. If you want a configured report to be executed both for a single selected object or for all objects of a class, you must define a configured report with a filter field that allows the report output to be limited to selected objects.

When the base class of a configured report is set with the **Base Object Query** attribute, the base object is determined by a query that returns a single object. The query can use Alfabet parameters referring to the

current working environment. The base object is determined by execution of the query when the user opens the configured report. Changing to another base object via an automatic filter is not possible when the base class is determined via a base object query.

When the configured report is applied to an object view, the Alfabet parameter `BASE`, referring to the object the user is currently working with, can be used in the **Base Object Query** attribute to determine the base object of the configured report. For example, when the configured report is assigned to an object view of an application, the **Base Object Query** attribute can find the ICT object the current application is assigned to as base object for the configured report.

The Alfabet parameter `BASE` can also be used in configured reports if the configured report is not applied to an object class by means of the attribute **Apply to Class** or **Base Object Query** but added to an object view. In this case, the Alfabet parameter `BASE` automatically specifies the object the user is currently working with. The selection of a different `BASE` object via a filter is not possible. A configured report using the `BASE` parameter in the query definition without being applied to a single class can be added to any class that can meaningfully be used as `BASE` definition. For example, a configured report displays all projects that have the current object as part of the target architecture definition. The project's target architecture can include objects of several classes. The same configured report can be added to the object view of all classes that may be part of a project's target architecture.

Specifying Base Classes Required for the Configured Report

When configuring view schemes for a user profile, object classes can be excluded from a view scheme. All Alfabet views for which the excluded class is the base class of the Alfabet view will be excluded.

The **Base Classes** attribute available for the configured report allows one or more object classes to be specified as the base classes for the configured report. This ensures that the configured report will not be visible if the user is logged in with a user profile for which the object class is excluded.

For more information about the exclusion of classes, see Refining Visibility Issues in the View Scheme in the chapter Configuring User Profiles for the User Community.

Configuring Filters to Define Search Criteria

A configured report can be specified to include filter fields that allow the user to specify search criteria to find objects for the report results. You can define filters for configured reports of the type `Query`, `NativeSQL` and `Custom`.

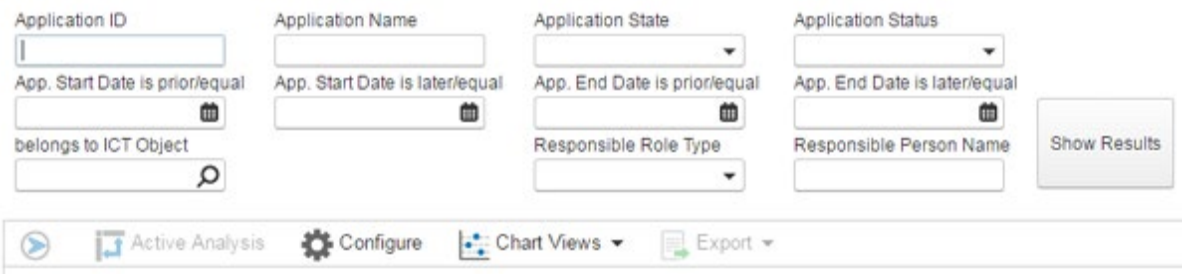


FIGURE: Example of filters that allow the user to define search criteria

Optionally, the filter area can be configured to provide the following functionality:

- Individual filter fields can be configured as mandatory fields. Mandatory filter fields are marked in red and with a red star in the user interface. If the user submits the configured report without setting the mandatory fields, a warning will be displayed.

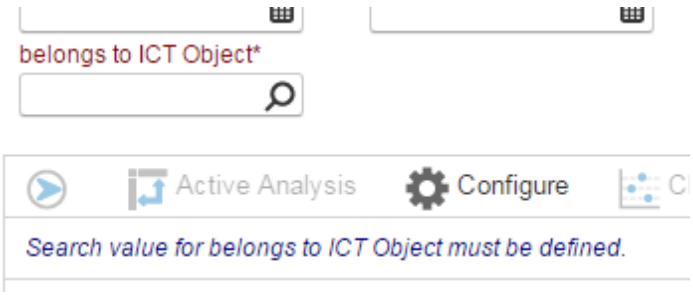

FIGURE: Warning message displayed if mandatory filter field is not defined

- The filter area can have a **Clear Search Patterns** button that allows the current filter settings to be cleared. If applicable, individual filter fields can be configured to be excluded from the clear action.
- The filter area can have a **Hide Filter Panel** button that allows the filter area to be collapsed. This is useful for configured reports with a significant number of filter fields.

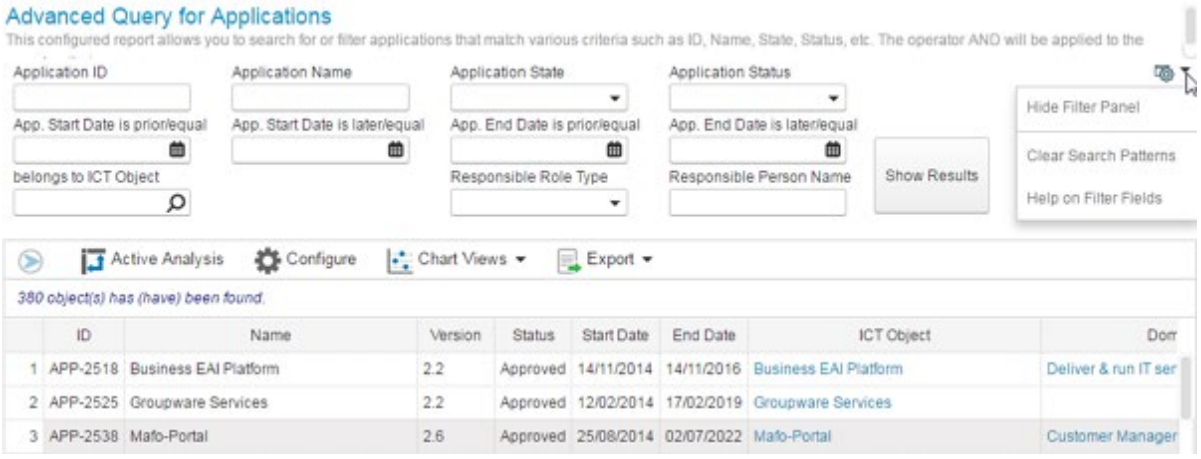

FIGURE: Configured report with expanded filter area

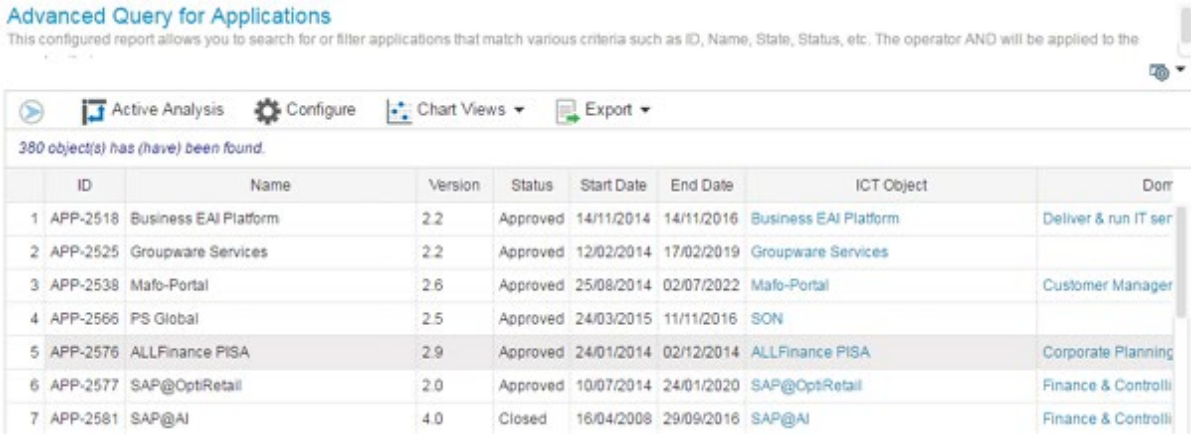

FIGURE: Configured report with collapsed filter area

- The selection that can be done in a drop-down list or a combo-box may depend on the setting that the user performed in another filter field. For example, a filter field allows an application to be selected and the drop-down list of the filter field available to select a local component will be filled with the local components of the currently selected application.
- For edit fields automatic settings of wild cards before and after the string that the user has entered into the field can be configured.
- By default, configured reports display unfiltered results when the user first opens the configured report. Filters can than be set by the user and the dataset will be reduced according to the filter conditions when the user clicks the **Submit** button. The configured report can be configured to show results after the user has clicked the **Submit** button for configured reports that would result in very large datasets when opening without filter settings.
- Filter settings can be reused for other configured reports. This requires a special configuration of the filter field to store the setting in a property of the class `UserGlobalData`.

The use of filters require a additional configuration which is described in the section Defining Filters for Configured Reports and Selectors in the chapter Defining Queries.

Invoking Start of a Workflow

A workflow can be started via a button in a configured report for either the base object or a selected object in a configured report. The menu button to start the workflow cannot be created or configured by the customer but must be ordered from Software AG.

Providing Additional Information in a Quality Widget

Additional information about data in a configured report or object cockpit can be provided via a quality widget displayed in a pop-up window. The quality widget is either a configured widget report or a configured business chart or gantt chart report that can be assigned to multiple configured reports or object cockpits. When the user opens or loads the configured report or object cockpit that the quality widget is assigned to, the quality widget will be displayed in a separate pop-up window that opens for a short time. The quality widget pop-up window opens by default in the upper right corner of the Alfabet user interface below the main menu. This position is configurable.

Depending on the configuration of the primary configured report, either the complete quality widget will be displayed or only the caption will be displayed in a title bar and the user can click the title to open the quality widget.

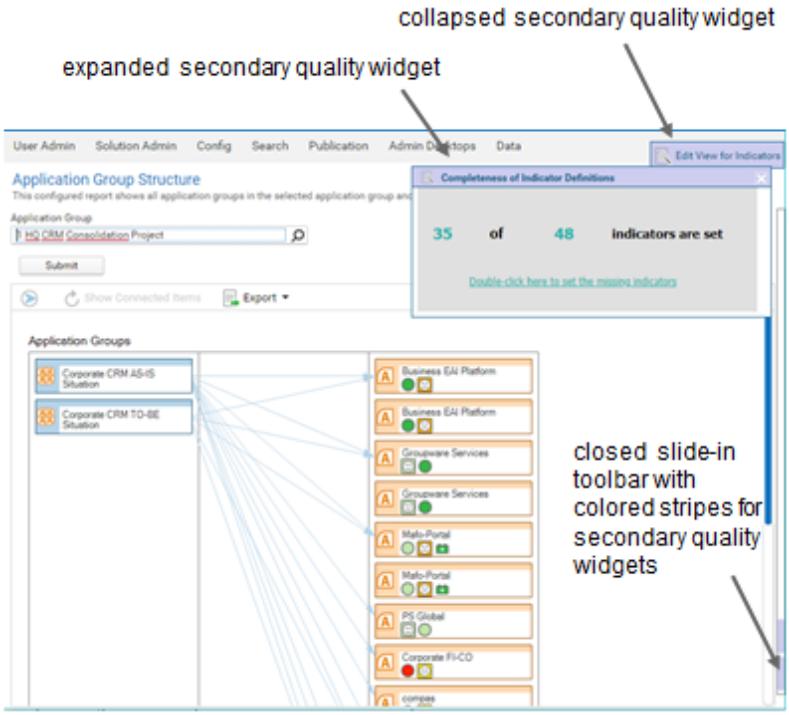

FIGURE: Configured report with a collapsed and an expanded quality widget

If the user does not click the quality widget during the short time that it is visible, the quality widget view will automatically drop into the slide-in toolbar on the right edge of the Alfabet user interface. The slide-in toolbar displays a colored notch for each of the available quality widgets (as well as for other forms of user assistance). The user can access the quality widget anytime by pointing to the notch in the slide-in toolbar and then clicking the quality widget icon to open it. The quality widget will remain open until the user clicks outside of the pop-up window or clicks the close button.

If navigation is configured from the quality widget view to another configured report or graphic view, the navigation target will open in a new browser tab.

A typical use case for quality widgets is a widget report that opens to provide information to the user about the quality of the data in the current view, which can be either a configured report or object cockpit. For example, if objects displayed in a configured report are colored according to an indicator value, the user could be provided with information about the completeness of the indicators specified for the objects in the configured report. A configured link available in the quality widget could then open a view that allows the user to provide the missing data and thus correct the issue. When the user clicks the link available in the quality widget report, the view will open in a new browser tab. The user can then define the relevant indicators and reload the original view with the updated data.

For information about how to define a secondary widget report for a configured report, see Integration of Quality Widgets in Configured Reports, Object Cockpits and Wizards.

Hiding Toolbar Buttons

Each configured report has a toolbar with all relevant buttons for the functionality assigned to the configured report. For example, report results may be analyzed in a Pivot table or the configured report can be exported to files.

You can configure the toolbar to hide buttons in the configured report. Configuration is done per view scheme so that a button may be visible to one user while another user will not have access to the button.

The configuration of the toolbar is described in the context of the view scheme configuration in the section Hiding Functionalities in a Page View or Configured Report in the chapter Configuring User Profiles for the User Community.

Restricting Access to the Alfabet database Via Configured Reports

A number of security mechanism has been implemented to restrict access to configured reports or to Alfabet objects via configured reports:

- In general, the Alfabet Web Application connects to the Alfabet database via a single database user that has ReadWrite access permissions for all tables in the Alfabet database independent from the individual access rights of Alfabet users for which requests are processed. For all or individual configured reports, a database user with restricted access permissions can be used for data requests. Two different methods are available:
  - The Alfabet Web Application can be configured to send requests for all configured reports via an Alfabet internal ReadOnly database user.
  - If the Alfabet database is hosted on a Microsoft® SQL server, customer defined database user with explicit access rights for indiviual database tables can be used for excecution of configured reports. Which database user is used for execution can be specified for all or for individual configured reports.

For information about the database access right restrictions that can be defined for configured reports, see Restriction of Database Access Permissions on Execution of Configured Reports.

Query-Based Tabular Reports

Configured reports of the type `Query` are based on the specification of an Alfabet query and configured reports of the type `nativeSQL` are based on a native SQL query. For both configured reports, the query defines which data should be displayed for a subset of objects in the configured report. The results are displayed in a table similar to the tables in standard Alfabet views.

The user can alter the width of the columns in the configured report at runtime. The column width is stored in the user context settings.

In configured reports displaying large datasets, the first 100 of those results will be displayed directly in the page. You can navigate to a next page showing the next 100 results by means of the floating toolbar in the lower right corner of the configured report and navigate to the next page, previous page, first page, or last page of results. The paging is also available in configured reports with large grouped datasets.

Tabular reports offer a wealth of functionality and display options that are described below.

If a feature is not available by default in the configured report, a link to the documentation describing the required configuration will be available. The basic configuration of configured reports of the type `Query` is described in the section Creating a Tabular Configured Report of the

Type Query. The basic configuration of configured reports of the type `native SQL` is described in the section Creating a Tabular Configured Report of the Type NativeSQL.

- Expandable Result Table
- Definition of Frozen Columns
- Adding Data to the Clipboard
- User Specific Table Layout
  - Allowing the User to Hide Columns and Change the Column Order
  - Allowing the User to Alter the Structure and Design of the Report
- Display of Results in Standard Alfabet Report Formats
- Display of Results in Customer Configured Views
- Configuring User Workspaces to Edit Objects in the Configured Report
- Analyzing a Configured Report in a Pivot Table Layout
- Asynchronous Execution For Long Running Reports

Expandable Result Table

Instead of displaying search results in a flat list, results may be hierarchically structured. The user can click an arrow in the second column on the left of the report table to expand the data table to display the next level of objects. In the example displayed below, domains are displayed on the first level, relevant business functions on the second level, and the applications providing the business functions on the third level.

	1 2 3	Domain / Function Name	Application	Status	Start Date	Er
1	▼	A.3.2 Product Business & Development Planning				
2	▼	Coordinate Business Case Approval				
3			Investment Banking Portal 1.0	Approved	18/07/2015	1(
4			SAP Enterprise Portal 4.7.c	Approved	29/01/2013	0(
5	▶	Define Business Case				
7	▶	A.3.1 Product Capability Definition				
17	▶	A.3.3 Product Design				
22	▶	A.3.5 Product Retirement				

FIGURE: Example for expandable report table

The first column in the report displays the running number of the row in the report. If a level is collapsed, rows are hidden, but nevertheless counted. In the example above, the riw number 5 is followed by the row number 7, indicating that there is one third level entry hidden business function 'Define Business Case' displayed at the second level in row 5.

The example also demonstrates that there are two ways to handle expandable levels:

- Two levels can be displayed in one column. Within the column, objects of the subordinate level are indented. In the example, domains and business functions are displayed in the same column with the business functions in an indented second level below the domain names.
- Two levels can be displayed in two different columns. In the example, applications are displayed in a separate column subordinate to the business functions that they are associated with.

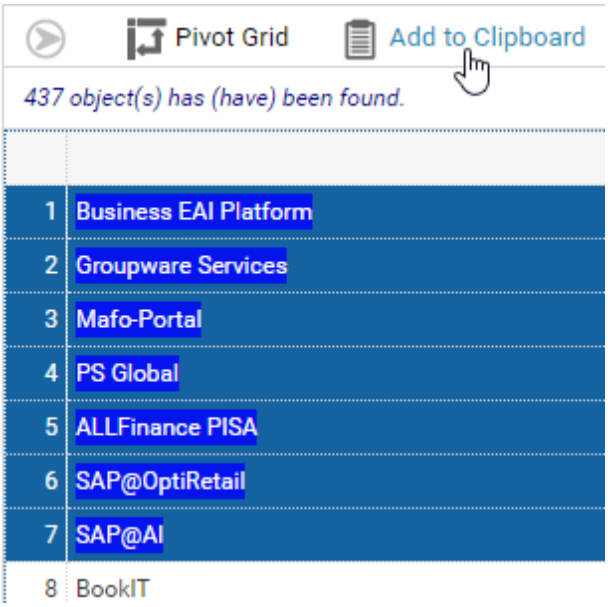
Expandable report tables require additional configuration which is described in the section Grouping Query Results in Expandable Reports in the chapter Defining Queries.

Definition of Frozen Columns

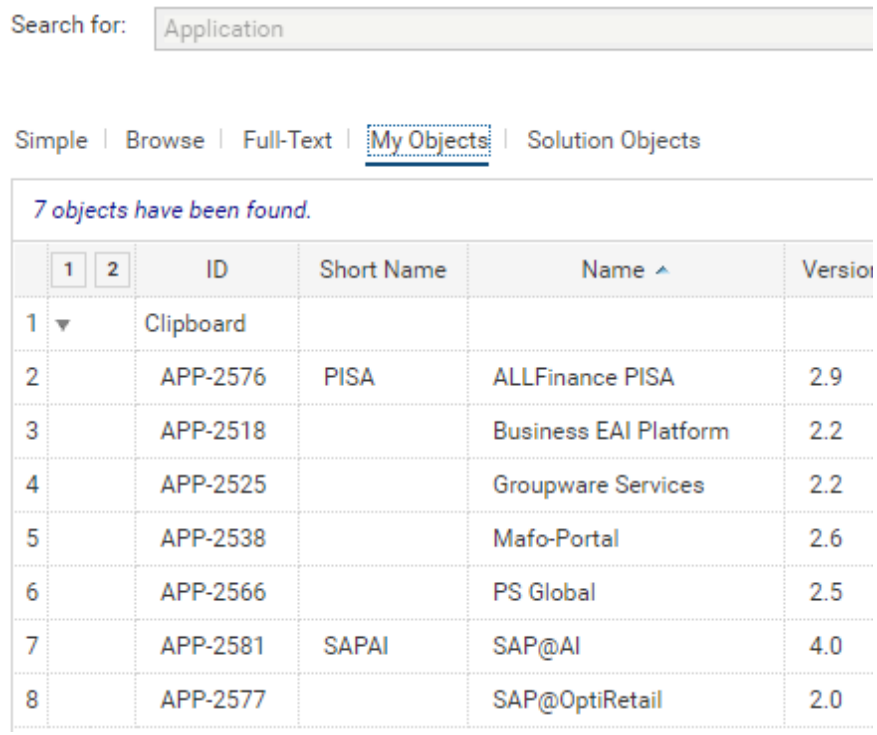
The first column or columns in the tabular dataset can be defined as frozen. Frozen columns remain visible during horizontal scrolling. The definition of frozen columns is done by a solution designer in the query definition. For more information, see Freezing Columns in Tabular Datasets.

Adding Data to the Clipboard

In configured tabular reports that are defined with Alfabet 10.6.1 or higher, an **Add to Clipboard** button is available in the toolbar of the report. The clipboard capability allows the user to select data in the table and click the **Add to Clipboard** button to copy the data.



The data will then be available in relevant standard selectors as well as custom selectors that are configured to display the **My Objects** tab. The saved objects are displayed in the **Clipboard** section in the **My Objects** tab, where they can be selected when defining references.



The **My Objects** view is available in standard selectors. It will only be available in custom selectors if the **Add My Objects Tab** attribute in the **Class Entry** of the custom selector is set to `True`. For more information about the configuration of custom selectors, see Configuring a Custom Selector for Search Functionalities.

Please note the following about the clipboard functionality:

- Data added to the clipboard will remain in the clipboard during the running sub-session. If the user opens another browser tab to open Alfabet or if the user logs out, the data will be removed from the clipboard. Changing the user profile will not empty the clipboard.
- Each time a user adds objects to the clipboard within a running session, the data will be added to the existing data in the clipboard.
- The **My Objects** tab will only display the sub-set of objects in the clipboard that may be selected via the selector. For example, if components and applications have been added to the clipboard, only applications will be displayed in an application selector, only components will be displayed in a components selector, and none of the objects will be displayed in a device selector.

User Specific Table Layout

Configured tabular reports can be designed to provide end user design capabilities. The user can either adapt the number and position of columns to his/her demands or re-define the complete design including coloring and picture assignment.

The following options are available:

- Allowing the User to Hide Columns and Change the Column Order
- Allowing the User to Alter the Structure and Design of the Report

Allowing the User to Hide Columns and Change the Column Order

User configuration can be enabled for individual configured reports. If user configuration is enabled, the table configured by a solution designer in Alfabet Expand as output of the configured report can be changed by the user opening the configured report on the Alfabet user interface:

A button **Configure**  is displayed in the toolbar of tabular configured reports. If the user clicks the button, an editor opens that displays all columns in the configured report. The user can hide columns in the configured report and change the order of columns in the table. The settings will then not only be applied at the current view, but stored in the user context settings and applied to the configured report each time this user opens the configured report, even if she/he is logged in with a different user profile. If another user opens the same configured report, she/he will see the default layout or a layout configured by her/him.

Configurations can only be applied to static tables. If the configured report displays a dynamic dataset where the number and kind of columns depends on the current search results, a layout defined by the user via the **Configure**  button will be applied to the current view and saved in the user context settings, but only applied to the configured report again if the configured report is displayed with the same number and kind of columns.

For information about the configuration of a configured tabular report to allow user configuration, see Allowing the User to Change the Number and Order of Columns in the Table for native SQL based tabular reports or Allowing the User to Change the Number and Order of Columns in the Table for Alfabet query language based tabular reports.

Allowing the User to Alter the Structure and Design of the Report

Tabular configured reports can be designed to provide a wealth of options for individual re-structuring and re-design by the user opening the configured report. This includes:

- Hiding data from the report or adding data to the report. If the report is based on Alfabet query language, the definition of columns defined by the solution designer is only a default layout that can be amended with any other object class property information about the involved object classes by the user. If the report is based on native SQL, the information accessible via the tabular report is limited to the data defined in the `SELECT` statement of the native SQL query. Columns can only be excluded, but additional data about the involved object classes cannot be added to the table.

- Data can be completely restructured. Columns can be moved, hidden and added and the layout can even be changed to a matrix layout with both column and row headers that can also be ordered in a hierarchy.
- Any data can be hidden or filters can be applied independent from the filter area on top of the configured report that is provided by the solution designer. All filters in the configured report are AND combined.
- Cells in the report can be highlighted with colors and pictures can be added according to end user defined rules.

For example, the following SQL based report shows application costs per year and cost type. the default layout displayed when the user opens the report for the first time is a simple table:

Number	Application	Cost Type Name	Year	Cost Value
53	Administrative Gen...	Expense	2017	3.00
54	Administrative Gen...	Expense	2018	31.00
55	Administrative Gen...	Expense	2019	112.00
56	Administrative Gen...	Maintenance & Su...	2019	168.00
57	Administrative Gen...	Other	2017	21.00
58	Administrative Gen...	Other	2018	24.00
59	Administrative Gen...	Other	2019	40.00
60	Administrative Gen...	Subscription	2017	85.00
61	Administrative Gen...	Subscription	2018	85.00
62	Administrative Gen...	Subscription	2019	700.00
63	AF Enterprise ConT...	Consulting	2015	69.00
64	AF Enterprise ConT...	Consulting	2016	323.00
65	AF Enterprise ConT...	Consulting	2017	378.00
66	AF Enterprise ConT...	Consulting	2018	106.00
67	AF Enterprise ConT...	Expense	2015	244.00
68	AF Enterprise ConT...	Expense	2016	1,129.00

The same report will look completely different if the user decides to structure it as a matrix providing an overview for costs per year for each cost type, where the costs for all applications matching the year and cost type definitions are summed up in the respective matrix cell. Icons are used to highlight higher or lower cost values:

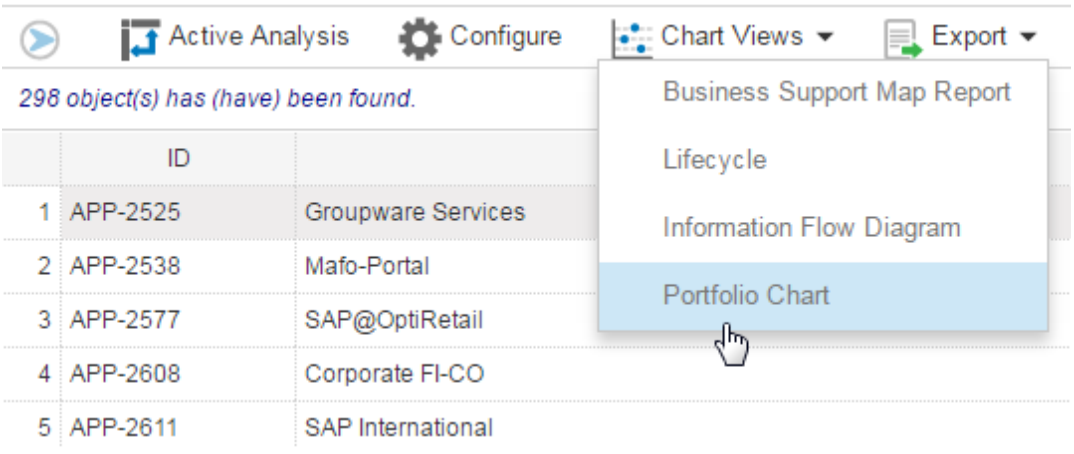
Year	Consulting Cost Value	Expense Cost Value	Other Cost Value	Subscription Cost Value
2008	667.00	2,307.00	316.00	705.00
2009	1,038.00	3,728.00	498.00	915.00
2010	1,393.00	5,013.00	758.00	1,670.00
2011	1,902.00	6,656.00	1,273.00	3,265.00
2012	3,051.00	10,802.00	2,330.00	6,170.00
2013	5,160.00	18,395.00	3,249.00	7,615.00
2014	9,612.00	34,051.00	5,640.00	13,120.00
2015	14,787.00	51,854.00	8,496.00	19,165.00
2016	23,254.00	81,617.00	12,029.00	24,935.00
2017	29,350.00	102,432.00	13,922.00	26,520.00
2018	33,181.00	115,694.00	15,729.00	29,325.00
2019	33,804.00	106,580.00	15,589.00	30,897.00

The end user design option are available if the template `DataTableReport` is assigned to the configured report. For information about defining a tabular configured report with enhanced user design capabilities, see Configuring a Data Table Report with Restructuring Options for the End User for native SQL based tabular reports or Configuring a Data Table Report with Restructuring Options for the End User for Alfabet query language based tabular reports.

A context sensitive help file is available in the standard Alfabet online help that explains the configuration capabilities of data table reports to end users. The context sensitive help is automatically available as soon as the template is selected for the configured report.

Display of Results in Standard Alfabet Report Formats

If the configured report presents the results in a simple table and one of the standard Alfabet reports listed above is available for the base class of the Alfabet query, the toolbar will automatically include a **Chart Views** button that provides access to relevant standard Alfabet report(s).



The following standard Alfabet reports may be available in a configured report for the objects found by the configured report's query:

- Lifecycle Chart
- Portfolio Chart
- Business Support Map Report
- Information Flow Diagram
- Project Tracking Overview (for configured reports with the base class Project)

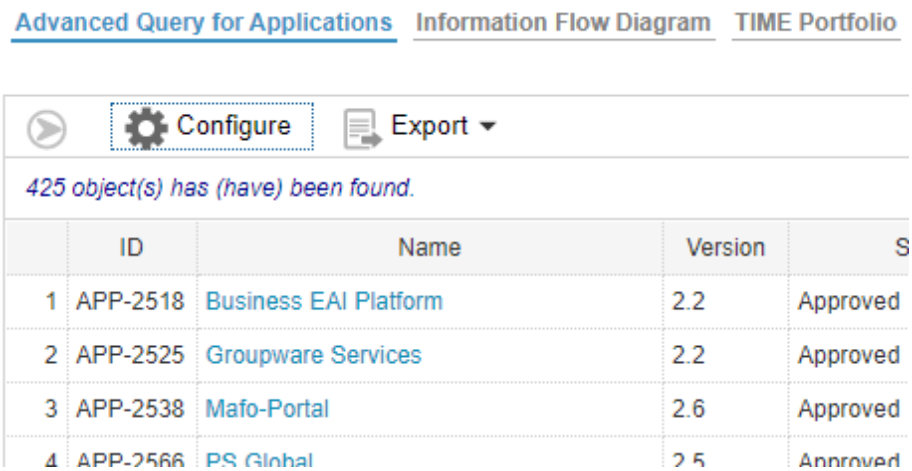
The drop-down list that opens when the **Chart Views** button is clicked will automatically display only the standard Alfabet reports that are available for the base class of the Alfabet query.

The **Save Layout** button of information flow diagrams opened via the **Chart Views** menu is hidden, because the layout cannot be saved for diagrams opened from configured reports. If filter settings for the diagram are stored in the user context settings, the diagram opens with filter settings as stored in the user context settings.

- This feature is only available for configured tabular reports of the type `Query` that do not include Alfabet query language instructions.
- For more information about which Alfabet report is available for which object class, see *Available Standard Reports for Base Object Classes in Configured Reports* in the reference manual *Configuring Alfabet with Alfabet Expand - Appendix*.
- When filters are defined for the configured report, the filter settings are not applied to the chart views. For example, when the filter settings of a configured report limit the display of applications to applications starting with the letter "a", chart views opened from the configured report may nevertheless include information about applications not starting with an "a".
- For an information flow diagram opened via the **Chart Views** button the layout cannot be saved.
- The **Chart Views** button can be excluded from a configured report by setting the attribute **Chart Views Mode** of the configured report to `None` or substituted with access to configured reports via tabs on top of the toolbar of the configured report.

Display of Results in Customer Configured Views

A report collection can be configured for object classes and object class stereotypes via the class settings. This report collection consists of specifically configured reports that provide additional information about the objects found in tabular configured reports returning objects of the object class or object class stereotype. Users can access reports from the report collection via tabs on top of the toolbar of the tabular dataset to view additional aspects like gantt charts or portfolios related to the set of objects currently displayed in the table.



If the user changes the tabular dataset via filters, the information in the reports from the report collection will change accordingly. With report collections different aspects that might be interesting for users interested in a sub-set of objects of a defined object class can be presented directly to the user opening the tabular report. As such, the tabular report is acting like a temporary group of objects that shall be analysed together.

For information about configuring report collections, see Integration of Configured Reports as Report Collection Into Tabular Configured Reports.

Configuring User Workspaces to Edit Objects in the Configured Report

Standard Alfabet views typically have toolbar buttons that allow objects to be edited. The available buttons could open a wizard or editor for the object or delete the object, or provide more complex functionalities such as the creation of a new object based on a copy of an existing object.

Per default, configured reports are for viewing purposes only. However, it is possible to provide edit functionalities in a configured report, if necessary:

- For the basic objects of the IT architecture, buttons can be added to a tabular reports via a preconfigured template. The templates add the buttons that are available in the standards Alfabet data capture functionality to the configured report. The template is available for the following classes:
  - Application
  - Component
  - Contract
  - Demand
  - Device
  - ICT object
  - Peripheral
  - Project

- Service product
- Vendor product
- Vendor

For information about the configuration of a report based on a data capture template, see Defining a Data Capture Environment for a Configured Report of the Type Query or Defining a Data Capture Environment for a Configured Report of the type NativeSQL.

- The functionalities for user management available in the **User Administration** view (`ADMIN_UsersOverview`) can be added to a tabular report via a preconfigured template. The template adds the buttons available for user administration to the configured report, with the exception of button sub-menu interactions that are triggering functionalities for all users in the Alfabet database. The underlying query of the configured report must find objects of the object class `Person`. The template can be used to provide limited access to the user management functionalities to administrators that are For example, only allowed to edit user data for a specific group of users or that are only responsible for a limited subset of administration processes.
- Edit functionalities can be implemented in other configured reports if they are available as the standard for the object class. Configured reports that allow objects to be edited are called "user workspaces". If a user workspace is required by your enterprise, a specific configuration is necessary that must be ordered from Software AG.

Buttons can be configured to be active for a subset of the objects in the configured report. For example, a configured report provide the means to edit only the applications based on a specified object class stereotype while applications based on other object class stereotypes are displayed in the configured report. Limiting button actions to a subset of the objects displayed in a configured report requires a special configuration of the query that the configured report is based on. The configuration is described in the section Limiting Toolbar Button Functionality To a Subset of Objects in a Configured Report in the chapter Defining Queries.

When planning to include a user workspace or a report based on a template for data capture or user management, you must consider access permissions and object availability as well as the location of the configured report in the Alfabet interface.

Analyzing a Configured Report in a Pivot Table Layout

A pivot table is an interactive table that you can use to view, organize, and analyze configured report data dynamically from within your Web browser. Additionally, you can define a layout for the data and then export the data to a Microsoft® Excel® XML Spreadsheet 2003, a CSV file or a PDF file.

Alfabet includes the DevExpress® component, providing capabilities for visualizing and analyzing data in chart and pivot table layouts.

The functionality is available for the following configured reports:

- Tabular reports with the exception of expandable report tables. Depending on the report configuration, the Pivot grid analysis either opens directly when the user accesses the report, or the tabular dataset of the configured report is displayed, and the user must click the **Pivot Grid**  button in the toolbar of the configured report to access the Pivot grid analysis view. Please note that it is not possible to open the Pivot grid analysis in a new tab.

The caption displayed in the column headers of the configured report must each be unique. For more information about the difference between column name and column caption and about altering the column caption, see Defining Column Names and Captions.

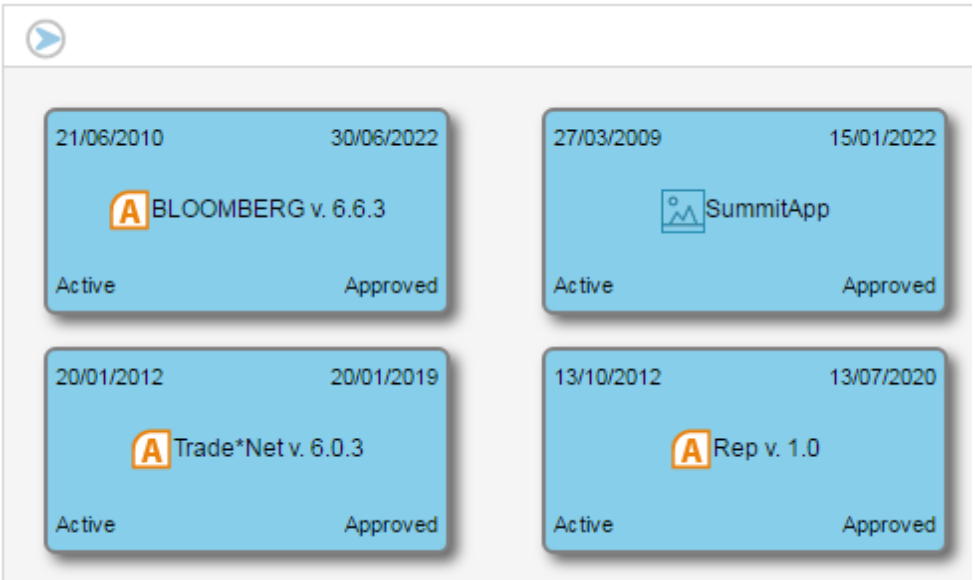
- Configured reports that retrieve data from an external data cube. For cube-based reports, the Pivot grid analysis view opens directly when you open the configured report. For more information about the configuration of cube based reports, see Defining Reports to Analyse Data Cubes.

Asynchronous Execution For Long Running Reports

Query Based Graphic Representations of Configured Reports

Configured reports of the type `Custom` allow search results from an Alfabet query or native SQL query to be displayed in preconfigured graphic formats that are described below. For the Alfabet user, the look and handling of a configured report is identical to the handling of a standard Alfabet report:

- The floating toolbar available for standard Alfabet reports with functionalities for zoom in and zoom out, printing, and for display of a legend is also available for configured reports.
- The design of boxes displayed in configured treemap, diagram matrix, lane and layered diagram reports is identical to the design of standard Alfabet reports, with text on white background displayed within a colored field.
- Links are displayed in the identical coloring and design as all links on the Alfabet user interface.
- If object icons are visible in the boxes of the report, and an object specific icon is defined for the object, the object specific icon is displayed:



The following types of graphic reports can be created and configured in Alfabet Expand:

- Branching Diagram Report

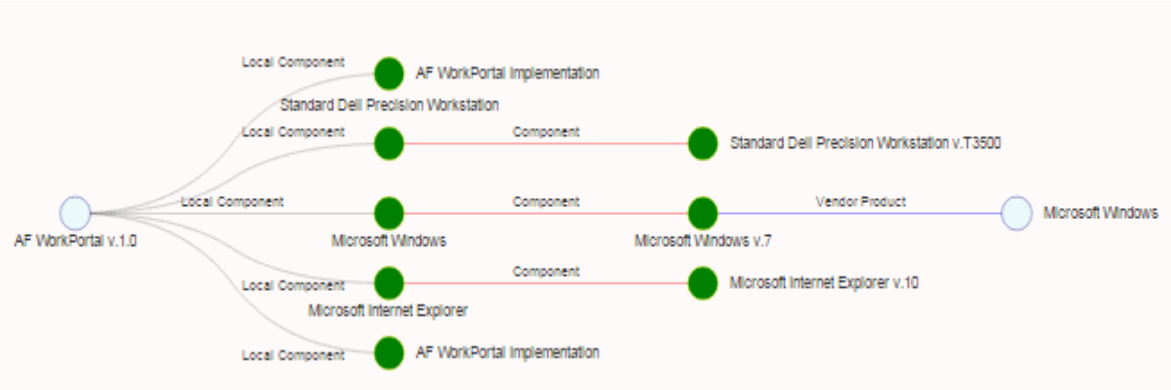
- Business Chart Reports
  - Bar Charts
  - Waterfall Charts
  - Line Charts And Spline Charts
  - Area Charts and Spline Area Charts
  - Pie Charts and Doughnut Charts
  - Multi-Level Pie Charts
  - Radar Charts
  - Combination Charts
- Circular Roadmap Reports
- Gallery Reports
- Node Arc Reports
- Portfolio Diagnostics Report
- Treemap Reports
- Rectangular Treemap configured reports
- Layered Diagram Reports
- Tree Reports
- Cluster Map Grid Reports
- Matrix Reports
- Gantt Chart Reports
-
  - Portfolio Reports
- Lane Report
- HTML Table Report for Display of Indicators
- Widget Reports
- Words Cloud Report

Branching Diagram Report

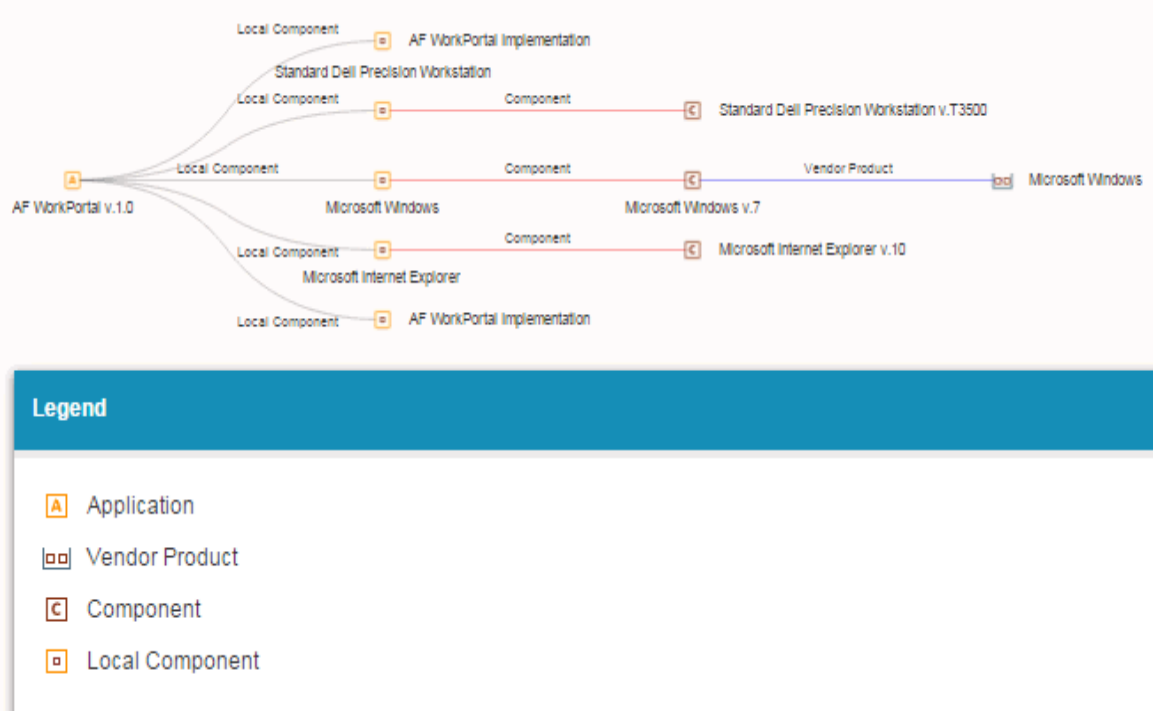
A branching diagram report is a graphic representation of a grouped tabular dataset that displays each level of objects as nodes in a column with the relation between objects represented by lines between the nodes.

The objects can be displayed in the following ways:

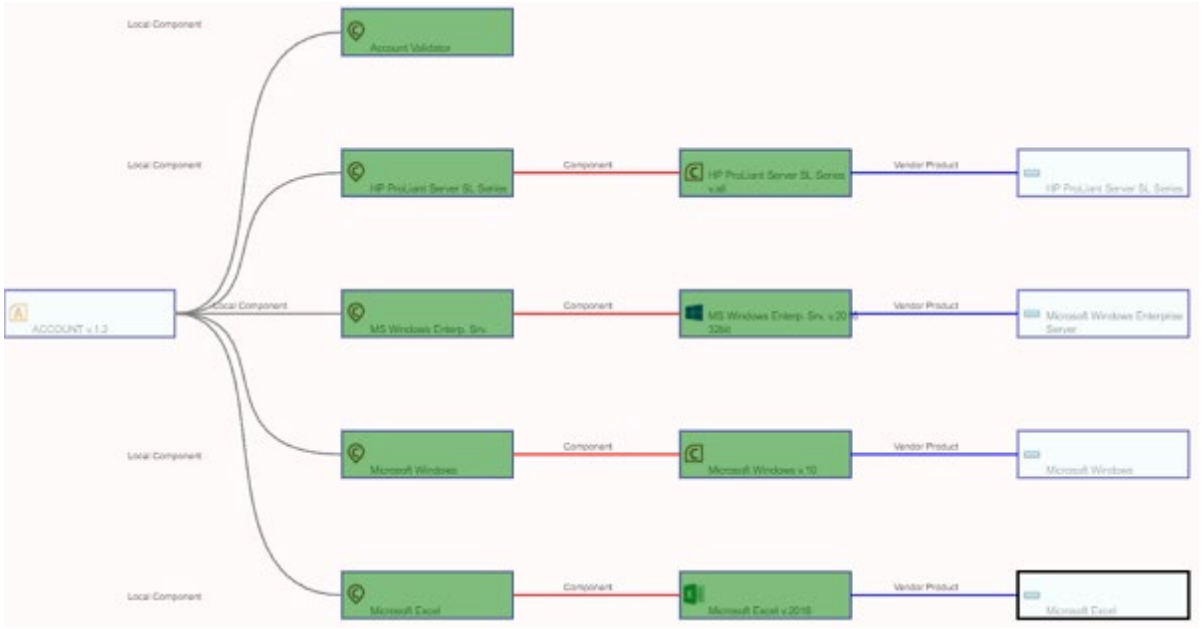
- Objects can be represented by colored circles with the a label:



- Objects can be represented by the icon configured for the object class in the class settings of the respective object class.



- Object can be represented by boxes with the label inside the box.



Branching diagram reports can also be displayed with a vertical orientation of the relation between objects. For branching diagrams with a vertical orientation the text can optionally also be displayed vertically.

FIGURE: Example of a branching diagram displaying object relations in a vertical direction

The branching diagram report can include the following options to display information for the user:

- The coloring of the circular nodes and the coloring of the lines between the nodes can be customer configured per node and line.
- A legend can be added explaining each node type.
- Text can be defined for the lines between the objects and for the nodes.

By default, the user can navigate to an object's profile by clicking a node and clicking the **Navigate** button or by double-clicking on the object node. The branching diagram report can be configured to open an alternative view if the user clicks a node in the report, For example, another configured report with the current object as base object.

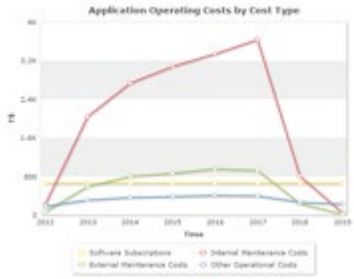
For more information about defining branching diagrams, see Defining Branching Diagram Reports.

Business Chart Reports

Business chart reports display numerical values (For example, indicator values or the number of results in a report) in a graphic. The following types of business charts are available:

Bar Charts

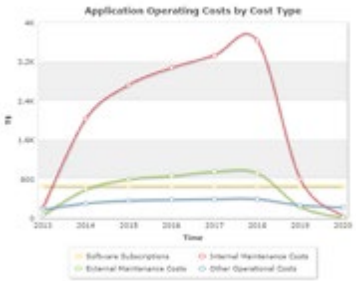
Line Charts



Pie Charts

Waterfall Charts

Spline Charts



Doughnut Charts

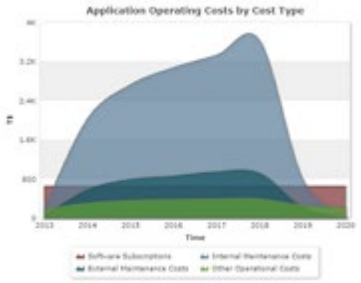
Radar Charts

Area Charts

Multi-Level Pie Charts

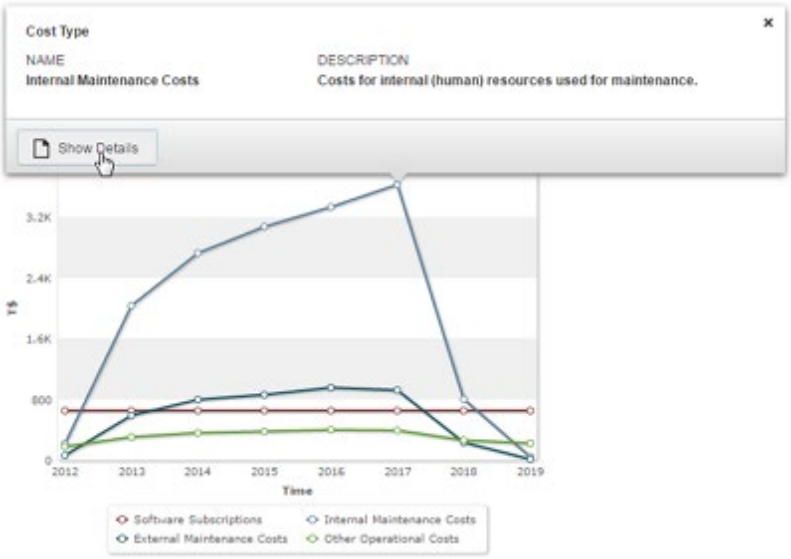
Combination Chart

Spline Area Charts



Configured business chart reports offer the following common additional features:

- The color used for objects in the chart can be changed by the user if the **Colors** button of the report is enabled or if a color selector is defined in a custom editor for the respective object class. Alternatively, the report can be configured to assign a fixed color to each graphic element in the result via a definition in the dataset the report is based on. The coloring of multi-level pie charts is an exception. It is not possible to define the coloring in the report.
- A tooltip is displayed when the user moves the mouse over a part of the graphic. The tooltip displays the combination of values that apply to that part of the chart, that means for line, spline, bar, area, spline area, waterfall and radar charts, the data series the value belongs to, the x-value and the y value are displayed comma separated.
- For all configured business chart reports except pie charts and doughnut charts, the color of the label text for values can be customized in the definition of the configured report.
- For bar, line, area, spline, spline area and combination charts, the color of the background area, and the color and thickness of the x-axis and the y-axis can be customized in the definition of the configured report. In addition, the color and thickness of the borders for area, spline area, and bar charts can be customized.
- A maximum and minimum value can be defined for the y-axis of configured business chart reports except for pie charts, doughnut charts and and multi level pie charts. By default, the y-axis starts with zero and the maximum value is evaluated from the data displayed in the chart. The definition of a fixed maximum and minimum value for the charts results in a fixed axis definition that is usefull for direct comparison of multiple chart reports displayed next to each other, For example, in an object cockpit. If an y value in a chart report is outside of the configured range for the y-axis, the configured maximum or minimum value is ignored to ensure that all data is displayed.
- Navigation from the configured business chart report is optionally available to open either the object profile of an object represented For example, by a bar in a bar chart or a sector in a pie chart, or to open any object view, standard Alfabet view or configured report defined for the respective result in the underlying query of the configured report. If navigation is activated, the user can click on a result displayed in the business chart to open a preview window. If the result represents an object, the preview window provides additional information about the object and displays a **Show Details** button that opens the object profile:



Otherwise the information is limited to the information about the current series:

Please note that for activation of navigation, you must click the part of the report representing a single result. For an area chart or spline area chart, this is any point representing a value on the border of the area. Clicking into the area itself will not activate any navigation.

For a detailed description about how to configure a business chart report, see Defining Chart Reports.

Bar Charts

Bar Charts can display results in bars that are either vertically or horizontally orientated.

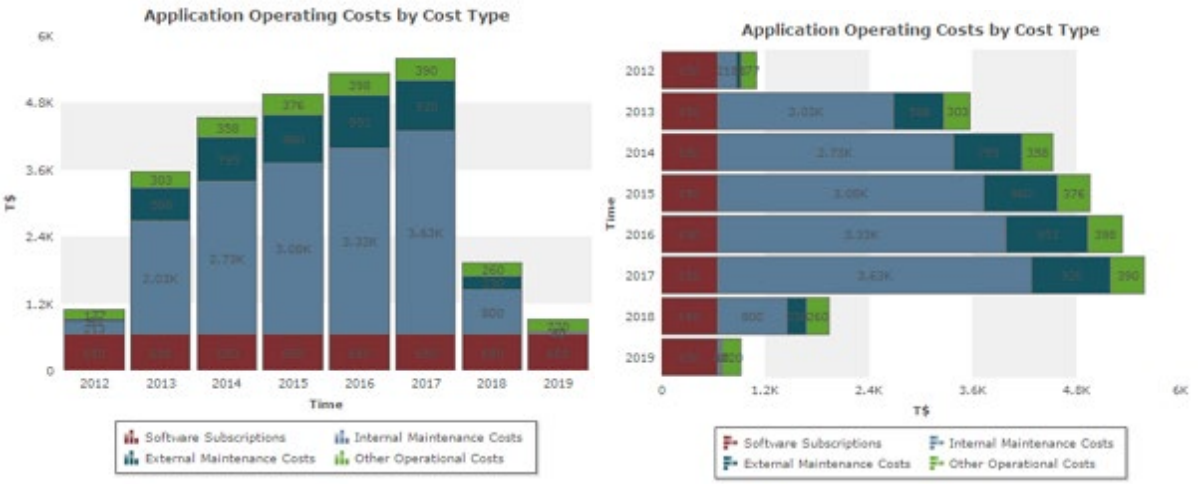


FIGURE: The same bar chart in vertical and in horizontal direction

In addition to the x and y-axis, bar charts can have a third dimension. Multiple series of results can be defined. The bars with the result for each serie can be displayed next to each other for each x value or on top of each other:

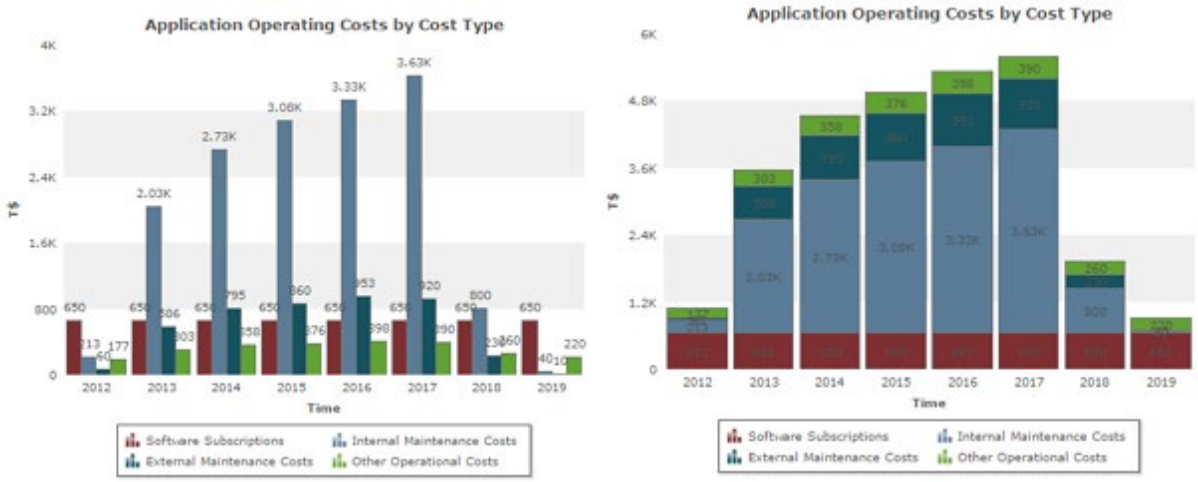

FIGURE: A same bar chart with independent and with stacked results

A legend beneath the report displays all series of bars that are visible in the bar chart. Clicking on a series in the legend removes the series from the chart. Clicking on the legend item will re-integrate the series into the report.

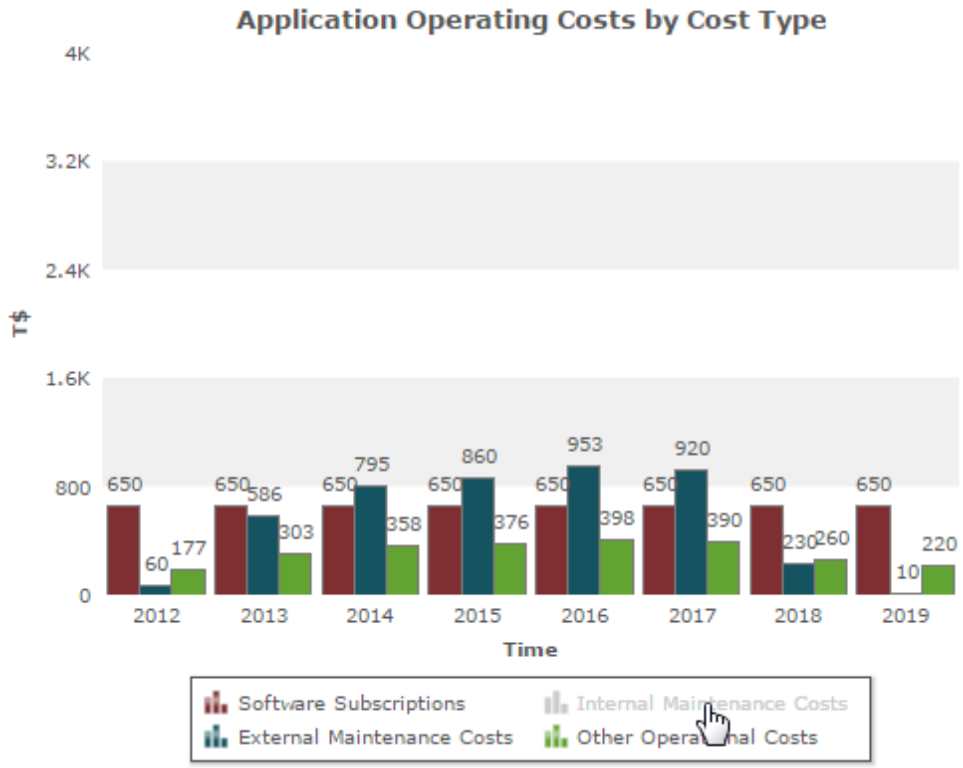

FIGURE: The bar chart in the example above with reduced dataset

Waterfall Charts

Waterfall charts display results for one or multiple series of data in a cumulative bar chart. While the first bar in the report starts at the baseline, the next bars are then each starting at the endpoint of the previous bar, cumulating the results of both bars. The transition of one bar to the other is optionally marked by a dotted line. The following figures show the same report both as a bar chart and as a waterfall chart to depict the differences between the two types of report. The example report shows both costs and income resulting from a project in a time line. In the bar chart, the costs and incomes are displayed, but the values are not related with each other. As a result, costs are always displayed in the negative range and incomes in the positive range:

In the waterfall chart, the graphic shows that in the first years the costs are exceeding the income, resulting in the columns of the report to be displayed in the negative y range, while at the end of the project, the sum of all costs and incomes results in a positive value:

The coloring of the bars in a waterfall chart can either be defined by color definition in the underlying query of the configured waterfall chart report to define coloring per bar or by defining a fixed color for positive and for negative values.

SUM columns can be added to the report at any position. The SUM colum can either display the SUM of all values between this SUM column and the last SUM column left to it, or a cumulative SUM column can be added that sums up all values of all columns displayed left to it no matter how many SUM columns are

included. If SUM columns are included into the report, they are not taken into account as column values by the cumulative SUM calculation.

In the follwing example, the costs and incomes of a project are summed up for each year (grey) and at the end of the report, a cumulative sum of all project costs and incomes is displayed in dark green:

Line Charts And Spline Charts

Line charts and spline charts show one or multiple series of values as lines connecting the y values in an x and y-axis diagram. While line charts connect the values with straight lines, spline charts draw a curve through the values:

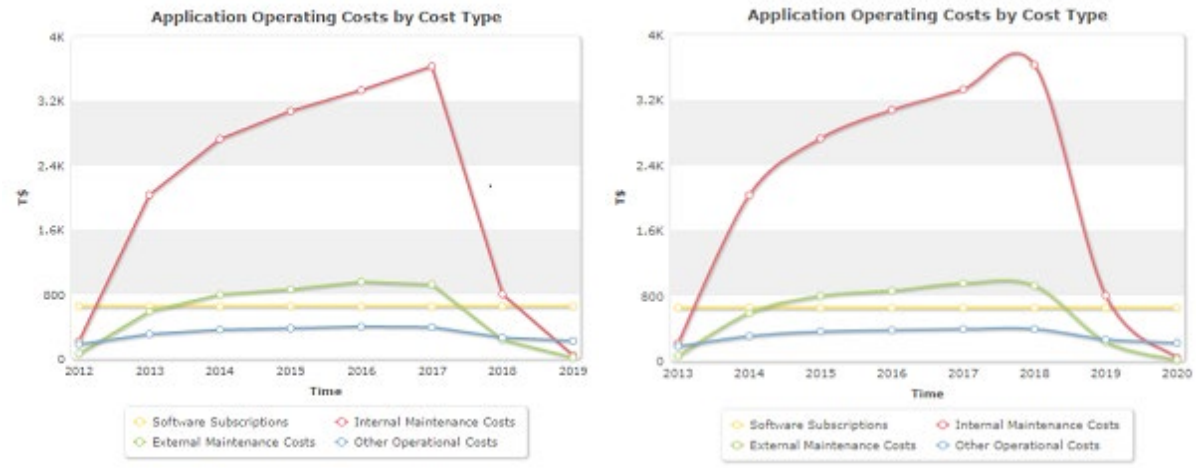

FIGURE: A line chart (left) and a spline chart (right) displaying the same data

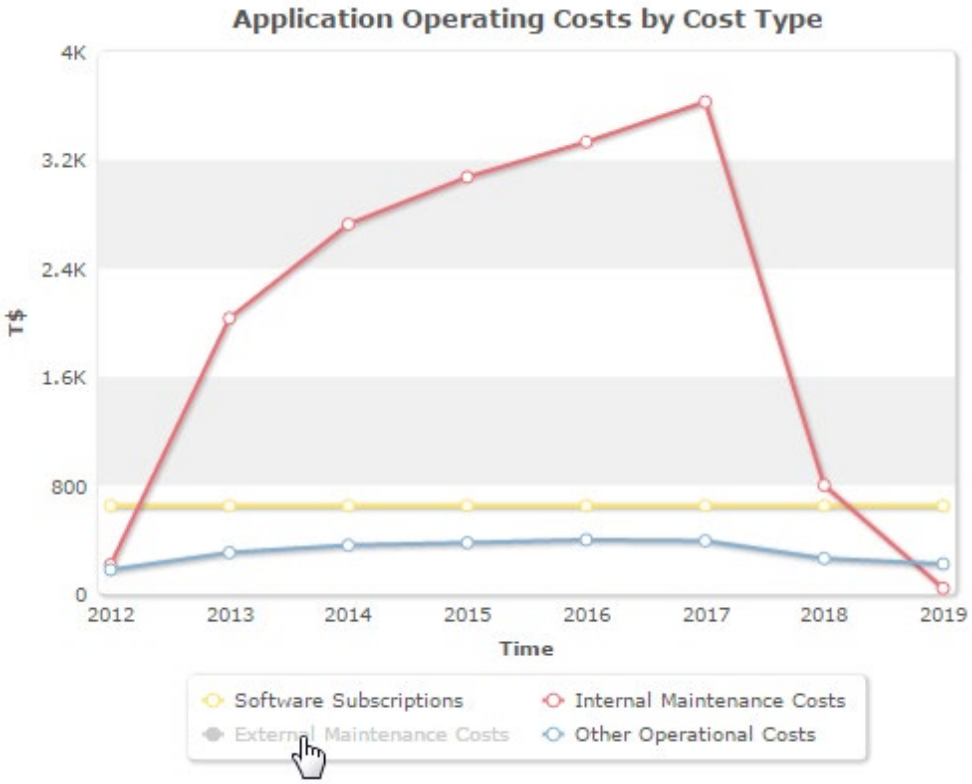
A legend beneath the report displays all lines that are visible in the line or spline chart. Clicking on a series in the legend removes the series from the chart:



The values of the lines are independent from each other. Removing one series does not alter the results for the other series. Clicking on the legend item will re-integrate the series into the report.

Area Charts and Spline Area Charts

Area charts show one or multiple series of values as areas. The boundaries of an area connect the y values of a data series in an x and y-axis diagram. While in area charts the boundary of an area connects the values with straight lines, spline area charts draw a curve through the values as boundary of the area:

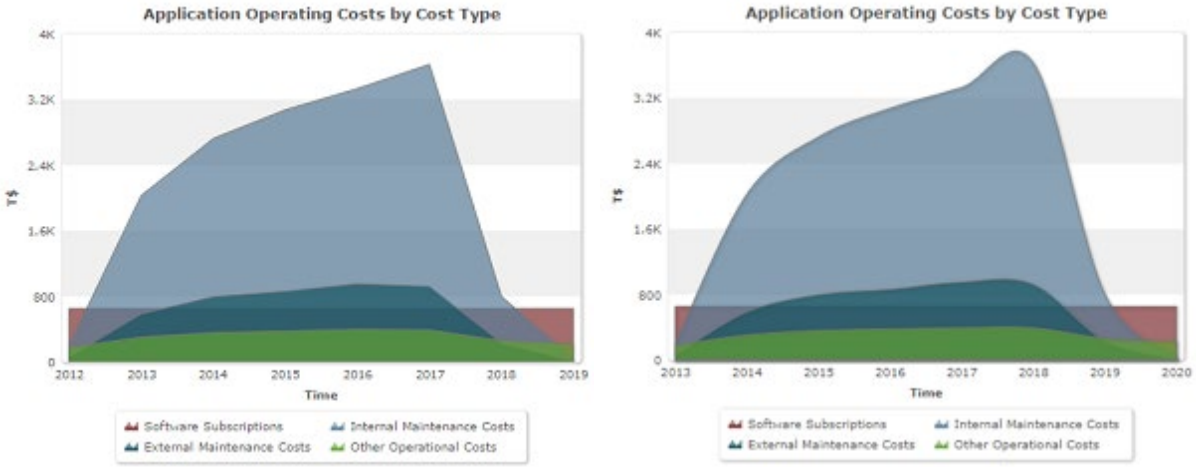


FIGURE: An area chart (left) and a spline area chart (right) both displaying the same data

In area charts, results of multiple series can either be displayed stacked on each other or independent from each other.

If the areas are displayed independent from each other, the areas overlap each other. Therefore, colors are displayed with opacity:

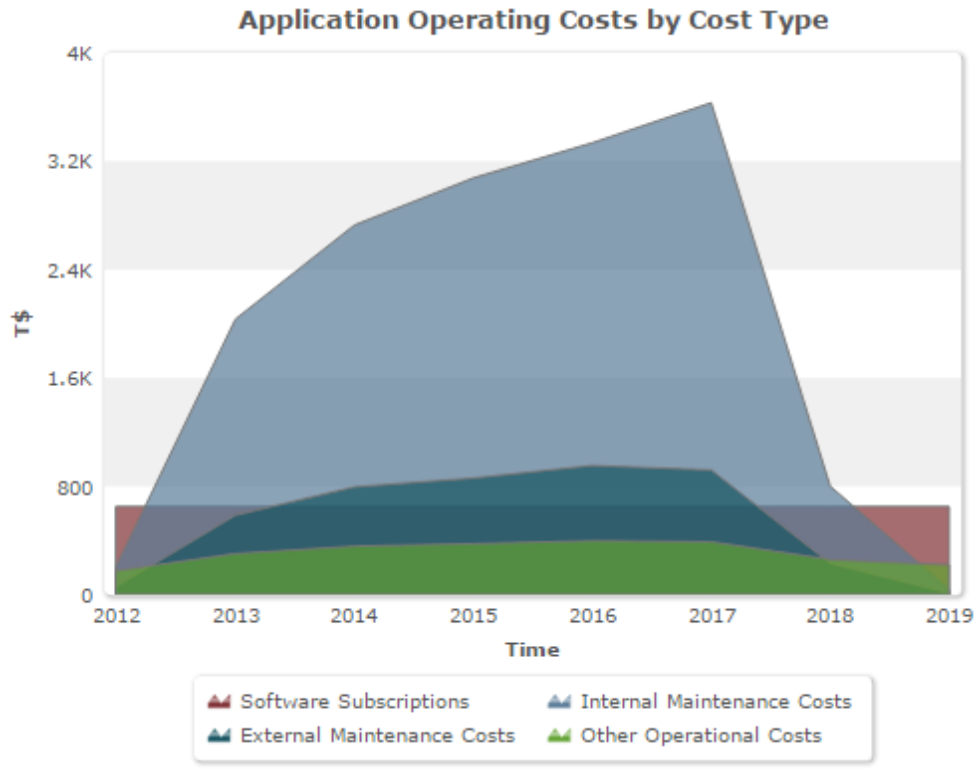

FIGURE: Example of an area chart with independent area

Stacked display means for two series, the first having a value of 3 and the other one a value of 2 for an x value, that the first series ends at the y value 3 and the second one at the y value 5 (3+2). Stacked area charts are displayed with solid colors:

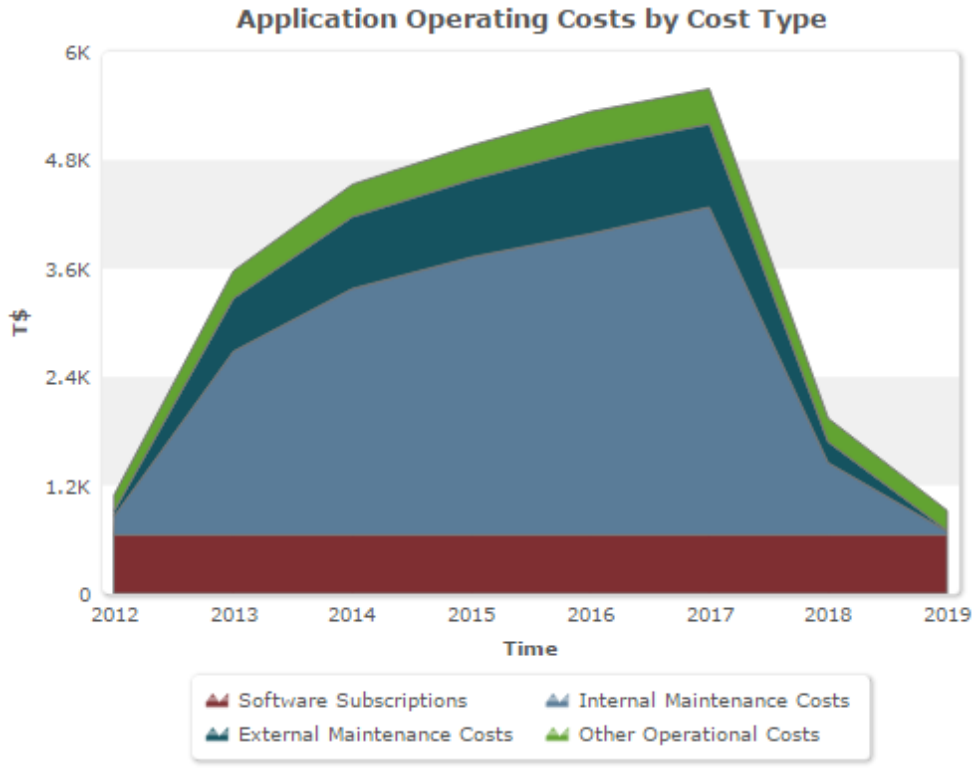

FIGURE: Example of an area chart with stacked areas

Spline area chart only render results independend from each other. The stacked display is not available.

A legend beneath the report displays all areas that are visible in the area chart or spline area chart. Clicking on a series in the legend removes the series from the chart. If an area chart displays stacked areas, removing one series will alter the sums displayed for the y values:

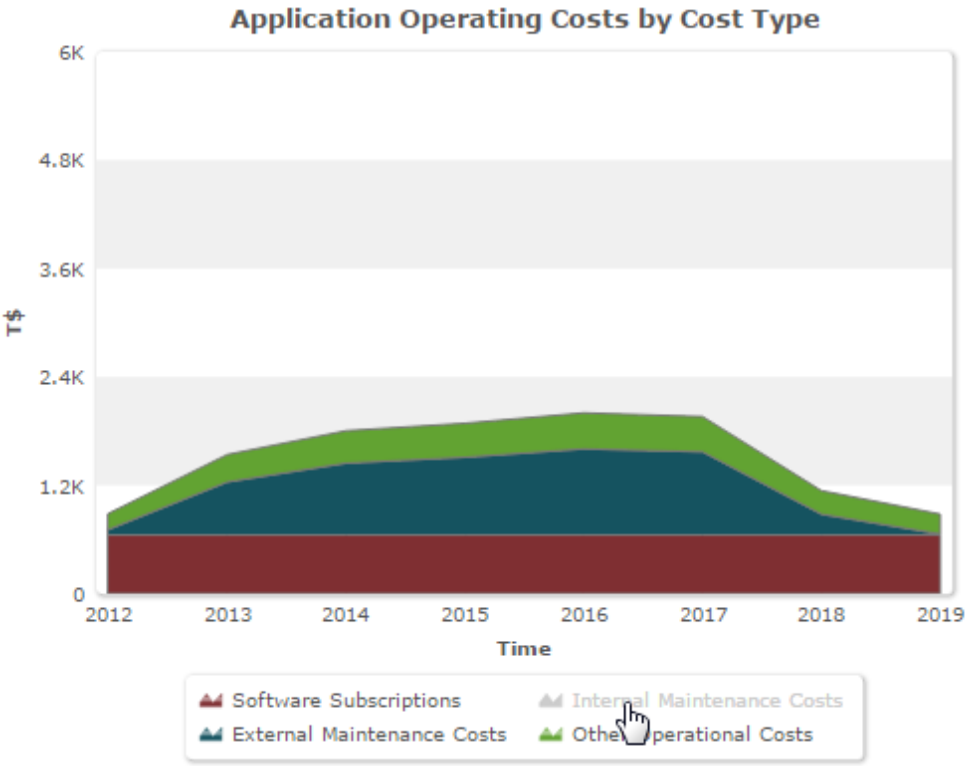

FIGURE: Stacked area chart with one area hidden from the report

Clicking on the legend item again will re-integrate the series into the report.

Pie Charts and Doughnut Charts

Pie charts and doughnut charts display an x and an y dimension. Each value of the x-axis is displayed as a slice of a pie or doughnut. The sizing of the pie or doughnut is evaluated in relation of the y-axis values for each slice.

The sum of all y values, that means the total sum represented by all slices in the pie can be displayed as subtitle of the graphic as part of a configurable text. In doughnut charts, the subtitle is displayed in the middle of the doughnut:

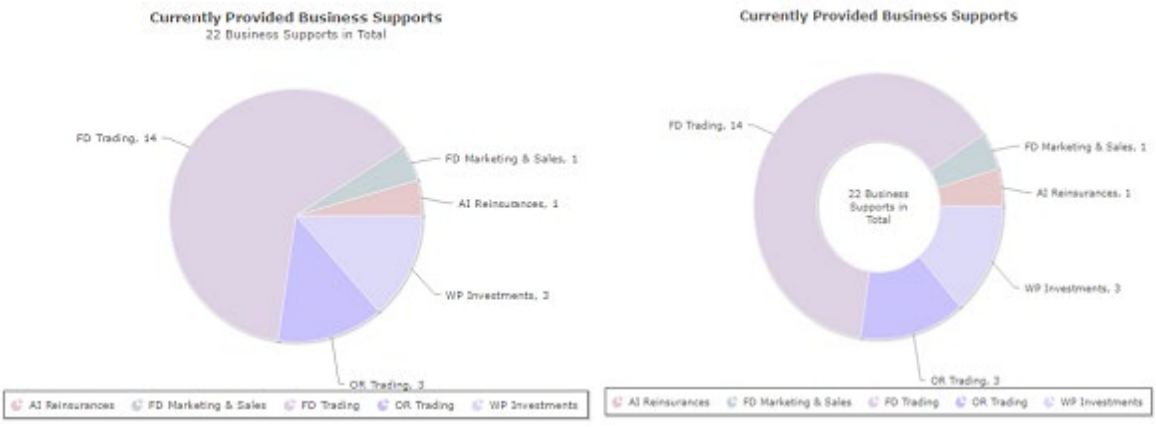

FIGURE: Example of a pie chart and a doughnut chart displaying the same data including a total sum as subtitle

Beneath the pie or doughnut, a legend informs the user, which object or value is represented by the slice. If the user clicks a value in the legend, the respective slice is moved out of the pie or doughnut. Clicking on a slice will also move the slice. The slice is moved in again by repeating the action.

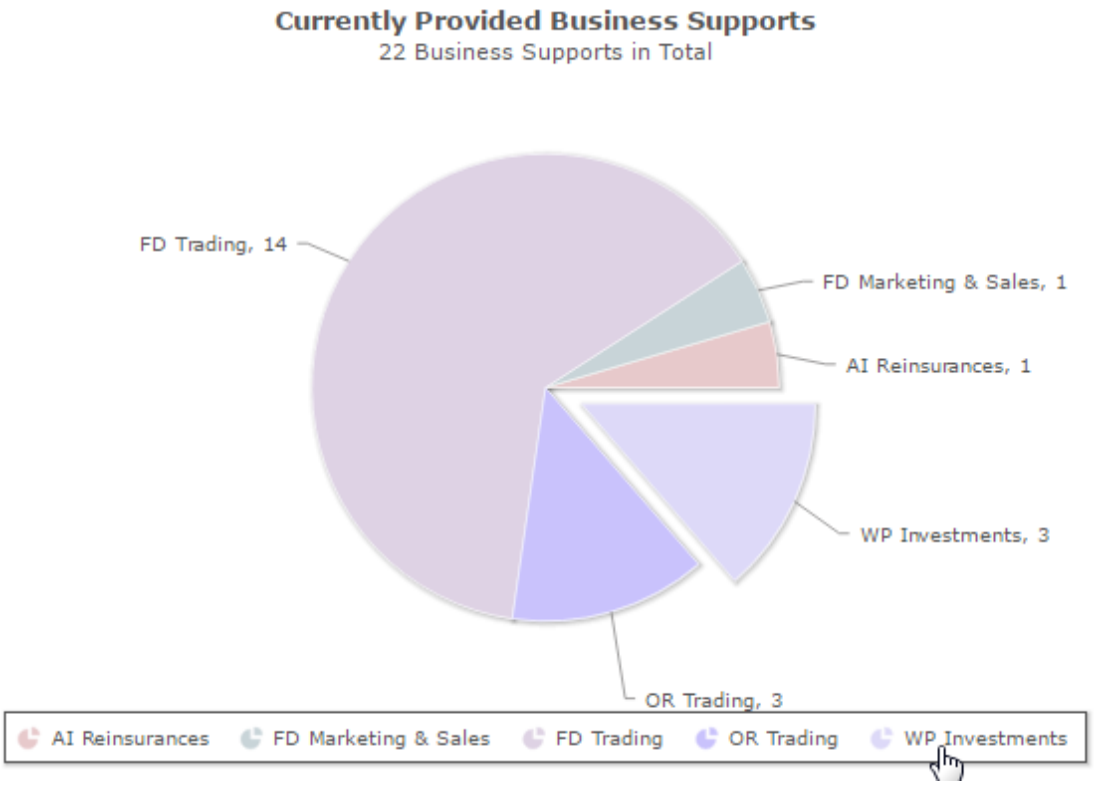

FIGURE: Example of a pie chart with one slice highlighted

Multi-Level Pie Charts

Multi-level pie charts display a pie split into multiple rings. Each ring displays an x and an y dimension whereby the x dimensions of the rings are related with each other. For example, the middle area of a multi-level pie chart can display applications that are part of a project architecture and the next ring displays the business support provided by each application.

If no data is available for a level, the level or part of the level are not displayed:

FIGURE: A pie chart where second level data is not available for some objects of the first level

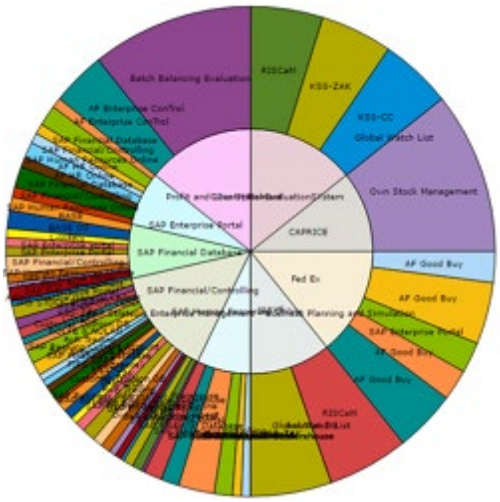
The y dimension is optional for multi-level pie charts. If no y dimension is defined, the objects are equally distributed.

FIGURE: The same multi-level pie chart report with and without y dimension

The distribution of the objects in the center of the multi-level pie chart depends on the defined y dimension only. Therefore, the sizing of the slices of the pie is directly giving information about the relation of the y values within the level. In the second level of the multi-level pie charts, objects are also sized according to the y dimension value, but the space available for the objects depend on the sizing of the element of the level below that the object belongs to and on the number of objects that are assigned to the same parent

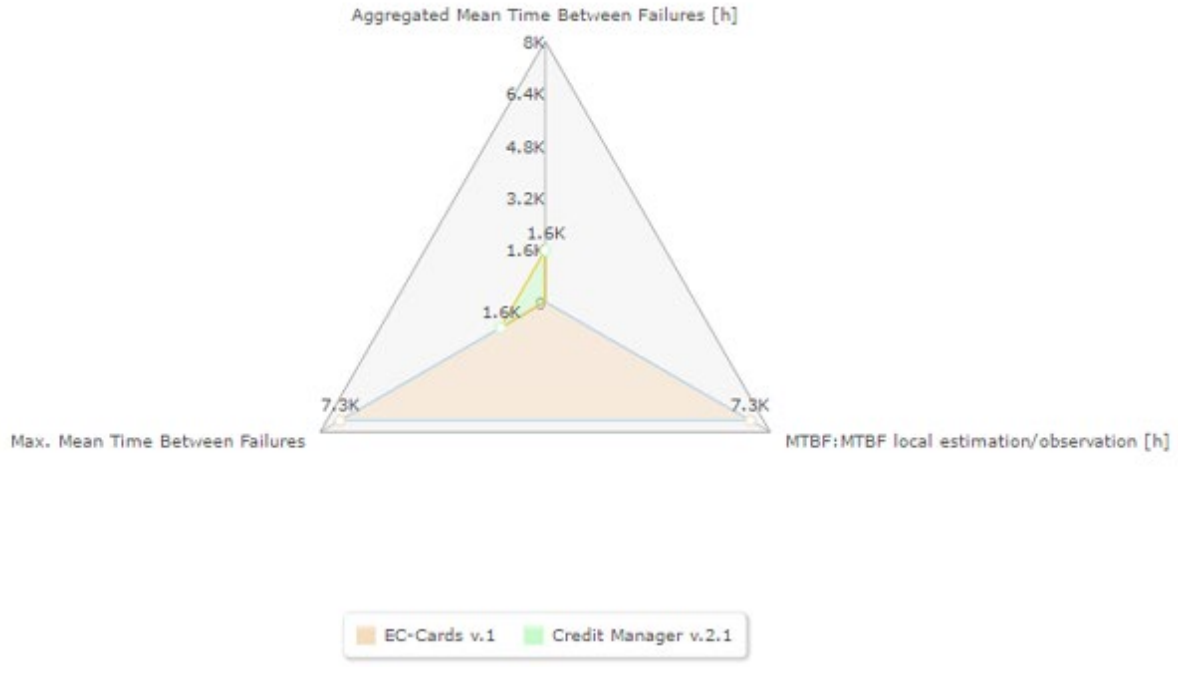
element in the inner level. Therefore, two objects with the same y value can be sized differently in the outer level.

In the following example, the y dimension has four values: 1, 2,3,4. While the sizing of the inner level is done according to the y dimension, the outer level displays objects on the left of the chart in very small slices, because multiple objects are assigned to a first multi-level object, while in the upper right part, the slices are much bigger because only up to three objects are assigned to the first level object. More than 4 different sizes are used for objects of the second level.

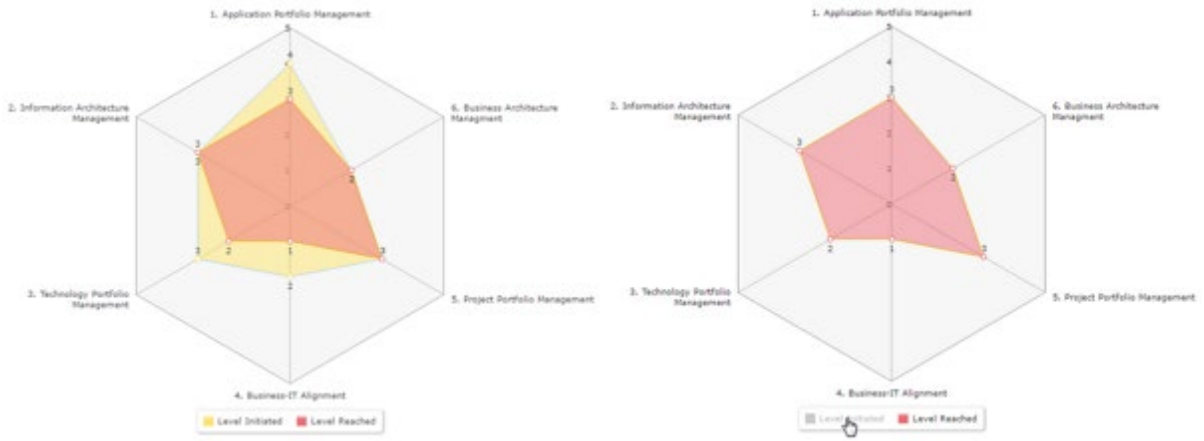


Radar Charts

Radar charts display multiple series of y values for an x value each on a different axis that start at the same point. The y values for the same x value are connected to each other and span a net each in a different color. For example, multiple indicators for applications can be displayed, with each indicator on a different axis and the indicator values for each application beeing connected:



A legend beneath the report displays all value nets that are visible in the radar chart. Clicking on an entry in the legend removes the value net from the chart:

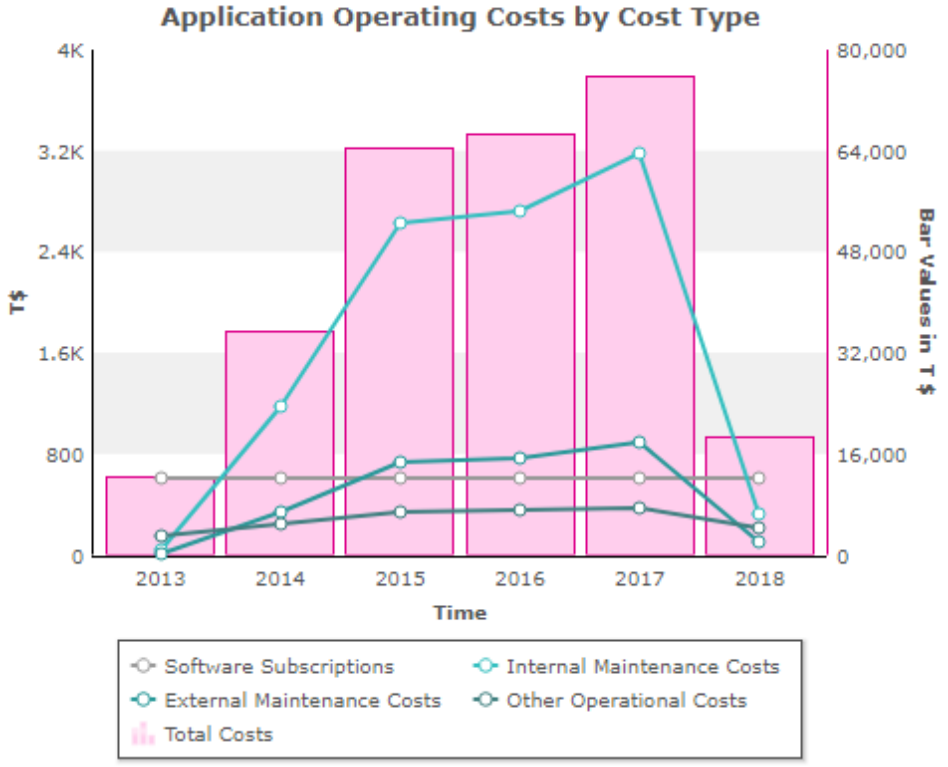


Combination Charts

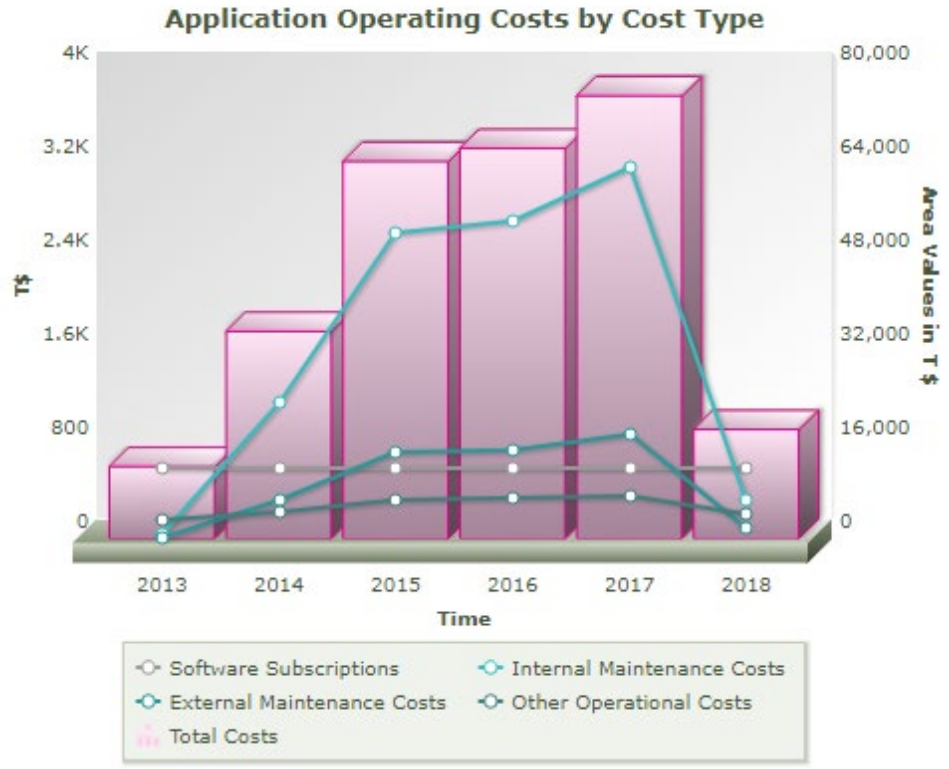
Line, area, and bar charts can be combined in a combination chart. The combination chart offers the following features for display of different kind of charts in the same graphic:

- Business charts of different chart types can be combined, For example, some series can be displayed as a bar and some as a line.
- Two different y axes can be defined, For example, to combine charts that require a different scale because the series are having different ranges of values or units of measure.
- For a better graphic display of the combined chart types, 3D effects can be added to the configured report. Only line and bar charts can be displayed in 3D. If the configured report contains areas, these are converted to bars.

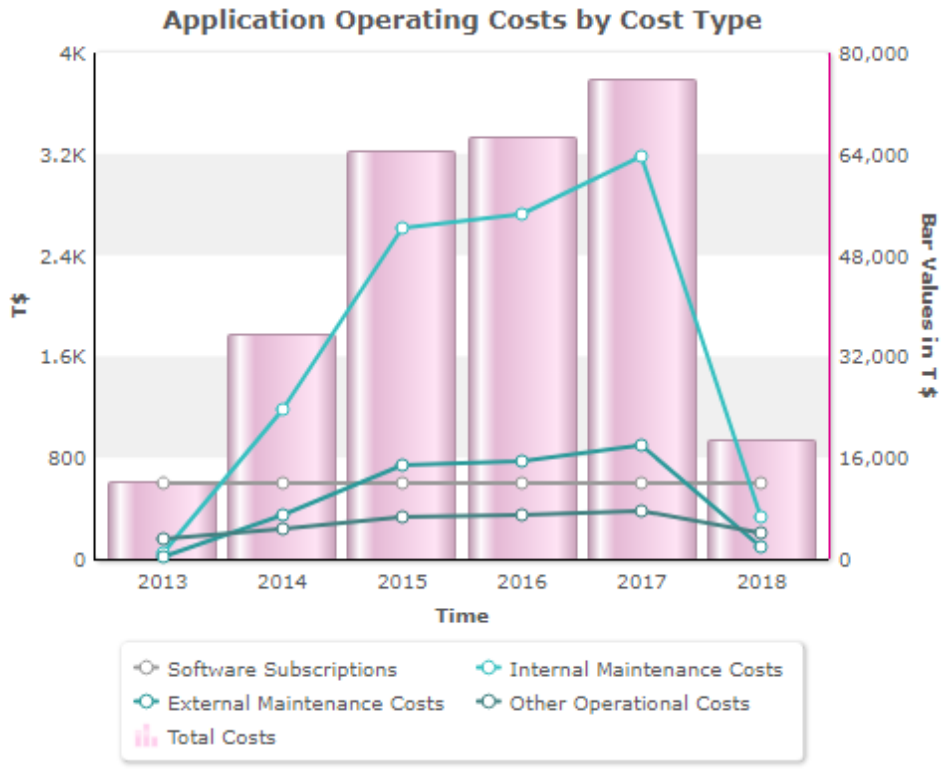
The following configured report shows the different types of costs for an application over the years as lines while the sum of the costs is displayed as bars with a separate axis with a higher range than the one for the single cost types:



The combination chart can alternatively be displayed in 3D-Design. Please note that coloring of the second y-axis is not visible in 3D design:



A 3D effect can alternatively be applied within the bars only:



Circular Roadmap Reports

Circular roadmap reports display objects as items in a circle that is divided both in horizontal and vertical orientation.

From the center of the circle until the border of the circle a time scale or a numerical scale is established, that is optically visible by dividing the circle into differently couloured shells. In addition, the circle is divided into sectors that typically represent objects related to the object elements in the circle. For example, if the objects displayed as items are applications, the sectors may represent domains that the applications are assigned to.

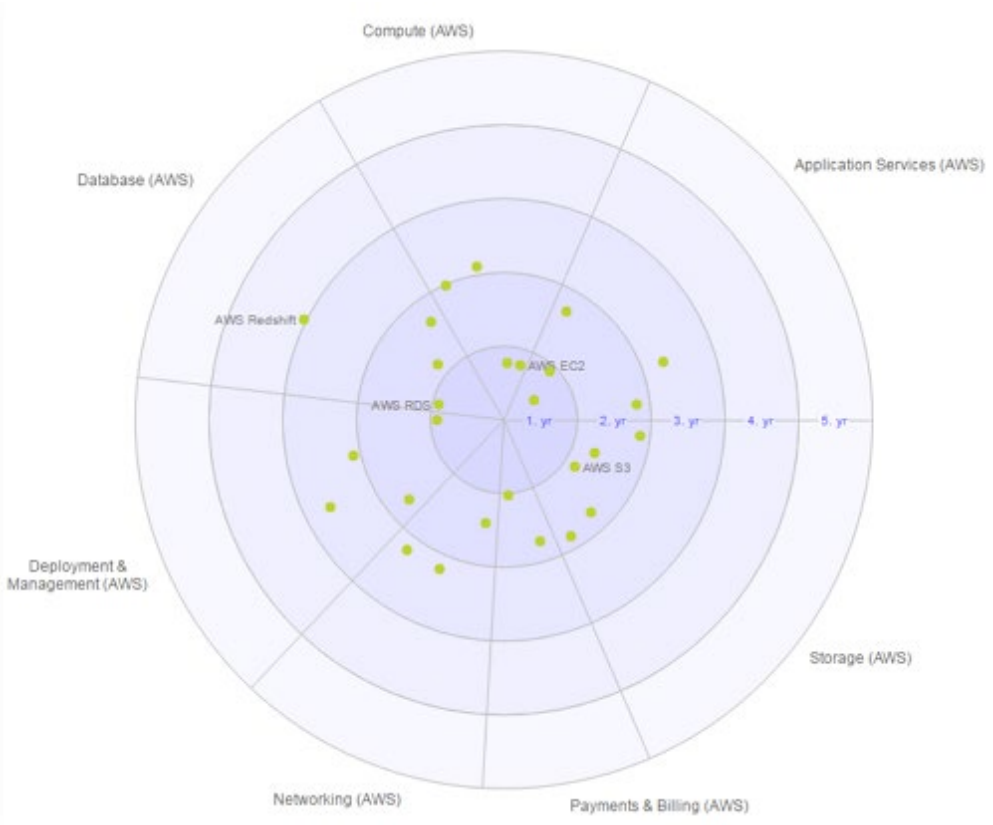


FIGURE: Circular roadmap displaying components placed into the circle according to their lifecycle end date and domain assignment

The object items are defined with a relation to both the shells and the sectors and are placed within the circle according to the values that they have on the shell scale and for the sector placement. To avoid placement of two object items on top of each other if they have the same value for shell and sector placement, a relative position from the middle axis of the sector can be defined for each object.

The items in the report can be represented by either graphic shapes, that may vary in size, color and shape according to defined criteria, or icons can be used to display the items.

In addition, relations between objects, like For example, versions of the same application or component succeeding each other, or information flows between components, can be displayed as arrows within the graphic.

FIGURE: Circular roadmap report displaying components as icons and arrows connecting successor versions

The circular roadmap report can provide navigation from both items and connecting arrows.

Gallery Reports

A gallery report displays data about objects in the Alfabet database as a gallery of identically sized graphic boxes:

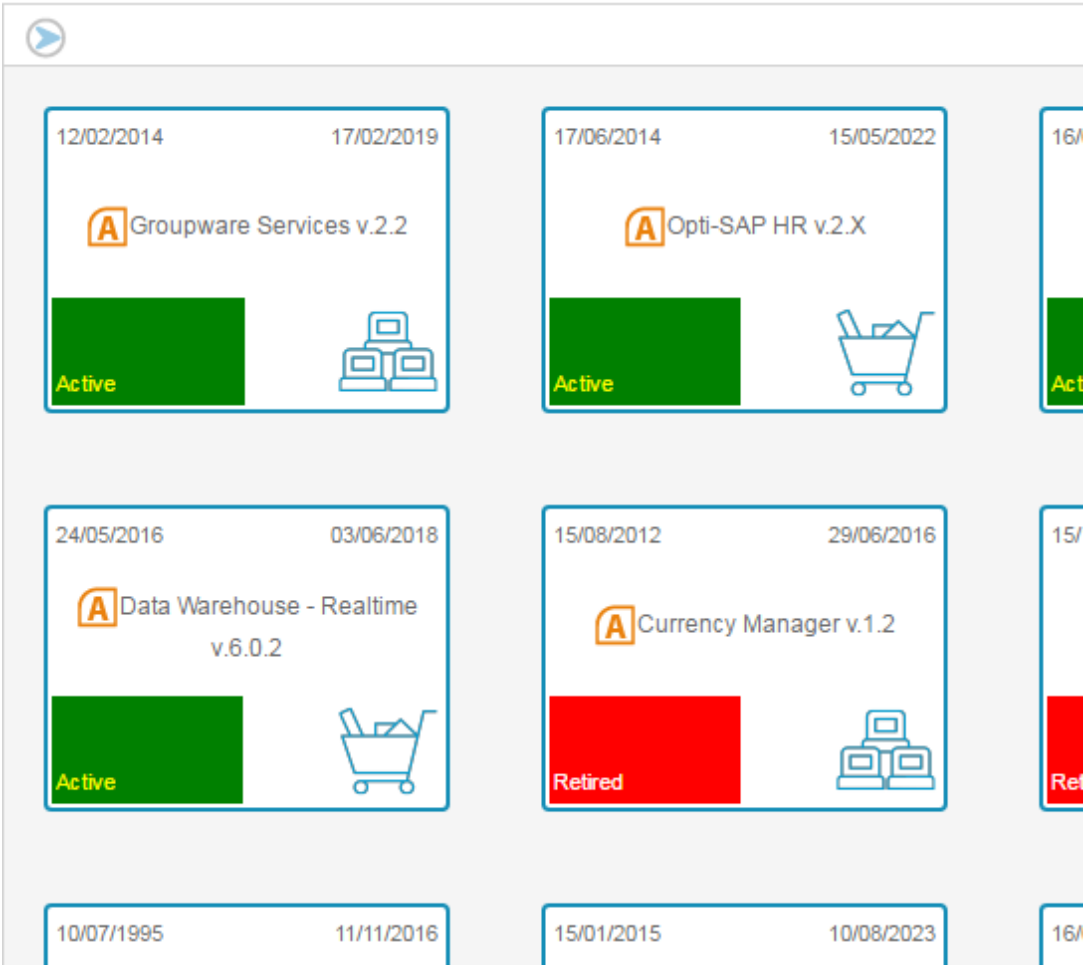

FIGURE: Part of a gallery report displaying the applications the current user is resonsible for

The boxes display configurable text in the center of the box. Typically the name of the object represented by the box is displayed in the center. Optionally, the icon of the object class the object belongs to can be displayed on the left of the text. The color of the text, the box and the border of the box can either be configured to be identical for all boxes or to depend on values from the return dataset of the underlying query of the configured gallery report.

In addition, four different attribute values related to the object can be displayed in the corners of each box. The information can either be displayed as plain text or as text on a colored background or represented by an icon. In the example above the application type information displayed in the lower right corner of each box is represented by an icon. A legend is available for the report that explains the meaning of the colors and icons used in the report.

The user can navigate ot the object profile of the object represented by a box in the configured gallery report by double-clicking on the box. Optionally, the configured report can be configured to open any other view of the Alfabet user interface instead of the object profile via double-click on an object box.

Node Arc Reports

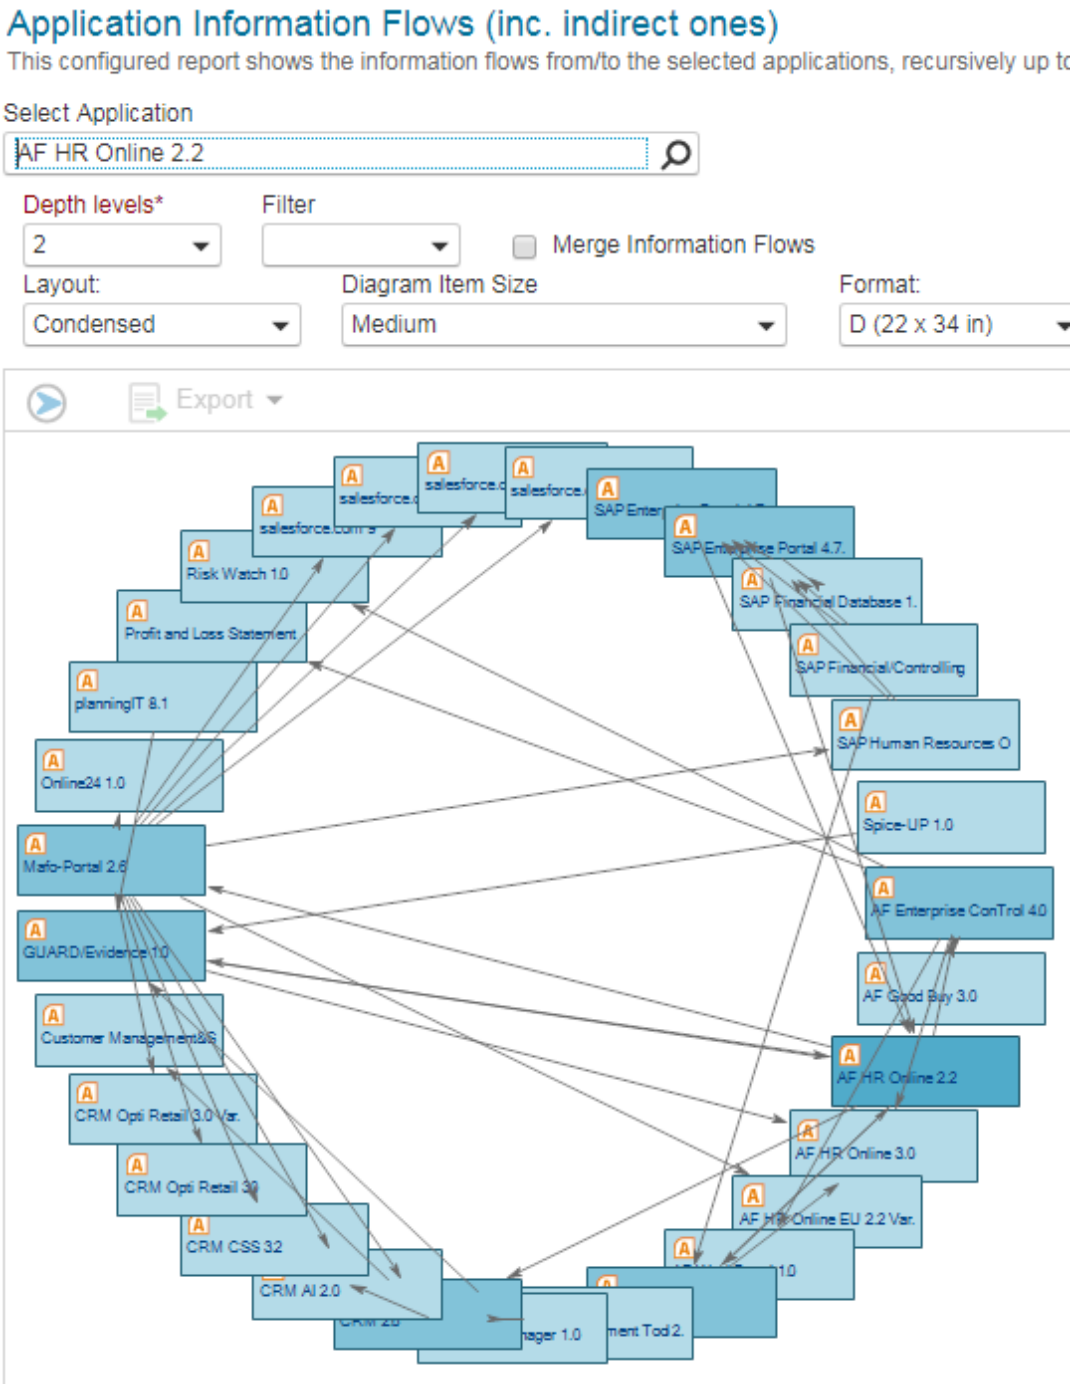
Configured node arc reports display connections between objects in the diagram layouts that are also available for standard Alfabet diagrams that were defined with the Alfabet Diagram Designer. Objects are displayed in object boxes that are based in design on the diagram item templates that can be customer

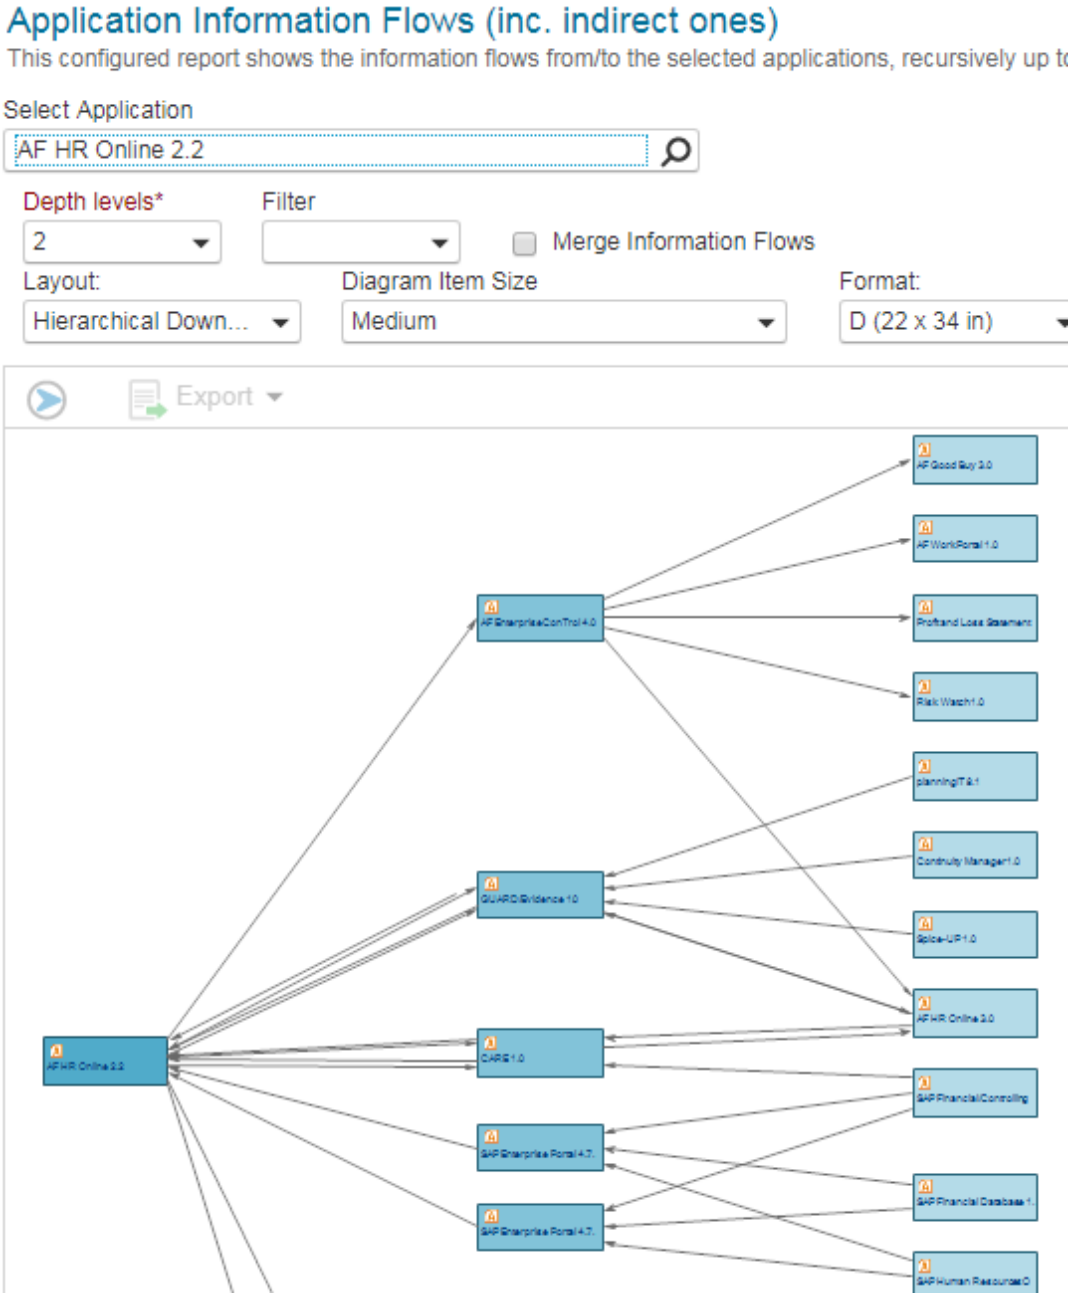
defined for use in diagrams. There are two different types of node arc reports which are different in the final layout options for the user:

- Node arc reports based on the template `NodeArcReport`:

The way boxes and connections between boxes are displayed is dynamically rendered at runtime according to the diagram layout selected by the customer. The filters that are available for all diagrams in standard Alfabet views are also added to the node arc reports designed by the customer. The standard filters can be set to hidden when the user should not be able to alter the design of the node arc report.

The following example displays the same node arc report with two different layouts applied:

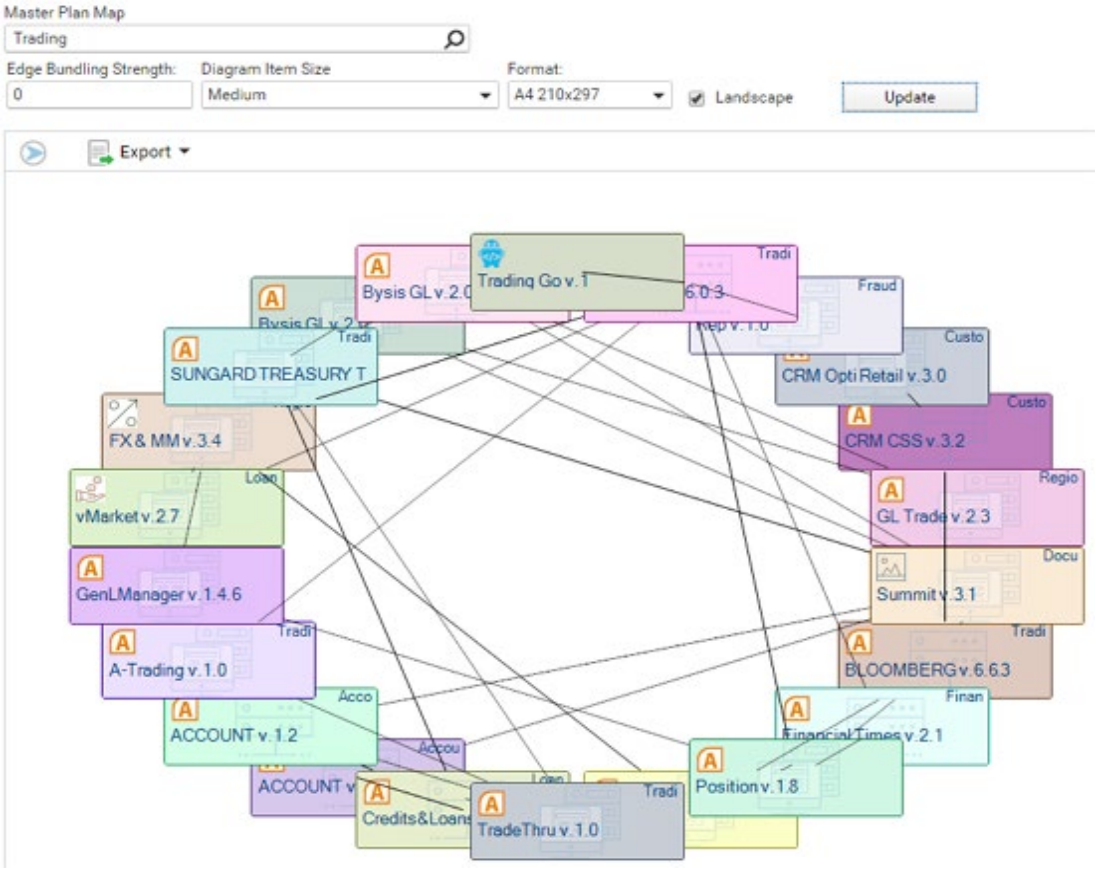


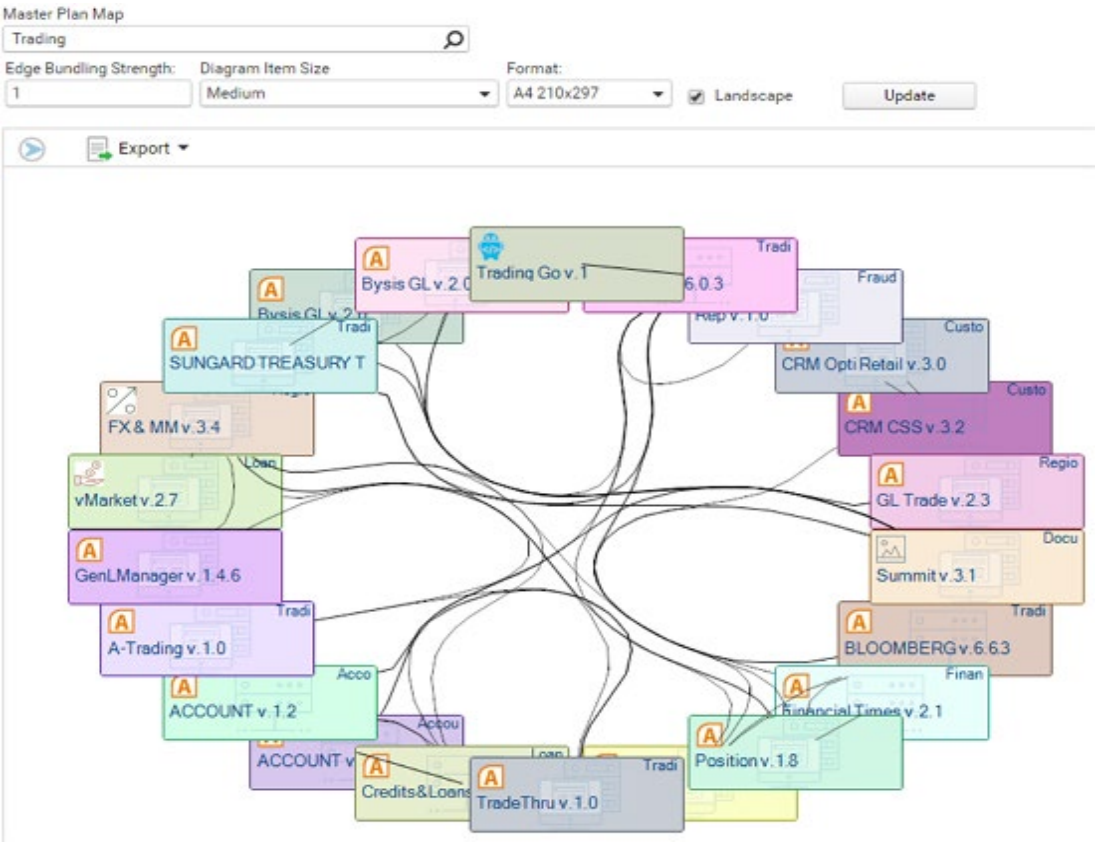


- Node arc reports based on the template `NodeArcReportWithBundling`:

Boxes and connections between boxes are displayed in the `Spring Layout` with connections beeing bundled to enhance the general overview for diagrams with a high number of connections. The user can decide at runtime whether and how much edge bundling is performed on the connections. The filters that are available for all diagrams in standard Alfabet views are also added to the node arc reports designed by the customer except for the **Layout** filter that is substituted with the **Edge Bundling Strength** filter. Edge bundling can be defined with a rational number between 0 and 1. Edge bundling of zero is identical with the normal condensed diagram layout with straight lines. Edge bundling strength will increase with a maximum at 1. The standard filters can be set to hidden when the user should not be able to alter the design of the node arc report.

The following examples show the same node arc report with edge bundling set to zero and to one:





The line style for connections and the design of the boxes representing objects in the configured report is highly configurable to provide additional information by using different coloring, line styling or labels in boxes.

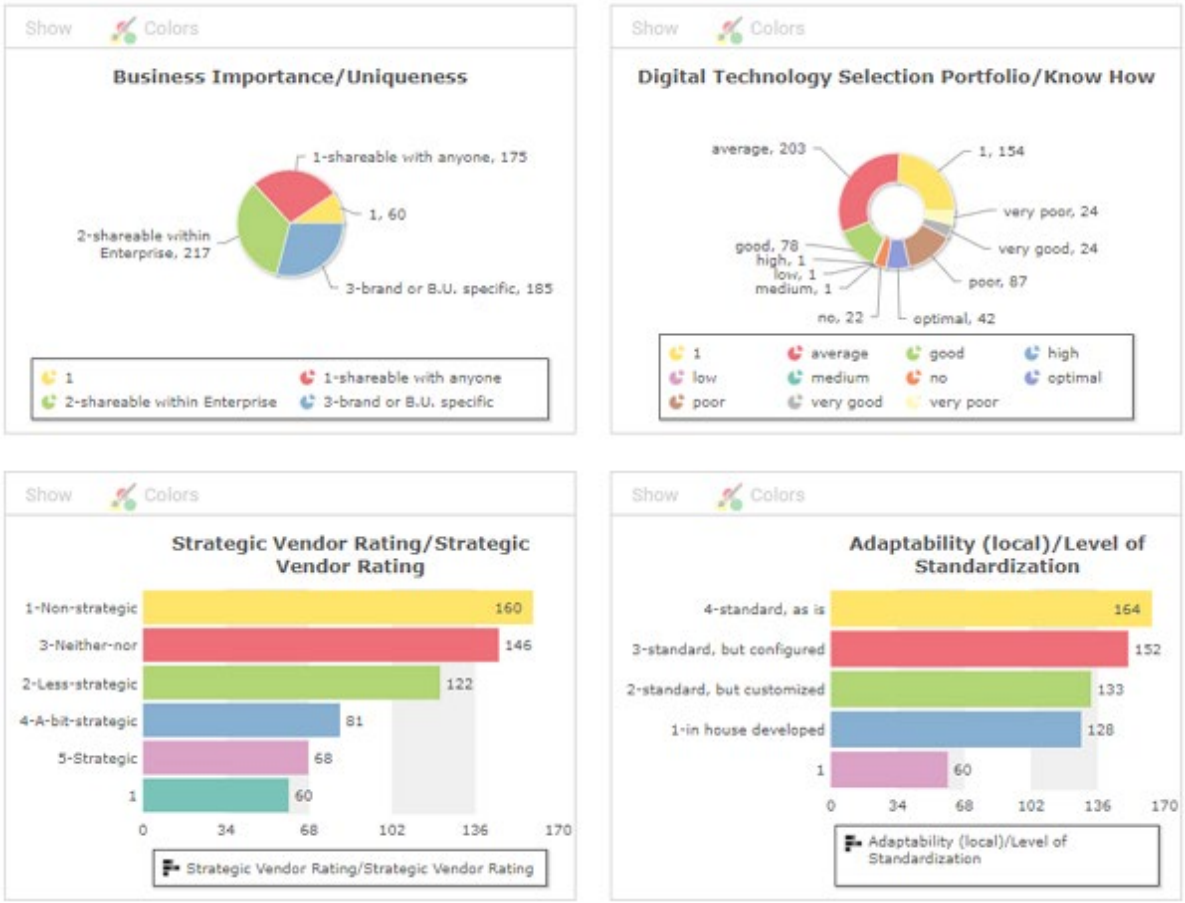
By default, navigation from the boxes to the object view of the object is enabled. Optionally, the node arc report can be configured to provide navigation from the object boxes to a standard page view or configured report instead of the standard navigation behaviour. If the connections between the boxes represent objects, navigation can be enabled for the connections as well. The user must then click either end of the connection and click the **Navigate** button. Clicking in the middle of the connection or the connection label does not enable the navigation option.

For information about configuring node arc reports, see Defining Node Arc Reports or Node Arc Reports With Edge Bundling.

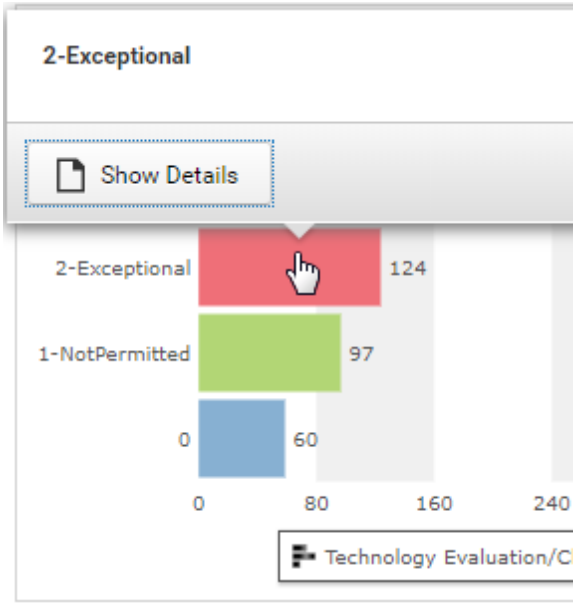
Portfolio Diagnostics Report

Portfolio Diagnostics reports use variance and factor analysis of a wide scope of measures to understand pain points in the IT architecture. The portfolio diagnostics report uses Software AG's augmented AI technology to provides users without prior knowledge of the details of the IT landscape with an entry point to explore and understand which aspects of the IT architecture may require change. Portfolio diagnostic reports are configured reports that analyze all or a subset of relevant indicators and numeric property settings for a defined object class. The report scans indicators and measures for inconsistencies to point the user to objects with a high deviation from the company's standard. Users can drill-down through report results for a deeper understanding where problems exist in the IT architecture and identify where action is needed.

The first level of the report uses variance analysis and displays the results for the indicators and measures that show the highest score of inconsistency in value settings. For each of these indicators and measures, a chart provides information about the number of objects with the occurring value for the indicator or measure:



The user can click-and-hold an area in one of the charts and click **Show Details** in the preview window to navigate to the next level of analysis:



The reports on all subsequent levels are factor analyses that take only the objects represented in the selected bar into account. The analysis searches for indicators and measures with values that closely correlate to the values of the indicator or measure in the previous selection. The indicators and measures with the highest correlation are displayed as charts with the number of objects per value. The user can then

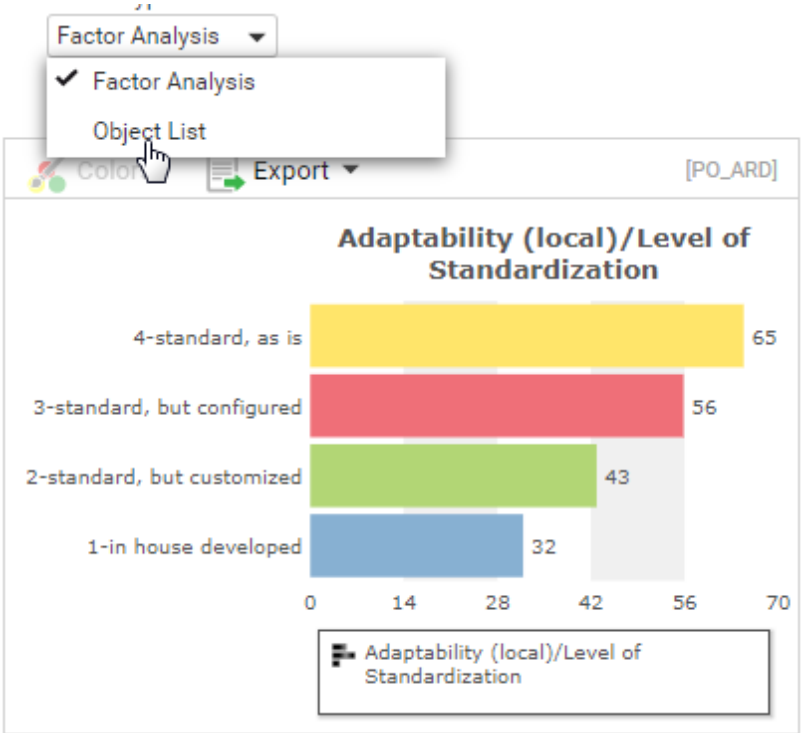
continue to drill down to the next level of factor analysis, whereby each level will display a smaller number of objects with the same combination of potentially problematic indicator settings. The selections made on each level are displayed as a text above the report.

The kind of chart that is displayed depends on the number of results to display. The following special rules apply:

- If results are displayed in a horizontal bar chart, the results are sorted top to bottom by Y-value, which means that For example, for an indicator, the order of the bars does not follow the order of the allowed indicator values from the lowest to the highest score, but the number of objects that are set to the indicator value.
- If results are displayed in a pie chart or doughnut chart, the results are sorted alphanumerically by X-value.
- If there are more than 20 values, X-Values are combined in buckets. The number of buckets is configurable for the configured report. The type of chart displayed depends on the number of buckets defined for the report. For example, for a report displaying 30 different X-values, representing values from 1 to 30, and a number of buckets of 10, the result dataset will display 10 results, one combining all Y-values for the X-values from 1 to 3, one combining all Y-values for the X-values from 4 to 6, and so on.

The user can exclude charts that are not regarded as relevant for analysis. To exclude a chart, the user must select the chart caption in the **Critical Measures** field above the, click the **Exclude** button, and then click the **Submit** button. If the user wants to re-include an excluded chart, he/she can select the excluded chart in the **Ad-Hoc Excluded Measures** field, click **Reinclude** and then click **Submit**.

At any point, the **Object List** option can be selected in the **Action Type** field above a report prior to opening the next level.



The next level will then be a dataset showing the relevant objects and their indicators and measures that were selected in the course of the analysis. The user can drill-down to the object profile/object cockpit of a selected object in order to understand the details about the object.

If a group infrastructure exists for the objects shown in the list, like For example, application groups for applications or component groups for components, the user can select one or multiple objects in the list and either assign them to an existing group or create a new group and add the selection to the new group in a single step. Both actions are available via the button **Action**. The **Action** button is currently available for the following object classes:

- Application
- Business Process
- Component
- Contract
- Cost Center
- Demand
- Device
- Domain
- ICT Object
- Policy
- Market Product
- Migration
- Organization
- Peripheral
- Project
- Service Product
- Technology
- Threat
- Value Stream
- Vendor
- Vendor Product

For information about how to create a portfolio diagnostics report, see Defining Portfolio Diagnostics Reports.

Treemap Reports

A treemap report shows Alfabet objects from the perspective of a specified object class. The configured report is structured in columns that represent an object class that is associated with the specified object class. For example, a configured report can show application groups in the column headers and the applications assigned to the respective application group as objects in the columns.

Each object in the configured report is displayed as a box with a configurable size, color and indicator icon in the object box. The color, size, and indicator symbol represent dimensions of object evaluation configured by the report designer.

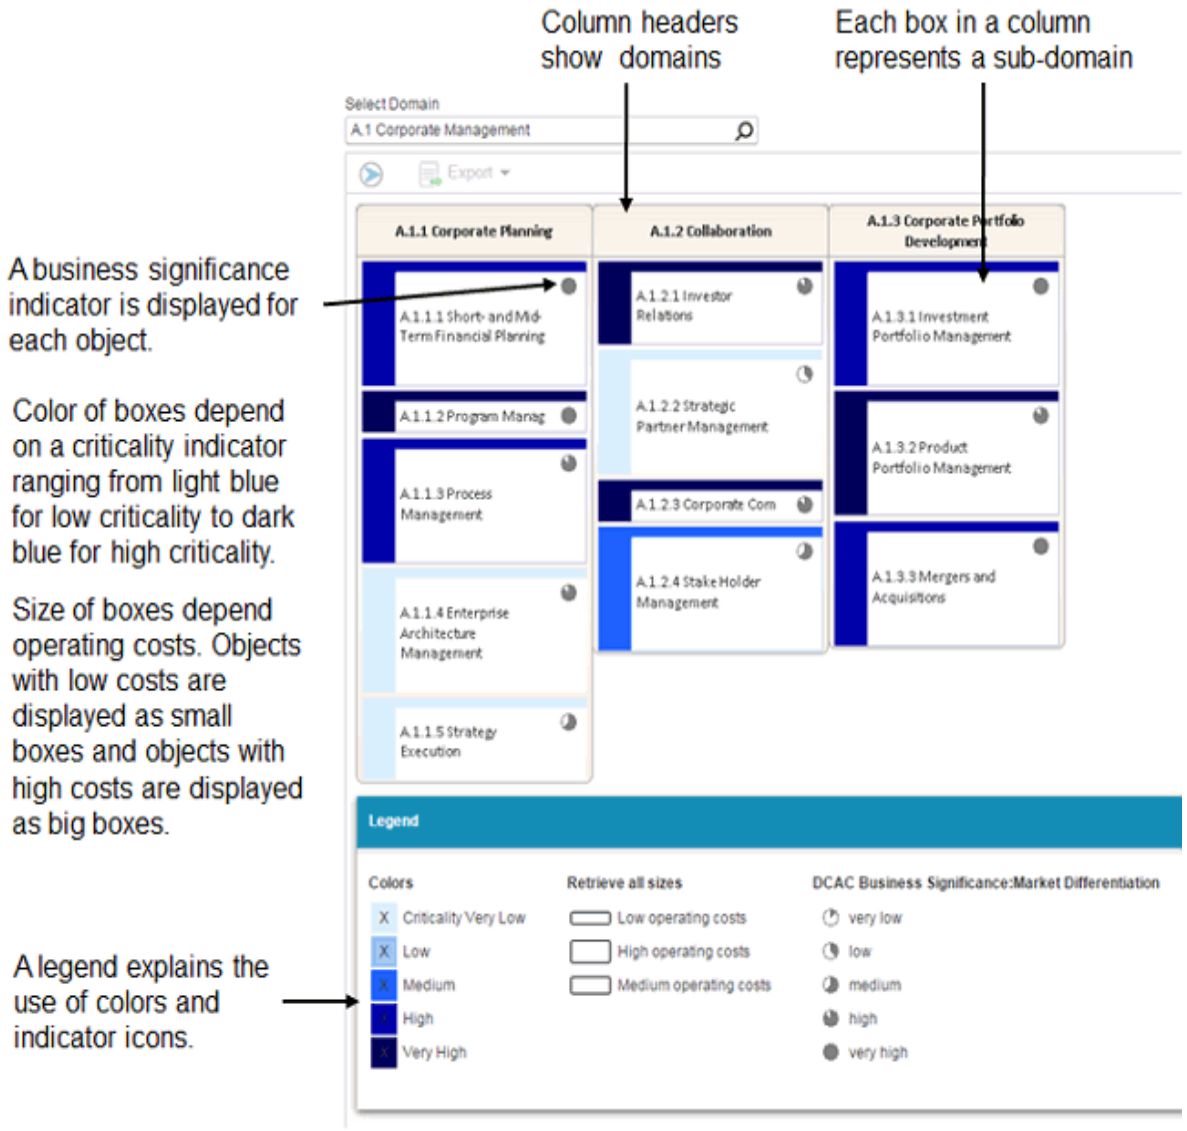


FIGURE: Example for treemap report displaying sub-domains sorted by parent domain.

In the example above, a domain with high criticality is displayed in dark blue whereas a domain with low criticality is displayed in light blue. The size of the domain represents its operating costs. The lower the operating costs, the smaller the box representing the object in the configured report. The indicator displayed on the box highlights a third aspect that is critical to the evaluation of the domain. In this case, a risk assessment for the domain is visualized.

The size, color and indicator are assigned automatically to the displayed objects based on configured rules. Users can easily find and select an object that requires an action or change and thus navigate to its object profile by double-clicking it in the configured report.

For a detailed description about how to configure a treemap configured report, see the section Defining a Treemap Report.

Rectangular Treemap configured reports

A rectangular treemap displays a hierarchical relation between objects as nested boxes. In Alfabet, rectangular treemap configured reports can display two levels of a hierarchy only. The objects of the subordinate level are displayed as boxes within the box of the superordinate object they belong to. The size of the object boxes depends on a measurable aspect of the object, like an indicator value or the number of relations to another object class.

For each object a name is displayed as text in the object box and in addition, a tooltip is displayed when the user moves the mouse over the text in the object box. The text and the tooltips are configurable.

An indicator can be displayed in each object box. In addition, the coloring of boxes can be defined to depend on a property of the object that the box represents. A legend is available for the indicator and the color coding in the configured report.

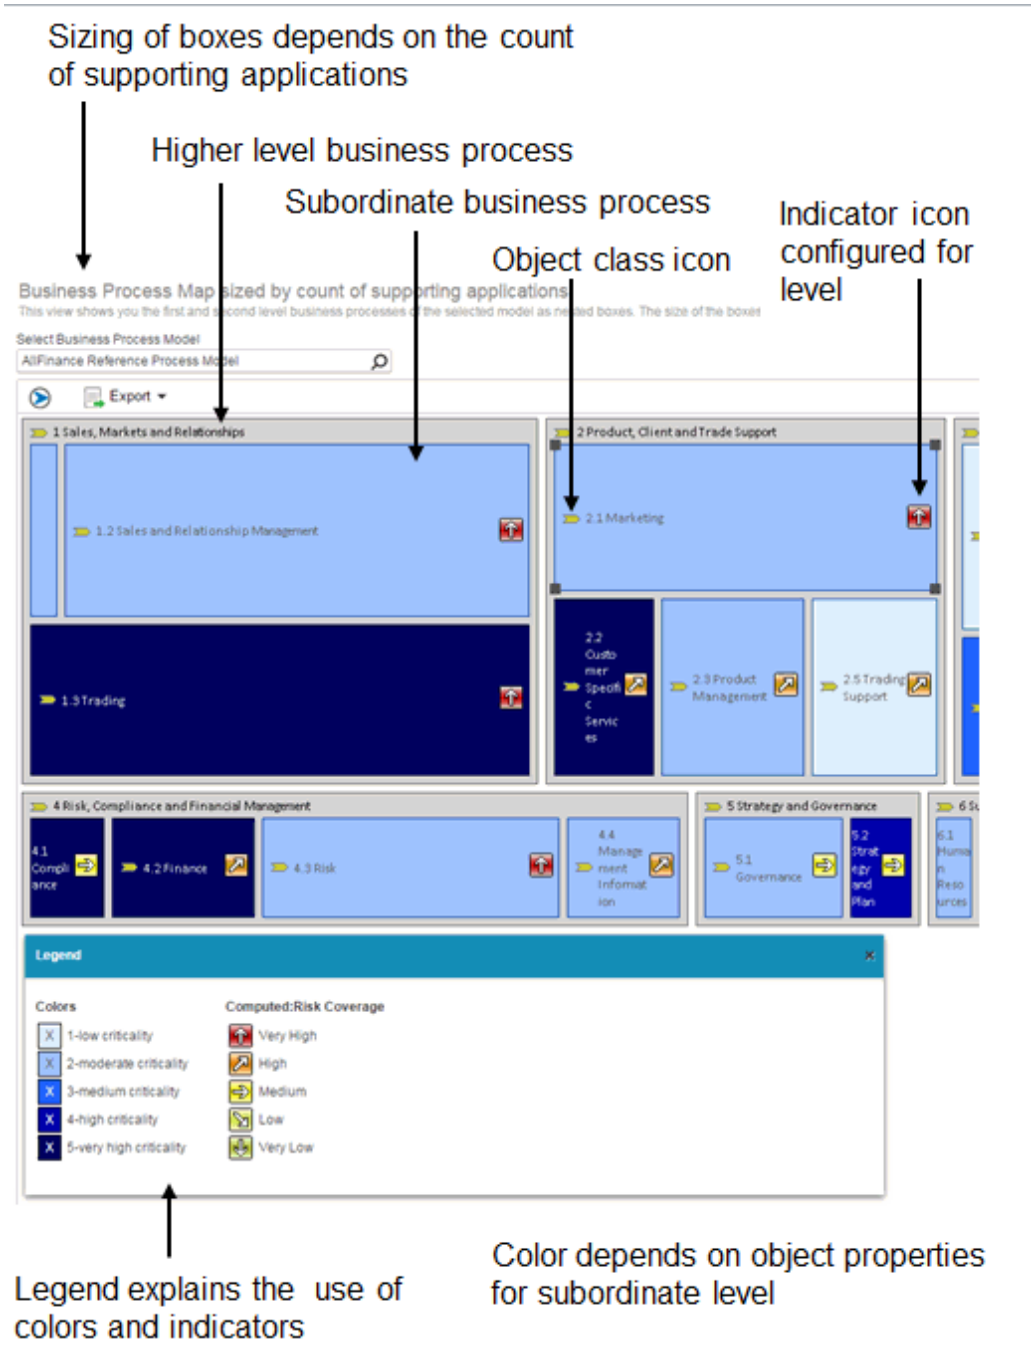

FIGURE: Example of a rectangular treemap report showing business processes and their child business processes

For a detailed description about how to configure a rectangular treemap report, see the section Defining a Rectangular Treemap Report.

Layered Diagram Reports

A layered diagram report shows objects from various object classes that are related to each other. Each object class is displayed in a separate layer and is related to the objects displayed in the layer directly above and below the current layer.

Each object in the report is displayed as a box showing a configured color and indicator icon. The color and indicator icon represent dimensions of object evaluation defined by the designer of the report. Various color coding and indicators can be defined per object class in the report.

For example, the colors of an object in an object class may depend on the number of open assignments while the colors displayed for objects of another object class may represent the object's criticality for the business.

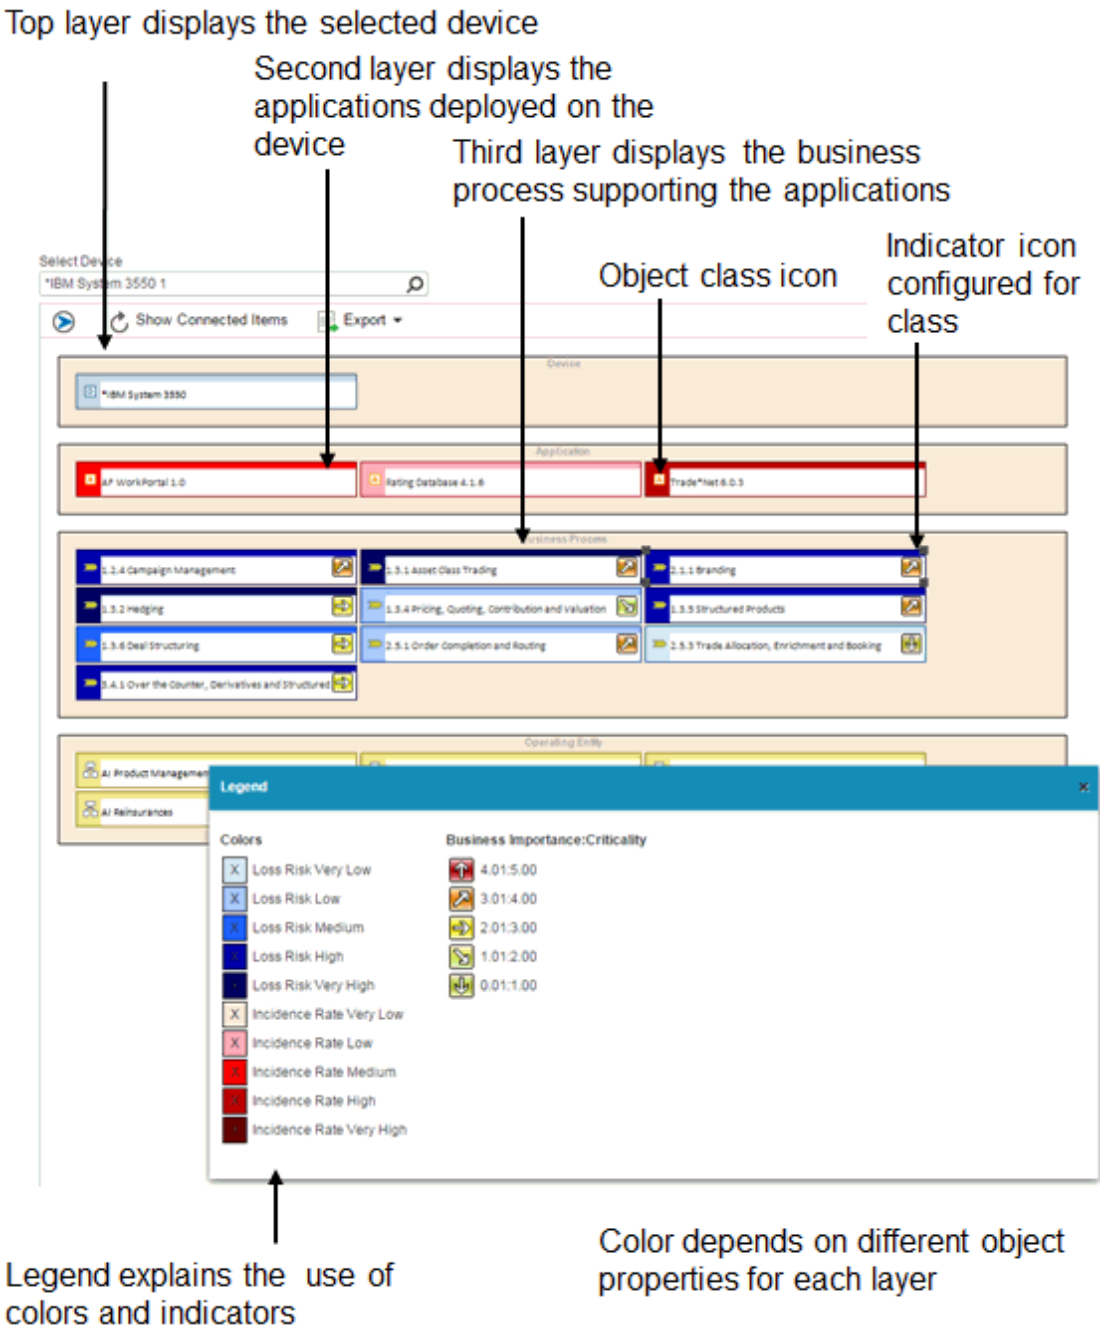

FIGURE: Example for a layered diagram report displaying devices in a selected device group and related objects

When the user selects an object in the report and clicks the **Show Connected Items** button in the toolbar, objects related to the selected objects are displayed in the colors determined by the color definition. Unrelated objects are displayed in grey.

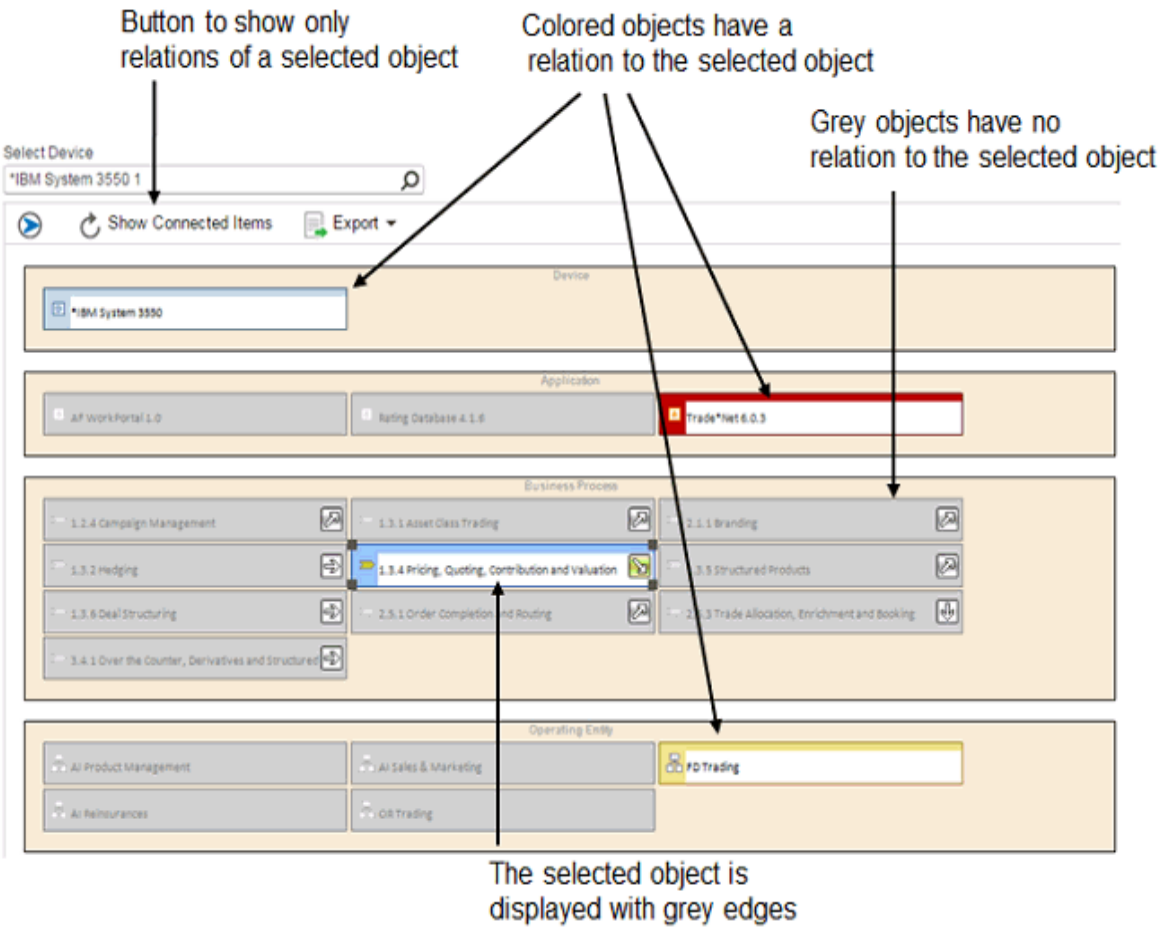

FIGURE: Example of a layered diagram report displaying devices and related objects and the relation of the objects in the layer with the selected business process

To display a report as a layered diagram report and configure the rules for the display of objects, an XML object must be configured in Alfabet Expand. The XML object is available via the attribute window of the report. For a detailed description about how to configure a layered diagram report, see Defining a Layered Diagram Report.

Tree Reports

A tree report shows a bi-directional tree displaying the relations between a selected object and related objects. In the middle of the tree, one base object or a set of base objects is displayed. Related objects found by queries are then displayed in a tree structure either in one or in two directions. The tree may be configured to span horizontally or vertically.

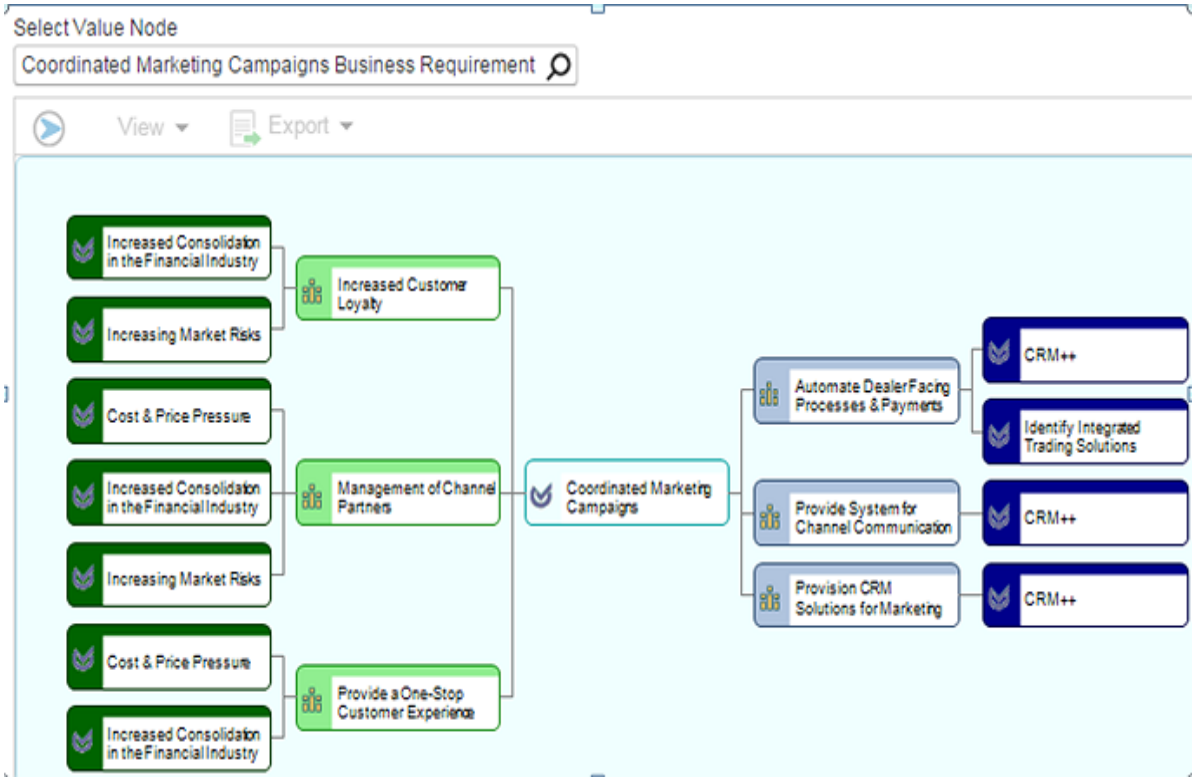

FIGURE: Example of a grid report with two trees in horizontal direction spanning from one selected object

Each object in the report is displayed as a box showing a configured color and indicator icon. The color and indicator icon represent dimensions of object evaluation defined by the report designer. Various colors and indicators can be defined per object class in the report.

For example, the colors of an object in an object class may depend on the number of open assignments while the colors displayed for objects of another object class may represent the object's criticality for the business.

A grid report can display multiple trees reflecting relations:

- The report can display more than one object as the starting point for the tree. The trees are then displayed next to each other. In this way, the queries defined to find related objects and the color rules and indicator rules used for the report are applied to all trees. All elements are displayed in the same size on the same background color.
- Multiple tree reports can be displayed in one report view. Cells in the report view may be filled with another definition of a tree report. The content of a cell is completely independent of the content of other cells in the report. Other objects can be displayed as the tree roots and the trees can reflect other relations. Colors and indicators are also specified separately for each cell. This makes it possible to specify, For example, multiple aspects of the same object or to compare different relations with one another.

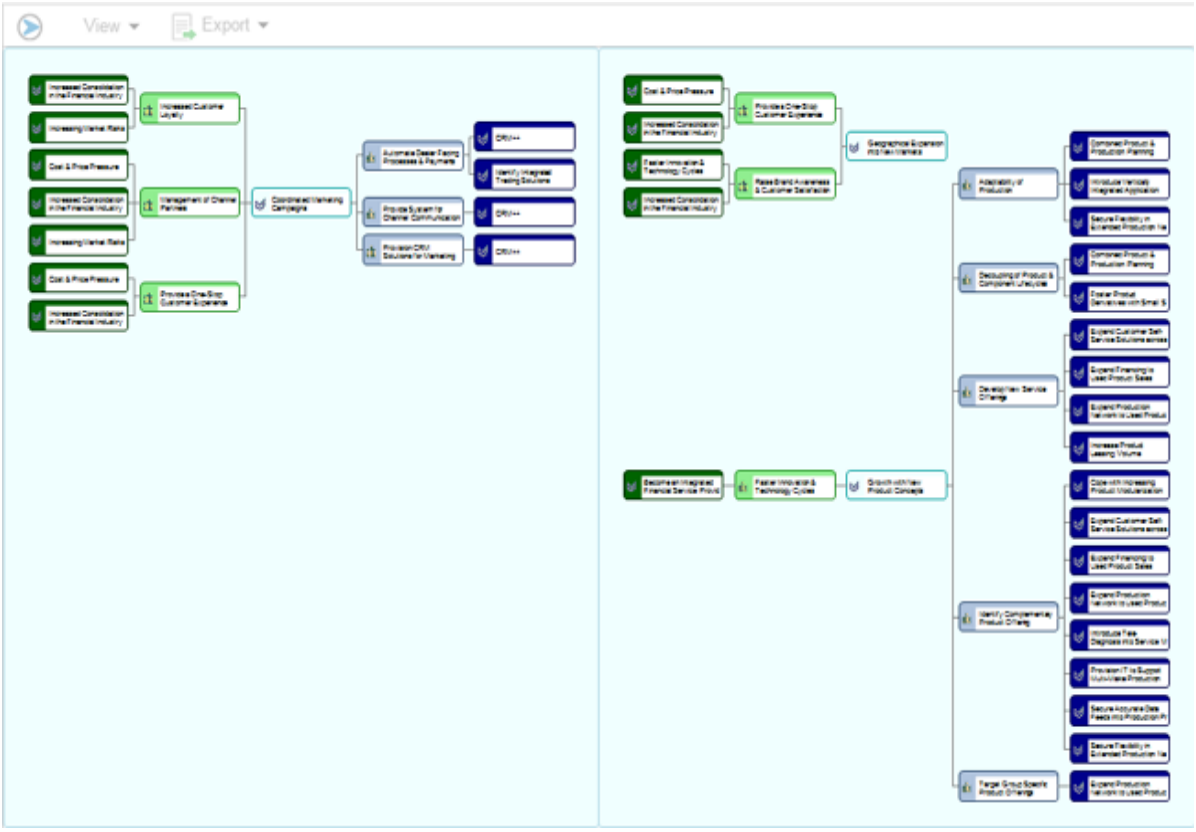

FIGURE: Example of a grid report with two cells. Cell one displays a one relation tree, while the second cell displays relations of three different base objects.

A legend is available in the report if color rules or indicator rules are specified. Color rules and indicator rules will be evaluated as described above for layered diagram reports.

For a detailed description about how to configure a grid report, see Defining a Grid Report.

Cluster Map Grid Reports

A cluster map report shows related objects in multiple levels of nested boxes. The outermost boxes could be arranged vertically or horizontally. The boxes represent objects that are found by means of queries that define the object relationships.

FIGURE: Example for a cluster map report (section thereof) showing sub-organizations of a base organization, the business processes executed by the organization and the applications providing business support for the business processes.

Each object in the report is displayed as a box highlighted by a configured color and an indicator icon (optional). The color and indicator icon represent dimensions of object evaluation defined by the report designer. Colors and indicators can be defined for each object class displayed in the report.

For example, the colors of an object in an object class may depend on the number of open assignments while the colors displayed for objects of another object class may represent the object's criticality for the business.

A legend is available in the report if color rules or indicator rules are specified. Color rules and indicator rules will be evaluated as described above for layered diagram reports.

Multiple cluster maps can be displayed in one report view. Cells in the report view may be filled with another definition of a cluster map.

For a detailed description about how to configure a grid report, see the section Defining a Grid Report.

Matrix Reports

Matrix reports shows object dependencies in a matrix. Columns and rows of the report represent objects in the Alfabet database. The cells display objects that are related to both the object in the row header and the object of the column header of the respective cell.

Each object in the report is displayed as a box displaying a configured color, border color and optionally an indicator icon. The colors and indicator icon represent dimensions of object evaluation defined by the report designer. Various color coding and indicators can be defined per object class in the report.

Two different designs are available for matrix reports: the affinity matrix and diagram matrix. The matrix types differ in style and functionality as well as in configurability:

Affinity Matrix

- Column and row headers are fixed during scrolling. The column header is excluded from vertical scrolling and the row header is excluded from horizontal scrolling.
- All cells in the report are displayed with sharp edges and the color is plain fill.
- Indicators cannot be displayed for objects in the matrix.

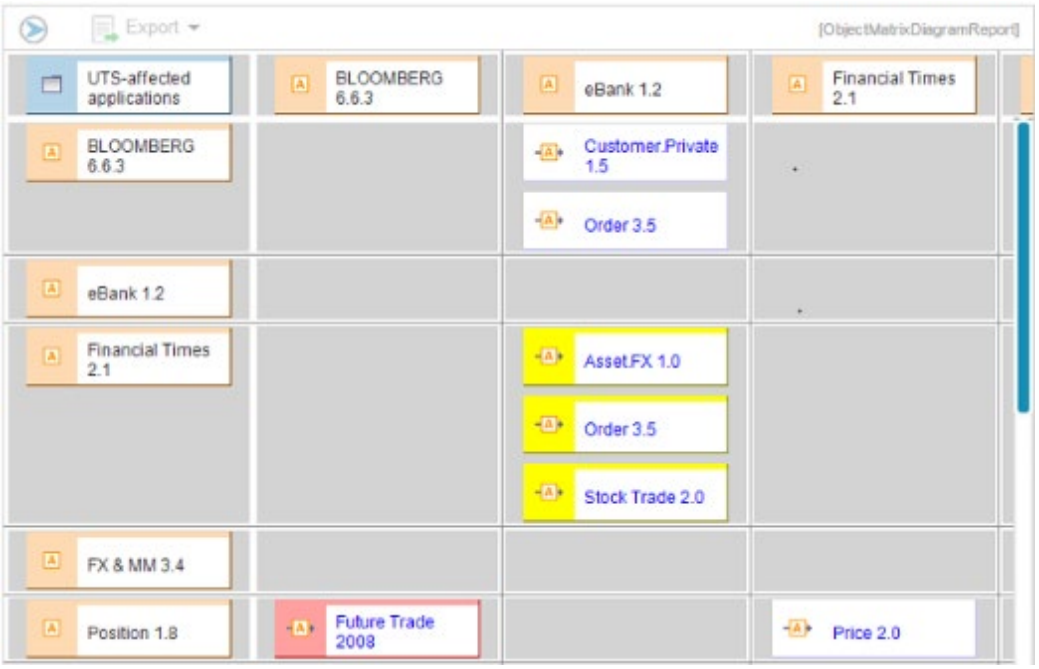

FIGURE: Upper-left corner of an affinity matrix before scrolling

FIGURE: Upper-left corner of the affinity matrix above after vertical scrolling

Diagram Matrix

- Column and row headers are included in scrolling and move out of sight when scrolling.
- All cells in the report are displayed either with rounded or sharp edges and with a color gradient.
- Indicator icons can be displayed in the object boxes in the cells of the matrix representing the indicator value for the object.

FIGURE: Matrix report of the type Diagram with indicators displayed for some objects on the right of the object boxes

For a detailed description about how to configure a matrix report, see the section Defining a Matrix Report.

Gantt Chart Reports

Gantt charts can be defined to display information about object lifecycle phases and start and end dates.

Gantt charts display the lifecycle and/or the start and end dates of objects selected via queries. The chart can display objects that depend on each other in a hierarchy. There are two different types of Gantt charts:

Hierarchical Gantt Charts

In the chart, there is a row for each object, with the hierarchy being displayed as a grouped dataset. The objects in the next level hierarchy in the report can be collapsed or expanded by the user.

The timeframe can be displayed per year, per quarter, per month, or per week. Changing the display of the timeframe is done via the zoom in and zoom out options of the floating toolbar.

The current date is displayed as a blue vertical line in the report.

Start and end times are either displayed as a line on top of the lifecycle, as a rectangle spanning the whole period between the start and end dates or as a bar indicating the start of the lifecycle. In the example below, the start and end dates of the project (displayed in the first row of the report) is displayed as a blue bar while the start and end dates of the other objects are displayed as a line on top of the lifecycle. Projects do not have a lifecycle defined but are included to enhance the visibility of the information.

Optionally, enterprise milestones and customer configured milestones can also be displayed in the report.

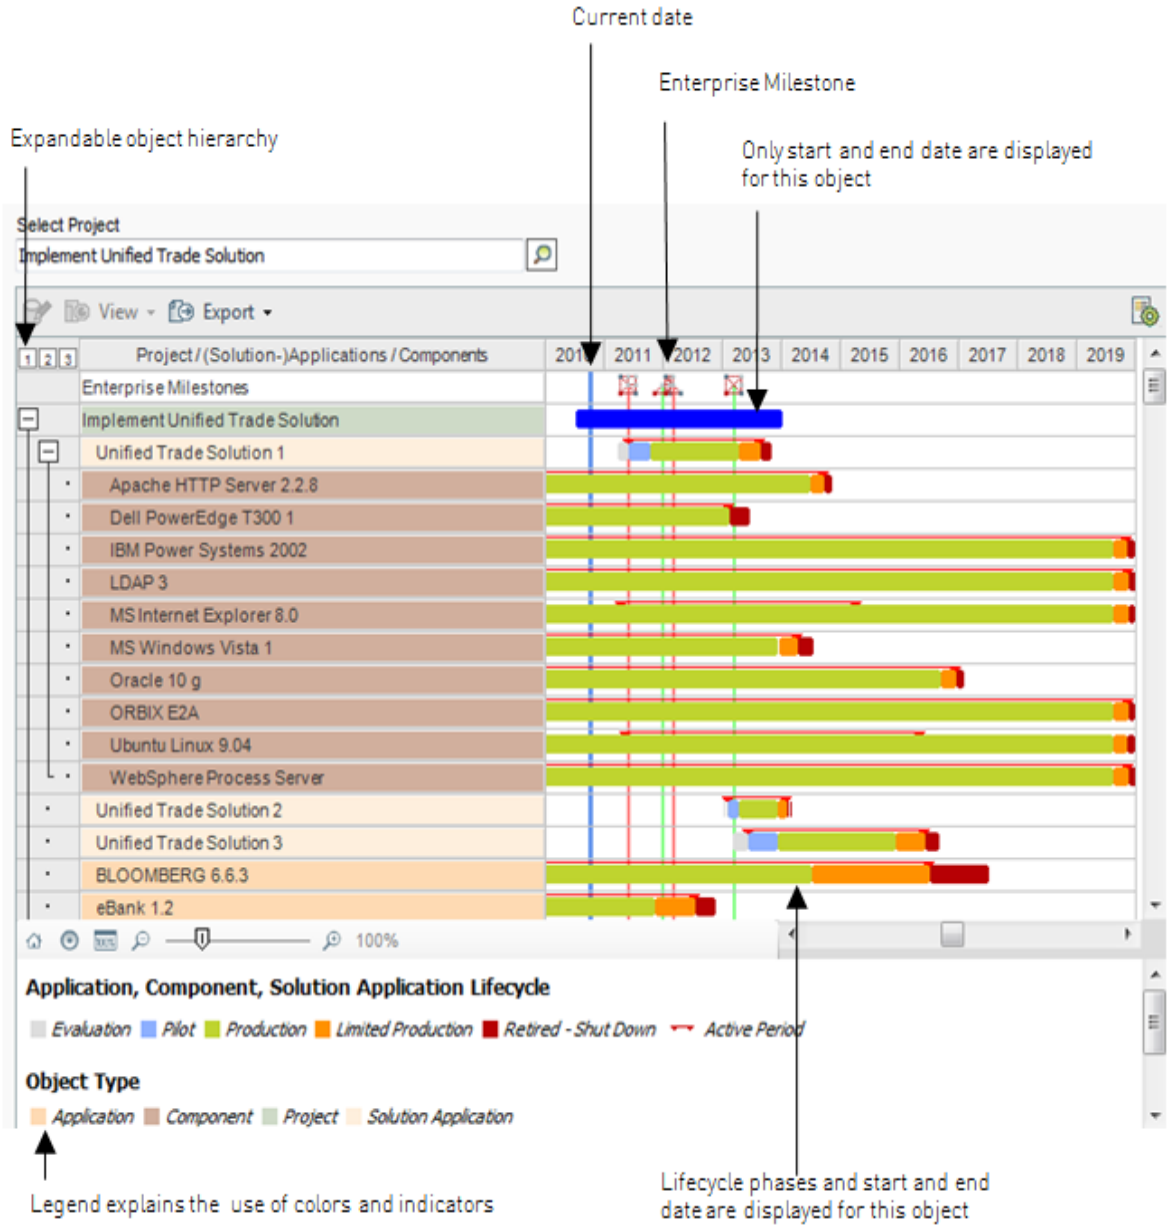

FIGURE: Gantt chart report displaying the lifecycle of applications and components relevant for a selected project

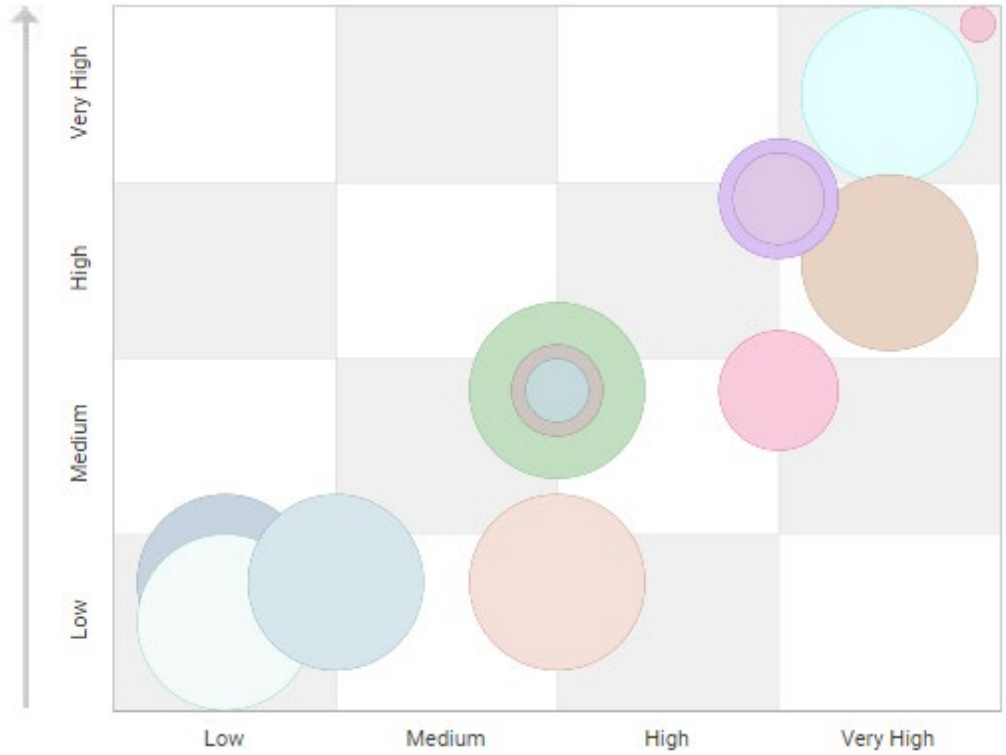
Clustered Gantt Chart

For a detailed description about how to configure a Gantt chart report, see Defining Gantt Chart Reports.

Portfolio Reports

Portfolio reports can be configured to show information that is not available in the standard portfolio reports in Alfabet. The objects displayed in the portfolio as well as the indicators that the evaluation is based on can be configured by the customer.



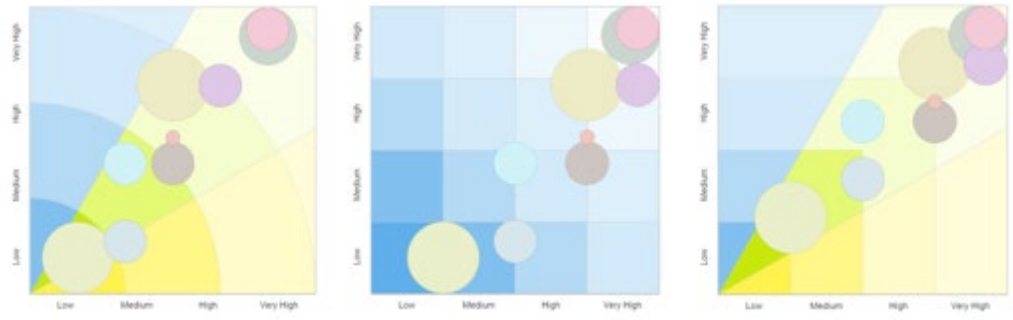
Configured portfolio reports differ from standard portfolio reports in the following:

- The underlying calculation mechanisms are different. Standard Alfabet portfolios are based on prioritization schemes that calculate values by weighting indicator values. The prioritization schemes have evaluation types assigned, which have at least one indicator type assigned. All indicators for an object associated with the indicator types assigned to an evaluation type are weighted according to the configuration of evaluation type weighting in the prioritization scheme. For more information about standard portfolio definition, see the chapter *Configuring Evaluations, Prioritization Schemes, and Portfolios* in the reference manual *Configuring Evaluation and Reference Data in Alfabet*.

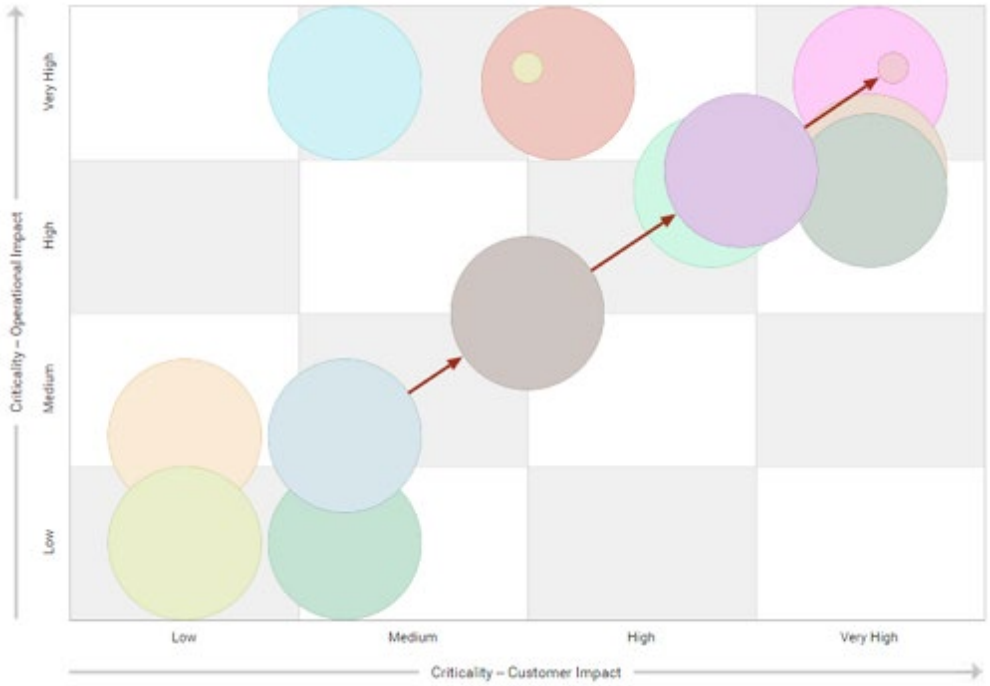
Configured portfolios show evaluations based on single indicator types. The configured report finds objects and their indicator values. The location of the object bubbles in the portfolio depends on the values defined for the indicator types for the X- and Y-axis. Optionally, the size of the bubbles in the configured report can vary depending on a third indicator defined as a third dimension (Z-axis) of evaluation.

- The way objects are represented in the portfolio can be changed from bubbles to different geometric shapes or icons. The coloring of geometric shapes is also configurable directly in the configured portfolio report.

- The background of the portfolio area can be colored with three different styles. A legend can be defined for the coloring.



- Connections can be drawn between objects in the portfolio report. A legend can be defined for the coloring.

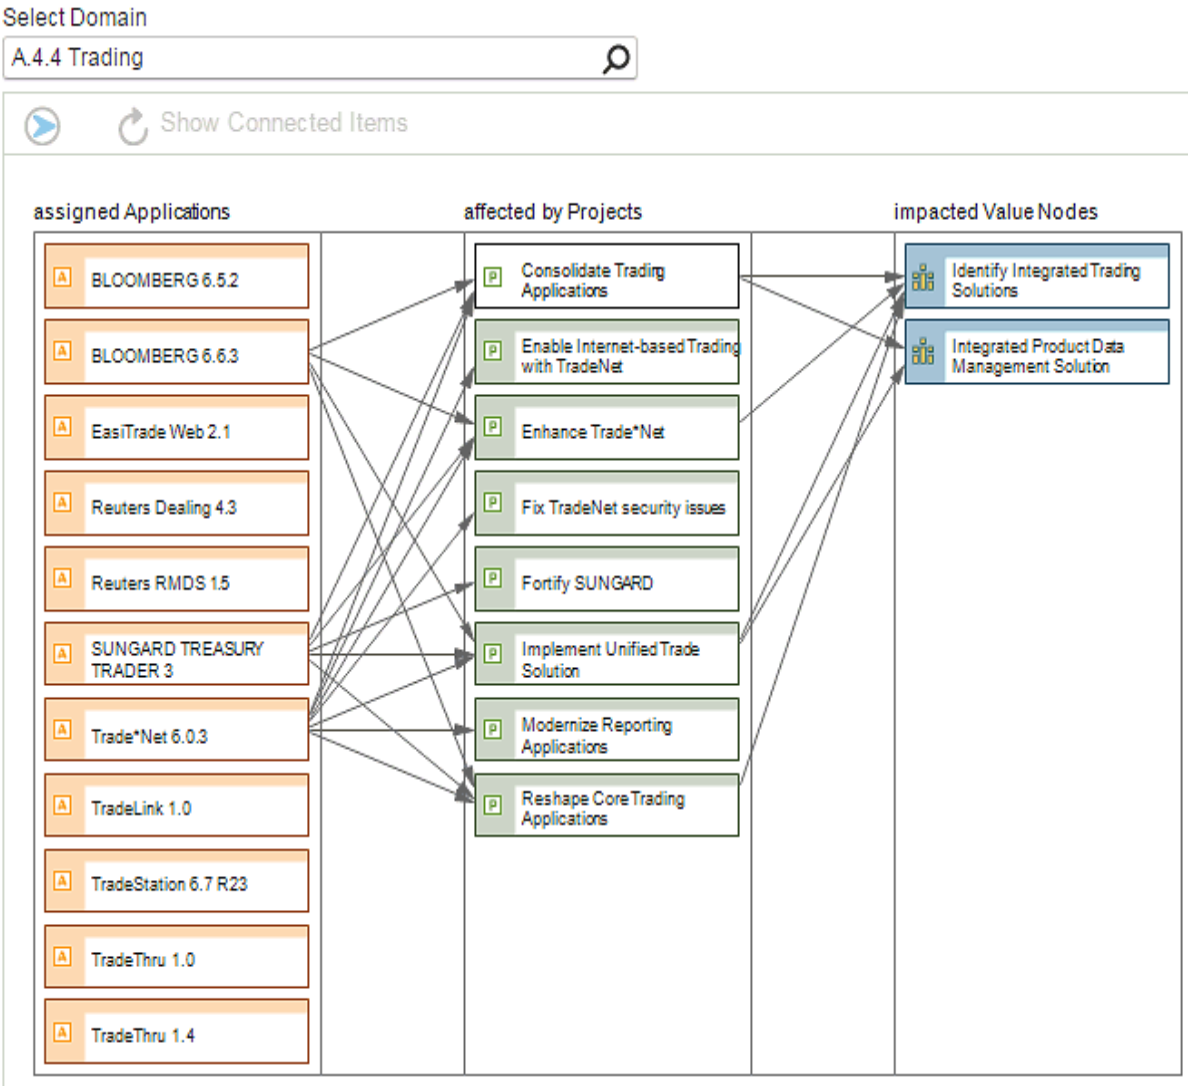


- The link target for navigation from objects in the portfolio is configurable and can open any Alfabet view. In standard portfolio views, navigation opens the object profile or object cockpit of the selected object.

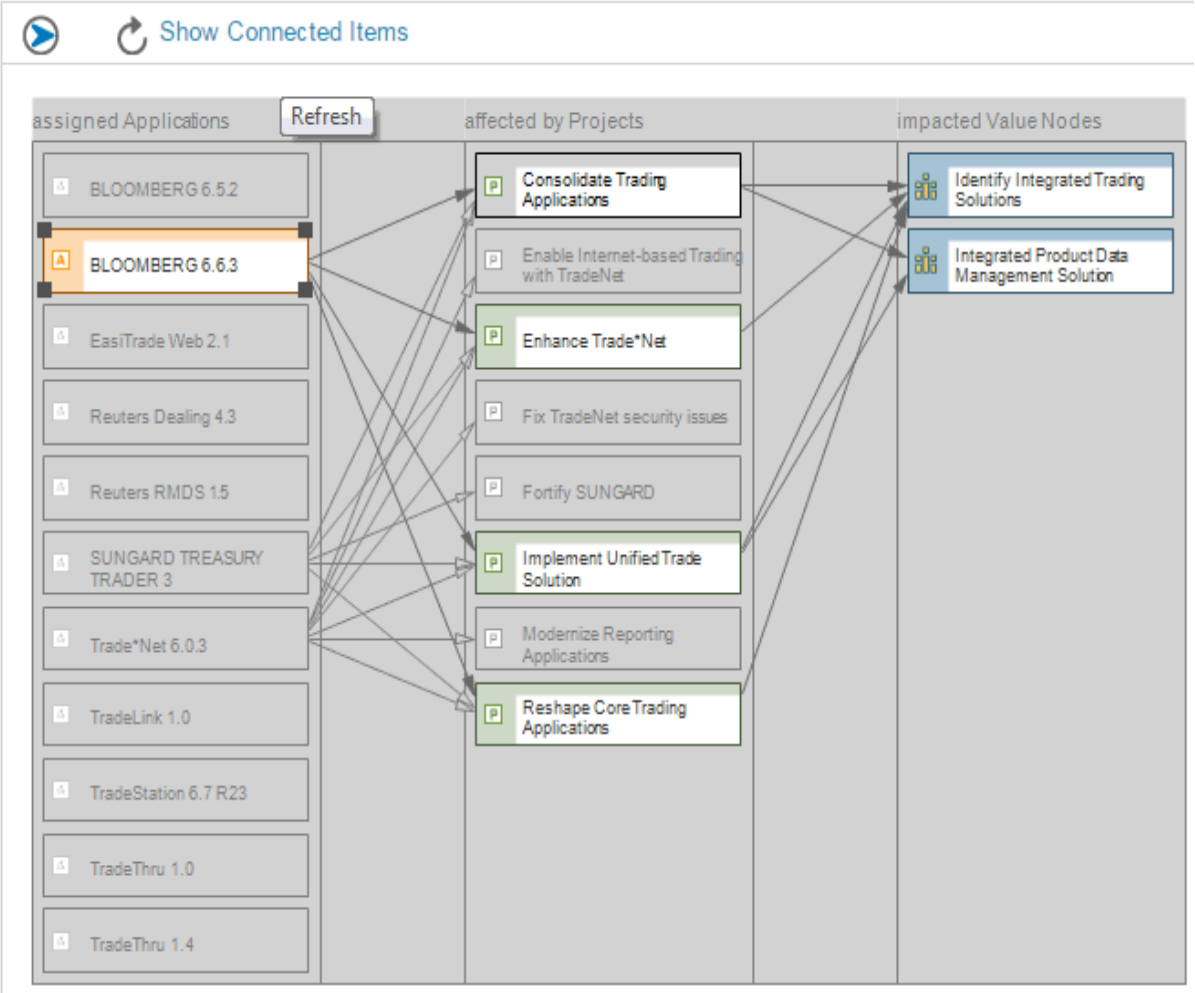
For a detailed description about how to configure a Portfolio report, see Defining Portfolio Reports.

Lane Report

A lane report displays different sets of objects in rows that are connected via links representing relations between the objects.



For a better overview, the objects directly connected to a selected object in the report can be highlighted by clicking **Show Connected Items** in the toolbar. All objects and connections not relevant for the selected objects are then displayed in light grey while the connections and objects related to the connected objects are displayed in the configured colors for the report:



For a detailed description about how to configure lane reports, see Defining Lane Reports.

HTML Table Report for Display of Indicators

Indicators for an object can be displayed in a table in HTML format in order to enhance the graphic visualization of indicator values.

For each indicator, a caption is displayed in the report that can be different from the name of the indicator. The value of the indicator for the selected object is displayed on the right. The indicator value is also displayed in a graphic format. Please note the following:

- If the indicator type that the indicator is based on has been configured to display icons rather than numerical values, the icon can be used to display the indicator.
- A scale can be included that displays the gradient of a configured maximum value that is reached by the indicator. The number of fields representing the gradient as well as the coloring and size of the gauge fields are configurable. A field will be colored if a numeric value lying in the range is reached. In the example below, a maximum of 200 was configured for the scale of Disaster Financial Amount of Loss. The indicator value of 70 is within the numerical range of 40 and 80 (2/5). Therefore, the first two fields are colored.

- The report can display up to 5 indicators. If you want more indicators to be displayed directly in an object view, then you must configure indicators to be displayed in any of the other types of configured reports, assign the report to the object view, and ensure that the report is expanded in the profile.

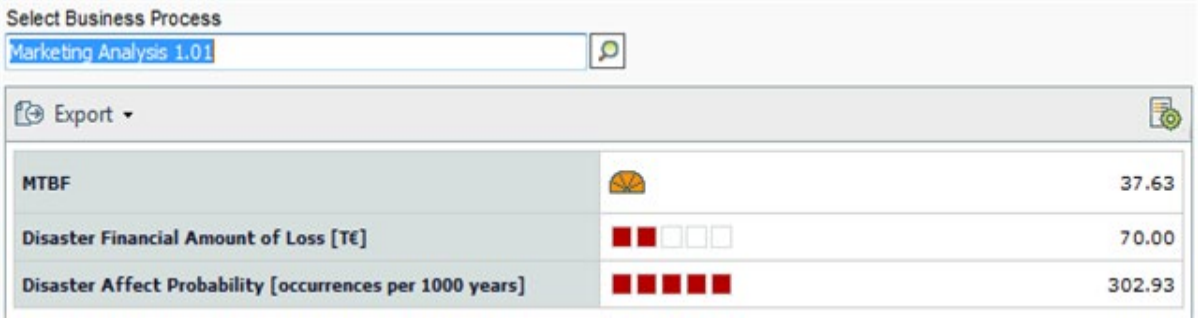


FIGURE: Example of HTML table report displaying indicator values for a selected business process.

HTML reports are configured reports of the type `Custom` and must be applied to an object class to specify the base object. An XML object must be configured in Alfabet Expand in order to define the graphic style and indicators to be displayed. The XML object is available via the attribute window of the report.

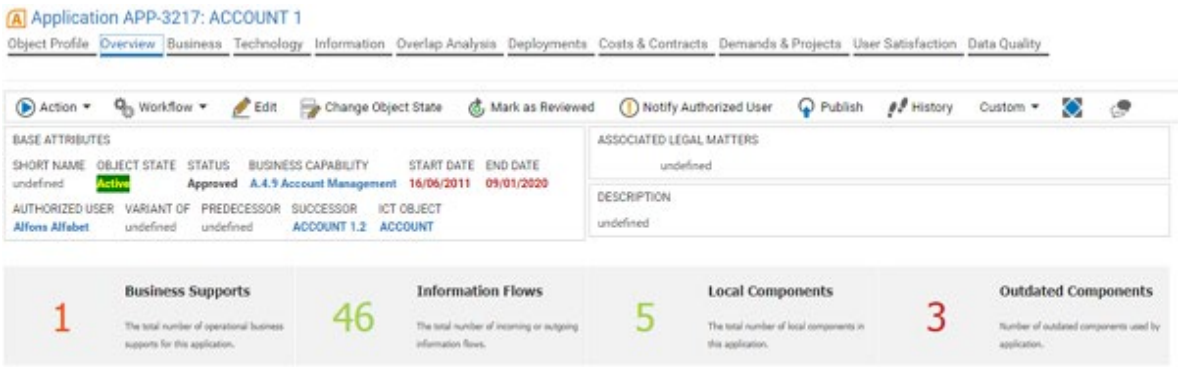
You can integrate HTML table reports in object views in order to provide the user responsible for the object with immediate information about the criticality of the object's indicators.

For a detailed description about how to configure an HTML table report, see Defining HTML Reports.

Widget Reports

A widget report is a small report displaying information in a predefined format. It is designed to fit into object cockpits to provide information in an easy to understand graphical manner.

For example, the object cockpit displayed in the image below contains four widget reports, each informing about the number of assigned objects of a specific subordinate object type (business support, information flow, local component and outdated component) for the current object:



Each information is a different widget report included into the object cockpit. The basic design of all widget reports in the example is identical. To ease configuration of a scenario with different widget reports equal in design, the design is defined in a separate configuration object called widget and reused for all configured widget reports. In the configured widget report, the widget is referenced and either static definitions or queries are defined to add images and text to the underlying text fields and image fields of the widget.

Coloring and font design can also be changed via the configured widget report. In the example above, text is changed from green to red to indicate critical numbers that may require changes to the selected application. The coloring is defined via the query that counts the number of subordinate objects.

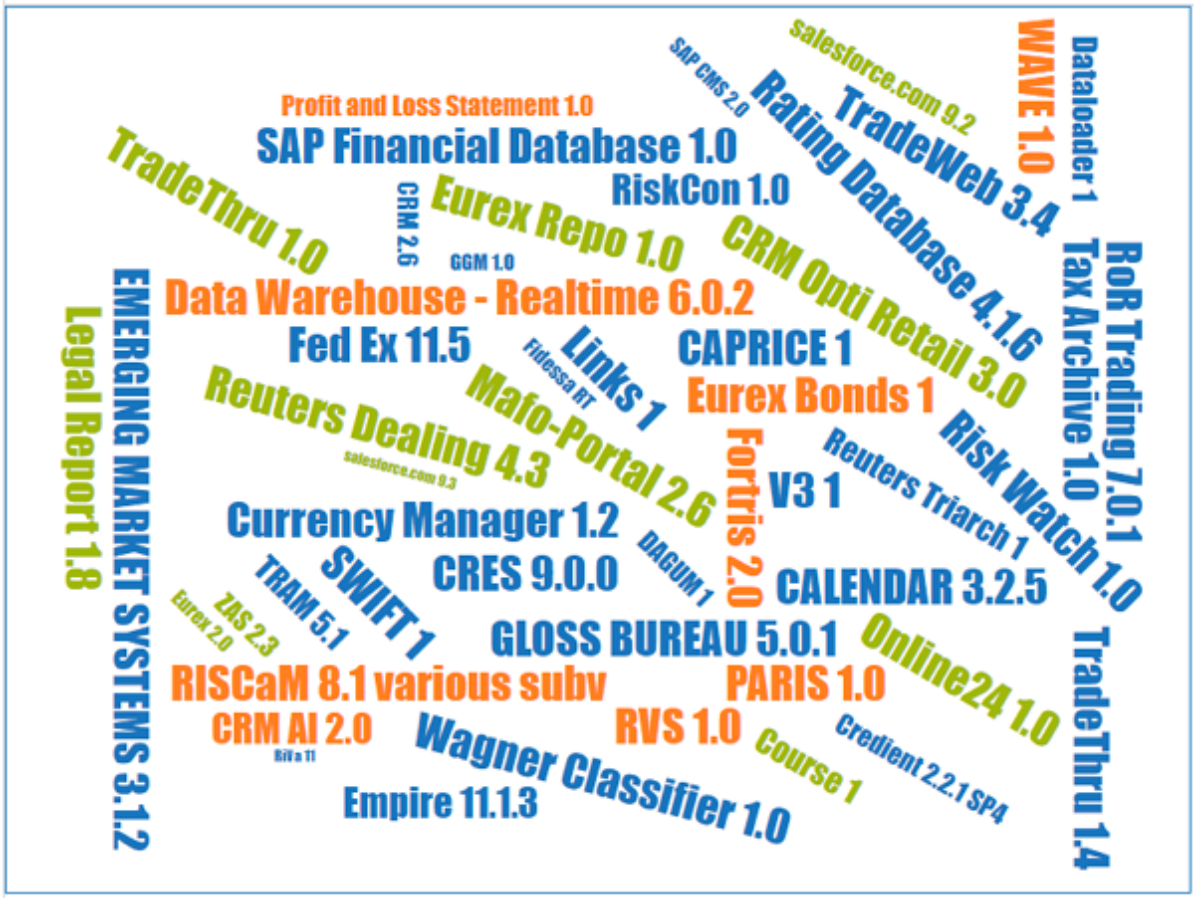
A widget report can contain multiple text and image elements. The following example for a widget report displays the object state of the current object in a graphic that shows the chronological order of object states available for an object as graphic elements and text. An arrow marks the current object state of the object. The location of the arrow is defined via a query. All other elements are static elements defined in the configured widget report for the underlying widget element.

Widget reports can also provide navigation from elements in the widget to Alfabet views both via the preview or via double-click on the element providing the link.

For information about defining widget reports, see Defining Widget Reports.

Words Cloud Report

A words cloud report displays textual information in a cloud where text color, text orientation and text size can depend on a configurable condition. In the example below, application names including version number are displayed in a words cloud with text size, text color and text orientation depending on the setting of three different indicators:



The text font type in words cloud reports cannot be changed. The font type displayed in the word cloud report is optimial for display in different font sizes and text orientations.

The algorithm of the words cloud report evaluates the location of text elements to make maximum use of the available space. Nevertheless, the space might not be sufficient to display all results found for the words cloud report. Above the report, the number of found and displayed objects is shown to inform the user about the completeness of information.

The position of elements in the report is re-calculated each time a user opens the words cloud report. Therefore, the position of each text element can vary even if no changes has been made to the underlying data.

A legend is available for the report as well as navigation to defined Alfabet views from the text strings in the report.

For information about defining words cloud reports, see Defining a Words Cloud Report.

Configured Reports Providing Ability for Mass Data Changes

Software AG provides configured report formats that allow a multi-editor for mass data update to be configured:

- Tabular Configured Report for Udate of Properties for a Selected Object Class
- Data Capture Matrix Reports for Business Supports or Object Relations

- Evaluation Reports

Tabular Configured Report for Udate of Properties for a Selected Object Class

Configured editable class view reports allow property values, indicator values and role responsibilities for selected objects of a single base class to be set. The configured report displays the objects in a tabular view based on a query. The user can select one or multiple objects in the result dataset and open an editor to change the property values.

The solution designer creating the configured report not only defines which properties are displayed in the tabular dataset, but also which properties are available in the editor of the configured report. These properties can be defined as view only to inform the user about data required for the setting of other properties, or as editable.

Edit permissions of the user are only taken into account if the configured report is configured to evaluate edit permissions. In the dataset, this is done via the query that may For example, restrict display to objects for that the current user is the authorized user. If the query of the configured report does not take editability of the object for the current user into account, the table will also display objects that are not editable.

In the editor, access permissions are taken into account if this is activated in the configured report configuration. If permission evaluation for the editor is configured, and the user selects objects in the dataset and opens the editor, only the subset of the selected objects that are editable by the user are displayed in the editor. If the user selects only objects that are not editable for him/her, an empty editor opens. If no objects are selected, the Edit button is deactivated.

A **Configure** button is available to the user that allows columns to be excluded from the configured report for the current user. Excluded columns are also excluded from the editor. The user can also change the number of freeze headers for the configured report, but a restructuring of the column order is not available for this type of configured report.

The toolbar contains two different options for editing objects. Both are only activated if objects are selected in the table:

- The **Edit** button opens an editor that lists the selected objects. If a property is not configured to be view only by the report designer, the user can set the property in the configured report. The way attributes are edited in the editor differs slightly from the processing in standard Alfabet editors. The edit field depends on the data type:
  - Properties of the type `String` are editable in a text edit field.
  - Properties of the type `Text` are editable in a text edit field with a pencil symbol on the right. If the user clicks the pencil, a wider text edit area opens to define long text.
  - Properties of the type `Text` based on an enumeration are editable via a multi-select combo box that lists all enumeration items of the enumeration the property is based on.
  - Properties of the type `String` based on an enumeration are editable via a single-select combo box that lists all enumeration items of the enumeration the property is based on.
  - The standard properties `Status` and `ObjectState` of the type `String` displaying an object state or release status a editable in a drop-down list.
  - Properties of the type `URL` can be displayed in the configured report and in the editor, but they are only available view only.

- Properties of the type `Integer` or `Real` are editable in a text edit field.
- Properties of the type `Date` are editable in a text field with a date picker on the right. The user can either type in the date in the correct format or select a date from the calendar in the date picker.
- Properties of the type `Boolean`: A checkbox is displayed that can be selected or deselected. For existing values, the checkbox is displayed as not checked if the boolean property is either not set or set to `False`.
- Properties of the type `Reference`: The solution designer configuring the report can configure which of the following edit options is available:
  - The reference can be set via a dropdown list displaying either all available objects of the object class or object classes that the reference is targeting, or a subset of these objects defined by the solution designer in the report configuration. The information displayed in the field is by default the object's name and, if applicable, the object's version with a whitespace as delimiter. This can be changed by the solution designer.
  - The reference can be set via an edit field with autocomplete functionality and, optionally, a selector button. When the user setting the reference in the editor types in text in the edit field, a dropdown list opens that displays all applicable objects in the Alfabet database with the name starting with the typed in text. A selection can then be made from the dropdown list. Objects are identified with the object's name and, if applicable, the object's version with a whitespace as delimiter. If the field is configured to provide access to a selector, the user can alternatively select the object from the selector.
- Properties of the type `ReferenceArray`: These properties are neither available in the tabular dataset of the configured report nor available for editing.
- Role Types: The solution designer configuring the report can configure which of the following edit options is available for a role type:
  - The role can be set via a dropdown list displaying either all users in the Alfabet database or a subset of users defined by the solution designer in the report configuration. The information displayed in the field is by default the family name followed by the first name with a whitespace as delimiter. This can be changed by the solution designer.
  - The role can be set via an edit field with autocomplete functionality and, optionally, a selector button. When the user setting the role in the editor types in text in the edit field, a dropdown list opens that displays all users in the Alfabet database with the family name starting with the typed in text. A selection can then be made from the dropdown list. Users are identified with the family name followed by the first name with a whitespace as delimiter. If the field is configured to provide access to a selector, the user can alternatively select the user from the selector. The users displayed in the autocomplete dropdown list are then limited to the users that are available via the selector.
- Indicators: How and if values can be defined for indicators depends on the configuration of the indicator.
  - For indicators with a range definition, the user can select one of the configured values from a dropdown list.

- Indicators that are automatically calculated are not displayed in the editor.
- For all other indicators, the user can set the value in a text field.

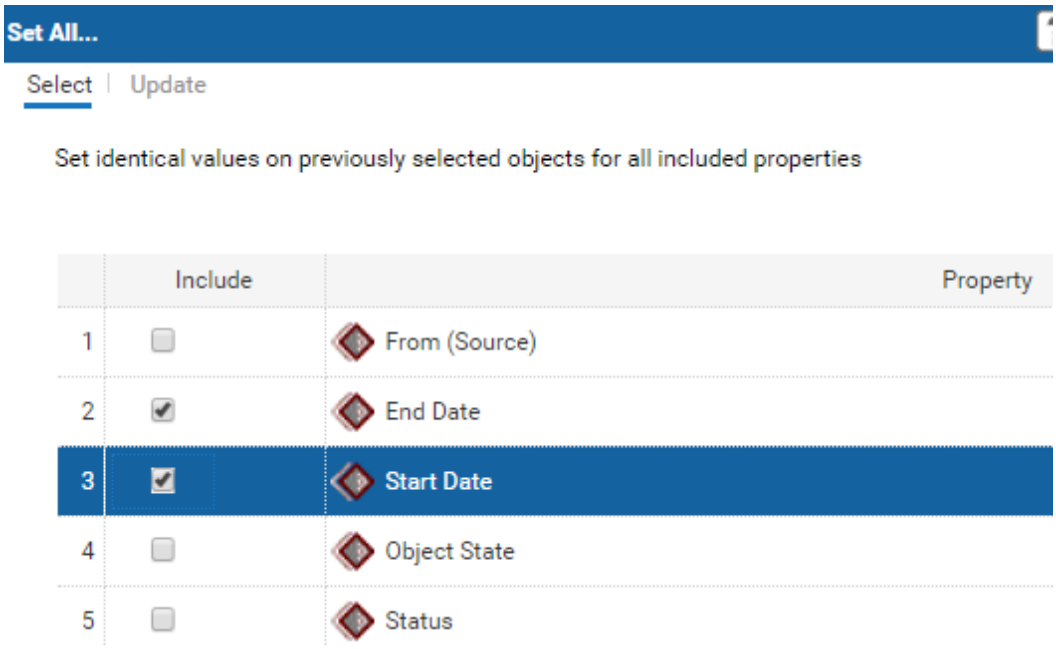
The editable fields in the configured report all display the default placeholder texts for the type of field. It is not possible to re-define placeholders, like For example, for editor fields.

If a value in a dropdown list is not fully displayed because it is longer than the width of the dropdown list field, the user can either change the size of the column in the editor to view a larger dropdown list area or move the cursor over the name that is not fully displayed. the full text is then displayed in a tooltip.

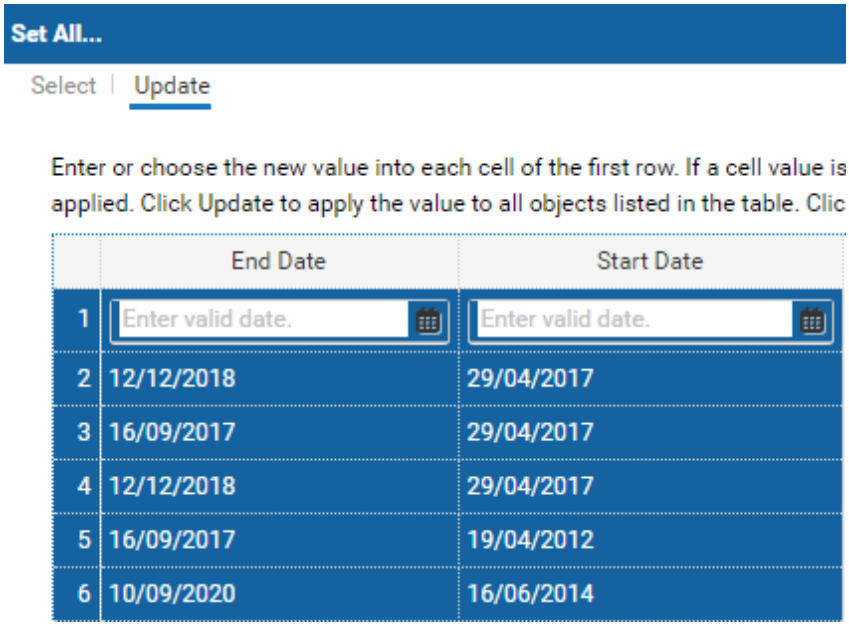
- The **Set all** button provides a dropdown list for selection of a data type. **Properties**, **Indicators** or **Role Types** can only be processed separately. The report designer can decide to remove properties, indicators or role types from the dropdown list. If properties, indicators and role types are all removed from the dropdown list, the button is not shown at all.

If a user selects an option from the dropdown list, an editor with two tabs opens:

- In the **Select** tab, the user must first select one or multiple properties to be defined:



- In the **Update** tab, a table is then displayed with one column for each selected property and one row for display of the current value of the property for each selected object. Above the listed values, there is a row with an editable field for each value. The value that the user sets in the editable field for a property will be applied to all selected objects after the user has clicked **OK** to close the editor. If the user does not provide a value for a selected property and clicks **OK**, the current values are removed from all selected objects.



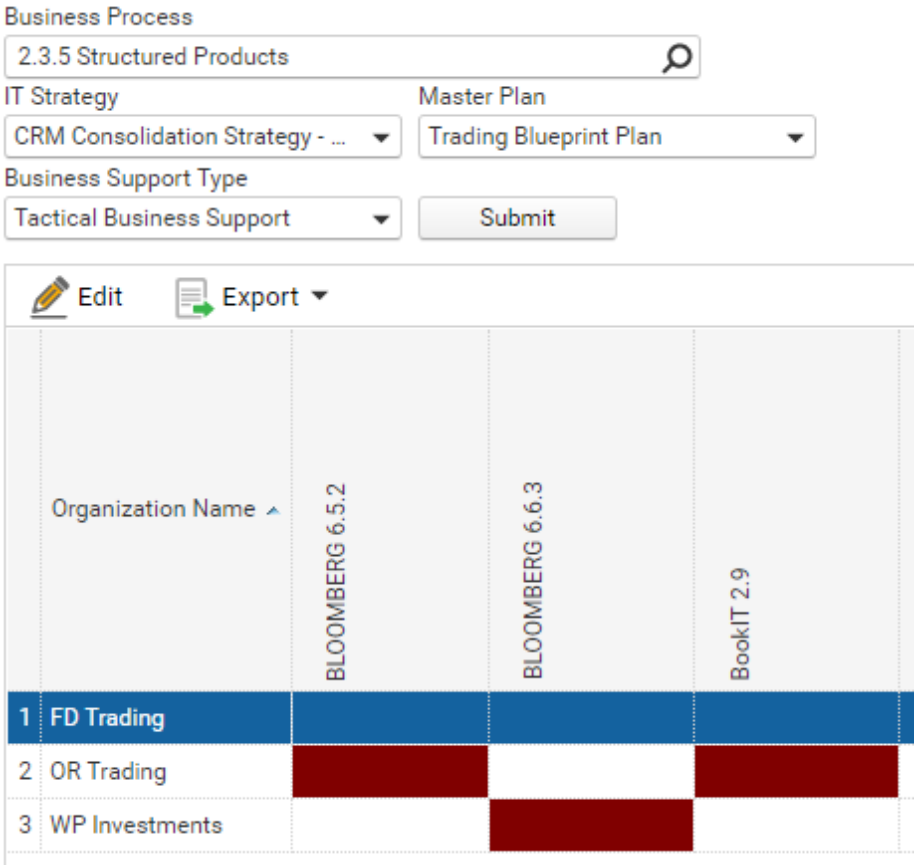
Data Capture Matrix Reports for Business Supports or Object Relations

Data capture matrix reports allow either business supports or relationships between objects to be defined by clicking relevant cells in a matrix. The matrix is customer defined and based on templates provided by Software AG. The objects displayed on the X-axis and Y-axis of the report are specified by the customer either in an Alfabet query or a native SQL query. A **Report Assistant** is available for the specification of rows and columns and for the relationship or business support defined in the matrix.

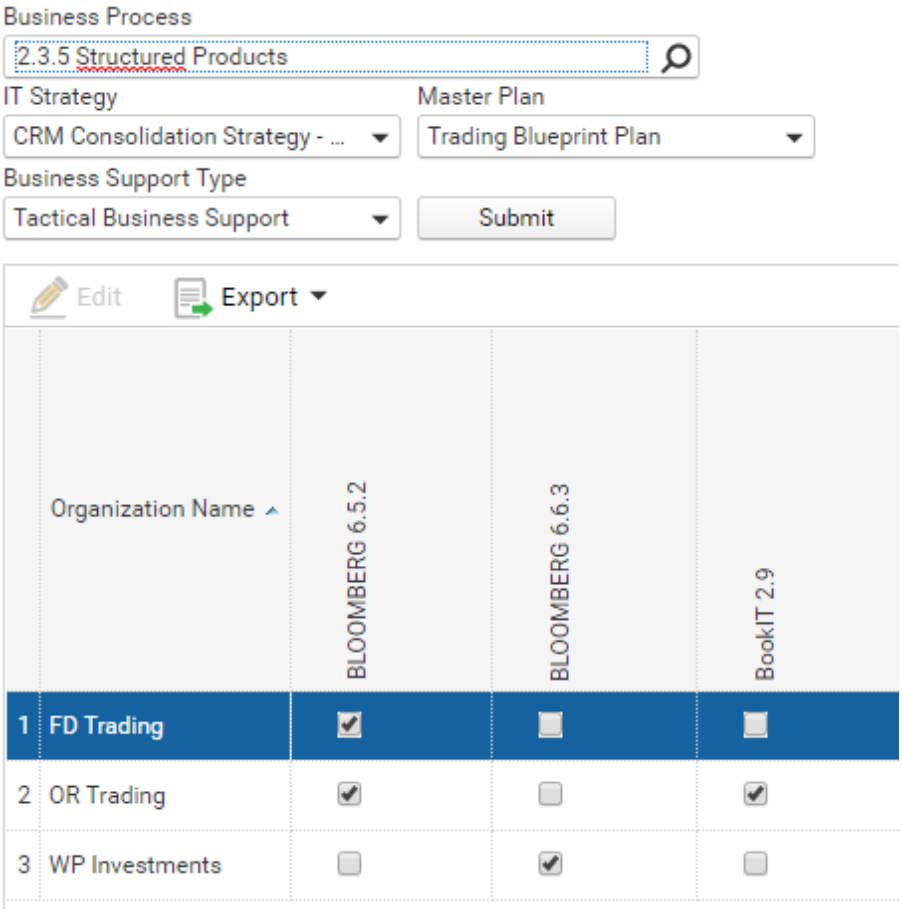
This kind of report can be used to provide multi-editing of relationships either in a separate view, opened For example, via an object view, a guide page or guide view or the Configured Reports functionality, or as part of a wizard.

The editability of the data depends on the configuration of the report.

- Business Support matrices display the existing settings in a matrix as colored bars in the matrix cells:



If the user clicks the **Edit** button in the toolbar, the matrix cells change to editable and display checkbox fields. The user can change the settings according to demands:



If the configured report is added to a wizard, the changes will be submitted when the user changes to the next wizard step. If the configured report is displayed as a separate view, the changes will be submitted when the user clicks the **Submit** button of the report. the view then changes back to display of the settings in a colored view-only matrix.

- For relationship matrices editability depends on the template used for the report. There is one template that permits direct editing within the report view. The matrix opens with all cells displaying editable checkboxes. It is recommended to use this relationship matrix in wizards. If the configured report is added to a wizard, the changes will be submitted when the user changes to the next wizard step. If the configured report is displayed as a separate view, the changes will be submitted when the user clicks the **Submit** button of the report. the view then changes back to display of the settings in a colored view-only matrix.
  - The template `Relationships_EditableTableReport` creates a configured report that permits direct editing within the report view. The matrix opens with all cells displaying editable checkboxes. It is recommended to use this relationship matrix in wizards. If the configured report is added to a wizard, the changes will be submitted when the user changes to the next wizard step. If the configured report is displayed as a separate view, the changes will be submitted when the user clicks the **Submit** button of the report. the view then changes back to display of the settings in a colored view-only matrix.
  - The template Relationships_TableReport creates a configured report displaying the current settings as colored cells in a non-editable matrix. To edit the values, the user must click the Edit button in the toolbar to open an editor that displays an editable version of the matrix. Changes are submitted when the user closes the editor.

Detailed information about the properties relevant for matrix-based maintenance reports supporting the multi-editing of objects is provided in the section *Analyzing Your Data in Page Views and Reports* in the reference manual *Getting Started with Alfabet*.

For a detailed description about how to configure a matrix-based maintenance report for multi-editing of objects, see Creating Configured Reports With Editing Capabilities.

Evaluation Reports

Evaluation reports allow indicator values to be edited for multiple objects in a table. An expandable row is displayed for each object in the table. A user can expand a row by clicking the + sign in front of a row in order to display the relevant evaluation types, indicator types and indicator values.

A separate row is displayed for each indicator type. The indicator types are sorted by evaluation type. The evaluation type is displayed in the **Evaluation** row. The evaluation type is displayed in the row of the first indicator type configured for that evaluation type.

Comments or icons defined for the indicator can also be displayed in the report. The report can either be configured to display existing indicator values only or to allow indicator values to be edited and comments to be written directly in the report table.

There are four ways to change an indicator in the report:

- Indicator values and comments assigned to the indicator can be written directly in the respective table cell if the report is configured to display the **Value** and/or **Comments** row. Depending on the configuration of the indicator type, indicator values can either be written into the **Value** cell or selected from a drop-down menu in the **Value** cell.
- Indicator values can be defined by selecting an indicator in the table, clicking the **Edit** button in the toolbar of the report, and editing the indicator value or writing a comment in the editor.
- If the same evaluation type is assigned to the parent and the child objects of a report and the report is configured to allow the same indicators to be set on both the parent and child level, the indicator values of the parent object can be batch copied to all child objects. If the row representing the parent object is selected, the toolbar option **Action** > **Copy Indicators to All Child Objects** can be used to take over the values for all relevant indicators on the child level.
- All computed indicators in the report can be recalculated using the toolbar option **Action** > **Compute Indicators for All Objects in the Report**.

  Please note the following about recalculation of computed indicators in the report:

  - The evaluation report can be configured to recalculate computed indicators when the user clicks the **Save** button. The option **Action** > **Compute Indicators for All Objects in the Report** is not available in reports that are configured to recalculate computed indicators each time indicator values are saved.

After changing one or multiple indicators, changes must be saved by clicking the **Save** button.

The object class Indicator has a property Name combining the indicator type and evaluation type names for the indicator. This property is not filled for new indicators created via an evaluation report, because the property Name of an indicator is obsolete and only available for backward compatibility reasons.

Computed indicators that are calculated automatically and cannot be set by the user are displayed in colored lines.

When the user selects an object in the report, an overview over the object data is displayed in a preview pane.

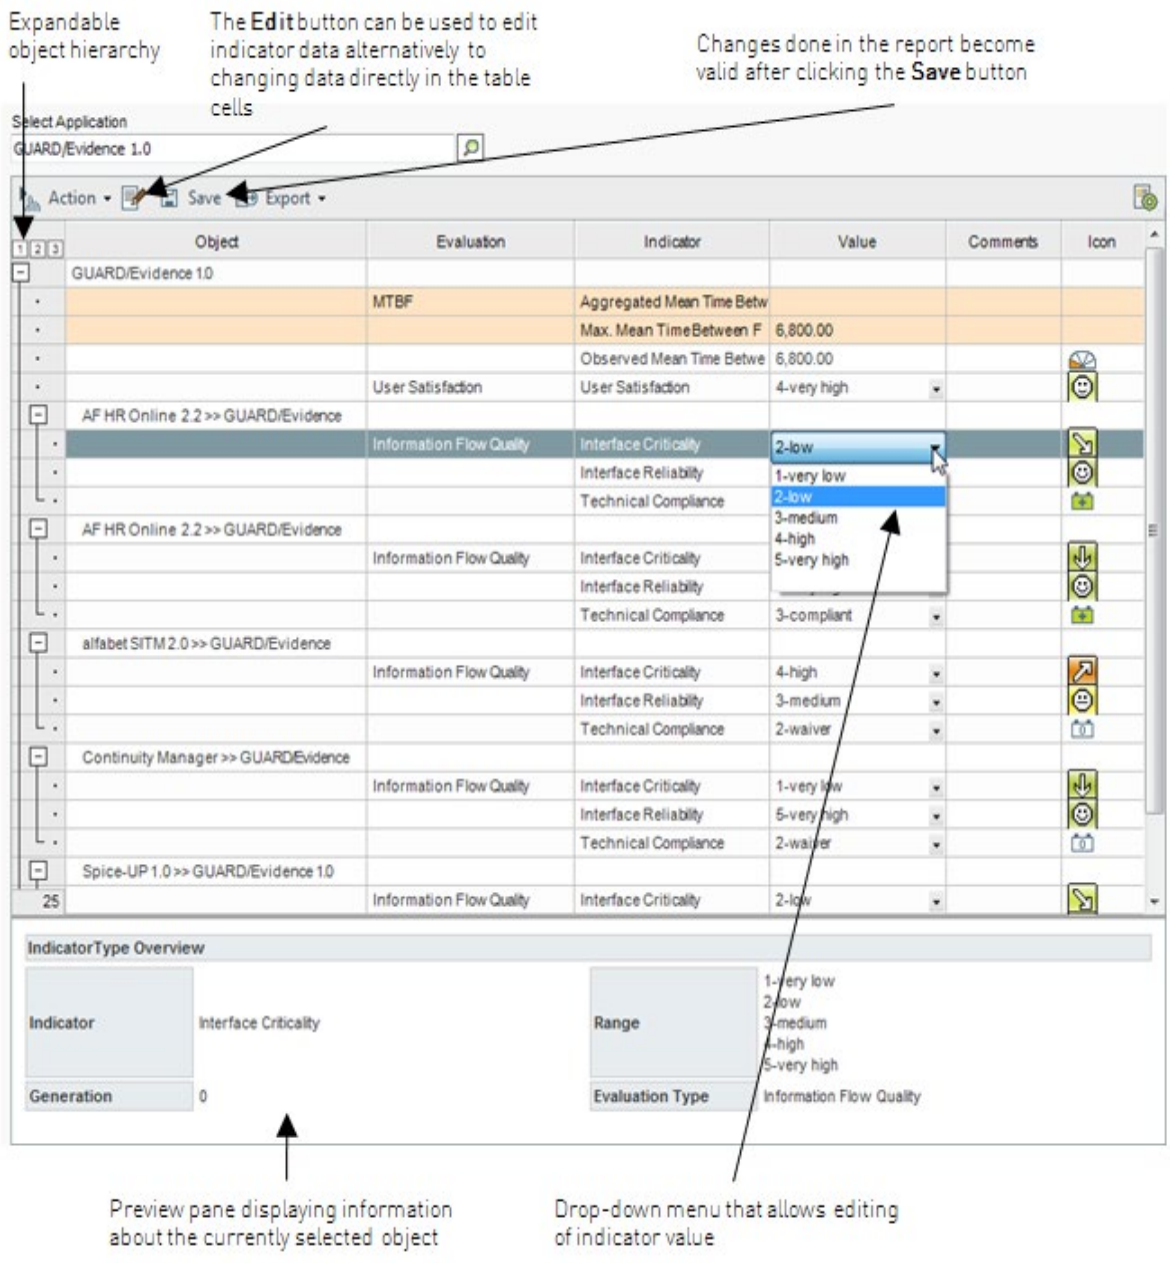


FIGURE: Evaluation report for the evaluation of a selected application and its incoming information flows

If the configured evaluation report is embedded into an object cockpit, editing is deactivated.

For a detailed description about how to configure an evaluation report, see the section Configuring a Report for Multi-Editing of Indicators.

Presenting Object Views or Object Cockpits in Configured Reports

Configured reports can be configured to display object views or object cockpits to provide access to data for an object class that the user doesn't have access to by means of the functionalities assigned to his/her user profile. While an object view is a workspace that provides access to a number of subordinate views for evaluating and editing of data, an object cockpit features a specified set of reports that the user can view directly in the cockpit.

Configured reports can provide access to one of the following:

- The object view of an object class configured in the ***Presentation*** tab of Alfabet Expand.
- An object cockpit configured for an object view in the ***Presentation*** tab of Alfabet Expand.
- An object cockpit defined directly in the configured report. In contrast to object cockpits defined for object views, an object cockpit defined in a configured report can have a filter area on top of the report and filter settings can be applied to all reports displayed in the object cockpit.

Configured Reports opening Existing Object Views or Object Cockpits

Configured reports of the type `ObjectView` can display object views or object cockpits configured for custom object views that feature a specified set of reports available for the object. In the report configuration, the object class must be defined as well as the relevant object view or object cockpit that you want to display. The user opening the configured report must select an object of the specified object class in a selector in order to view either the relevant object view or object cockpit.

If multiple object cockpits are defined in a custom object view, the availability of object cockpits via the configured report is controlled by the view scheme configuration of the user profile used when opening the configured report.

Configured reports of the type `ObjectView` can be used, For example, to provide access to data for an object class that the user doesn't have access to by means of the functionalities assigned to his/her user profile. For a detailed description about how to configure a report of the type `ObjectView`, see Creating an Alfabet Configured Report That Opens an External Report.

Configuring Console Reports

Console reports are configured reports of the type `Custom` that include an object cockpit definition that is directly defined within the configured report and an optional filter area. The filter area can be defined to apply filter settings to all configured reports that are either included into the object cockpit definition or opened via navigation from one of the configured reports in the object cockpit.

Please note that console reports are not suitable for the use in:

- Publications

- The Mobile Portfolio Manager
- Object Cockpits
- Object Views
- Wizards

If a console report is added to a publication or opened via the Mobile Portfolio Manager, the first subordinate report added to the console report is displayed instead of the console report.

For a detailed description about how to configure a console report see Creating Console Reports.

Combining Multiple, Cascading Reports in One View

Multiple reports can be combined in one view and configured to be cascading. When a user clicks an object in the report that is configured to be the master report, the data in the subordinate report changes and displays information related to the selected object.

In the example below, a graphic representation of domains that are sub-domains of a selected domain is displayed. As subordinate report, a tabular report displaying information about the applications assigned to the domain currently selected in the master report.

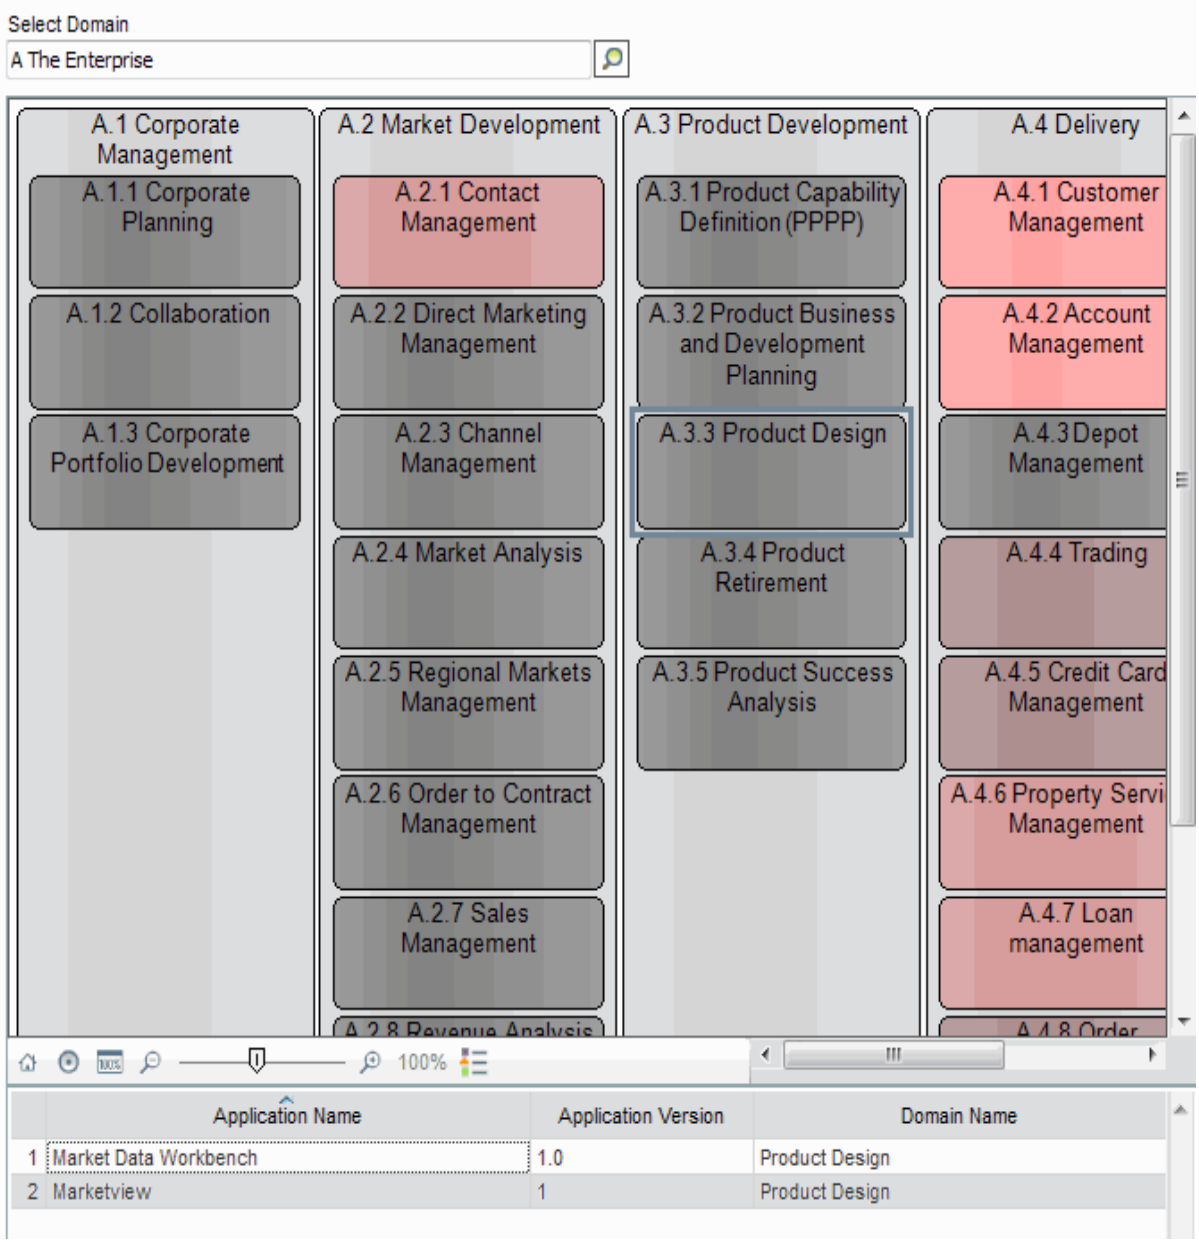

FIGURE: Cascading report with a master and a subordinate report

For a detailed description about how to configure a cascading report see Creating Cascading Reports.

Presenting Geographically Relevant Data in Maps

For international companies it might be useful to present the geographic relevance of data in geographic maps. For example, to display which locations depend on support from applications from other locations or how many deployments of an applications are available in which region.

In Alfabet, geo map reports displaying geographic maps based on FusionMaps® from FusionCharts that can be configured to display data from the Alfabet database. Regions or countries in the map can be colored according to their relevance with regard to specific data in the Alfabet database. Markers can be set at customer defined locations. The markers can differ in coloring and size according to their relevance with

regard to specific data in the Alfabet database. Connecting lines can be configured to display dependencies between markers. When a user moves the mouse over an element in the map, a tooltip is displayed. The information displayed in the tooltip is configurable in the report configuration. For color codings, a legend can be added to the report.

Multiple geo map reports can be connected with each other. For example, a world map can be configured to open a map of the respective country if a user clicks on the country in the world map.

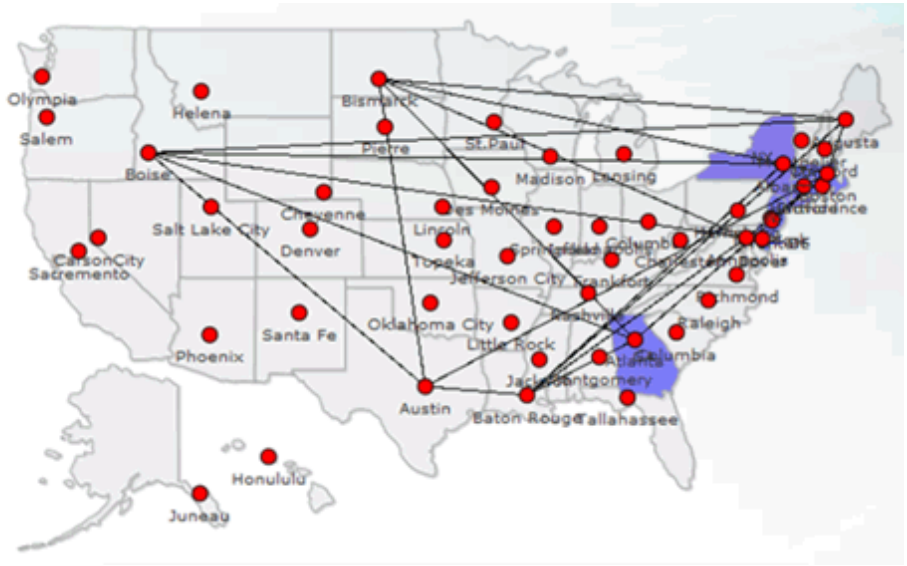

FIGURE: World map displaying interconnected markers and colored regions

For a detailed description about how to configure a geo map report, see Creating Geo Map Reports.

Integration of External Reports

You can include any report generated by third-party components (For example, reporting tools) in the Alfabet interface. The external reports are generated independently of any Alfabet components. An external report is accessible in the Alfabet interface via a configured report of the type `Extern` that basically consists of a link to its URL. When the user accesses the configured report from the Alfabet interface, the external report will open in a new window and the user will work outside of the Alfabet interface as long as he/she works with the external report.

It is possible to scan the Alfabet database with standard SQL in order to present the data in the external report. Software AG also provides a link syntax that is required in order to link from an external report to the Alfabet interface.

You can include either static external reports or external reports that are executed at runtime.

For more information about configuring the interfaces for external reporting, see the section *Accessing the Alfabet Database with External Applications* in the reference manual *System Administration*.

The following table describes the advantages and disadvantages of Software AG 's internal mechanism of reporting versus the use of external reporting tools:

Type	Data Collection and Presentation	Advantages	Limits

`Query`
 	
`Custom`
 	
`ObjectView`
	You can use the Alfabet query language or native SQL to find objects in the database and display the results of the query either in a configurable table or in a treemap report or layered diagram report in the Alfabet interface. Alternatively, you can configure reports that display object views of objects in the database or display an object cockpit showing a specified set of reports available for the object. The query-based reports are executed by the user at runtime and display the current results.
	
	You can use the tool Alfabet Expand to define the configured report. The query-based configured report allows you to customize the information available in the Alfabet interface.
		Knowledge about SQL query language or a scripting language or other programming skills are not required.
		
		The access rights defined for objects in Alfabet apply. This includes authorized access and mandate-specific access rights.
		
		It is possible to navigate to the object views of object's in the report during the same Alfabet session.
			Data from data sources other than the Alfabet database cannot be included in the results.
			
			The display of results is limited to the formats designed by Software AG.

`Extern`	You can include any report generated by third-party components (For example, reporting tools) in the Alfabet interface by referencing the URL of the report. These external reports of the type `Extern` are generated independently of any Alfabet components. An external report is accessible in the Alfabet interface via a report that consists of a link to its URL. When the user accesses the report from the Alfabet interface, the report will open in a new window and the user will work outside of the Alfabet interface as long as he/she works with the report. It is possible to scan the Alfabet database with standard SQL for the presentation of data in external reports. Alfabet also provides a link syntax in order to link from an external report to the Alfabet interface. You can include either static reports or reports that are executed at runtime.	The means to visualize the results via graphics are enhanced, as they depend exclusively on the external tool used to generate the report.	Knowledge about the SQL query language and the handling of the external reporting tool or scripting language is required for the report. The access rights to objects configured in Alfabet (authorized access and mandates concept) do NOT apply to the results displayed in reports. When a user accesses the Alfabet interface via a link from an external report, a new Alfabet session will open and the user might see only the view or the view based on a different user profile.

For a detailed description about how to integrate an external report into the Alfabet interface, see Creating an Alfabet Configured Report That Opens an External Report.

General Guidelines for Creating Configured Reports

Customer configured reports can be created using the following tools:

- Alfabet Expand
- The **Reports Administration** functionality of Alfabet provides a subset of the functionalities for configured report creation and editing for demonstration purpose. Only configured reports of the type `Extern`, `Query` or `NativeSql` can be created in the **Reports Administration** functionality. It is recommended that you use Alfabet Expand in stand-alone mode for configured report creation.

Configured reports can be created and edited during runtime of the Alfabet Web Application. To avoid conflicts resulting from a user executing a configured report at the same time that the configured report is edited by a solution designer, the configured report is either editable or can be executed depending on the setting of the **Report State** attribute of the configured report. A configured report can have the following **Report State**:

- ***Plan***: A configured report that is in a `Plan` state may have modifications made to the configuration and is not accessible in the Alfabet interface:
  - The configured report is no longer available in the list of configured reports that can be added to the **Configured Reports** view.
  - If a user already added the configured report to his/her table in the **Configured Reports** view, the configured report remains in the table, but the button **Open Report** is deactivated for the configured report.
  - If the configured report is added as a view to an object profile, the user opening the configured report is informed that the configured report is currently under construction.
- ***Active***: A configured report that is in an `Active` state can no longer be edited and is visible to authorized users in the **Configured Reports** functionality and optionally on **Configured Reports** page views of object profiles. Configured reports assigned to object profiles or used in the **Compliance Management** functionality are visible in the Alfabet interface independent of the configured report's **Report State**.

  If the report view for a configured report is opened in the central editor pane of Alfabet Expand and the **Report State** of the configured report is set to `Active`, the report view editor is not closed and the content of the report view is still editable, and changes can be saved for the configured report as long as the editor pane is not closed.

- ***Retired***: Once a configured report is set to `Retired`, it can no longer be accessed in the **Configured Reports** functionality and optionally on **Configured Reports** page views of object profiles. Configured reports assigned to object profiles or used in **Compliance Management** functionality are visible in the Alfabet interface independent of the configured report's **Report State**.

In Alfabet Expand, the attribute **Report State** is not editable in the attribute window for the configured report.

Do the following to change the **Report State** attribute of a single configured report:

1) In the explorer of the **Reports** tab of Alfabet Expand, right-click the configured report for which you want to alter the **Report State** attribute and select **Set Report State to 'Plan'**, **Set Report State to 'Active'**, or **Set Report State to 'Retired'**.

The **Report State** attribute of the configured report is changed according to your selection. It is not required to save this change via the **Save** button.

To change the **Report State** attribute of all configured reports in a report folder:

- In the explorer of the **Reports** tab of Alfabet Expand, right-click the report folder for which you want to alter the **Report State** attribute of all subordinate configured reports and select **Set Report State to 'Plan'**, **Set Report State to 'Active'**, or **Set Report State to 'Retired'**.

The **Report State** attribute of all configured report that are subordinate to the report folder is changed according to your selection. This includes all configured reports directly located in the folder and all configured reports located in sub-folders of the report folder. It is not required to save this change via the **Save** button.

Please consider the following when editing configured reports during runtime of the Alfabet Web Application:

- When configured reports that are already available to the user community are changed during runtime of the Alfabet Web Application, changes may become visible to the users with a delay of about 10 minutes. Configured reports are stored in a cache that is updated in regular intervals. Change to a configured report will become valid with the next cache update. Alternatively, restart the Web server to load the configured report to the cache of the Alfabet Web Application.

It is recommended to follow the best practice procedure described below for configuring reports. Next to best practice procedure, this section describes configurations with general relevance for configured reports:

- Best Practice Procedure for Configuring Reports
- Using Server Variables in Web Link and Database Server-Related Specifications
- Restriction of Database Access Permissions on Execution of Configured Reports
  - Using an Alfabet Internal ReadOnly User for Report Execution
  - Configuring Database Users With Explicit Access Rights for Individual Configured Reports
- Restricting Access to Administrative User Profiles
- Activating Navigation From Reports to Object Classes Not Automatically Offering Navigation
- Specifying Custom Help for a Configured Report
- Assigning a Category for Specific Functional Use to a Configured Report
- Handling Long Running Reports
  - Defining an Execution Timeout for Long Running Reports
  - Open Tabular Reports with Filters Without Immediate Execution
  - Configuring Offline Execution for Long Running Tabular Reports with Filters
- Analysis of Reports via the Semantic Analyser
  - Adding an Object Class to the Semantic Analysis
  - Adding an Object Class Property to the Semantic Analysis

- Removing Manually Added Entries From the Semantic Analysis

Best Practice Procedure for Configuring Reports

Configured reports shall be created in a design environment and tested prior to use in the production environment. The report configuration of the test environment can then be saved together with other configurations to an updater file or separately into an XML file and read or merged into the production environment during a short, planned server outage.

The advantages of this procedure are:

- Avoidance of complaints about unavailability of page views in object profiles because users cannot distinguish between standard Alfabet views or configured reports in the customized object profiles and would regard unavailability because of configuration maintenance as software malfunction.
- Maximum security of data integrity in the Alfabet database. Configured reports can also be configured to allow objects to be edited directly in configured reports. Therefore, report configurations should be thoroughly tested in a test environment before they are implemented in the production database to make sure that no access permission violations are incurred by the report configuration.
- Ad-hoc reports required to answer one-time questions about data in the Alfabet database can be configured and executed in the test environment without the need to specify access permissions that inhibit visibility to users other than the executing administrator.

Normally, Ad Hoc reports should not be part of the configuration that is later used in the production environment. If you create reports for one-time execution only at the root level directly below the **Reports** folder and store all other configured reports in sub-folders of the **Reports** folder, you will be able to batch delete all Ad Hoc reports without losing relevant reports. To do so, right-click the **Reports** folder and select **Delete All Root Reports**. Configured reports on the root level will be deleted while the configured reports in the sub-folders are still available.

The configuration of all available types of configured reports is described in detail in the following sections.

After completion of the report configuration in the test environment, you can use one of the following methods to import the report configuration to the production environment:

- The configuration of reports can be saved to an AMM update file either separately or in combination with other configurations specified in Alfabet Expand. The AMM update file can then be used to replace or merge the configuration in the updater file with the configuration of a target database. This method requires that you are using Alfabet Expand in stand-alone mode. It is part of the overall database update methods and described in the chapter Applying Configuration Changes to Other Databases.
- The configuration of all configured reports, the content of a report folder or a single configured report can be saved to an XML file. This file can be merged with the report configuration in a target database or replace the report configuration in the target database. The method is available in stand-alone and remote mode. The procedure is described below.
- The configuration of a single configured report can be directly copied from one environment to another if both Alfabet Expand tools connecting to the test and the production environment are run

on the same machine using the copy and paste functionality. The method is available in stand-alone and remote mode. The procedure is described below.

To update the report configuration of the production environment with all or part of a configuration from a test environment stored in an XML file:

1) In the test environment, open Alfabet Expand.
2) In the **Reports** tab, right-click the folder **Reports** and select **Save As**.
3) In the explorer window that opens, select a location for the XML file that is accessible via Alfabet Expand in the production environment and click **Save** to save the file.
4) In the production environment, open Alfabet Expand.
5) In the **Reports** tab, right-click the folder **Reports** and select one of the following:
   - **Replace from File** to overwrite the current configuration with the configuration in the XML file. The whole report configuration is deleted and then the configuration stored in the XML file is applied. That means that all configured reports and report folder in the XML file will overwrite corresponding objects in the database. Database objects that have no corresponding object in the XML file will be deleted.
   - **Merge from File** to merge the current configuration with the configuration in the XML file. All configured reports in the XML file will overwrite corresponding configured reports in the database. Database objects that have no corresponding object in the XML file will remain unchanged. Configured reports that are only available in the XML file will be added.
6) In the explorer window that opens, select the XML file with your new report configuration.
7) Confirm the warning message. The report configuration in the production environment is changed.

To update a single report configuration of the production environment or add a single report from the test environment:

1) In the test environment, open Alfabet Expand.
2) In the **Reports** tab, right-click the configured report that you want to copy to the production environment and select **Copy**.
3) In the production environment, open Alfabet Expand.
4) In the **Reports** tab, right-click the root folder **Reports** or the report folder in which the configured report shall be updated or added, and select **Paste**. The configured report is added to the report configuration in the production environment or, if a configured report with the same technical name existed in the production environment, that configured report is updated.

After replacing or merging a report configuration and after upgrade to another Alfabet release, it is recommended that you test whether changes in the meta-model require you to adapt configured reports to the new model (For example, to change a `JOIN` or a `WHERE` statement in an Alfabet query) A test mechanism is provided that controls whether the Alfabet query of a configured report matches the current meta-model. The test can be conducted for all configured reports, all configured reports in a report folder, or for a single configured report.

You can define queries for Alfabet configurations in native SQL instead of the Alfabet query language, but the test mechanism described here only tests queries defined in the Alfabet query language.

To test the configuration of configured reports, carry out one of the following steps:

- In the **Reports** tab, right-click the folder **Reports** (or a report folder or a configured report) and select **Check and Update AQL Based Reports**. An error report is generated in Microsoft® Word® format.
- In the Alfabet Expand menu bar, select **Meta-Model** > **Check All AQL Queries**. An error report is displayed directly in Alfabet Expand and allows you to navigate to incorrect Alfabet queries directly from the report. For more information about locating and correcting errors with this functionality, see Testing Queries for Compliance with the Current Release in the section Defining Queries.

The procedure to define a configured report will depend on the type of configured report you plan to create. Therefore, the definition of configured reports of different types is described separately in the following sections.

The attributes that can be defined for a configured report are specific to the type of configured report that is being created. The following descriptions list all attributes that can be defined for the specific type of configured report you are defining. If an attribute is not mentioned, it is not possible to set it for the selected report type.

Using Server Variables in Web Link and Database Server-Related Specifications

The definition of server variables allows information For example, about the target of web links to be defined in the server alias configuration. Defining the information about the URL in the server alias configuration instead of directly defining it in the configured report definitions eases the propagation of changes.

For example, the configuration of external reporting for Alfabet is done first in a test environment, and the test environment is an exact copy of the production environment except that the components are installed on different servers. Therefore, all URLs defined will be identical in the test and the production environment except for the Web server name. When migrating to the production environment, the Web server name must be changed in all URL definitions in Alfabet Expand. But if the server name is defined as server variable in the server alias, the configurations done in Alfabet Expand reference the Web server name as variable in the URL definition and can be reused without changes in the production environment. Only the variable definition in the server alias of the production environment must be set to the current Web server.

Server variables are defined in the Alfabet Administrator:

1) In the Alfabet Administrator, click the **Alfabet Aliases** node in the **Administrator** explorer.
2) In the table on the right, select the server alias that you want to define a server variable for and click the **Edit**  button. The alias editor opens.
3) Go to the **Variables** tab and click the **New** button. A dialog box opens.
4) In the **Variable Name** field, enter a unique name for the server variable.

   The server variable name may only contain letters (English alphabet), numbers, and the underscore symbol.

5) In the **Variable Value** field, enter all or part of the URL that should be the target of the Web link.

   If the Web link contains a special character according to XML standards (For example,: &, %, ;,<,>), these characters must be replaced by their XML conformant variant (For example,: `&` for &)

6) Click **OK** to save your changes. The server variable definition appears in the list of server variables.

To edit or delete the server variable, select the server variable in the table and click the **Edit** or **Delete** button below the table.

7) Click **OK** to save your changes and close the editor. The server variable definition is now available in the server alias configuration and can be used for the URL definition specified in Alfabet Expand.

You can use the server variable definitions in the following configurations for configured reports:

- in the definition of the **URL** property of external reports of the type `Extern`.
- in the definition of the **Help Index** attribute and **Custom Help Index** attribute of any configured report. For more information about configuring custom help, see the section Specifying Custom Help for a Configured Report or the chapter Providing Custom Online Help to the User Community.
- in the definition of database user names and passwords in the XML object ***DatabaseUsers*** that allows database access permissions to be restricted for configured reports of the type `Query` and `NativeSQL`.
- in any query results the content of a cell can be replaced with the value of a server variable using the instruction ReplaceServerVariable. For more information, see Adding the Value of a Server Variable to the Dataset.

A variable is referenced as `$`<server variable name>. For example, a server variable called `SQLSERVER` is referenced as `$SQLSERVER`.

In the definition of the **URL** property of external reports and in the definition of the **Help Index** attribute and **Custom Help Index** attribute of any configured report, the variable definition can either substitute the whole connection string or only part of the connection string. It is also possible to build the URL from a number of concatenated server variables. For the definition of database users in the XML object ***DatabaseUsers***, the value of a database user name and password can only be substituted completely with a server variable.

For example, an external report hosted on the company Web server is first tested on a test Web server. Therefore, the following Web server variables are defined in the server alias:

- `WEBSERVER`, specifying the Web server used
- `APPLICATION`, specifying the virtual directory for the referenced external reporting functionality on the Web server

The URL definition in the configuration of the dynamic Web link contains the variables instead of the current Web server name and virtual directory thereof:

```
HRef=http://$WEBSERVER/$APPLICATION/OrganizationReport.aspx
```

The definition is automatically converted into a valid link containing the values of the server variables. For example,:

```
HRef=http://localhost/Reports/OrganizationReport.aspx
```

Restriction of Database Access Permissions on Execution of Configured Reports

On the database server, multiple users can be created for a database with restricted rights. Users can have restricted rights for the complete database, like For example, read only rights or even different access rights to different database tables, like For example, read only access to one table only while access to other database tables is completely denied.

The database user that is used for connections from the Alfabet Web Application to the database server for access of the Alfabet database has very extended rights. You can configure all or individual reports to be executed with a database user different from the standard database user for connections from the Alfabet Web Application to enhance security. There are two levels of restrictions:

- The Alfabet Web Application can be configured to use a user with restricted access permissions for executing all configured reports. The database user is automatically created on the database server during installation and has read only access permissions to the database This option should not be selected if data cube based configured reports shall be executed. Access permissions of the automatically created database user with ReadOnly access do not allow cube processing.
- SQL users with password having specific access permission rights can be defined by the customer on the database server. The configured reports can then be configured to be executed with one of the customer defined database users. If a user opens a configured report and the database user defined for the execution of the configured report does not allow report execution, an error message informing the user about the inadequate access permissions for report execution and asking him/her to contact the system administrator for resolution of the issue. This method is currently only available for configured reports of the type `Query` and `NativeSql`. For configured reports of the type `Query` and `NativeSql`, the user of custom configured database users supersedes the configuration to use the Alfabet internal ReadOnly user.

The implementation of both security mechanisms includes system administration tasks that may not be executed by a solution designer. In the following all required configuration steps for both methods are described, including the tasks not performed with Alfabet Expand.

Using an Alfabet Internal ReadOnly User for Report Execution

During installation of the Alfabet components, a ReadOnly database user is automatically created on the database server for the Alfabet database. This ReadOnly user is re-created after each meta-model update. The Alfabet Web Application can be configured to connect to the Alfabet database with the database user with ReadOnly access rights when executing configured reports.

Please note that cube based reports cannot be executed when the database connection is set up with the ReadOnly database user.

Configuration is done with the tool Alfabet Administrator:

For information about how to access and work with the Alfabet database, see the chapter *Working with the Alfabet Administrator* in the reference manual *System Administration*.

1) In the explorer of the Alfabet Administrator, click the **Alfabet Aliases** node.
2) In the table, click the server alias that you want to configure.
3) In the toolbar, click the **Edit**  button. An editor opens.

4) In the editor, go to the **Server Settings** tab and open the tab **General**
5) Select the checkmark **Use ReadOnly User for Report Execution**.
6) Click **OK** to save your changes.

Configuring Database Users With Explicit Access Rights for Individual Configured Reports

Customer defined SQL users with password that are available at the database server can be used for connections of the Alfabet Web Application to the Alfabet database when executing configured reports of the type `Query` or `NativeSQL`.

One of the SQL users with password can be used as default user for all configured reports of the type `Query` or `NativeSQL`. Additional SQL users with password can be specified for execution of one or multiple individual configured reports.

The setting **Use ReadOnly User for Report Execution** in the server alias of the Alfabet Web Application is ignored if a definition of customer defined database users for report execution is available. The customer defined database users are only applied on configured reports of the type `Query` or `NativeSQL`. All other configured reports are then executed with the database user with extended rights that is the standard database user the Alfabet Web Application is connecting with to the database server.

The configuration includes three steps:

First step: Definition of SQL users with password on the database server host

An SQL user with password must be created and the access permissions configured on the database server. This is typically done by a database administrator. For details see the documentation of the database server used.

The access permissions to the Alfabet database for SQL users with password on the database server might be overwritten on update of the meta-model, For example, when migrating to another release or when taking over a configuration to the production environment via AMM file. It is recommended to use auto-run ADIFschemes for re-constitution of the permissions for SQL users with password after migration. For more information about ADIF schemes, see the reference manual *Alfabet Data Integration Framework*.

Second Step: Configuring the Alfabet Web Application to find the SQL users with password

The login credentials of all SQL users with password that shall be used for execution of configured reports must be defined in the configuration of the meta-model of the current database in Alfabet Expand. The SQL users with password are defined as database users in the Alfabet configuration.

1) Open Alfabet Expand and go to the **Presentation** tab.
2) Expand the node **XML Objects** > ***Administration***.
3) Right-click on ***DatabaseUsers*** and select **Edit XML** from the context menu. The XML object opens in the middle pane.
4) In the XML object, add one or multiple XML elements ***DatabaseUser*** to the XML root element ***DatabaseUsers*** and set the following XML attributes for each XML element ***DatabaseUser***:

- `Name`: Define a unique name for the database user. The name will be displayed in the drop-down list in the attribute **Database Restricted User** of configured reports of the type `Query` or `NativeSQL` that allows a database user to be assigned to the configured report.
- `DBUserName`: Enter the name of the SQL user with password defined in the database server that shall be used for authentication against the database server. Server variables can be used to define the name. For more information on server variables, see Using Server Variables in Web Link and Database Server-Related Specifications.
- `DBUserPassword`: Enter the password of the SQL user with password defined in the database server that shall be used for authentication against the database server. Server variables can be used to define the password. For more information on server variables, see Using Server Variables in Web Link and Database Server-Related Specifications.
- `IsDefaultForReports`: Set to `true`, if the database user shall be used for execution of all configured reports of the type `Query` or `NativeSQL` that do not have a database user explicitly defined. If the XML attribute is `false` or not set, the database user is not the default user.

  Only one of the defined database users can be defined as default for reports.

5) In the toolbar, click the **Save**  button to save your changes.

Step 3: Configuring reports to be executed with one of the defined database users

If the database user specification in the XML object ***DatabaseUsers*** includes the definition of a default user, all configured reports of the type Query or NativeSql are executed with the default database user without any further configuration required on the level of report configuration. If no database user is defined as default or if a default is defined, but a report shall be executed with another database user than the default database user, the database user for execution must be explicitly defined in the configured report's attributes:

1) Open Alfabet Expand and go to the **Reports** tab.
2) In the explorer, click on the node of the report for that you want to define a database user.
3) In the attribute window, select a database user from the drop-down list in the field **Database Restricted User**.

Restricting Access to Administrative User Profiles

User profiles can be defined as administrative user profiles with the **Is Administrative User Profile** attribute of the user profile. Access to a configured report can be limited to users currently logged in with an administrative user profile. Please note however, that this only applies to access via the **Configured Reports** functionality or page view. If a configured report is embedded into a guide page or an object cockpit, or object view, it is accessible to all users with access permissions to the guide page, object cockpit, or object view.

To restrict access to a configured report via the **Configured Reports** functionality or page view to users logged in with an administrative user profile:

1) If a report view has not yet been defined for the configured report, right-click the configured report and select **Create SQL Report View**. In the explorer, the SQL Report View is displayed as a subordinate object of the configured report.
2) Click the SQL Report View node and set the **Restrict to Administrative User Profiles** attribute to `True`.

Activating Navigation From Reports to Object Classes Not Automatically Offering Navigation

The user can navigate to the object view of an object displayed in configured reports of the type `Query`, `NativeSQL` or `Custom`.

Navigation to a base class of the configured report is activated per default for a preconfigured subset of object classes. For these object classes, navigation is available without further configuration for configured reports based on an Alfabet query and for configured reports based on a native SQL query, if the first argument in the `SELECT` clause returns the `REFSTR` of the base object class.

- For an overview of the navigable object classes for that navigation is activated by default, see *Overview of Configurable Features for Object Classes* in the reference manual *Configuring Alfabet with Alfabet Expand - Appendix*.
- For configured reports of the type Custom that are based on the template CustomPivotTable, navigation is not available by default. To activate navigation, the **Component** attribute of the report assistant for the configured report must be set to `PivotGrid` and navigation must be activated for all object classes, including the object classes that are automatically navigable from other reports, with the mechanism described below. Please note that activation of navigation for the object class `Artifact` will batch activate navigation to the object classes for that navigation is automatically available for other report types.
- For configured reports of the type `Custom` that display a chart report, like For example, a bar or line chart, navigation is not available by default. The required configuration is described in the section Configuring Navigation from a Chart Report.

If an object class is not offering navigation by default, navigation can be activated for that object class per configured report:

1) In the explorer of the **Reports** tab, expand the node of the configured report that shall provide navigation to the object class.

   The configured report must have a configured report view defined. If the node is not expandable, right-click the configured report's node and select **Create Sql Report View** for a configured report of the type `NativeSql` or `Query` or `Create Custom Report View` for a configured report of the type `Custom`.

2) Expand the report view node that is sub-node of the configured report's node.
3) Right-click the presentation object sub-node under the report view node and select **Create Item** from the context menu.
4) In the class selector, select the object class for that you want to activate navigation and click **OK**.

5) Make sure that the **Can Navigate** attribute of the new item is set to `True`.

For graphic configured reports of the **Type** `Custom`, the presentation object contains an item `Artifact` by default. If you would like to restrict navigation to a specific object class, you can delete the Artifact item that batch activates navigation to the object classes for that navigation is automatically available by default and add a new item for the object class that would like to navigate to.

Specifying Custom Help for a Configured Report

You can provide a link to custom help for any configured report created by your solution designer. You can specify only one custom online help per configured report. Users will be able to access the online help for the configured report that is currently displayed in the Alfabet user interface.

The custom help that you provide for your user community must be available via a URL that can be viewed in a browser. For each configured report, you can decide whether custom online help should be displayed and whether the standard online help should or should not be displayed. If you specify that both the standard online help and the custom online help are to be displayed, the link for the standard online help will be listed first in the **Help Selector**, followed by the custom help link. The online help entry will be displayed in the **Help Selector** with the syntax **Custom Help on<Configured Report Caption>**. For general information about the standard and custom context-sensitive help, see the section Understanding the Context-Sensitive Help.

Furthermore, you can specify content for the automated help assistant and make it available to a selected configured report. The automated help assistant will be displayed in a fly-in element in the upper-right corner of the user interface when the user accesses the configured report in the Alfabet user interface. The automated help assistant can be closed, whereby it will drop into the slide-in toolbar and can be opened for the current view at another time. For general information about the automated help assistant capability, see the section Understanding the Automated Help Assistant.

The custom help that you assign to a configured report will be available for every instance of that configured report. For example, a custom help link assigned to the configured report **Data Quality Checklist** in the context of a custom object view configured for the class `Application` will also be available in the configured report **Data Quality Checklist** in the context the object view for the class `Component`.

Server variables can be used in the **Custom Context-Sensitive Help URL** attribute and the **Automated Assistant URL** attribute to specify the custom help links. Server variables allow you to define all or part of the URL definition in the alias server setting instead of directly defining it in the configuration in Alfabet Expand. Use of server variables is, For example, useful in order to change a Web server name defined in multiple URL definitions in Alfabet Expand. Instead of changing all URL definitions, only the variable value in the alias server setting must be updated. For more information about defining server variables for custom online help, see the section Configuring Server Variables for the Custom Help.

To specify custom help for a configured report:

1) Go to the **Reports** tab and navigate to the configured report that you want to define a custom help for.
2) Ensure that the configured report has **Report State** set to **Plan**. To change the report state, right-click the configured report and select **Set Report State to 'Plan'**.

3) Click the report view node below the configured report to open the attribute grid. Define the following attributes, as needed:

- **Automated Assistant URL**: Enter the URL or server variable that targets the content to display in the automated help assistant assigned to the configured report.

  The size of the automated help assistant, its header color and position in the Alfabet user interface, and the notch in the slide-in toolbar are configured for each configuration object type in the GUI scheme. For more information about defining GUI schemes, see the section Configuring GUI Scheme Definitions for the Alfabet Interface. For details about the individual GUI scheme attributes that are relevant for the automated help assistant, see the section *Overview of GUI Scheme Attributes* in the reference manual *Configuring Alfabet with Alfabet Expand - Appendix*.

- **Custom Context-Sensitive Help URL**: Enter the URL or server variable that targets the custom context-sensitive help.
- **Standard Context-Sensitive Help Index**: This field will be empty for a configured report.

  The **Standard Context-Sensitive Help Index** attribute on the configured report node (not the configured report view node) can be edited for purposes of backward compatibility. Prior to release 10.1, users specified the location of the external help file using the following syntax: `CUSTOM_HELP:<URL>` (For example,: `CUSTOM_HELP:http://helphost/report1.html`). The link to the external help file will be displayed in the **Help Selector**. Server variables can be used in the help links. It is recommended that you specify your custom help by means of the **Custom Context-Sensitive Help URL** attribute on the report view node.

- **Standard Context-Sensitive Help Visible**: Select `True` to display both the standard and custom context-sensitive help file in the **Help Selector** Select `False` if the link to the standard context-sensitive help should not be available and should not be displayed in the **Help Selector**.

4) In the toolbar, click the **Save** button to save your changes.

Assigning a Category for Specific Functional Use to a Configured Report

For the following Alfabet functionality, configured reports either must or can optionally provide required data in a defined structure:

- Compliance policies
- Compliance prioritization for compliance projects
- Questionnaire policies
- ADIF schemes
- Constraints
- Events
- Data capture templates
- Conditions

- Rules for custom diagram definitions
- Chart view reports

Reports can only be used for these functionalities if they are assigned to a category related with the functionality. The name of the categorie related to each functionality can be assigned to the functionality by the customer in the XML object ***UseCaseCategories***. After having assigned a name for the category in the XML object ***UseCaseCategories***, the category must then be assigned to the configured report via the attribute **Category** of the configured report.

To set the category name in the XML object ***UseCaseCategories***:

1) In the **Presentation** tab of Alfabet Expand, expand the explorer node **XML Objects**.
2) Right-click on the XML object ***UseCaseCategories*** in the explorer and select **Edit XML** from the context menu. The XML object opens in the middle pane.
3) In the XML object, add an XML element `UseCaseInfo` as child element of the root XML element `UseCaseCategories` with the following XML attributes and child elements:

```
<UseCaseInfo UseCase="UseCaseName">
<ScopeInfo Scope="Report" Categories="CommaSeparatedListOfCategories" />
</UseCaseInfo>
...
```

4) Set the XML attributes `UseCase` and `Categories` as follows:
   - `UseCase`: Enter the value corresponding to the functionality you want to implement:
     - `Compliance`: Configuring compliance policies for compliance management. For more information about the functionality, see Configuring Queries for Compliance Policies.
     - `QuestionnairePolicies`: Defining users to answer questions in a questionnaire and objects about which questions shall be answered. For more information about the functionality, see Configuring Reports Finding Objects Or Users for the Questionnaire Policy.
     - `Diagrams`: Defining rules to automatically add objects to custom diagrams. For more information about the functionality, see Defining Rules to Automatically Add Objects to New Diagrams.
     - `Conditions`: Configuring conditional constraints for object profiles and object cockpits. For more information about the functionality, see Configuring Conditional Constraints for an Object Profile and Configuring Conditional Restraints in the Object Cockpit.
     - `JobScheduler`: Limiting the rescanning of indicators via the Job Schedule functionality to a subset of objects of a defined object class. For more information about the functionality, see Configurations for Scheduling Rescan of Indicators.
     - `Events`: Configuring events for triggering a RESTful service call with a dynamic method path or with a JSON payload. For more information about this functionality, see Defining a Dynamic Method Path for the RESTful Service Call and Defining the JSON Payload for the Body of the Service Call.
     - `CustomChartViews`: Generating a configured report that will be used in a report collection for an object class or object class stereotype. The configured report will be

available via a tab in all tabular configured reports about the object class or object class stereotype and provides additional information about all objects listed in the tabular report. For more information about this functionality, see Integration of Configured Reports as Report Collection Into Tabular Configured Reports.

- GenericOASIntegration:
- `DataCaptureTemplates`: Providing data for the generation of data capture templates. For more information about this functionality, see *Capturing Data with Data Capture Templates*.

- `Categories`: Enter a category name. If you enter more than one name comma separated, all names will be valid as category name for the functionality.

5) In the toolbar, click the **Save** button.

Handling Long Running Reports

While a configured report is loading, the user cannot perform any other activity on the Alfabet user interface of the current session. This can lead to problems with long running reports. If report execution requires For example, 10 minutes, the user will have to wait for the report execution to finish prior to doing other work in Alfabet without the ability to interrupt report execution. There are several mechanisms available for dealing with long running reports:

- Defining an Execution Timeout for Long Running Reports
- Open Tabular Reports with Filters Without Immediate Execution
- Configuring Offline Execution for Long Running Tabular Reports with Filters

Defining an Execution Timeout for Long Running Reports

You can configure a maximum time that the Alfabet Web Application shall try to execute a report that requires an exceedingly long execution time. The report execution will be terminated with an error message after the defined time has elapsed. This mechanism prevents a user session from being blocked for an excessively long time because of a long running report execution.

Report execution timeout is configured in the serer alias of the Alfabet Web Application. Server alias configuration is done in the tool Alfabet Administrator:

1) In the explorer of the Alfabet Administrator, click the **Alfabet Aliases** node.
2) In the table, click the server alias that you want to configure.
3) In the toolbar, click the **Edit** button. An editor opens.
4) In the editor, go to the **Command** tab.
5) Define the following attribute:

- **Report Execution Timeout**: Define the time in seconds after which the report execution will be terminated with an error message. By default, the Report Execution Timeout attribute is set to -1 and there is no restriction in report execution time.

Please note that **Report Execution Timeout** should have a lower value than the HTTP request timeout defined for the Alfabet Web Application. The definition of the HTTP request timeout will supersede the specification of the **Report Execution Timeout** attribute. The default HTTP request timeout of the web server is 110 seconds, if not otherwise specified in the `web.config` file of the Alfabet Web Application. If the value of the **Report Execution Timeout** attribute is higher than the HTTP request timeout, the number of seconds of the **Report Execution Timeout** attribute will be reduced to the HTTP request timeout minus ten seconds. The example `web.config` files delivered with Alfabet will contain a specification of an HTTP request timeout of 60 seconds with the entry: `<httpRuntime executionTimeout="60" />`

6) Click **OK** to save your changes.

Open Tabular Reports with Filters Without Immediate Execution

By default, configured reports are executed directly when opened by a user. This behavior can be changed for tabular reports of the type `Query` or `NativeSql` to avoid exceedingly large result datasets on execution with empty filter fields. The report will then only show results when the user clicks the **Submit** button for the filter.

Do the following to prevent a tabular configured report from being executed immediately on access:

1) Open Alfabet Expand and go to the **Reports** tab.
2) In the explorer, click on the node of the report for that you want to execute on submit only.
3) In the attribute window, set the **Execute on Enter** attribute to `False`.

When you set **Execute on Enter** to `False`, you must make sure that the **Submit** button is available in the SQL report view of the configured report. If the **Submit** button is deleted from the SQL report view, the configured report cannot be displayed. The setting and execution of the **Execute on Enter** attribute is independent from the definition of filters for a configured report. A configured report without filters must nevertheless have a **Submit** button when **Execute on Enter** is set to `False`.

Configuring Offline Execution for Long Running Tabular Reports with Filters

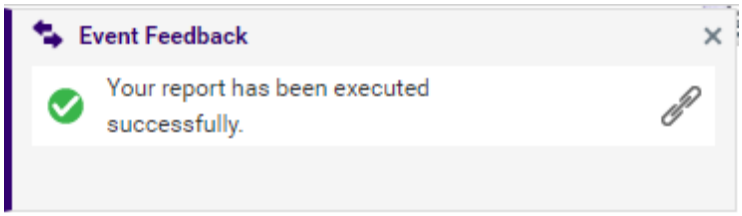
An offline execution mechanism is available for long running tabular reports that allows users to work in the Alfabet user interface while the configured report is being executed. Instead of requiring the user to wait for the report to load, the user will be prompted to define a name for the resulting report output when he/she opens the report or submits changed filter definitions for the report.

The user can then continue working on other Alfabet views until the report is fully loaded. He/she will be notified via an asynchronous response window which provides a link to open the report results in a new browser tab. This enables the user to view the report results while at the same time keeping the view open that he/she is currently working in when report results are available. Filters are displayed view only in the report results.

It is recommended not to execute configured reports with filter fields storing the filter settings into the `UserGlobalData` object class offline. On rendering of the offline executed report results, the values stored in the `UserGlobalData` object class will be overwritten with the filter values defined on triggering the report execution of the current report results. The opening of offline executed report results in a new tab might change a filter setting depending on the same object of the `UserGlobalData` object class for a report opened in parallel in the original tab for working with Alfabet without further notice.

For more information about filter field values stored in the `UserGlobalData` object class, see Configuring Reusability of Filter Settings Across Reports.

The event feedback window displays a text that is configurable for each offline executed report and a link symbol. Moving the cursor over the link symbol will show the name the user defined for the execution of the report in a tooltip.



The asynchronous response window opens for a few seconds and then moves into the slide-in toolbar where it is available as long as the user is working with the same view that was open when the message appeared. If the user changes to another view or logs out and logs in again, the asynchronous response cannot be opened separately any longer, but report results are still available for a configurable period of time and the user can access the report results during this time period via one of the following mechanisms:

- The **My Last Event Feedback** notch in the slide-in toolbar provides a link to the report results similar to the one in the **Event Feedback** window.
- If the user re-opens the long-running configured report while report results are available, he/she is offered to view the existing report results instead of triggering a new report execution.

Offline execution limits the availability of the configured report for other functionalities:

- Offline executed reports cannot be embedded in object cockpits. They are Therefore, not displayed in the drop-down list in the **Source** attribute to select a configured report as the source of a presentation object control in an object cockpit. If offline execution is configured for a configured report already embedded in an object cockpit, a user opening the object cockpit will see a message that the report cannot be displayed because of offline execution.
- Offline executed reports must not be used for REST API calls to the objects endpoint of the Alfabet RESTful services.

Offline execution requires the following preconditions:

- Offline execution is only available for configured reports of the type `Query` or `NativeSql` with a filter definition.
- Offline execution must be activated and configured in the attributes of the configured report. The configured report is then executed offline for all users having access to the configured report.
- An Alfabet Server must be running that is connected to the same Alfabet database than the Alfabet Web Application.

To execute a report offline, the following configuration is required:

1) Open Alfabet Expand and go to the **Reports** tab.
2) In the explorer, click on the node of the report for that you want to execute offline.
3) In the attribute window, set the **Execute Offline** attribute to `True`.
4) In the attribute window, set the following attributes:
   - **Estimated Execution Time**: The maximum time in minutes allowed for report execution. This value overwrites a general report execution timeout on the Alfabet Web Application for this report.
   - **Offline Completion Message**: A message that will be displayed to the user in the slide-in **Event Feedback** window that opens when the report execution has finished. If no text is provided, the message window will not contain any text but only the symbol for execution success and the link to the report results.
   - **Offline Result Retention Time**: The time in hours that a generated result for the configured report will be available for the user. A regular process is in place to remove results from offline executed reports once their retention time has elapsed.
5) In the toolbar, click the **Save**  button to save your changes.

Analysis of Reports via the Semantic Analyser

The semantic analysis functionality for configured reports scans all queries in a configured report for references to Alfabet object classes and object class properties thereof.

The information is used for the following functionalities:

- The **Show Usage** functionality in the context menu of object class properties evaluates the use of the object class property in configured reports on basis of the semantic analysis results.
- The AlfaBot uses the semantic analysis to fine tune the search results for the `Analyze` intent finding configured reports displaying information about defined object class properties and values thereof.

The results are listed in a node **Semantic Analysis** beneath the node of each configured report in a hierarchical structure going down from object classes to object class properties to values of object class properties. The Name property of object classes and object class properties is used in the explorer.

If object class properties restrict the display of objects in the report via a `WHERE` clause definition, the values will be included into the semantic analysis for object class properties returning one of the following:

- The value of a standard `Stereotype` object class property.

The semantic analysis ignores value definitions including a wildcard and checks whether the object class stereotype name equals a stereotype name defined for the object class. Only existing object class stereotypes are listed.

- The value of a the `Name` of an object.

The semantic analysis ignores value definitions including a wildcard.

- A Boolean value.
- A value from an enumeration.

The semantic analysis ignores value definitions including a wildcard and checks whether the enumeration value is defined for the enumeration defined for the object class property. Only existing enumeration items are listed.

Scanning is done automatically when the report state is set to `Active`.

Please note the following:

- If the **Semantic Analysis** node is empty after setting the configured report to `Active`, this is an idicator for an error in the underlying query, For example, a typo in an object class name.
- If you are importing configured reports stored in an XML file or AMM file from a database version Alfabet 10.6.x or lower, the semantic analysis node will not be available for the imported reports. The status of the imported configured reports must be re-set to `Plan` and set back to `Active` to start the analysis.

The analysis scans both Alfabet queries and native SQL queries. It comprises object class properties referenced by any part of the query including joins and the object class properties of the type `ReferenceArray` which are included in native SQL queries via the `PROPERTY` column of the `RELATIONS` database table.

Alfabet queries and native SQL queries are handled differently:

- The queries in a report based exclusively on Alfabet queries will be re-scanned each time the report state is set to `Active`. The solution designer cannot edit the list of results.

Indicator and role definitions added via the show properties of the type `Indicator` or `Role` are not included into the semantic analysis results.

The REFSTR object class property of the FIND class of the Alfabet Alfabet query is added as object class property to the semantic analysis.

- Native SQL queries can be very complex and in some cases, the scanning mechanism may not find all relevant object classes and object class properties. Therefore, the solution designer can add missing information to the semantic analysis of any report including at least one native SQL query via the **Add Properties** option in the context menu of the **Semantic Analysis** node. Object class property values included in the semantic analysis are ReadOnly and excluded from editing. The semantic analysis is executed each time the report state is set to Active. The manually-added semantic analysis results will be left unchanged during a subsequent semantic analysis.

Information about object classes and object class properties may be missing in the analysis for one of the following reasons:

- The query definition is incorrect. For example, an object class or object class property name may have been added with a typo. It is recommended to check the query definition for correctness if the semantic analysis is incomplete.
- Native SQL queries can be very complex and the scanning mechanism for semantic analysis may fail to identify object class or object class property specification.

If the semantic analysis of a correct native SQL query is incomplete, missing information can be added manually to complete the analysis:

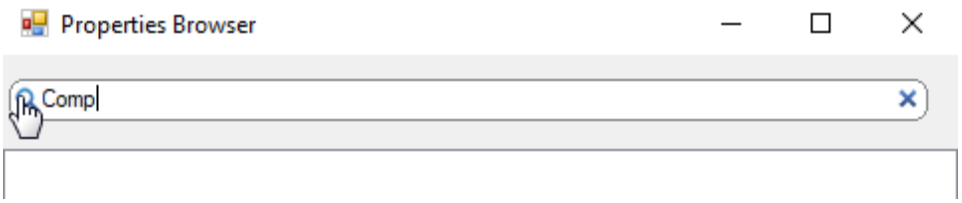
- Adding an Object Class to the Semantic Analysis
- Adding an Object Class Property to the Semantic Analysis
- Removing Manually Added Entries From the Semantic Analysis

If you encounter similar problems with the semantic analysis for various different native SQL queries, please inform Software AG Support. this will enable Software AG to futher enhance the automatic scanning of native SQL queries.

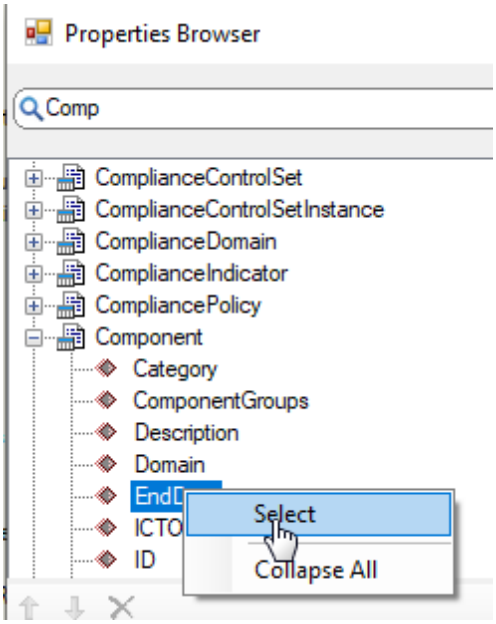
Adding an Object Class to the Semantic Analysis

To add information about an object class missing in the automatic semantic analysis output:

1) Right-click the **Semantic Analysis** node and select **Add Properties**.
2) In the selector window, type at least the first three letters of the object class name into the search field and click the search icon on the left of the field.



3) All object classes matching your search are listed in the middle field of the selector. Expand the relevant object class node, right-click the relevant property and select **Select** from the context menu.



4) Click OK. The object class and the selected object class property is added to the semantic analysis explorer persistently.

Adding an Object Class Property to the Semantic Analysis

To add information about an object class property missing in the automatic semantic analysis output for an object class already included in the semantic analysis:

1) Right-click the object class node and select **Add Properties**.
2) In the selector window, right-click the relevant property and select **Select** from the context menu.
3) Click **OK**. The object class property is added to the semantic analysis explorer persistently.

Removing Manually Added Entries From the Semantic Analysis

If you added an object class property manually to the semantic analysis of a configured report, it will not be removed the next time the configured report status will be set to `Active`, even if it is no longer used in the query. Manually added entries in the semantic analysis can only be removed manually:

- To remove a manually added object class property from the semantic analysis, right-click the object class property node and select **Remove Property**.
- To remove a manually added object class including all object class properties thereof from the semantic analysis, right-click the object class node and select **Remove Class**

Creating a Tabular Configured Report of the Type Query

To generate a configured report of the type `Query`:

- In the **Reports** tab of Alfabet Expand, create a new configured report and define the general attributes for the configured report and the attributes specific for Alfabet query-based configured reports. For more information about creating a configured report and defining the configured report's attributes, see Creating a New Alfabet Query-Based Configured Report.
- Configure an Alfabet query for the configured report. For more information, see Configuring an Alfabet Query for a Configured Report. If the configured report result shall be an expandable table, the Alfabet query must be configured to contain instructions. This is described separately in the section Grouping Query Results in Expandable Reports in the chapter Defining Queries.
- If the configured report has filters defined, create an SQL report view, check the functionality of the filters, and optionally change the captions and look of the filter fields. For more information, see Defining Filters for Configured Reports and Selectors in the chapter Defining Queries.
- Define access rights for the configured report in the **Reports Administration** functionality of Alfabet. By default, access is possible for all users. For more information, see the chapter *Defining and Managing User Access to Configured Reports* in the *User and Solution Administration* reference manual.
- Set the **Report State** of the configured report to `Active`. For information on how to change theattribute of the configured report, see.

The following information is available:

- Creating a New Alfabet Query-Based Configured Report
- Configuring an Alfabet Query for a Configured Report
- Defining Filters for an Alfabet Query Based Configured Report
  - Defining a Where Clause that Causes the Generation of a Filter Field in the Configured Report
  - Creating SQL Report Views to Configure Filters
- Defining a Data Capture Environment for a Configured Report of the Type Query
- Defining a User Management Functionality via a Configured Report of the Type Query
- Allowing the User to Change the Number and Order of Columns in the Table
- Configuring the Analysis of the Tabular Report in a Pivot Grid
- Configuring a Data Table Report with Restructuring Options for the End User

Creating a New Alfabet Query-Based Configured Report

To create a new Alfabet query-based configured report in Alfabet Expand:

1) In the **Reports** tab, right-click the **Reports** folder or a sub-folder thereof and select **Create New Report**. You will see the new configured report listed below the selected report folder.

As an alternative to defining all attributes for a new configured report, you can copy and paste an existing configured report and make modifications, as needed. To do so, right-click the existing configured report that you want to copy and select **Copy**. Right-click the new configured report and select **Paste**. Modify the necessary attributes described below.

2) In the property window, define the following attributes for the configured report:

- **Name**: Optionally, change the technical name of the configured report. The technical name of the configured report must be unique.

  The technical name is used for identification of the configured report in the context of technical processes such as merging the report configuration with a report configuration saved as an XML file. Therefore, the following is required when defining the name of a configured report:

  - The name must be unique. The name must be unique regardless of the report folder it is structured in.
  - The name may not be changed once a configured report has been created.
  - A validation mechanism checks for correct syntax when defining a technical name. Please note that names may not begin with an empty space nor include special characters. For a list of the special characters that are not allowed, see the section Defining Attributes for Configuration Objects in the chapter Getting Started with Alfabet Expand.
  - If the technical name of the configured report is changed, the name will be correctly updated in other configuration objects referencing the changed report during design time.

  Please note that the name of a changed configuration object will not be updated in guide pages or guide views. If you plan to change the name of a configuration object, the reference in the navigation page should be changed prior to changing the configuration object name. You can use the **Show Usage** functionality in the context menu of the configured report to evaluate whether the configured report has been added to a guide view or guide page.

- **Caption**: Enter a caption for the configured report. The caption you define here will be displayed in the **Reports Administration** functionality in the **Administration** module and the **Configured Reports** views of the Alfabet interface. If the configured report is assigned to an object view as a page view, the text will be displayed as the page view caption in the object view. The caption of the configured report may exceed the conventional 64 character limit.
- **Description**: Provide a short information about the configured report that is useful to Alfabet users. This comment will be displayed on the Alfabet user interface in the header of the configured report in a single line under the report caption and the **Description** field for the configured report in the table of all views listing configured reports, like the **Configured Reports** views of the **Search** functionalities. If the configured report is assigned to an object view as a page view, the text will be displayed under the page view caption as short description in the object view.

In the configured report, the description will be truncated if it is longer than one line on the screen. Therefore, the description should be short to ensure complete display in the configured report header.

- **Usage Guideline**: Provide information that helps users to execute and interpret the configured report. This information will not be displayed directly on the user interface. The user can access the information using the following mechanisms:
  - If the user moves the cursor over the description provided for the configured report with the attribute **Description**, a tooltip opens that includes both the description and the usage guideline.
  - The **Options**  button will be displayed on the upper right with an option **Help On Filter Fields** to open a new window displaying the usage guideline in addition to any filter field hints, if configured.

    For views that have filters defined, the **Options**  button will only be displayed if the filter panel either allows batch clearing of filter fields or collapsing and expanding of the filter panel. For more information about the configuration of these functionalities, see Configuring the Complete Filter Area to be Collapsible and Allowing the User to Clear the Filter Area.

- **Technical Comment**: Provide information that is useful for solution designers working with Alfabet Expand in order to better understand the configured report from a technical perspective. The **Technical Comment** will not be displayed in the user interface. Nevertheless, you can configure the interface to display the information in, For example, the attribute section of the configured report's object profile in the **Reports Administration** functionality.
- **Type**: Select `Query`. This is the default for new configured reports.
- **Report State**: The **Report State** attribute is view only and is set to `Plan` for new configured reports. The configured report can only be edited when the **Report State** attribute is set to `Plan`. After finishing all configuration steps described in the following, the **Report State** attribute must be set to `Active` as described in the section General Guidelines for Creating Configured Reports. The configured report is then visible to users in the Alfabet user interface.
- **Alfabet Query**: Click the **Browse**  button to open the **Alfabet Query Builder** and define the Alfabet query for the configured report.

  For information about how to work with the **Alfabet Query Builder**, see the chapter Defining Queries.

  For special hints for building an Alfabet query for configured reports, see Configuring an Alfabet Query for a Configured Report in this section.

  For a description of how to define report filters in an Alfabet query, see Defining Filters for an Alfabet Query Based Configured Report.

  For a description of how to define Alfabet queries for expandable report tables, see the section Grouping Query Results in Expandable Reports in the chapter Defining Queries.

- **Execute on Enter**: Set to `True` to execute the configured report with empty filter settings when the user opens the configured report on the Alfabet interface. Set to `False` to open the configured report without execution of the Alfabet query with empty filter settings. By default, this attribute is set to `True`. It should only be set to `False` when a configured report would result in an exceedingly big dataset when executed with empty filter settings.

  When you set **Execute on Enter** to `False`, you must make sure that the **Submit** button is available in the SQL report view of the configured report. If the **Submit** button is deleted from the SQL report view, the configured report cannot be displayed. The setting and execution of the **Execute on Enter** attribute is independent from the definition of filters for a configured report. A configured report without filters must nevertheless have a **Submit** button when **Execute on Enter** is set to `False`.

- **Help Index**: Specify the location of the external Help file using the following syntax:(For example,:). The external help file will be displayed when the user clicks the context-sensitive Help link in the standardHelp menu.

  Server variables can be used in the Help links. Server variables allow you to define all or part of the URL definition in the server alias configuration of the Alfabet Server instead of directly defining it in the configuration in Alfabet Expand. Use of server variables is useful, For example, in order to change a Web server name defined in multiple URL definitions in Alfabet Expand. Instead of changing all URL definitions, only the variable value in the server alias configuration must be updated. The use of server variables is described in the section Using Server Variables in Web Link and Database Server-Related Specifications in the chapter Configuring Reports.

- **Apply to Class**: To make the configured report available on the object profile of objects of one specified object class, click the **Browse**  button to open a dialog box and select the object class or object class stereotype to which you want to apply the configured report and click **OK**. If the attribute **Apply to Class** is set, the Alfabet query for the configured report must include a `WHERE` clause using the Alfabet parameter:`BASE` to refer to the current object. When the user opens the configured report, results related to the current object are displayed. A selector that is automatically added to the top of the configured report allows the user to select another object of the object class or object class stereotype that the configured report is applied to and view the results related to the selected object. If the configured report is added to a custom object profile or an object cockpit of the selected object class or object class stereotype, it opens automatically for the current object.

- **Database Restricted User**: Optionally select a database user that shall be used by the Alfabet Web Application for connecting to the Alfabet database instead of the standard database user with extended access permission when executing the configured report. The drop-down list is only filled if the use of different database users for configured report is specified in the XML object ***DatabaseUsers***. For more information about the concept of restricting access permissions for configured reports and the implementation of execution of configured reports with restricted database user rights, see the section Restriction of Database Access Permissions on Execution of Configured Reports.

- **Selector Behavior**: The attribute can be used to exclude configured reports that are defined for special purposes, like For example, triggering of data export via the RESTful API, from being selectable in the **Configured Reports** table. By default, the attribute is set to `Visible` and the configured report is visible in the selector for adding configured reports to the **Configured Reports** table if all other conditions for access to the configured report apply. If the attribute is set to `NotVisible`, the configured report is excluded from the selector for

adding configured reports to the **Configured Reports** functionality. Please note however, that this setting is not excluding the configured report from any standard views or customer configured views and selectors, but exclusively from the standard selector for configured reports implemented in Alfabet.

The attribute cannot be edited in the attribute window directly. To change the setting, right-click the configured report and select **Set Report Selector Behavior to 'Not Visible'** or **Set Report Selector Behavior to 'Visible'** respectively.

- **Applicable for AlfaBot**: Specify whether the configured report is accessible via the AlfaBot. By default, the attribute will be set to `True` for new reports. Set the attribute to `False` if the configured report should not be opened outside of a specific context. For example, this may be relevant for reports that are specifically designed to be embedded in an object cockpit.

  This attribute is only relevant if the AlfaBot is implemented. For information about the implementation of the AlfaBot, see Implementing the AlfaBot for Navigation via a Full-Text Command.

- **Business Problem Statement**: Optionally enter a description that will help users to search for the configured report in the AlfaBot. The text is not displayed in the user interface, but it is of special relevance for the search mechanisms implemented for the AlfaBot. If the report caption entered by the user in the AlfaBot for a request to open a configured report does not match the caption of one of the available configured reports, the AlfaBot will split the caption entered by the user into keywords and will perform a keyword search on the **Caption**, **Description** and the **Business Problem Statement** attributes of the configured reports that are accessible via the AlfaBot. In addition to a keyword search, a synonym search is performed on the text provided in the **Business Problem Statement** attribute.

  This attribute is only relevant if the AlfaBot is implemented. For information about the implementation of the AlfaBot, see Implementing the AlfaBot for Navigation via a Full-Text Command.

- **Base Classes**: Define the object classes that must be available to run the configured report. If this attribute is set, the Alfabet Server checks whether the object classes specified as base classes are excluded from the view scheme used to access the configured report. If the user does not have access permissions to one of the base classes, the configured report will be disabled. To set the attribute, click the **Browse** button to select the object classes that are required to run the configured report and click **OK**.

- **Can Create Express View**: Select `True` if an express view may be created for the report. Select `False` if an express view may not be created for the report. Please note that for reports that have a custom report view, the setting must be consistent with the setting of the attribute **Can Create Express View** of the custom report view.

  An express view is a link to a specific Alfabet view displaying data that allows individuals inside or outside of the user community to view information in Alfabet. When the express view is created, an email notification is automatically mailed to a specified recipient. The recipient receives a URL that allows him/her to access the current page view in Alfabet. For more information, see the section *Sending and Receiving Express Views* in the reference manual *Getting Started with Alfabet*.

- **Chart Views Mode**: This attribute defines whether additional information about the objects found in the configured report will be available via standard page views or configured reports directly accessible via links from the configured report view. Select one of the following:
  - `Standard`: A button **Chart Views** for opening a standard lifecycle chart, business support map, information flow diagram or portfolio for an object selected in the result dataset of the configured report is available automatically in the toolbar of the configured report if the following applies:
    - At least one of these standard reports is available for the object class the report finds objects for.
    - No Alfabet query language instruction is defined in the Alfabet query of the configured report.
    - The **Enable Chart Views** attribute is set to **True**.
  - `Custom`: All configured reports defined in the **Supplementary Reports** attribute of the class settings of the object class found via this configured tabular report are available via tabs on top of the toolbar of the tabular dataset. If a filter is available, the tabs are located between the filter area and the toolbar of the dataset. For information about the configuration of configured reports suitable to be opened via tabs in tabular configured reports and the configuration of the class setting to provide the configured reports, see Integration of Configured Reports as Report Collection Into Tabular Configured Reports.
  - `None`: Neither standard page views nor configured reports are directly accessible via links from the configured report view.
- **Custom Chart View Base Class**: This attribute is only visible if the **Chart Views Mode** attribute is set to `Custom`. Select the object class or object class stereotype for which the tabs opening the configured reports for the report collection shall be displayed. The configured reports defined in the **Supplementary Reports** attribute of the class settings of the object class or object class stereotype will be available via tabs. Please note that the selected object class must be identical to the object class found in the tabular dataset of the configured report you are currently configuring. If the objects found in the tabular dataset do not match the setting, the report will not show the tabular dataset, but an error message about the incorrect setting in the configuration.

3) In the toolbar, click the **Save** button to save your changes.

Configuring an Alfabet Query for a Configured Report

To define or edit the Alfabet query of a configured report:

1) In the table, select the configured report whose Alfabet query you want to define or edit.
2) Click the **Browse** button in the **Alfabet Query** attribute. In the dialog box that opens, select the base class for the Alfabet query. This class is the object class a user can navigate to when clicking a result in the configured report. The **Alfabet Query Builder** opens.
3) In the **Query** tab of the **Alfabet Query Builder**, define the Alfabet query for the selection of objects for the configured report.

For information about how to work with the **Alfabet Query Builder**, see the section Defining Queries.

The following is important for the generation of an Alfabet query for a configured report:

- If the configured report is applied to an object class with the attribute **Apply to Class**, you must configure the Alfabet query to show results for the current object that is selected by the user when opening the configured report only. To refer to the current object, use the Alfabet parameter "`:BASE`". For example, a configured report with the base class `Application` with a `WHERE` clause "`WHERE Application.REFSTR=:BASE`" will show results for the application that the user is currently working with only. A selector is added automatically to each configured report that is applied to an object class by means of the attribute **Apply to Class** . The selector allows the user to display other base objects in the configured report. If you do not specify a `WHERE` clause with the Alfabet parameter:`BASE`, the selector will still be present, but it will not have any impact on the resulting configured report.
- You can define filters for a configured report to allow the users to specify the range of results in the configured report. You can generate a filter from any `WHERE` clause of the configured report by clicking the checkbox **Parameter** in the condition value field. For more information about configuring filters, see Defining Filters for Configured Reports and Selectors in the chapter Defining Queries.

4) In the **Show Properties** pane, define the object class properties that are displayed in the columns of the configured report. In the **Sort Properties** pane, you can optionally select object class properties to sort the results sets in alpha-numeric order when the configured report is executed. The user can change the sort order of datasets in the report table by clicking the header of any column to display results in alpha-numeric order of the selected column's values.
5) Click **OK** to save the Alfabet query.
6) In the toolbar, click the **Save** button to save your changes.
7) In the explorer, right-click the configured report and select **Review Report**. The configured report opens in a web browser. If the results are not as expected, you can edit the Alfabet query until the output of the configured report meets your expectations.

The **Review Report** functionality also allows the visibility of toolbar buttons of the configured report to be defined for different view schemes. For more information, see Refining Visibility Issues in the View Scheme.

The amount of data that can be displayed in a configured report is restricted in order to avoid exceeding memory size usage. If a configured report results in an error message informing you that the data set is too large, refine the query to return only a subset of the results. If you do not want to exclude objects from the configured report but rather would like to limit the set of data that is displayed, you can define filters that allow the user to restrict the data display as needed (For example, by displaying only objects with a name starting with a specific character or objects assigned to a specific ascendant object).

Defining Filters for an Alfabet Query Based Configured Report

You can allow users to select the output of a configured report at runtime by means of filters that you configure.

The following steps are required to define filters for a configured report based on an Alfabet query:

- Define one or more `Where` clauses in the Alfabet query that are configured to generate a filter field. For more information, see Defining a Where Clause that Causes the Generation of a Filter Field in the Configured Report.
- Create an **SQL Report View** for the configured report and edit the attributes of the filter fields in the SQL report view, if applicable. For more information, see Creating SQL Report Views to Configure Filters.
- Test the functionality of the filter fields in the configured report or custom selector.

Defining a Where Clause that Causes the Generation of a Filter Field in the Configured Report

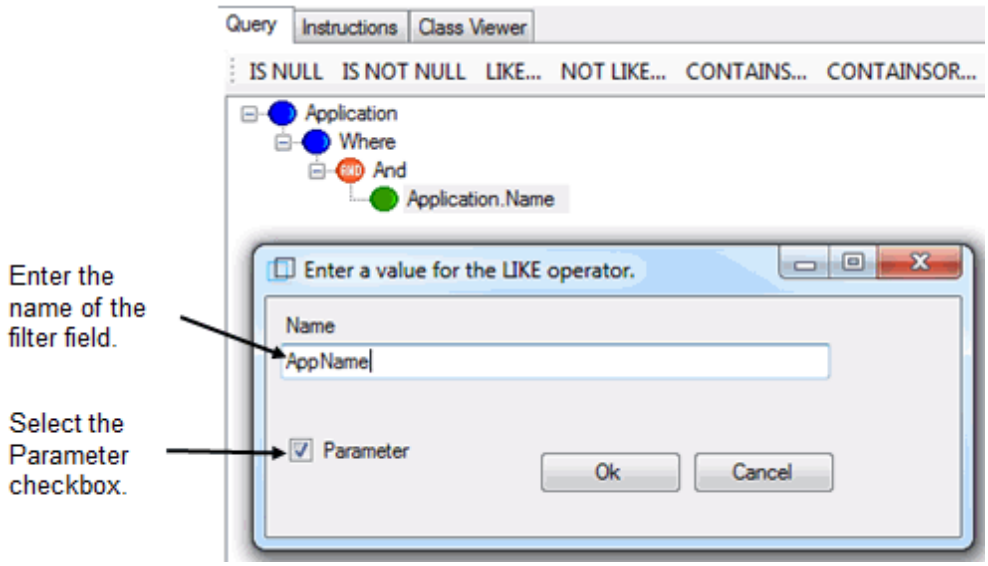
To set a filter for a configured report, you must configure a `Where` clause for the object class property you want the user to define in the filter field. The `Where` clause must be defined as follows:

- When defining the value for the condition, enter `@` followed by a technical name of the filter field. The value is not used to search in the property, but rather only to assign a technical name to the filter field.

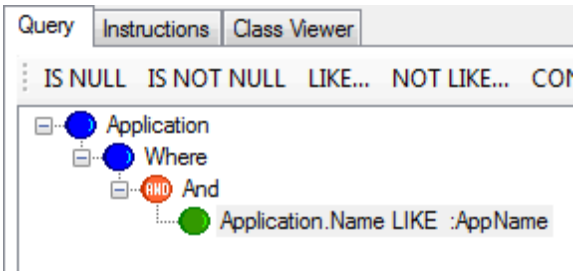
An example `Where` clause for the generation of a filter field:

```
WHERE APPLICATION.NAME LIKE (@AppName)
```

When defining the value for the condition in the **Alfabet Query Builder**, select the checkbox **Parameter** in the dialog box, shown below. In the **Name** field, enter a technical name of the filter field. The value in the **Name** field is not used to search in the object class property, but rather only to assign a technical name to the filter field.



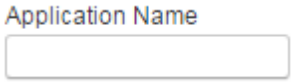
After clicking **OK**, you will see the `Where` clause in the **Alfabet Query Builder** with a colon written before the value. This is an alternative syntax to the definition of the parameter with an `@` prefix.



- Select a condition operator that allows the specification of a value. For example, `IS NULL` cannot be used for a filter because it does not require the specification of a value whereas, For example, the condition `LIKE` allow the specification of filter fields.

Depending on the data type of the property and condition that you have configured, different type of filter fields may be defined:

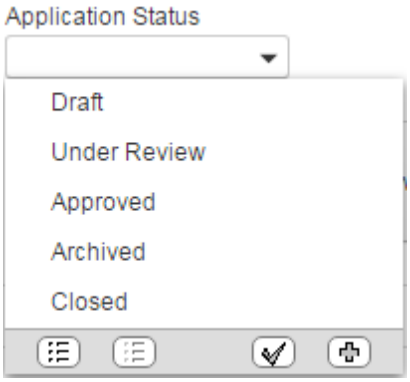
- Editable fields:



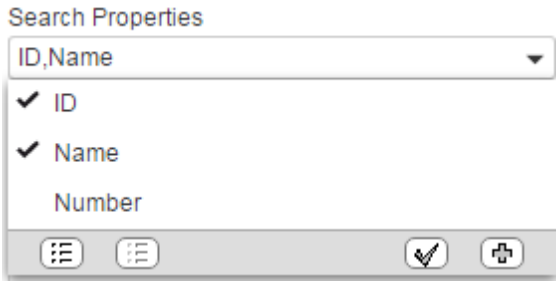
Editable fields can either allow wildcards in the search string or to search for a completely matching string only.

- Editable fields with a selector that allows to select an object from an object selector:

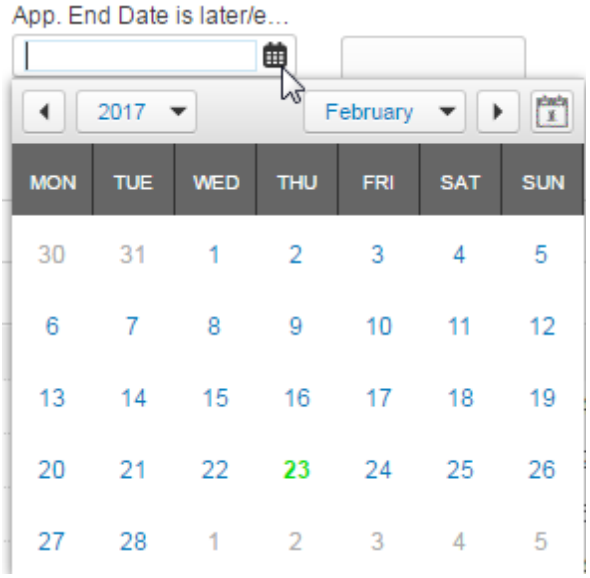
- Combo boxes allowing one value to be selected from a set of values



- Checked combo boxes allowing multiple values to be selected from a set of values



- Calendar fields with date pickers



The following tables lists all condition operators that allow the generation of filter fields for a specific data type and the corresponding type of filter field. Some of the filter fields require configuration of the attributes of the filter fields after creation of the SQL report view for the configured report. If this is required, it is also mentioned in the table.

In Alfabet query language the following combinations of conditions and data types can be used for filter fields:

Property Data Type	Condition	Resulting Filter Field Type	Required Configuration of Filter Field Attributes	Remark
`String`	=,<>	Edit field without wildcards	If the ***AutoWildCard*** attribute of the XML object ***SearchManager*** is set to `true`, the attribute **Allow Wildcards** of the filter field must be set to `False`. For more information, see Automatically Adding Wildcards to Search Strings	<> means different from, = means identical to. In both cases, the complete string in the search field is compared with the complete string of the property value. Wildcards are not allowed.
`String`	<,>,<=,>=	Edit field without wildcards	If the ***AutoWildCard*** attribute of the XML object ***SearchManager*** is set to `true`, the attribute **Allow Wildcards** of the filter field must be set to `False`. For more information, see Automatically Adding Wildcards to Search Strings	The less than and greater than operators are interpreted alphanumerically when applied on a string property. For example, if the greater than operator is used for a filter for application name and you enter "`alfa`" into the filter field, all applications with names in the alphabetical order before or identical to "`alfa`" are not displayed. The application with the name "`account`" will not be displayed, while the application with the name "`Alfabet`" For example, is displayed, because it is coming after `alfa` in the alphabetical order.
`String`	`LIKE, NOT LIKE, CONTAINS, CONTAINSOR`	Edit field with wildcards		In the resulting edit field, part of a string value can be entered with an asterisk (*) as wildcard to search for property values including a defined string.
`StringArray`	`LIKE, NOT LIKE, CONTAINS, CONTAINSOR`	Edit field with wildcards		In the resulting edit field, part of a string value can be entered with an asterisk (*) as wildcard to search for property values including a defined string.

Property Data Type	Condition	Resulting Filter Field Type	Required Configuration of Filter Field Attributes	Remark
`String` based on an enumeration or a definition in an XML object (release status, object state, lifecycle status, stereotype definitions with a hierarchical order)	`LIKE, NOT LIKE`	Edit field with wildcards		
`String` based on an enumeration or a definition in an XML object (release status, object state, lifecycle status, stereotype definitions with a hierarchical order)	`CONTAINS, =`	Combo box	If the release status definition is different for different stereotypes of a class, a filter field can only display the release status definitions of one of the stereotypes and the stereotype name must be defined with the attribute **Custom Property** of the filter field.	Stereotype definitions that do not have a hierarchical order defined will generate a normal string filter field, that means an edit field with (`CONTAINS`) or without (=) allowing wildcard settings.
`String` based on an enumeration or a definition in an XML object (release status, object state, lifecycle status, stereotype definitions with a hierarchical order)	`CONTAINSOR`	Checked combo box	If the release status definition is different for different stereotypes of a class, a filter field can only display the release status definitions of one of the stereotypes and the stereotype name must be defined with the attribute **Custom Attribute** of the filter field.	Stereotype definitions that do not have a hierarchical order defined will generate a normal string filter field, that means an edit field allowing wildcard settings.
`String` based on an enumeration or a definition in an XML object (release status, object state, lifecycle status, stereotype definitions with a hierarchical order)	<,>,<=,>=	Edit field without wildcards	If the ***AutoWildCard*** attribute of the XML object ***SearchManager*** is set to `true`, the attribute **Allow Wildcards** of the filter field must be set to `False`. For more information, see Automatically Adding Wildcards to Search Strings	The less than and greater than operators are interpreted alphanumerically when applied on a string property. For example, if the greater than operator is used for a filter for application name and you enter "`alfa`" into the filter field, all applications with names in the alphabetical order before or identical to "`alfa`" are not displayed. The

Property Data Type	Condition	Resulting Filter Field Type	Required Configuration of Filter Field Attributes	Remark
				application with the name "account" will not be displayed, while the application with the name "Alfabet" For example, is displayed, because it is coming after alfa in the alphabetical order.
Text	LIKE, NOT LIKE	Edit field with wildcards		
Date	=,<>,<=, >=,<,>	Date picker		
DateTime	=,<>,<=, >=,<,>	Edit field without wildcards		If the operator = is used, the complete date and time definition in the correct culture format must be specified in the filter field to find a match.
Integer / Real	=,<>,<=, >=,<,>	Edit without wildcards		
Boolean	=	Combo box		
Reference / ReferenceArray	CONTAINS	Edit search (selector)		
Reference	CONTAINSOR, IN, NOT IN	Checked combo box	The content of the checked combo box must be defined with an Alfabet query or native SQL query in the attribute **Alfabet Query/Query As Text** of the filter field.	

Property Data Type	Condition	Resulting Filter Field Type	Required Configuration of Filter Field Attributes	Remark
`ReferenceArray`	`CONTAINSOR`	Checked combo box	The content of the combo box must be defined with an Alfabet query or native SQL query in the attribute **Alfabet Query/Query As Text** of the filter field.	

Note the following when defining filter field name parameters in `Where` clauses:

- A filter field value can be used in multiple `Where` clauses by defining the same Alfabet parameter name.
- When a filter field is not filled, the query processing mechanisms of the Alfabet components delete the condition with the filter parameter from the `Where` statement before executing the query. For example, the following `Where` statement of an Alfabet query

```
WHERE
AND (
    APPLICATION.STATUS = 'Plan'
    APPLICATION.NAME LIKE @PARAM
)
```

is shortened to the following statement before executing the query if the filter field with the name `@PARAM` is not filled:

```
WHERE APPLICATION.STATUS = 'Plan'
```

- In standard Alfabet views and configured reports based on Alfabet queries entries in filter fields are interpreted case insensitive.
- The search behaviour in edit fields is controlled by the setting of the ***AutoWildCard*** attribute of the XML object ***SearchManager***. When ***AutowildCard*** is set to `true`, a wildcard is added automatically to search strings entered by the user. Therefore, the `=` condition cannot be used for the definition of edit fields because the condition does not allow wildcards in the argument. It is also recommended to inform users with a static text in the filter section whether wildcards are automatically added to strings.

For more information about the ***AutoWildCard*** setting in the XML object ***SearchManager***, see Configuring the Wildcard for Standard and Custom Search Functionalities.

Creating SQL Report Views to Configure Filters

Once the filter fields are defined in the query, an SQL report view must be created to generate filter fields automatically. In the SQL report view, you can change the display of the filters by, For example, specifying new captions for the filter fields or rearranging the fields within the filter area. For checked combo-boxes, combo-boxes, and edit fields not allowing wildcard settings, the filters may require additional specification of the content.

This is done in an SQL report view. The SQL report view must be created for a configured report after all filters have been defined in the Alfabet query.

Make sure that all required filters for the configured report are specified before you generate an SQL report view. When adding a new filter to a configured report with an already tested and configured SQL report view, you have to delete and re-create the SQL report view. Then you will lose the configurations previously defined for the filter fields.

To create an SQL report view:

1) In the explorer, right-click the configured report and select **Create SQL Report View**. The view editor opens and displays the SQL report view with the automatically generated filter fields. In the explorer, the SQL report view is displayed as a subordinate object of the configured report.
2) For combo boxes, checked combo boxes and edit fields not allowing wildcard settings, click the filter field and edit the following attributes in the attribute window:
   - **For edit fields not allowing wildcard settings**: Set the attribute **Allow Wildcards** to `False`.
   - **For (checked) combo boxes for the selection of a lifecycle status**: The lifecycle status definition is different for each object class. You must specify the name of the object class in order to display lifecycle definitions for an object class. For more information about lifecycle status definitions, see the section Configuring Lifecycle Definitions for Object Classes. in the chapter Configuring the Class Model.
   - **For (checked) combo boxes for the selection of a release status for a class with stereotype definitions**: If the release status of a class is different for different stereotypes of an object class, the name of the stereotype must be defined in the attribute **Custom Attribute** of the filter field.
   - **For (checked) combo boxes for the selection of a reference target**: When the filter field allows to select objects referenced by a property of the type `Reference` or `ReferenceArray`, define an Alfabet query or a native SQL query in the attribute **Alfabet Query/Query As Text** to refine the filter field. The output of the query specified here defines the values that will be displayed in the (checked) combo-box.

     Note the following about the display of the properties in the (checked) combo-box:
     - When defining filter field content with a native SQL query, the first `SELECT` statement must be the `REFSTR` of the selected object and is not displayed in the combo box.
     - When you specify more than one show property in an Alfabet query or more than one result column in the `SELECT` clause of a native SQL query, the values of the properties are displayed in the combo box in one row per object separated with a whitespace.

- If you want two property values to be displayed with a fixed string between them, For example, the properties for Name and Version with a "v." in between, you can use the `JoinColumns` instruction to define the string. For information about the `JoinColumns` instruction, see Aggregating Multiple Query Results in One Column of a Configured Report in the chapter Defining Queries.
- You can define `SORT` properties to define the order of values in the combo box or checked combo box.

A configured report shall allow users to select applications with a specific name and show all incoming and outgoing information flows of a specific connection type. The Alfabet query for the configured report joins the object class `Information-Flow` to the base class `Application` and defines the search conditions as filters:

```
ALFABET_QUERY_500

FIND Application

InnerJoin

   InformationFlow ON (Or InformationFlow.From =
   Application.REFSTR InformationFlow.To =
   Application.REFSTR)

WHERE

   (AND

      Application.Name LIKE:AppName

      InformationFlow.ConnectionType
      CONTAINSOR:ConnectionType)

QUERY_XML

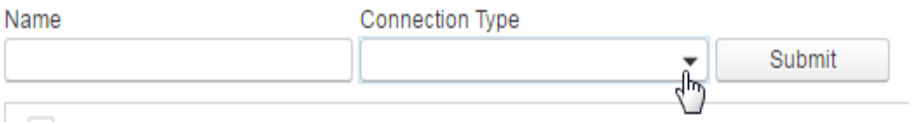
<QueryDef>

   <ShowProperty Type="Property" ClassName="Application"
   Name="Name" />

   <ShowProperty Type="Property"
   ClassName="InformationFlow" Name="ConnectionType" />

</QueryDef>
```

The test of the configured report shows a filter with a text input field for the application name and a combo box to select one or multiple connection types. The checked combo box for the connection types is empty and does not open when clicking the arrow at the right of the field:



To display the available connection types in the checked combo box, you must specify an Alfabet query for the **Connection Type** checked combo box. The Alfabet query must find connection types and defines the attribute **Name** of the connection type as a Show property:

```
ALFABET_QUERY_500

FIND ConnectionType
```

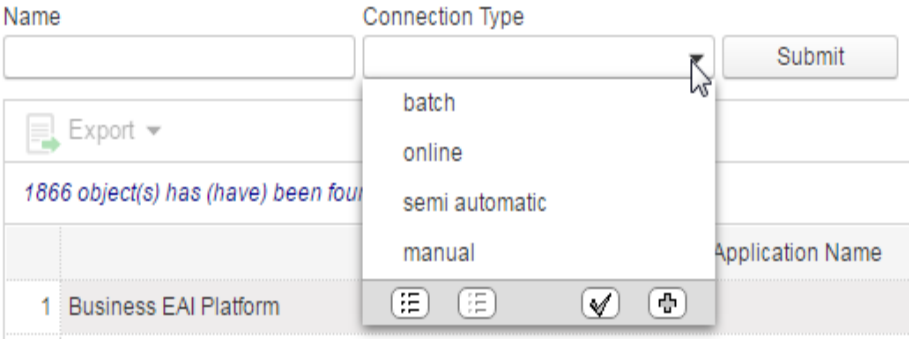
```
QUERY_XML

<QueryDef>

    <ShowProperty Type="Property"
    ClassName="ConnectionType" Name="Name" />

</QueryDef>
```

The checked combo box will then allow the user to select between the available connection types:



3) Optionally, you can further configure the display and behaviour of the filter. The options for the configuration of filter panels and filter fields are described in the section Defining Filters for Configured Reports and Selectors in the chapter Defining Queries. the following configurations can be performed:

- Grouping Filters on the Filter Panel
- Adding Static Information to the Filter Panel
- Configuring the Complete Filter Area to be Collapsible
- Defining Mandatory Filter Fields
- Automatically Adding Wildcards to Search Strings
- Configuring Cascading Filters
- Excluding Filters From Storage in Bookmarks

4) In the toolbar, click the **Save** button to save your changes.

Defining a Data Capture Environment for a Configured Report of the Type Query

The buttons that are available in standard data capture functionalities in Alfabet can also be added to a configured report that displays data about the respective class in a table. Standard data capture functionalities are available for the object classes application, component, device, peripheral, ICT object and service product.

Note the following about the configuration:

- The attribute **Template** of the configured report must be set prior to creating the custom report view. If a configured report already has a custom report view defined, setting of the Template attribute will not add the buttons unless the custom report view is deleted and re-created.
- The objects found be the query the configured report is based on must be of the object class or object class stereotype for that the data capture environment is defined. Please note that for the `CaptureProjects` template, the report must be limited to a defined object class stereotype to deliver valid results.
- If the configured data capture report shall be limited to editing of objects of a specific stereotype only, the following is required:
  - All objects that are displayed in the report can be edited regardless of the stereotype. If you want to limit editing to data with a specific steretype, you must limit display of objects in the report table to objects of that stereotype via the query definition of the configured report.
  - To limit creation of new objects to object of a specific stereotype, enter the name of the stereotype into the attribute **Parameter** of the configured report. This setting must be performed prior to creating the report view.

To add the buttons available in a standard data capture environment to the configured report, the following configuration is required in addition to the configuration described above for general configuration of the configured report:

1) In the attributes window of the configured report, set the attribute **Template** to one of the following values:
   - `CaptureApplications`
   - `CaptureComponents`
   - `CaptureContracts`
   - `CaptureDemands`
   - `CaptureDevices`
   - `CaptureIssues`
   - `CapturePeripherals`
   - `CaptureProjects`
   - `CaptureICTObjects`
   - `CaptureServiceProducts`
   - `CaptureVendorProducts`
   - `CaptureVendors`
2) If you have selected the template `CaptureIssues`,set the **Apply to Class** attribute of the configured report to the object class that the issues shall be created for.
3) If creating of objects shall be limited to a defined stereotype, enter the name of the stereotype into the attribute **Parameter** of the report. If you have selected the template `CaptureIssues`, you can add a comma separated list of stereotype names in the **Parameter** attribute to restrict the creation of issues to issues of all specified stereotypes. The sub-menu of the **New** button in the toolbar of the report will be adapted to inform the user which issue stereotypes can be selected.

4) Right-click the configured report and select **Create Report View**.

5) Optionally, you can define which buttons will be displayed in the toolbar:

- You can hide standard buttons from the toolbar. For information about the required settings, see Hiding Functionalities in a Page View or Configured Report.

- You can substitute the standard mass update functionalities in the data capture functionality with the editor available from a configured report for multi-editing of object class properties. The editor will be available via a button **Bulk Edit** that will be automatically added to the toolbar for all data capture environment report that have a configured report for multi-editing of object class properties assigned. The button will have submenu options for opening the editor or, if available via the configured report for multi-editing of object class properties, the options for setting the same value for all selected indicators, properties or roles. The editor will open for the objects selected in the table and the rules for visibility and editability of properties defined in the configured report for multi-editing of object class properties will be applied. Do the following to enable mass update in an editor from a configured report for multi-editing of object class properties.

  - Create a configured report for multi-editing of object class properties based on the template `EditableClassViewReport`. Make sure that the report is targeting the same object class as your data capture report and that the edit rights are in accordance with the edit rights that you would like users to have for objects when working in your configured data capture environment. For information about the definition of a report for multi-editing of object class properties based on the template `EditableClassViewReport`, see Creating Configured Reports With Editing Capabilities.

  - Right-click the data capture report and select **Start Alfabet Report Assistant**. In the assistant, select the configured report for multi-editing of object class properties in the dropdown list of the field **Editable View Report**. Click **OK**.

Defining a User Management Functionality via a Configured Report of the Type Query

The functionalities for user management that are available in the standard Alfabet views **User Administration** (`ADMIN_UsersOverview`) and **Contact Administration** (`ADMIN_ContactsOverview`) can also be added to a configured report that displays user data in a table. The administrative functionalities available in the configured report are limited to the functionalities that apply to selected users in the table. All functionalities that apply changes to all users in the database are not included in the configured report.

Via the configured reports, users can be provided with administrative access to the user data for a selected sub-set of users in the Alfabet database, For example, to all users that are in a defined user group. In addition, the view can be adapted to the specific tasks of the user that will administrate users for the configured report by adding filter fields and configuring the tabular dataset of the report to include information about a user that is not available in the standard **User Administration** view.

Note the following about the configuration:

- The attribute **Template** of the configured report must be set prior to creating the SQL report view. If a configured report already has an SQL report view defined, setting of the **Template** attribute will not add the buttons unless the custom report view is deleted and re-created.

- The objects found be the query the configured report is based on must be of the object class `PERSON` for that the data capture environment is defined.

- You can limit the availability of the configured report to access from user profiles with administrative rights. If you set the attribute **Restrict to Administrative User Profiles** of the SQL report view is set to `True`, the configured report can only be opened if the user is logged in with a user profiles for that the attribute **Is Administrative User Profile** is set to `True`.

To add the the functionality available in the standard **User Administration** view for administration of selected users to the configured report, the following configuration is required in addition to the configuration described above for general configuration of the configured report:

1) In the attributes window of the configured report, set the attribute **Template** to `UserManagementReport` or `ContactManagementReport`.
2) Right-click the configured report and select **Create SQL Report View**.
3) Optionally, click the SQL report view and set the attribute **Restrict to Administrative User Profiles** of the SQL report view to `True`.

Allowing the User to Change the Number and Order of Columns in the Table

A tabular configured report can be configured to display a **Configure** button in the toolbar of the configured report. The user can do the following in the editor opened via the button:

- Change the order of columns in the table.
- Hide columns from the table.

The following configuration is required to display the **Configure** button:

1) If a report view has not yet been defined for the configured report, right-click the configured report and select **Create SQL Report View** . In the explorer, the SQL Report View is displayed as a subordinate object of the configured report.
2) Expand the SQL Report View node under the explorer node of the configured report and click the Presentation Object node under the SQL Report View node. The attribute window displays the attributes of the presentation object.
3) Set the attribute **Configurable** of the Presentation Object to `True`.

Configuring the Analysis of the Tabular Report in a Pivot Grid

A tabular configured report can be analysed in a Pivot grid and the graphical representation thereof. By default, new configured tabular reports have a button **Pivot Grid** that opens a new view with the Pivot functionality. This default behaviour can be changed to other analysis modes or deactivated.

The third party component DevExpress® is used to render results in a Pivot table.

DevExpress® must be activated in the web.config file of the Alfabet Web Application to be used in configured reports. For more information about the activation, see *Prerequisits for Using DevExpress®* in the *Technical Requirements*.

If you would like to offer Pivot grid analysis for a tabular report, you should note the following when creating the query for the report:

- The analysis is performed on basis of the result dataset. Columns are identified by their caption. Therefore, the caption of the columns must be unique. In addition, the user cannot see the data table when working with the Pivot Table Analysis. Captions should be designed to provide information about the kind of data returned in the respective column to enable the user to decide where to place the data in the Pivot grid.
- At least one column in the result dataset must return a numerical value. Only numerical values can be added to the cells in the matrix of the Pivot Grid.
- If navigation from the table to the object profile or object cockpit of a base object for each result dataset is provided, it is also identically available in the Pivot Grid.
- If you would like the user to analyze multiple numerical values that are having a different aspect, For example, costs that are having a different cost type, the aspects can only be summed up if you list the aspect, For example, the cost type, in one column and the value in a second column. If you add one column for each aspect, that each contain the respective values for this aspect, the data can only be analysed next to each other, but not merged.

For example, if a configured report shall return for applications in application groups the current costs over the years separately for each cost type. The way the data can be analyzed in a Pivot Grid depends on the structure of the tabular output of the report:

- The tabular output of the configured report may display one line returning the cost type name and one row returning the budget value for all cost types:

	Application Group Name	Application Name	Cost Type Name	Budget Value Value	Budget Value Year
1	2. Trade Entry	EMERGING MARKET SYSTEMS v. 3.1.2	Subscription	25.00	2015
2	2. Trade Entry	EMERGING MARKET SYSTEMS v. 3.1.2	Expense	115.00	2015
3	2. Trade Entry	EMERGING MARKET SYSTEMS v. 3.1.2	Consulting	31.00	2015
4	2. Trade Entry	EMERGING MARKET SYSTEMS v. 3.1.2	Other	14.00	2015
5	2. Trade Entry	EMERGING MARKET SYSTEMS v. 3.1.2	Subscription	25.00	2016
6	2. Trade Entry	EMERGING MARKET SYSTEMS v. 3.1.2	Expense	129.00	2016
7	2. Trade Entry	EMERGING MARKET SYSTEMS v. 3.1.2	Consulting	37.00	2016
8	2. Trade Entry	EMERGING MARKET SYSTEMS v. 3.1.2	Other	15.00	2016
9	2. Trade Entry	EMERGING MARKET SYSTEMS v. 3.1.2	Subscription	25.00	2017
10	2. Trade Entry	EMERGING MARKET SYSTEMS v. 3.1.2	Expense	132.00	2017
11	2. Trade Entry	EMERGING MARKET SYSTEMS v. 3.1.2	Consulting	37.00	2017

If the report is analyzed in a Pivot Grid for application group costs per year. The cost values are all from the same column and Therefore, the Pivot Grid can be configured to display costs independent from the cost type. The cells in the matrix then display a sum of the costs for all cost types belonging to the same year and application group:

	Budget Value Year				
Application Group Name	2015	2016	2017	2018	Grand Total
1. Market Data	5857	6611	9485	9697	31650
2. Trade Entry	13615	14990	14803	15346	58754
3. Front Office	12174	14412	15439	15396	57421
4. Back Office	18231	20295	20683	377891	437100
5. Customer Relations	1340	2199	7013	9599	20151
6. Risk Reporting	4241	5566	9366	10139	29312
7. Finance Reporting	6083	6957	7612	1705340	1725992
8. Accounting	3408	4284	4484	1511832	1524008
9. Payments	3561	4168	4444	4861	17034
Grand Total	68510	79482	93329	3660101	3901422

Alternatively, the Pivot Grid can display costs per cost type by adding the cost types as column header:

	Budget Value Year						
	⊟ 2015					⊟ 2016	
Application Group Name	Consulting	Expense	Other	Subscription	2015 Total	Consulting	Ex
1. Market Data	920	3178	544	1215	5857	1048	
2. Trade Entry	2405	8507	1013	1690	13615	2671	
3. Front Office	2150	7265	974	1785	12174	2518	
4. Back Office	3223	10974	1414	2620	18231	3555	
5. Customer Relations	95	342	198	705	1340	270	
6. Risk Reporting	604	2125	417	1095	4241	876	
7. Finance Reporting	978	3300	545	1260	6083	1099	
8. Accounting	593	2144	251	420	3408	675	
9. Payments	640	2087	289	545	3561	765	
Grand Total	11608	39922	5645	11335	68510	13477	

A filter field is then displayed on top of the column headers that allows to remove costs for singel cost types from the dataset.

For each year, a total sum is calculated, displaying the total costs independent from the cost type. On the right of the grid, the **Grand Total** column calculates the total costs per application group and year:

⊟ 2018				2018 Total	Grand Total
Consulting	Expense	Other	Subscription		
1731	5946	735	1285	9697	31650
2692	10021	1093	1540	15346	58754
2670	9805	1111	1810	15396	57421
3109	370402	1545	2835	377891	437100
1689	5689	760	1461	9599	20151
1892	5986	821	1440	10139	29312
957	342963	645	1360775	1705340	1725992
983	209988	441	1300420	1511832	1524008
871	3097	348	545	4861	17034

- The tabular output may alternatively display one line per cost type with the cost type name given as column header and the cost type value listed in the respective row:

	Application Group	Application	Subscription	Expense	Consulting	Other	Year
1	OptiRetail CRM As-Is Situation	Business EAI Platform 2.2	110.00	4.00	1.00	28.00	2015
2	Corporate CRM AS-IS Situation	Business EAI Platform 2.2	110.00	4.00	1.00	28.00	2015
3	Corporate CRM TO-BE Situation	Business EAI Platform 2.2	110.00	4.00	1.00	28.00	2015
4	Applications Using UDB	Groupware Services 2.2	60.00	29.00	7.00	16.00	2015
5	Corporate CRM AS-IS Situation	Groupware Services 2.2	60.00	29.00	7.00	16.00	2015
6	Corporate CRM TO-BE Situation	Groupware Services 2.2	60.00	29.00	7.00	16.00	2015
7	5. Customer Relations	Mafo-Portal 2.6	500.00	63.00	17.00	129.00	2015

11	Customer Management	Mafo-Portal 2.6	500.00	63.00	17.00	129.00	2015
12	OptiRetail CRM As-Is Situation	Mafo-Portal 2.6	500.00	63.00	17.00	129.00	2015

To analyze the data in a Pivot Grid including all cost types, the columns containing cost type values must all be added to the matrix cells. The cost types are then added as sub-headers to the columns, but there is neither a filter nor a total per year calculated, because the columns are regarded ans independent from each other:

Application Group	2015				2016	
	Consulting	Subscription	Expense	Other	Consulting	Subscription
1. Market Data	920	1215	3178	544	1048	1280
2. Trade Entry	2405	1690	8507	1013	2671	1690
3. Front Office	2150	1785	7265	974	2518	1785
4. Back Office	3223	2620	10974	1414	3555	2620
5. Customer Relations	95	705	342	198	270	705
6. Risk Reporting	604	1095	2125	417	876	1095
7. Finance Reporting	978	1260	3300	545	1099	1345
8. Accounting	593	420	2144	251	675	770
9. Payments	640	545	2087	289	765	545
Grand Total	11608	11335	39922	5645	13477	11835

The **Grand Total** column is also splitted into the sub-columns:

2018				Grand Total			
ting	Expense	Subscription	Other	Consulting	Expense	Subscription	Other
1731	5946	1260	729	5305	18357	5285	2672
2665	10021	1540	1032	10499	37360	6610	4197
2670	9805	1785	1105	10144	35845	7140	4261
3109	370402	2835	1545	13553	406800	10695	6052
1689	5689	1390	743	3140	10792	4295	1836
1804	5986	1380	785	4835	16847	5010	2436
957	342960	1360660	605	4246	354481	1364675	2432
983	209988	1300420	441	3028	217175	1302380	1425

16479	963894	2671815	7333	57830	1108144	2708270	26598

The report can be configured to display the table with a button in the toolbar that changes the view to the Pivot table analysis. The configured report can alternatively be configured to open directly in the Pivot table analysis view.

Do the following to enable Pivot table analysis:

1) In the explorer of the **Reports** tab, click the configured report.
2) In the attribute window, select one of the following options in the **Analysis Mode** attribute:

- `Optional`: A button **Pivot Grid**  is displayed in the tabular report to open a Pivot analysis. This is the default setting for new reports.
- `Always`: The report directly opens in the Pivot table analysis view.
- `Never`: A Pivot table analysis is not provided.

3) In the toolbar, click the **Save**  button to save your changes.

Please note that changing the **Analysis Mode** for existing configured reports might require a re-creation of the report view. It is recommended that the configured report be tested and the report view recreated only if changes were not applied.

If you would like the user to be informed about the functionality of the Pivot grid analysis view via the context sensitive help, you can do the following:

- An Alfabet specific standard help file is available for Pivot grid analysis. The standard help is only displayed if it is activated for the configured report:
  - If the **Analysis Mode** is changed to `Optional` or `Always`, the name of the standard help file is automatically written into the attribute **Help Index** of the report. The file is then offered to the user as context sensitive help for the configured report. Once the **Help Index** is set, it is not automatically removed when the Analysis Mode is changed again, but it can be removed manually.
  - The default setting for the report is `Optional`. Nevertheless the **Help Index** attribute is empty by default. To activate the standard help while keeping the default setting, you must either set the **Analysis Mode** to `Never` and then back to `Optional`, or manually enter `PivotTableAnalysis.html` in the **Help Index** attribute.
- A customer specific help can be opened. The method for defining customer specific help is described in the section Specifying Custom Help for a Configured Report.

Configuring a Data Table Report with Restructuring Options for the End User

End user design option can be added to a tabular configured report based on an Alfabet query. The configured report will then be displayed in the design defined via the Alfabet query it is based on, but it can be reconfigured by the user. The end user can select properties of any of the object classes that are added to the Alfabet query either as `FIND` class or via a `JOIN` as additional show properties and deselect show properties from the default layout. Furthermore, the report design can be changed from tabular to matrix and pictures and colors can be added to the design.

Any tabular configured report can be defined as data table report with end user design capabilities by adding the following configuration to the report:

1) In the explorer of the **Reports** tab, click the configured report.
2) In the attribute window, select `DataTableReport` from the dropdown list of the **Template** attribute.

   The attribute **Standard Context-Sensitive Help Index** is filled automatically with the correct link to the end user help file in the standard Alfabet online help on selection of the `DataTableReport` template. The standard help can be deactivated by deleting the value from the **Standard Context-Sensitive Help Index** attribute. A customer specific help can be opened. The method for defining customer specific help is described in the section Specifying Custom Help for a Configured Report.

3) In the toolbar, click the **Save**  button to save your changes.

Note the following about the definition of the Alfabet query for the report:

- The report must have a default layout defined via the **Show Properties**. If no default layout is defined, the report will not be displayed to the user and the design options will also be missing.
- The user will be able to select all properties of the object classes included into the Alfabet query except for the properties of the type `Reference` or `Reference Array`. References to other object classes are only available if a `JOIN` to the respective object class is defined.
- If you would like to restrict the properties available via the report to a subset of the properties of the object classes involved, you can define a database view containing the relevant data and create the report about the database view instead of the object class tables.
- If you would like the user to add role assignments or indicators to the configured report, you must either include all indicators and roles as show properties of the type `Indicator` or `Role` to the Alfabet query, or add the involved object classes via `JOINS`. The indicator and role definitions that are available in the property overview of the Alfabet Query Builder for an object class will not be part of the properties that are only selectable by the user, but not available via the standard layout.
- **Sort Properties** definitions are ignored.
- In the **Data Source** editor that allows the user to select the data for display in the report, the object class properties are listed as ObjectClassCaption.PropertyCaption. If an alias is defined for the object class or object class property, the alias name is displayed instead of the object class caption or property caption. The definition of a `SetColumnShowName` instruction supersedes an alias definition for the object class property. The end user can change the caption of the columns that are defined via the Alfabet query of the report directly in the report.
- Navigation from the report to the object view or object profile of objects that are accessible via the configured report is not available by default. You can define columns in the tabular report to provide navigation. Navigation can be defined for any data and any number of columns. For example, for a configured report that displays information flows and the source and target applications thereof, the report can be configured to provide navigation to the information flows if the user double clicks on the information flow name, to the source applications if the user double clicks the name of a source application and to the target applications if the user double clicks the name of the target application.

Navigation is provided via the Alfabet query language instruction `CreateRefImage`, that merges a column returning the `REFSTR` of an object with any other column in the report. As a result, a single, navigable column is displayed at the position of the column returning the `REFSTR`, but showing the information from the other merged column. For information about the definition of the instruction, see Configuring Cells in a Data Table Report to Provide Navigation to an Object Profile in the section Using Instructions to Format the Results of an Alfabet or Native SQL Query.

- In general, Alfabet query language instructions can be used in the Alfabet query, with the limitation that the result must not involve dependencies between cells in different columns of the resulting dataset. For example,:
  - You can color cells using a `ColorAssignment` instruction, because the coloring depends on the results in the current column only, but a `RowColorAssignment` instruction will be ignored, because cell coloring of cells of one column would depend on the result of cells in another column.
  - You can use a `JoinColumns` instruction. The result is a single, independent column in that will be presented as selectable or deselectable data to the end user and the results in the joined column will be displayed wherever the end user selects it to be displayed in a tabular or matrix

structure. In contrast, you cannot use a `GroupBy_Ex` instruction, because the instruction creates a structure in the result dataset that involves more than one column to be created.

- You cannot use a `LinkAssignment` instruction because the link displayed in one column depends on an object specification in another column of the dataset.

- Coloring and picture assignment defined in the Alfabet query for data in a column will only be available in a tabular layout. If the user changes the design to a matrix layout, the default picture and color assignment will be removed. The end user can define own color and picture rules that supersede the default color and picture rules. Color rules and picture rules defined in the Alfabet query are not added to the legend of the data table report. The legend is limited to user defined coloring and picture assignment.

Creating a Tabular Configured Report of the Type NativeSQL

To generate a configured report of the type `NativeSQL`:

- In the **Reports** tab of Alfabet Expand, create a new configured report and define the general attributes for the configured report and the attributes specific for native SQL query-based configured reports. For more information about creating a configured report and defining the configured report's attributes, see Creating a New Native SQL Query-Based Configured Report.

- Configure a native SQL query for the configured report. For more information, see Configuring a Native SQL Query for a Configured Report. If the report result shall be an expandable table, the native SQL query must be configured to contain instructions. This is described separately in the section Grouping Query Results in Expandable Reports in the chapter Defining Queries.

- If the configured report has filters defined, create an SQL report view, check the functionality of the filters, and optionally change the captions and look of the filter fields. For more information, see Defining Filters for Configured Reports and Selectors in the chapter Defining Queries.

- Define access rights for the configured report in the **Reports Administration** functionality of Alfabet. By default, access is possible for all users. For more information, see the chapter *Defining and Managing User Access to Configured Reports* in the reference manual *User and Solution Administration*.

- Set the **Report State** attribute of the configured report to `Active`. For information on how to change theattribute of the configured report, see.

The following information is available:

- Creating a New Native SQL Query-Based Configured Report
- Configuring a Native SQL Query for a Configured Report
- Defining a Data Capture Environment for a Configured Report of the type NativeSQL
- Defining a User Management Functionality via a Configured Report of the Type NativeSQL
- Allowing the User to Change the Number and Order of Columns in the Table

- Configuring the Analysis of the Tabular Report in a Pivot Grid
- Configuring a Data Table Report with Restructuring Options for the End User
- Defining Audit Management Related Configured Reports

Creating a New Native SQL Query-Based Configured Report

To create a new native SQL query-based configured report in Alfabet Expand:

1) In the **Reports** tab, right-click the **Reports** folder or a sub-folder thereof and select **Create New Report**. You will see the new configured report listed below the selected folder.

As an alternative to defining all attributes for a new configured report, you can copy and paste an existing configured report and make modifications, as needed. To do so, right-click the existing configured report that you want to copy and select **Copy**. Right-click the new configured report and select **Paste**. Modify the necessary attributes described below.

2) In the attribute window, select `NativeSQL` in the **Type** field.
3) In the attribute window, define the following attributes for the configured report:
   - **Name**: Optionally, change the technical name of the configured report. The technical name of the configured report must be unique.

The technical name is used for identification of the configured report in the context of technical processes such as merging the report configuration with a report configuration saved as an XML file. Therefore, the following is required when defining the name of a configured report:

- The name must be unique. The name must be unique regardless of the report folder it is structured in.
- The name may not be changed once a configured report has been created.
- A validation mechanism checks for correct syntax when defining a technical name. Please note that names may not begin with an empty space nor include special characters. For a list of the special characters that are not allowed, see the section Defining Attributes for Configuration Objects in the chapter Getting Started with Alfabet Expand.
- If the technical name of the configured report is changed, the name will be correctly updated in other configuration objects referencing the changed report during design time.

Please note that the name of a changed configuration object will not be updated in guide pages or guide views. If you plan to change the name of a configuration object, the reference in the navigation page should be changed prior to changing the configuration object name. You can use the **Show Usage** functionality in the context menu of the configured report to evaluate whether the configured report has been added to a guide view or guide page.

   - **Caption**: Enter a caption for the configured report. The caption you define here will be displayed in the **Reports Administration** functionality in the **Administration** module and the

Configured Reports views of the Alfabet interface. If the configured report is assigned to an object view as a page view, the text will be displayed as the page view caption in the object view. The caption of the configured report may exceed the conventional 64 character limit.

- **Description**: Provide a short information about the configured report that is useful to Alfabet users. This comment will be displayed on the Alfabet user interface in the header of the configured report in a single line under the report caption and the **Description** field for the configured report in the table of all views listing configured reports, like the **Configured Reports** views of the **Search** functionalities. If the configured report is assigned to an object view as a page view, the text will be displayed under the page view caption as short description in the object view.

  In the configured report, the description will be truncated if it is longer than one line on the screen. Therefore, the description should be short to ensure complete display in the configured report header.

- **Usage Guideline**: Provide information that helps users to execute and interpret the configured report. This information will not be displayed directly on the user interface. The user can access the information using the following mechanisms:

  - If the user moves the cursor over the description provided for the configured report with the attribute **Description**, a tooltip opens that includes both the description and the usage guideline.
  - The **Options**  button will be displayed on the upper right with an option **Help On Filter Fields** to open a new window displaying the usage guideline in addition to any filter field hints, if configured.

    For views that have filters defined, the **Options**  button will only be displayed if the filter panel either allows batch clearing of filter fields or collapsing and expanding of the filter panel. For more information about the configuration of these functionalities, see Configuring the Complete Filter Area to be Collapsible and Allowing the User to Clear the Filter Area.

- **Technical Comment**: Provide information that is useful for solution designers working with Alfabet Expand in order to better understand the configured report from a technical perspective. The **Technical Comment** will not be displayed in the user interface. Nevertheless, you can configure the interface to display the information in, For example, the attribute section of the configured report's object profile in the **Reports Administration** functionality.
- **Report State**: The **Report State** attribute is view only and is set to `Plan` for new configured reports. The configured report can only be edited when the **Report State** attribute is set to `Plan`. After finishing all configuration steps described in the following, the **Report State** attribute must be set to `Active` as described in the section General Guidelines for Creating Configured Reports. The configured report is then visible to users in the Alfabet user interface.
- **Native SQL**: Click the **Browse**  button to open an editor and define the native SQL query for the configured report. Optionally, you can define instructions in Alfabet query language to alter the display of the query results.

For basic information about how to define native SQL queries, consult the relevant literature.

For special information about how to define native SQL for Alfabet, see the section Defining Native SQL Queries in the chapter Defining Queries.

For special hints for building a native SQL query for configured reports, see Configuring a Native SQL Query for a Configured Report in this section.

For a description of how to define report filters in a native SQL query, see Defining Filters for Configured Reports and Selectors in the chapter Defining Queries

For a description of how to define native SQL queries in combination with Alfabet instructions to built an expandable report table, see the section Grouping Query Results in Expandable Reports in the chapter Defining Queries.

- **Execute on Enter**: Set to `True` to execute the configured report with empty filter settings when the user opens the configured report on the Alfabet interface. Set to `False` to open the configured report without execution of the native SQL query with empty filter settings. By default, this attribute is set to `True`. It should only be set to `False` when a configured report would result in an exceedingly big dataset when executed with empty filter settings.

  When you set **Execute on Enter** to `False`, you must make sure that the **Submit** button is available in the SQL report view of the configured report. If the **Submit** button is deleted from the SQL report view, the configured report cannot be displayed. The setting and execution of the **Execute on Enter** attribute is independent from the definition of filters for a configured report. A configured report without filters must nevertheless have a **Submit** button when **Execute on Enter** is set to `False`.

- **Help Index**: Specify the location of the external Help file using the following syntax:(For example,:). The external help file will be displayed when the user clicks the context-sensitive Help link in the standardHelp menu.

  Server variables can be used in the Help links. Server variables allow you to define all or part of the URL definition in the server alias configuration of the Alfabet Server instead of directly defining it in the configuration in Alfabet Expand. Use of server variables is useful, For example, in order to change a Web server name defined in multiple URL definitions in Alfabet Expand. Instead of changing all URL definitions, only the variable value in the server alias configuration must be updated. The use of server variables is described in the section Using Server Variables in Web Link and Database Server-Related Specifications in the chapter Configuring Reports.

- **Apply to Class**: When the configured report is applied to an object class or object class stereotype, a base object can be selected for the configured report. A filter for selection of a base object will automatically be set on top of the configured report. When configuring queries for the configured report, you can use the Alfabet parameter `BASE` to refer to the object selected in the filter and define search conditions dependent on the base object. To apply the configured report to a base class, click the **Browse** button to open a dialog box and select the object class to which you want to apply the configured report and click **OK**.

  Note the following:

- If the configured report is assigned to the object view of an object of the class it is applied to, the configured report will automatically open with the current object selected as base object, even if **Apply to Class** is not set.
- If the configured report is applied to an object class stereotype, the filter field for selection of the base object will use the caption of the object class stereotype as caption of the filter field and the selector defined in the class settings for the object class stereotype for selection of the base object.
- Alternatively, the base object of a configured report can be set with the attribute **Base Query**. While the attribute **Apply to Class** enables the user to determine the current base object by setting a filter, the **Base Query** evaluates the base object by execution of a query when opening the configured report. A filter field is not available and the user cannot change the base object.
- The parameter **Apply to Class** also influences the availability of the configured report on the Alfabet interface. Select a class to make the configured report available in the **Configured Reports** page view on the object view of objects of the selected object class. If you do not set the attribute, the configured report is only available in the **Configured Reports** functionality. The configured report can be assigned to object views and wizards independent from the parameter.

- **Base Object Query**: When a base object query is defined for the configured report, a base object is evaluated for the configured report at runtime. When configuring the other queries for the configured report, you can use the Alfabet parameter `BASE` to refer to the object returned by the base object query and define search conditions dependent on the base object. To apply the configured report to a base class, click the **Browse** button to open a text editor, define either a native SQL query or an Alfabet query that returns a single object, and click **OK**.

  Note the following:

  - Alternatively, the base object of a configured report can be set with the attribute **Apply To Class**. While the setting of **Base Object Query** triggers the evaluation of the base object by execution of a query when opening the configured report, the attribute **Apply to Class** enables the user to determine the current base object by setting of an automatically generated filter.
  - The query defined for base object query is executed when the user opens the configured report to evaluate the base object at runtime. Parameters referring to the current working environment can be used in the query to find a base object dependent For example, on the user opening the configured report or the user profile used for login. A base object query may also find For example, the ICT object that a specific application is currently assigned to.
  - If **Base Object Query** is set and the configured report is assigned as a view to an object profile, the Alfabet parameter `BASE` referring to the `REFSTR` of the object the user is working with when opening the configured report can be used in the base object query.

- **Database Restricted User**: Optionally select a database user that shall be used by the Alfabet Web Application for connecting to the Alfabet database instead of the standard

database user with extended access permission when executing the configured report. The drop-down list is only filled if the use of different database users for configured report is specified in the XML object ***DatabaseUsers***. For more information about the concept of restricting access permissions for configured reports and the implementation of execution of configured reports with restricted database user rights, see the section Restriction of Database Access Permissions on Execution of Configured Reports.

- **Selector Behavior**: The attribute can be used to exclude configured reports that are defined for special purposes, like For example, triggering of data export via the RESTful API, from being selectable in the **Configured Reports** table. By default, the attribute is set to `Visible` and the configured report is visible in the selector for adding configured reports to the **Configured Reports** table if all other conditions for access to the configured report apply. If the attribute is set to `NotVisible`, the configured report is excluded from the selector for adding configured reports to the **Configured Reports** functionality. Please note however, that this setting is not excluding the configured report from any standard views or customer configured views and selectors, but exclusively from the standard selector for configured reports implemented in Alfabet.

The attribute cannot be edited in the attribute window directly. To change the setting, right-click the configured report and select **Set Report Selector Behavior to 'Not Visible'** or **Set Report Selector Behavior to 'Visible'** respectively.

- **Applicable for AlfaBot**: Specify whether the configured report is accessible via the AlfaBot. By default, the attribute will be set to `True` for new reports. Set the attribute to `False` if the configured report should not be opened outside of a specific context. For example, this may be relevant for reports that are specifically designed to be embedded in an object cockpit.

  This attribute is only relevant if the AlfaBot is implemented. For information about the implementation of the AlfaBot, see Implementing the AlfaBot for Navigation via a Full-Text Command.

- **Business Problem Statement**: Optionally enter a description that will help users to search for the configured report in the AlfaBot. The text is not displayed in the user interface, but it is of special relevance for the search mechanisms implemented for the AlfaBot. If the report caption entered by the user in the AlfaBot for a request to open a configured report does not match the caption of one of the available configured reports, the AlfaBot will split the caption entered by the user into keywords and will perform a keyword search on the **Caption**, **Description** and the **Business Problem Statement** attributes of the configured reports that are accessible via the AlfaBot. In addition to a keyword search, a synonym search is performed on the text provided in the **Business Problem Statement** attribute.

  This attribute is only relevant if the AlfaBot is implemented. For information about the implementation of the AlfaBot, see Implementing the AlfaBot for Navigation via a Full-Text Command.

- **Base Classes**: Define the object classes that must be available to run the configured report. If this attribute is set, the Alfabet Server checks whether the object classes specified as base classes are excluded from the view scheme used to access the configured report. If the user does not have access permissions to one of the base classes, the configured report will be disabled. To set the attribute, click the **Browse** button to select the object classes that are required to run the configured report and click **OK**.

- **Can Create Express View**: Select `True` if an express view may be created for the report. Select `False` if an express view may not be created for the report. Please note that for reports that have a custom report view, the setting must be consistent with the setting of the attribute **Can Create Express View** of the custom report view.

  An express view is a link to a specific Alfabet view displaying data that allows individuals inside or outside of the user community to view information in Alfabet. When the express view is created, an email notification is automatically mailed to a specified recipient. The recipient receives a URL that allows him/her to access the current page view in Alfabet. For more information, see the section *Sending and Receiving Express Views* in the reference manual *Getting Started with Alfabet*.

- **Chart Views Mode**: This attribute defines whether additional information about the objects found in the configured report will be available via standard page views or configured reports directly accessible via links from the configured report view. Select one of the following:

  - `Standard`: A button **Chart Views** for opening a standard lifecycle chart, business support map, information flow diagram or portfolio for an object selected in the result dataset of the configured report is available automatically in the toolbar of the configured report if the following applies:

    - At least one of these standard reports is available for the object class the report finds objects for.
    - No Alfabet query language instruction is defined in the Alfabet query of the configured report.
    - The **Enable Chart Views** attribute is set to **True**.

  - `Custom`: All configured reports defined in the **Supplementary Reports** attribute of the class settings of the object class found via this configured tabular report are available via tabs on top of the toolbar of the tabular dataset. If a filter is available, the tabs are located between the filter area and the toolbar of the dataset. For information about the configuration of configured reports suitable to be opened via tabs in tabular configured reports and the configuration of the class setting to provide the configured reports, see Integration of Configured Reports as Report Collection Into Tabular Configured Reports.

  - `None`: Neither standard page views nor configured reports are directly accessible via links from the configured report view.

- **Custom Chart View Base Class**: This attribute is only visible if the **Chart Views Mode** attribute is set to `Custom`. Select the object class or object class stereotype for which the tabs opening the configured reports for the report collection shall be displayed. The configured reports defined in the **Supplementary Reports** attribute of the class settings of the object class or object class stereotype will be available via tabs. Please note that the selected object class must be identical to the object class found in the tabular dataset of the configured report you are currently configuring. If the objects found in the tabular dataset do not match the setting, the report will not show the tabular dataset, but an error message about the incorrect setting in the configuration.

4) In the toolbar, click the **Save**  button to save your changes.

Configuring a Native SQL Query for a Configured Report

To define or edit the native SQL query of a configured report:

1) In the table, select the configured report whose native SQL query you want to define or edit.
2) Click the **Browse** button in the **Native SQL** attribute. A text editor opens.
3) In the **Native Query** tab of the text editor, define the native SQL query for the selection of objects for the configured report.

   The following is important for the generation of a native SQL query for a configured report:

   - If the configured report is applied to an object class with the attribute **Apply to Class**, you must configure the native SQL query to show results for the current object that is selected by the user when opening the configured report only. To refer to the current object, use the Alfabet parameter "`@BASE`". For example, a configured report with the base class `Application` with a `WHERE` clause "`WHERE Application.REFSTR=@BASE`" will show results for the application that the user is currently working with only. A selector is added automatically to each configured report that is applied to an object class by means of the attribute **Apply to Class** . The selector allows the user to display other base objects in the configured report. If you do not specify a `WHERE` clause with the Alfabet parameter `@BASE`, the selector will still be present, but it will not have any impact on the resulting configured report.
   - You can define filters for a configured report to allow the users to specify the range of results in the configured report. You can generate a filter from any `WHERE` clause of the configured report by defining the value of the `WHERE` condition as Alfabet parameter. For more information about configuring filters, see Defining Filters for Configured Reports and Selectors in the chapter Defining Queries.
   - You can combine the native SQL query with Alfabet instructions written in Alfabet query language. The instructions are defined separately in the tab **Instructions**. Instructions allow you For example, to define the output format for date and time information and to generate expandable report tables. For information about configuring Alfabet instructions, see Using Instructions to Format the Results of an Alfabet or Native SQL Query in the chapter Defining Queries .

     To check whether the syntax and the use of Alfabet parameters is correct in the native SQL query, click **Check**. The **Check** button checks the query for Alfabet conformance. Database vendor specific SQL constructs, requirements, or dialects are not taken into account for this check.

4) Click **OK** to save the native SQL query.
5) If the query contains `WHERE` clauses that trigger the generation of filter fields, right-click the configured report and select **Create SQL Report View**. The view editor opens and displays the SQL report view with the automatically generated filter fields. In the explorer, the SQL report view is displayed as a subordinate object of the configured report.

   In the SQL report view, a filter field is automatically generated for each Alfabet parameter specification in a `WHERE` clause of the query of the configured report. Each combination of property data type and condition in the `WHERE` clause lead to the generation of a specific filter field.

   For some data types, the generated fields need further configuration by the report designer to work properly. In addition, filter fields can be removed and substituted by other filter field types.

For example, a combo box can be substituted by a checked combo box to allow the user to select multiple values.

The following table lists the filter fields that result from automatic generation of filter fields and whether processing is required. Detailed information about the types of filter fields available for configured reports and the configurations that are required to generate and design filters is available in the section Defining Filters for Configured Reports and Selectors in the chapter Defining Queries.

Condition	Property Data Type	Resulting Filter Field Type	Required additional configuration of filter field
=,!=	`String`	Edit (one-line text field; no wildcards allowed in text entered into the field)	If automatic setting of wild cards is defined in the XML object `SearchManager`, the attribute **Allow Wildcards** of the edit fields must be set to `False`. For more information, see Configuring Edit Fields in the section Defining Filters for Configured Reports and Selectors.
LIKE, NOT LIKE, IN	`String`	Edit (one-line text field; wildcards allowed in text entered into the field)	
=, <>, LIKE, NOT LIKE, IN	`String (Property based on configuration in XML object or enumeration)`	Combo box	Some of the combo boxes require further setting of attributes to read the data from the correct configuration objects. For more information, see Configuring Radio Button Groups, Combo-Boxes, Checked Combo-Boxes, List Boxes or Checked List Boxes in the section Defining Filters for Configured Reports and Selectors.
LIKE, NOT LIKE	`StringArray`	Combo box	The content of the combo box must be defined in the attributes of the combo box. For more information, see Configuring Radio Button Groups, Combo-Boxes, Checked Combo-Boxes, List Boxes or Checked List Boxes in the section Defining Filters for Configured Reports and Selectors.
=,!=, <>,<=, >=,<,>	`Date`	Date picker	

Condition	Property Data Type	Resulting Filter Field Type	Required additional configuration of filter field
=,!=, <>,<=, >=,<,>	`Integer / Real`	Edit	
=, !=, LIKE, NOT LIKE, IN	`Boolean`	Combo box	Filter fields for boolean properties cannot be generated automatically for technical reasons. The automatically generated combo box will not work and must be substituted with a check box. For more information, see Configuring Check Boxes in the section Defining Filters for Configured Reports and Selectors.
=, !=, LIKE, NOT LIKE, IN	`Reference / ReferenceArray`	Combo box	The content of the combo box must be defined in the attributes of the combo box. For more information, see Configuring Radio Button Groups, Combo-Boxes, Checked Combo-Boxes, List Boxes or Checked List Boxes in the section Defining Filters for Configured Reports and Selectors.

6) In the explorer, right-click the configured report and select **Review Report**. The configured report opens in a web browser. If the results are not as expected, you can edit the native SQL query until the output of the configured report meets your expectations.

The **Review Report** functionality also allows the visibility of toolbar buttons of the configured report to be defined for different view schemes. For more information, see Refining Visibility Issues in the View Scheme.

7) In the toolbar, click the **Save** button to save your changes.

The amount of data that can be displayed in a configured report is restricted in order to avoid exceeding memory size usage. If a configured report results in an error message informing you that the data set is too large, refine the query to return only a subset of the results. If you do not want to exclude objects from the configured report but rather would like to limit the set of data that is displayed, you can define filters that allow the user to restrict the data display as needed (For example, by displaying only objects with a name starting with a specific character or objects assigned to a specific ascendant object).

Defining a Data Capture Environment for a Configured Report of the type NativeSQL

The buttons that are available in standard data capture functionalities in Alfabet can also be added to a configured report that displays data about the respective class in a table. Standard data capture functionalities are available for the object classes application, component, device, peripheral, ICT object and service product.

Note the following about the configuration:

- The attribute **Template** of the configured report must be set prior to creating the custom report view. If a configured report already has a custom report view defined, setting of the Template attribute will not add the buttons unless the custom report view is deleted and re-created.
- The objects found be the query the configured report is based on must be of the object class or object class stereotype for that the data capture environment is defined. Please note that for the `CaptureProjects` template, the report must be limited to a defined object class stereotype to deliver valid results.
- If the configured data capture report shall be limited to editing of objects of a specific stereotype only, the following is required:
  - All objects that are displayed in the report can be edited regardless of the stereotype. If you want to limit editing to data with a specific steretype, you must limit display of objects in the report table to objects of that stereotype via the query definition of the configured report.
  - To limit creation of new objects to object of a specific stereotype, enter the name of the stereotype into the attribute **Parameter** of the configured report. This setting must be performed prior to creating the report view.

To add the buttons available in a standard data capture environment to the configured report, the following configuration is required in addition to the configuration described above for general configuration of the configured report:

1) In the attributes window of the configured report, set the attribute **Template** to one of the following values:
   - `CaptureApplications`
   - `CaptureComponents`
   - `CaptureContracts`
   - `CaptureDemands`
   - `CaptureDevices`
   - `CaptureIssues`
   - `CapturePeripherals`
   - `CaptureProjects`
   - `CaptureICTObjects`
   - `CaptureServiceProducts`
   - `CaptureVendorProducts`
   - `CaptureVendors`
2) If you have selected the template `CaptureIssues`,set the **Apply to Class** attribute of the configured report to the object class that the issues shall be created for.
3) If creating of objects shall be limited to a defined stereotype, enter the name of the stereotype into the attribute **Parameter** of the report. If you have selected the template `CaptureIssues`, you can add a comma separated list of stereotype names in the **Parameter** attribute to restrict the

creation of issues to issues of all specified stereotypes. The sub-menu of the **New** button in the toolbar of the report will be adapted to inform the user which issue stereotypes can be selected.

4) Right-click the configured report and select **Create Report View**.

5) Optionally, you can define which buttons will be displayed in the toolbar:

- You can hide standard buttons from the toolbar. For information about the required settings, see Hiding Functionalities in a Page View or Configured Report.

- You can substitute the standard mass update functionalities in the data capture functionality with the editor available from a configured report for multi-editing of object class properties. The editor will be available via a button **Bulk Edit** that will be automatically added to the toolbar for all data capture environment report that have a configured report for multi-editing of object class properties assigned. The button will have submenu options for opening the editor or, if available via the configured report for multi-editing of object class properties, the options for setting the same value for all selected indicators, properties or roles. The editor will open for the objects selected in the table and the rules for visibility and editability of properties defined in the configured report for multi-editing of object class properties will be applied. Do the following to enable mass update in an editor from a configured report for multi-editing of object class properties.

  - Create a configured report for multi-editing of object class properties based on the template `EditableClassViewReport`. Make sure that the report is targeting the same object class as your data capture report and that the edit rights are in accordance with the edit rights that you would like users to have for objects when working in your configured data capture environment. For information about the definition of a report for multi-editing of object class properties based on the template `EditableClassViewReport`, see Creating Configured Reports With Editing Capabilities.

  - Right-click the data capture report and select **Start Alfabet Report Assistant**. In the assistant, select the configured report for multi-editing of object class properties in the dropdown list of the field **Editable View Report**. Click **OK**.

Defining a User Management Functionality via a Configured Report of the Type NativeSQL

The functionalities for user management that are available in the standard Alfabet views **User Administration** (`ADMIN_UsersOverview`) and **Contact Administration** (`ADMIN_ContactsOverview`) can also be added to a configured report that displays user data in a table. The administrative functionalities available in the configured report are limited to the functionalities that apply to selected users in the table. All functionalities that apply changes to all users in the database are not included in the configured report.

Via the configured reports, users can be provided with administrative access to the user data for a selected sub-set of users in the Alfabet database, For example, to all users that are in a defined user group. In addition, the view can be adapted to the specific tasks of the user that will administrate users for the configured report by adding filter fields and configuring the tabular dataset of the report to include information about a user that is not available in the standard **User Administration** view.

Note the following about the configuration:

- The attribute **Template** of the configured report must be set prior to creating the SQL report view. If a configured report already has an SQL report view defined, setting of the **Template** attribute will not add the buttons unless the custom report view is deleted and re-created.
- The objects found be the query the configured report is based on must be of the object class `PERSON` for that the data capture environment is defined.
- You can limit the availability of the configured report to access from user profiles with administrative rights. If you set the attribute **Restrict to Administrative User Profiles** of the SQL report view is set to `True`, the configured report can only be opened if the user is logged in with a user profiles for that the attribute **Is Administrative User Profile** is set to `True`.

To add the the functionality available in the standard **User Administration** view for administration of selected users to the configured report, the following configuration is required in addition to the configuration described above for general configuration of the configured report:

1) In the attributes window of the configured report, set the attribute **Template** to `UserManagementReport` or `ContactManagementReport`.
2) Right-click the configured report and select **Create SQL Report View**.
3) Optionally, click the SQL report view and set the attribute **Restrict to Administrative User Profiles** of the SQL report view to `True`.

Allowing the User to Change the Number and Order of Columns in the Table

A tabular configured report can be configured to display a **Configure** button in the toolbar of the configured report. The user can do the following in the editor opened via the button:

- Change the order of columns in the table.
- Hide columns from the table.

The following configuration is required to display the **Configure** button:

1) If a report view has not yet been defined for the configured report, right-click the configured report and select **Create SQL Report View** . In the explorer, the SQL Report View is displayed as a subordinate object of the configured report.
2) Expand the SQL Report View node under the explorer node of the configured report and click the Presentation Object node under the SQL Report View node. The attribute window displays the attributes of the presentation object.
3) Set the attribute **Configurable** of the Presentation Object to `True`.

Configuring the Analysis of the Tabular Report in a Pivot Grid

A tabular configured report can be analysed in a Pivot grid and the graphical representation thereof. By default, new configured tabular reports have a button **Pivot Grid** that opens a new view with the Pivot functionality. This default behaviour can be changed to other analysis modes or deactivated.

The third party component DevExpress® is used to render results in a Pivot table.

DevExpress® must be activated in the web.config file of the Alfabet Web Application to be used in configured reports. For more information about the activation, see *Prerequisits for Using DevExpress®* in the *Technical Requirements*.

If you would like to offer Pivot grid analysis for a tabular report, you should note the following when creating the query for the report:

- The analysis is performed on basis of the result dataset. Columns are identified by their caption. Therefore, the caption of the columns must be unique. In addition, the user cannot see the data table when working with the Pivot Table Analysis. Captions should be designed to provide information about the kind of data returned in the respective column to enable the user to decide where to place the data in the Pivot grid.
- At least one column in the result dataset must return a numerical value. Only numerical values can be added to the cells in the matrix of the Pivot Grid.
- If navigation from the table to the object profile or object cockpit of a base object for each result dataset is provided, it is also identically available in the Pivot Grid.
- If you would like the user to analyze multiple numerical values that are having a different aspect, For example, costs that are having a different cost type, the aspects can only be summed up if you list the aspect, For example, the cost type, in one column and the value in a second column. If you add one column for each aspect, that each contain the respective values for this aspect, the data can only be analysed next to each other, but not merged.

  For example, if a configured report shall return for applications in application groups the current costs over the years separately for each cost type. The way the data can be analyzed in a Pivot Grid depends on the structure of the tabular output of the report:

  - The tabular output of the configured report may display one line returning the cost type name and one row returning the budget value for all cost types:

	Application Group Name	Application Name	Cost Type Name	Budget Value Value	Budget Value Year
1	2. Trade Entry	EMERGING MARKET SYSTEMS v. 3.1.2	Subscription	25.00	2015
2	2. Trade Entry	EMERGING MARKET SYSTEMS v. 3.1.2	Expense	115.00	2015
3	2. Trade Entry	EMERGING MARKET SYSTEMS v. 3.1.2	Consulting	31.00	2015
4	2. Trade Entry	EMERGING MARKET SYSTEMS v. 3.1.2	Other	14.00	2015
5	2. Trade Entry	EMERGING MARKET SYSTEMS v. 3.1.2	Subscription	25.00	2016
6	2. Trade Entry	EMERGING MARKET SYSTEMS v. 3.1.2	Expense	129.00	2016
7	2. Trade Entry	EMERGING MARKET SYSTEMS v. 3.1.2	Consulting	37.00	2016
8	2. Trade Entry	EMERGING MARKET SYSTEMS v. 3.1.2	Other	15.00	2016
9	2. Trade Entry	EMERGING MARKET SYSTEMS v. 3.1.2	Subscription	25.00	2017
10	2. Trade Entry	EMERGING MARKET SYSTEMS v. 3.1.2	Expense	132.00	2017
11	2. Trade Entry	EMERGING MARKET SYSTEMS v. 3.1.2	Consulting	37.00	2017

  If the report is analyzed in a Pivot Grid for application group costs per year. The cost values are all from the same column and Therefore, the Pivot Grid can be configured to display costs independent from the cost type. The cells in the matrix then display a sum of the costs for all cost types belonging to the same year and application group:

	Budget Value Year				
Application Group Name	2015	2016	2017	2018	Grand Total
1. Market Data	5857	6611	9485	9697	31650
2. Trade Entry	13615	14990	14803	15346	58754
3. Front Office	12174	14412	15439	15396	57421
4. Back Office	18231	20295	20683	377891	437100
5. Customer Relations	1340	2199	7013	9599	20151
6. Risk Reporting	4241	5566	9366	10139	29312
7. Finance Reporting	6083	6957	7612	1705340	1725992
8. Accounting	3408	4284	4484	1511832	1524008
9. Payments	3561	4168	4444	4861	17034
Grand Total	68510	79482	93329	3660101	3901422

Alternatively, the Pivot Grid can display costs per cost type by adding the cost types as column header:

	Budget Value Year		Cost Type Name				
Application Group Name	2015				2015 Total	2016	
	Consulting	Expense	Other	Subscription		Consulting	Ex
1. Market Data	920	3178	544	1215	5857	1048	
2. Trade Entry	2405	8507	1013	1690	13615	2671	
3. Front Office	2150	7265	974	1785	12174	2518	
4. Back Office	3223	10974	1414	2620	18231	3555	
5. Customer Relations	95	342	198	705	1340	270	
6. Risk Reporting	604	2125	417	1095	4241	876	
7. Finance Reporting	978	3300	545	1260	6083	1099	
8. Accounting	593	2144	251	420	3408	675	
9. Payments	640	2087	289	545	3561	765	
Grand Total	11608	39922	5645	11335	68510	13477	

A filter field is then displayed on top of the column headers that allows to remove costs for singel cost types from the dataset.

For each year, a total sum is calculated, displaying the total costs independent from the cost type. On the right of the grid, the **Grand Total** column calculates the total costs per application group and year:

⊟ 2018				2018 Total	Grand Total
Consulting	Expense	Other	Subscription		
1731	5946	735	1285	9697	31650
2692	10021	1093	1540	15346	58754
2670	9805	1111	1810	15396	57421
3109	370402	1545	2835	377891	437100
1689	5689	760	1461	9599	20151
1892	5986	821	1440	10139	29312
957	342963	645	1360775	1705340	1725992
983	209988	441	1300420	1511832	1524008
871	3097	348	545	4861	17034

- The tabular output may alternatively display one line per cost type with the cost type name given as column header and the cost type value listed in the respective row:

	Application Group	Application	Subscription	Expense	Consulting	Other	Year
1	OptiRetail CRM As-Is Situation	Business EAI Platform 2.2	110.00	4.00	1.00	28.00	2015
2	Corporate CRM AS-IS Situation	Business EAI Platform 2.2	110.00	4.00	1.00	28.00	2015
3	Corporate CRM TO-BE Situation	Business EAI Platform 2.2	110.00	4.00	1.00	28.00	2015
4	Applications Using UDB	Groupware Services 2.2	60.00	29.00	7.00	16.00	2015
5	Corporate CRM AS-IS Situation	Groupware Services 2.2	60.00	29.00	7.00	16.00	2015
6	Corporate CRM TO-BE Situation	Groupware Services 2.2	60.00	29.00	7.00	16.00	2015
7	5. Customer Relations	Mafo-Portal 2.6	500.00	63.00	17.00	129.00	2015
8	CRM Analysis	Mafo-Portal 2.6	500.00	63.00	17.00	129.00	2015
9	Applications Using UDB	Mafo-Portal 2.6	500.00	63.00	17.00	129.00	2015
10	SAP Landscape	Mafo-Portal 2.6	500.00	63.00	17.00	129.00	2015
11	Customer Management	Mafo-Portal 2.6	500.00	63.00	17.00	129.00	2015
12	OptiRetail CRM As-Is Situation	Mafo-Portal 2.6	500.00	63.00	17.00	129.00	2015

To analyze the data in a Pivot Grid including all cost types, the columns containing cost type values must all be added to the matrix cells. The cost types are then added as sub-headers to the columns, but there is neither a filter nor a total per year calculated, because the columns are regarded ans independent from each other:

Application Group	2015				2016		
	Consulting	Subscription	Expense	Other	Consulting	Subscription	E
1. Market Data	920	1215	3178	544	1048	1280	
2. Trade Entry	2405	1690	8507	1013	2671	1690	
3. Front Office	2150	1785	7265	974	2518	1785	
4. Back Office	3223	2620	10974	1414	3555	2620	
5. Customer Relations	95	705	342	198	270	705	
6. Risk Reporting	604	1095	2125	417	876	1095	
7. Finance Reporting	978	1260	3300	545	1099	1345	
8. Accounting	593	420	2144	251	675	770	
9. Payments	640	545	2087	289	765	545	
Grand Total	11608	11335	39922	5645	13477	11835	

The **Grand Total** column is also splitted into the sub-columns:

2018				Grand Total			
ting	Expense	Subscription	Other	Consulting	Expense	Subscription	Other
1731	5946	1260	729	5305	18357	5285	2672
2665	10021	1540	1032	10499	37360	6610	4197
2670	9805	1785	1105	10144	35845	7140	4261
3109	370402	2835	1545	13553	406800	10695	6052
1689	5689	1390	743	3140	10792	4295	1836
1804	5986	1380	785	4835	16847	5010	2436
957	342960	1360660	605	4246	354481	1364675	2432
983	209988	1300420	441	3028	217175	1302380	1425
871	3097	545	348	3080	10487	2180	1287
16479	963894	2671815	7333	57830	1108144	2708270	26598

The report can be configured to display the table with a button in the toolbar that changes the view to the Pivot table analysis. The configured report can alternatively be configured to open directly in the Pivot table analysis view.

Do the following to enable Pivot table analysis:

1) In the explorer of the **Reports** tab, click the configured report.
2) In the attribute window, select one of the following options in the **Analysis Mode** attribute:

- `Optional`: A button **Pivot Grid**  is displayed in the tabular report to open a Pivot analysis. This is the default setting for new reports.
- `Always`: The report directly opens in the Pivot table analysis view.
- `Never`: A Pivot table analysis is not provided.

3) In the toolbar, click the **Save**  button to save your changes.

Please note that changing the **Analysis Mode** for existing configured reports might require a re-creation of the report view. It is recommended that the configured report be tested and the report view recreated only if changes were not applied.

If you would like the user to be informed about the functionality of the Pivot grid analysis view via the context sensitive help, you can do the following:

- An Alfabet specific standard help file is available for Pivot grid analysis. The standard help is only displayed if it is activated for the configured report:
  - If the **Analysis Mode** is changed to `Optional` or `Always`, the name of the standard help file is automatically written into the attribute **Help Index** of the report. The file is then offered to the user as context sensitive help for the configured report. Once the **Help Index** is set, it is not automatically removed when the Analysis Mode is changed again, but it can be removed manually.
  - The default setting for the report is `Optional`. Nevertheless the **Help Index** attribute is empty by default. To activate the standard help while keeping the default setting, you must either set the **Analysis Mode** to `Never` and then back to `Optional`, or manually enter `PivotTableAnalysis.html` in the **Help Index** attribute.
- A customer specific help can be opened. The method for defining customer specific help is described in the section Specifying Custom Help for a Configured Report.

Configuring a Data Table Report with Restructuring Options for the End User

End user design option can be added to a tabular configured report based on a native SQL query. The configured report will then be displayed in the design defined via the `SELECT` statement of the native SQL query it is based on, but it can be reconfigured by the user. The user can deselect columns from display, change the sort order of columns and change the report design from tabular to matrix. Furthermore, pictures and colors can be added to the design.

Any tabular configured report can be defined as data table report with end user design capabilities by adding the following configuration to the report:

1) In the explorer of the **Reports** tab, click the configured report.
2) In the attribute window, select `DataTableReport` from the dropdown list of the **Template** attribute.

The attribute **Standard Context-Sensitive Help Index** is filled automatically with the correct link to the end user help file in the standard Alfabet online help on selection of the `DataTableReport` template. The standard help can be deactivated by deleting the value from the **Standard Context-Sensitive Help Index** attribute. A customer specific help can be opened. The method for defining customer specific help is described in the section Specifying Custom Help for a Configured Report.

3) In the toolbar, click the **Save**  button to save your changes.

Note the following about the definition of the native SQL query for the report:

- In the **Data Source** editor that allows the user to select the data for display in the report, the object class properties are listed as defined in the column names of the `SELECT` statement. The end user can change the caption of the columns that are defined via the native SQL query of the report directly in the report.
- If the `DataTableReport` template is used, the first argument of the `SELECT` statement is not hidden in the tabular output of the configured repor and is not automatically providing navigation capabilities if returning the REFSTR values of objects.
- Navigation from the report to the object view or object profile of objects that are accessible via the configured report is not available by default. You can define columns in the tabular report to provide navigation. Navigation can be defined for any data and any number of columns. For example, for a configured report that displays information flows and the source and target applications thereof, the report can be configured to provide navigation to the information flows if the user double clicks on the information flow name, to the source applications if the user double clicks the name of a source application and to the target applications if the user double clicks the name of the target application.

Navigation is provided via the Alfabet query language instruction `CreateRefImage`, that merges a column returning the `REFSTR` of an object with any other column in the report. As a result, a single, navigable column is displayed at the position of the column returning the `REFSTR`, but showing the information from the other merged column. For information about the definition of the instruction, see Configuring Cells in a Data Table Report to Provide Navigation to an Object Profile in the section Using Instructions to Format the Results of an Alfabet or Native SQL Query.

- In general, Alfabet query language instructions can be used with the native SQL query, with the limitation that the result must not involve dependencies between cells in different columns of the resulting dataset. For example,:
  - You can color cells using a `ColorAssignment` instruction, because the coloring depends on the results in the current column only, but a `RowColorAssignment` instruction will be ignored, because cell coloring of cells of one column would depend on the result of cells in another column.
  - You can use a `JoinColumns` instruction. The result is a single, independent column in that will be presented as selectable or deselectable data to the end user and the results in the joined column will be displayed wherever the end user selects it to be displayed in a tabular or matrix structure. In contrast, you cannot use a `GroupBy_Ex` instruction, because the instruction creates a structure in the result dataset that involves more than one column to be created.
  - You cannot use a `LinkAssignment` instruction because the link displayed in one column depends on an object specification in another column of the dataset.
- Coloring and picture assignment defined in the native SQL query for data in a column will only be available in a tabular layout. If the user changes the design to a matrix layout, the default picture and color assignment will be removed. The end user can define own color and picture rules that supersede the default color and picture rules. Color rules and picture rules defined in the native SQL query are not added to the legend of the data table report. The legend is limited to user defined coloring and picture assignment.

Defining Audit Management Related Configured Reports

The audit history is available for an object in an object class for which the **Audit** attribute is set to "`true`".

The complete audit history is available for an object when the user clicks the **Audit Trail** button in the toolbar of the object profile.

Nevertheless it might be required to define a customized audit history via a configured report of the type `NativeSQL` for the following reasons:

- Because the **Object Audit** view displayed for a selected object displays all information about the object independent of the access permission available to the user viewing the audit information, it is recommended that you customize the display of audit information for users. To this end, you can create native SQL-based configured reports to extract specific information from the audit history such as the changes made to the object by a specific user or specific types of changes made to the object (For example, new information flows added to an application).
- Although property values based on an enumeration, indicator range values, object states and statuses are translatable, the translations are not considered in the audit trail displayed in the **Object Audit** view. If you want translated values to be displayed, you must define a native SQL-based configured report that displays the translated values. For information about the required query configuration to display the translated values in the configured report, see the section Translating Configured Reports.

Please note the following:

- If you want to define filters for configured reports displaying audit history information, you must add the filters manually. For more information, see the section Defining Filters for Configured Reports and Selectors in the chapter Defining Queries.
- Once the report is configured, you must make it available in the toolbar of the relevant custom object view by configuring a custom button for the object view. For more information about how to configure a custom button, see thesection Configuring Custom Buttons for the Toolbar of a Custom Object View in the chapter Configuring Object Views.
- For general information about how to make the auditing capability available for an object class, see the section Specifying History Tracking for an Object Class in the chapter Configuring the Class Model.

This chapter provides information about the audit database table that is required to build native SQL queries to display audit information.

Audit information is stored in a separate audit table for each object class. For each object class for which the property **Audit** is set to "`true`", a table named <TechnicalNameOfObjectClass>`_AU` is created. Whenever an object is changed, a new line is written in the audit table. The audit table has the following columns:

- ***AUDIT_TIME1***: The start date of the validity of the row. In other words, the date when the change was performed.
- ***AUDIT_TIME2***: End data of the validity of the row. This is set to `NULL` during creation of the row. When the next change to the object occurs, a new row is added for the object and the time is set to the ***AUDIT_TIME1*** of the next change. In other words, if the ***AUDIT_TIME2*** is set, the object was changed again after the change written to the ***AUDIT_TIME1*** row. For the last change to the object, the ***AUDIT_TIME2*** is `NULL`.

The ***AUDIT_TIME2*** is not necessarily identical with the ***AUDIT_TIME1*** of the next row in the audit table. For example, data import via the Alfabet Data Integration Framework (ADIF) can result in irrelevant audit table entries that document a change to the object that is not relevant to any of the object class properties listed in the audit table. As a result, audit table rows identical in all object properties are created. ADIF allows a mechanism to be activated that deletes the irrelevant entries from the audit table after data import is performed. Only the first of a number of identical audit table entries is kept. For audit table cleanup performed prior to Alfabet 10.6, the ***AUDIT_TIME2*** of that entry was not identical to the ***AUDIT_TIME1*** of the next relevant entry in the table. For audit table cleanup performed with Alfabet 10.6 and higher, a mechanism has been implemented to close the time gap between the previous and next meaningful entry in the table. Entries are not only removed, but the audit times are aligned. ***AUDIT_TIME2*** (end time) of the previous row is set to ***AUDIT_TIME1*** (start time) of the next row to ensure a gapless coverage of the history timeline.

- ***AUDIT_USER***: The user name of the user that performed the change.

  The storage of the user name in the database table depends on the setting of the parameter **Update History User Name** of the alias configuration of the Alfabet Web Application. Either the user name or the technical name of the user can be stored as user name in the audit tables.

- ***DELETE_USER***: The user name of the user that deleted the object. This row is only filled on deletion of an object.

  The storage of the user name in the database table depends on the setting of the parameter **Update History User Name** of the alias configuration of the Alfabet Web Application. Either the user name or the technical name of the user can be stored as user name in the audit tables.

- ***AUDIT_TR***: The unique GUID of the transaction.
- ***REFSTR***: The `REFSTR` of the object that was changed. This column specifies the object that has been changed.
- <OtherTableProperties>: For each column in the object class' database table, a column with an identical column header exists in the audit table. All properties of the objects are written in the respective row of the audit table when one of the properties is changed. Therefore, each row of the audit table is a complete image of the object for the time period between ***AUDIT_TIME1*** and ***AUDIT_TIME2***.

	AUDIT_TIME1	AUDIT_TIME2	AUDIT_USER	DELETE_USER	AUDIT_TR	REFSTR	INSTGUID	ID	NAME
1	1993-02-06 15:00:00.000	2010-03-25 11:24:00.420	PICARD	NULL	68EA5CA135C911	76-2934-0	3383726EB8614(	APP-2934	GAA-POS
2	2010-03-25 11:24:00.420	2010-03-25 11:24:25.130	CUSTOMER	NULL	27460FEC312D40	76-2934-0	3383726EB8614(	APP-2934	GAA-POS
3	2010-03-25 11:24:25.130	2010-03-25 16:24:03.160	CUSTOMER	NULL	0B968D9217574E	76-2934-0	3383726EB8614(	APP-2934	GAA-POS
4	2010-03-25 16:24:03.160	NULL	PICARD	NULL	63FE6B7535C911	76-2934-0	3383726EB8614(	APP-2934	GAA-POS

FIGURE: Example for the change history of an object in the object table

It is recommended that you create an index for the audit table when a configured report is implemented for audit information. An index is automatically created for the audit table if you set an audit key for the object class for which the audit table is assigned. For more information about creating an index, see *Creating an Index to Improve Performance for Query Searches in Database Tables* in the chapter Defining Queries.

Creating a Card View Report

To generate a configured report of the type **Custom** that displays graphic containers for each row of data from search results:

- In the **Reports** tab of Alfabet Expand, create a new configured report and define the attributes for the configured report. For more information about creating a configured report and defining the configured report's attributes, see Creating a New Card View Report.
- Define a custom report view for the configured report. For more information, seeCreating a New Card View Report.
- Open the **Report Assistant** and configure the configured report. For more information, see Configuring the Card View Report with the Report Assistant.
- If the configured report has filters defined, check the functionality of the filters and optionally change the captions and look of the filter fields. For more information, see Defining Filters for Configured Reports and Selectors in the chapter Defining Alfabet Queries.
- If the configured report has no filters defined, you can optionally edit or delete the parameter panel of the configured report.
- Set the **Report State** of the report to **Active**. For information on how to change the attribute of the configured report, see General Guidelines for Creating Configured Reports.
- You can define the visibility of toolbar buttons of the configured report for different view schemes using the **Configure Report** functionality in the context menu of the report. For more information, see Refining Visibility Issues in the View Scheme.
- Define access rights for the configured report in the **Reports Administration** functionality of Alfabet. By default, access is possible for all users. For more information, see the chapter *Defining and Managing User Access to Configured Reports* in the reference manual .

The following information is available:

Creating a New Card View Report

To create a new configured report of the type `Custom` in Alfabet Expand:

1) In the **Reports** tab, right-click the **Reports** folder or a sub-folder thereof and select **Create New Report**. You will see the new configured report listed below the selected folder.

As an alternative to defining all attributes for a new configured report, you can copy and paste an existing configured report and make modifications, as needed. To do so, right-click the existing configured report that you want to copy and select **Copy**. Right-click

the new configured report and select **Paste**. Modify the necessary attributes described below.

2) In the attribute window, select `Custom` in the **Type** field.

3) In the attribute window, define the following attributes for the configured report.

- **Name**: Optionally, change the technical name of the configured report. The technical name of the configured report must be unique.

  The technical name is used for identification of the configured report in the context of technical processes such as merging the report configuration with a report configuration saved as an XML file. Therefore, the following is required when defining the name of a configured report:

  - The name must be unique. The name must be unique regardless of the report folder it is structured in.
  - The name may not be changed once a configured report has been created.
  - A validation mechanism checks for correct syntax when defining a technical name. Please note that names may not begin with an empty space nor include special characters. For a list of the special characters that are not allowed, see the section Defining Attributes for Configuration Objects in the chapter Getting Started with Alfabet Expand.
  - If the technical name of the configured report is changed, the name will be correctly updated in other configuration objects referencing the changed report during design time.

  Please note that the name of a changed configuration object will not be updated in guide pages or guide views. If you plan to change the name of a configuration object, the reference in the navigation page should be changed prior to changing the configuration object name. You can use the **Show Usage** functionality in the context menu of the configured report to evaluate whether the configured report has been added to a guide view or guide page.

- **Caption**: Enter a caption for the configured report. The caption you define here will be displayed in the **Reports Administration** functionality in the **Administration** module and the **Configured Reports** views of the Alfabet interface. If the configured report is assigned to an object view as a page view, the text will be displayed as the page view caption in the object view. The caption of the configured report may exceed the conventional 64-character limit.
- **Description**: Provide short information about the configured report that is useful to Alfabet users. This comment will be displayed on the Alfabet user interface in the header of the configured report in a single line under the report caption and in the **Description** field for the configured report in the table of all views listing configured reports, like the **Configured Reports** views of the **Search** functionalities. If the configured report is assigned to an object view as a page view, the text will be displayed under the page view caption as short description in the object view.

  In the configured report, the description will be truncated if it is longer than one line on the screen. Therefore, the description should be short to ensure complete display in the configured report header.

- **Usage Guideline**: Provide information that helps users to execute and interpret the configured report. This information will not be displayed directly on the user interface.

The user can access the information using the following mechanisms:

- If the user moves the cursor over the description provided for the configured report with the attribute **Description**, a tooltip opens that includes both the description and the usage guideline.
- The **Options**  button will be displayed on the upper right with an option **Help On Filter Fields** to open a new window displaying the usage guideline in addition to any filter field hints, if configured.

  For views that have filters defined, the **Options**  button will only be displayed if the filter panel either allows batch clearing of filter fields or collapsing and expanding of the filter panel. For more information about the configuration of these functionalities, see Configuring the Complete Filter Area to be Collapsible and Allowing the User to Clear the Filter Area.

- **Technical Comment**: Provide information that is useful for solution designers working with Alfabet Expand in order to better understand the configured report from a technical perspective. The **Technical Comment** will not be displayed in the user interface. Nevertheless, you can configure the interface to display the information in, For example, the attribute section of the configured report's object profile in the **Reports Administration** functionality.
- **Template**: Select `CardsViewReport` to create a configured report that displays information for each row of search results in card containers.
- **Report State**: The **Report State** attribute is view-only and is set to `Plan` for new configured reports. The configured report can only be edited when the **Report State** attribute is set to `Plan`. After finishing all configuration steps described in the following, the **Report State** attribute must be set to `Active` as described in the section General Guidelines for Creating Configured Reports. The configured report is then visible to users in the Alfabet user interface.
- **Help Index**: Specify the location of the external Help file using the following syntax:`CUSTOM_HELP:<URL>`(For example,:`CUSTOM_HELP:http://helphost/report1.html`). The external help file will be displayed when the user clicks the context-sensitive Help link in the standard Help menu.

  Server variables can be used in the Help links. Server variables allow you to define all or part of the URL definition in the server alias configuration of the Alfabet Server instead of directly defining it in the configuration in Alfabet Expand. Use of server variables is useful, For example, in order to change a Web server name defined in multiple URL definitions in Alfabet Expand. Instead of changing all URL definitions, only the variable value in the server alias configuration must be updated. The use of server variables is described in the section Using Server Variables in Web Link and Database Server-Related Specifications in the chapter Configuring Reports.

- **Apply to Class**: When the configured report is applied to an object class or object class stereotype, a base object can be selected for the configured report. A filter for selection of a base object will automatically be set on top of the configured report. When configuring queries for the configured report, you can use the Alfabet parameter `BASE` to refer to the

object selected in the filter and define search conditions dependent on the base object. To apply the configured report to a base class, click the **Browse** button to open a dialog box and select the object class or object class stereotype to which you want to apply the configured report and click **OK**.

Please note the following:

- If the configured report is assigned to the object view for the relevant object class, the configured report will automatically open with the current object selected as the base object even if the **Apply to Class** attribute is not set.
- If the configured report is applied to an object class stereotype, the filter field for selection of the base object will use the caption of the object class stereotype as caption of the filter field and the selector defined in the class settings for the object class stereotype for selection of the base object.
- Alternatively, the base object of a configured report can be set with the **Base Object Query** attribute. Whereas the **Apply to Class** attribute enables the user to determine the current base object by setting a filter, the **Base Object Query** attribute evaluates the base object by executing a query when the configured report is opened. A filter field is not available and the user cannot change the base object.
- The **Apply to Class** attribute also influences the availability of the configured report in the Alfabet interface. Select a class to make the configured report available in the **Configured Reports** page view in the object view for the selected object class. If you do not set the attribute, the configured report will only be available in the **Configured Reports** functionality. The configured report can be assigned to object views and wizards independent of the attribute.

- **Base Object Query**: If a base object query is defined for the configured report, a base object will be evaluated for the configured report at runtime. When configuring the other queries for the configured report, you can use the Alfabet parameter `BASE` to refer to the object returned by the base object query and define search conditions dependent on the base object. To apply the configured report to a base class, click the **Browse** button to open a text editor, define either a native SQL query or an Alfabet query that returns a single object, and click **OK**.

  Note the following:

  - Alternatively, the base object of a configured report can be set by means of the **Apply To Class** attribute. Whereas the setting of the **Base Object Query** attribute triggers the evaluation of the base object by executing a query when the configured report is opened, the **Apply to Class** attribute enables the user to determine the current base object by setting of an automatically-generated filter.
  - The query defined for the base object query is executed when the user opens the configured report to evaluate the base object at runtime. Parameters referring to the current working environment can be used in the query to find a base object dependent on the user opening the configured report or the user profile used for login, For example,. A base object query may also find,

For example, the ICT object that a specific application is currently assigned to.

- If the **Base Object Query** attribute is set and the configured report is assigned as a view to an object profile, the Alfabet parameter `BASE` referring to the `REFSTR` of the object that the user is working with when the configured report is opened can be used in the base object query.

- **Execute on Enter**: Set to `True` to execute the configured report with empty filter settings when the user opens the configured report on the Alfabet interface. Set to `False` to open the configured report without execution of the Alfabet query with empty filter settings. By default, this attribute is set to `True`. It should only be set to `False` when a configured report would result in an exceedingly big dataset when executed with empty filter settings.

  When you set **Execute on Enter** to `False`, you must make sure that the **Submit** button is available in the custom report view of the configured report. If the **Submit** button is deleted from the custom report view, the configured report cannot be displayed. The setting and execution of the **Execute on Enter** attribute is independent from the definition of filters for a configured report. A configured report without filters must nevertheless have a **Submit** button when **Execute on Enter** is set to `False`.

- Selector Behavior: The attribute can be used to exclude configured reports that are defined for special purposes, like For example, triggering of data export via the RESTful API, from being selectable in the **Configured Reports** table. By default, the attribute is set to `Visible` and the configured report is visible in the selector for adding configured reports to the **Configured Reports** table if all other conditions for access to the configured report apply. If the attribute is set to `NotVisible`, the configured report is excluded from the selector for adding configured reports to the **Configured Reports** functionality. Please note however, that this setting is not excluding the configured report from any standard views or customer configured views and selectors, but exclusively from the standard selector for configured reports implemented in Alfabet. The attribute cannot be edited in the attribute window directly. To change the setting, right-click the configured report and select **Set Report Selector Behavior to 'Not Visible'** or **Set Report Selector Behavior to 'Visible'** respectively.

- **Base Classes**: Define the object classes that must be available to run the configured report. If this attribute is set, the Alfabet Server checks whether the object classes specified as base classes are excluded from the view scheme used to access the configured report. If the user does not have access permissions to one of the base classes, the configured report will be disabled. To set the attribute, click the **Browse**  button to select the object classes that are required to run the configured report and click **OK**.

- **Can Create Express View**: Select `True` if an express view may be created for the report. Select `False` if an express view may not be created for the report. Please note that if the report has a custom report view, the setting must be consistent with the setting of the attribute **Can Create Express View** of the custom report view.

  An express view is a link to a specific Alfabet view displaying data that allows individuals inside or outside of the user community to view information in Alfabet. When the express view is created, an email notification is automatically mailed to a specified recipient. The recipient receives a URL that allows him/her to access the current page view in Alfabet. For more information, see the section *Sending and Receiving Express Views* in the reference manual Getting Started with Alfabet Expand.

4) In the explorer, right-click the configured report and select **Create Configured Report View**. The view editor opens. In the explorer, the custom report view is displayed as a subordinate object of the configured report. The attributes for the custom report view are displayed in the attribute window. You can optionally edit the following attributes:

   - **Name**: Optionally you can change the name for the custom report view. The **Name** must be unique for custom report views.
   - **Can Create Bookmark**: Select `True` if a bookmark may be created for the configured report. Select `False` if a bookmark may not be created for the configured report.
   - **Can Create Express View**: Select `True` if an express view may be created for the configured report. Select `False` if an express view may not be created for the configured report. Please note that the setting must be consistent with the setting of the attribute **Can Create Express View** of the configured report.

     The custom report view initiates the **Report Assistant**. A custom report view shall never be deleted from the configured report after the **Report Assistant** was already used to configure the configured report. When you delete the custom report view of an existing template-based configured report and create a new one, the **Report Assistant** is reset to the example specified by default and your configuration is lost.

5) In the explorer, right-click the configured report and select **Start Alfabet Report Assistant**. The **Report Assistant** opens.
6) Card View Reports are designed in the **Report Assistant**. Configure the report as described below in the section Configuring the Card View Report with the Report Assistant.
7) Click **OK** to save the configuration.
8) In the toolbar, click the **Save** button to save your changes.
9) In the explorer, right-click the configured report and select **Review Report**. The configured report opens in a web browser. If the results are not as expected, you can edit the configured report until the output of the configured report meets your expectations.

Configuring the Card View Report with the Report Assistant

The **Report Assistant** allows you to define the content of the **Card View Report** and to design the graphic display. For information about how to open the **Report Assistant**, see Creating a New Card View Report. For general information about working with the **Report Assistant**, see the section Configuring the Report with the Report Assistant in the chapterCreating a Graphic Report.

The content and layout of the Card View report are defined and designed via the attributes of the node elements of the explorer in the **Report Assistant**.

The following table lists the types of explorer node elements that can be added to the report configuration to specify the content of the Card View report. Information is provided in the table about the purpose of each explorer node element:

Explorer Node Element	Required to Configure:
Root Node	General layout of the card view report and mapping of the information provided by the queries of the card view report to the relevant graphic display in the card view report.
Root Query	Definition of a query that defines the display of card view elements depending on data in the Alfabet database.
Picture rendering definitions	Design of specific picture data columns of be displayed. For each picture column to be displayed, use the **Add Picture Definition** context menu option to create a new rendering definition. You must then name the column according to how it is named in the query and define the image height desired.

Defining the Content of the Card View Report

The content of the card view report and all object specific design and information are defined in a native SQL or Alfabet query in the **Query** section of the **Root Query** node element. For general information about how to query a dataset for a configured report, see Defining Query Attributes in the chapter Creating a Graphic Report.

The following settings can be applied:

Attribute	Description
Name	Defines the name of the **Query** element displayed in the explorer of the **Report Assistant**.
Alfabet Query/Query as Text/Native SQL	Defines a query to find the objects that are displayed in the report and the instructions used to format the boxes in the card view.

The query defined for the Card View Report must find the objects that shall be displayed in the report and the relevant information about the objects which shall be displayed in the form of card boxes. For each row in the result dataset, a box is added to the report.

For native SQL queries, the first argument of the `SELECT` statement must return the `REFSTR` of the object to be displayed in the report in addition to defining the following information in the `SELECT` statement.

For information about defining Alfabet queries, see the chapter Defining Queries. For information about the rules that apply to the definition of native SQL queries when used in Alfabet configurations, see Defining Native SQL Queries in the chapter Defining Queries.

Alfabet instructions can be used in configuring the output format of the card view or to rename and remove columns. For example, the `MakeReferenceValue` instruction allows a string value to be presented as a link that enables navigation to an object. The `CreateDSInfo` instruction is useful to change the the caption of columns displayed as headings for data in the cards. The Alfabet instruction `SetObjectIcon` can also be used to display the icon assigned to a class. For more information about configuring Alfabet instructions, see Using Instructions to Format the Results of an Alfabet or Native SQL Query in the chapter Defining Queries.

For example, a configured card view report shall display information about applications, the users assigned to those applications and the role of the users. A sample query is defined in the SQL query below:

```
SELECT app.REFSTR, app.NAME AS 'ApplicationName', app.STARTDATE AS
'StartDate', app.ENDDATE AS 'EndDate', app.STATUS AS 'Status',
per.PICTURE AS 'Picture', per.REFSTR AS 'UserResp', per.TECH_NAME AS
'PName', rtp.NAME AS 'Role'

FROM APPLICATION app

LEFT JOIN ROLE AS rol ON rol.OBJECT = app.REFSTR

LEFT JOIN PERSON AS per ON rol.RESPONSIBLE = per.REFSTR

LEFT JOIN ROLETYPE AS rtp ON rol.ROLETYPE = rtp.REFSTR

WHERE per.PICTURE IS NOT NULL

Instructions

CreateDSInfo("ApplicationName,Status,StartDate,EndDate,Picture,UserR
esp,Role", "Application Name,Status,Start Date,End
Date,Picture,Responsible User,User Role");

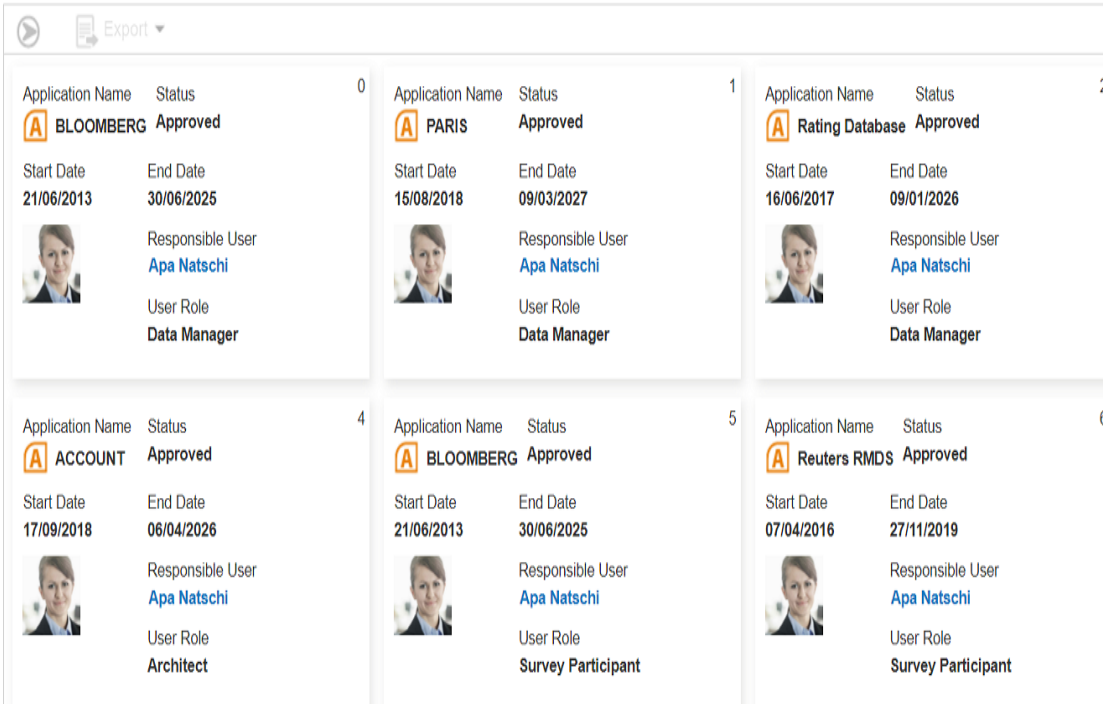
MakeReferenceValue(UserResp, PName);

RemoveColumns("PName");

SetObjectIcon("ApplicationName","IconText");

EndOfInstructions
```

The resulting card view report displays a card box for each row in the result dataset of the query. In each card box, the column names are displayed as captions above each value and the row number of the resulting dataset is at the top-right corner of the box. The icon assigned to the application is displayed alongside the name of the application. The image of the user responsible for the application is also displayed, while the name of the user has been converted into a link using the `MakeReferenceValue` instruction to provide navigation to the object cockpit of the user to display further information about the user. The order of columns and and the column names have been edited using the `CreateDSInfo` instruction:



This example report can also be generated using a simple tabular report, however, without the picture rendering and other graphic elements:

SQL Test Report

Export

Defining the Basic Design of the Card View Report

The basic design of the card view report, like For example, any design that applies to all content independent from the displayed data is defined in the section **Layout**:

Attribute	Description
Apply Common Container Skin	Set to `True` if you want to display all object boxes with the container skin defined in the GUI scheme used for the Alfabet user interface when rendering the report. If you set the attribute to `False`, the cards will be displayed with white background and black, thin border.
Control Layout	Select the desired design of the card boxes to be displayed in the window. • Set to `Stack` if you want each card box to occupy an entire row of the window. • Set to `Flow` if you want as many cards placed side-by-side in a row as the responsive display window permits.
Card Width	Define the width of the individual object boxes in pixel when **Control Layout** is set to `Flow`.
Max Value Item Width	Define the maximum width in pixels that the items in each box can occupy.
Min Value Item Width	Define the minimum width in pixels that the items in each box can occupy.
Show Data-Set Row Numbers	Set to `True` if you want to display the row number of an object box. Please note: • The row number can only be displayed in the top right-hand corner of each object box.
Show Undefined Values	Set to `True` if you want to show values that are not defined to be displayed in the card box.
Values Followed by new lines	Specify where you would like to force a line break in each card box.
Values with no captions	Specify which values in a card box should be displayed without their captions.

When dealing with data that contains images, the attributes of each image column to be displayed must be defined in the **Picture Rendering Definitions** node element:

Attribute	Description
Column Name	Define the name of the specific image column.
Height	Define the height of the image in pixel to be displayed in the card box.

Creating a Graphic Report

To generate a configured report of the type `Custom` that displays graphical representations of search results:

- In the **Reports** tab of Alfabet Expand, create a new configured report and define the attributes for the configured report. For more information about creating a configured report and defining the configured report's attributes, see Creating a New Graphic Report.
- Define a custom report view for the configured report. For more information, see Creating a New Graphic Report.
- Open the **Report Assistant** and configure the configured report. For more information, see Configuring the Report with the Report Assistant.
- If the configured report has filters defined, check the functionality of the filters and optionally change the captions and look of the filter fields. For more information, see Defining Filters for Configured Reports and Selectors in the chapter Defining Queries.
- If the configured report has no filters defined, you can optionally edit or delete the parameter panel of the configured report.
- Set the **Report State** of the report to `Active`. For information on how to change theattribute of the configured report, see.
- You can define the visibility of toolbar buttons of the configured report for different view schemes using the **Configure Report** functionality in the context menu of the report. For more information, see Refining Visibility Issues in the View Scheme.
- Define access rights for the configured report in the **Reports Administration** functionality of Alfabet. By default, access is possible for all users. For more information, see the chapter *Defining and Managing User Access to Configured Reports* in the reference manual *User and Solution Administration*.

The following information is available:

- Creating a New Graphic Report
- Configuring the Report with the Report Assistant
  - Defining Elements of the Report
  - Configuring the Attributes of Report Elements

Creating a New Graphic Report

To create a new configured report of the type `Custom` in Alfabet Expand:

1) In the **Reports** tab, right-click the **Reports** folder or a sub-folder thereof and select **Create New Report**. You will see the new configured report listed below the selected folder.

As an alternative to defining all attributes for a new configured report, you can copy and paste an existing configured report and make modifications, as needed. To do so, right-click the existing configured report that you want to copy and select **Copy**. Right-click

the new configured report and select **Paste**. Modify the necessary attributes described below.

2) In the attribute window, select `Custom` in the **Type** field.

3) In the attribute window, define the following attributes for the configured report.

- **Name**: Optionally, change the technical name of the configured report. The technical name of the configured report must be unique.

  

  The technical name is used for identification of the configured report in the context of technical processes such as merging the report configuration with a report configuration saved as an XML file. Therefore, the following is required when defining the name of a configured report:

  - The name must be unique. The name must be unique regardless of the report folder it is structured in.
  - The name may not be changed once a configured report has been created.
  - A validation mechanism checks for correct syntax when defining a technical name. Please note that names may not begin with an empty space nor include special characters. For a list of the special characters that are not allowed, see the section Defining Attributes for Configuration Objects in the chapter Getting Started with Alfabet Expand.
  - If the technical name of the configured report is changed, the name will be correctly updated in other configuration objects referencing the changed report during design time.

  Please note that the name of a changed configuration object will not be updated in guide pages or guide views. If you plan to change the name of a configuration object, the reference in the navigation page should be changed prior to changing the configuration object name. You can use the **Show Usage** functionality in the context menu of the configured report to evaluate whether the configured report has been added to a guide view or guide page.

- **Caption**: Enter a caption for the configured report. The caption you define here will be displayed in the **Reports Administration** functionality in the **Administration** module and the **Configured Reports** views of the Alfabet interface. If the configured report is assigned to an object view as a page view, the text will be displayed as the page view caption in the object view. The caption of the configured report may exceed the conventional 64 character limit.
- **Description**: Provide a short information about the configured report that is useful to Alfabet users. This comment will be displayed on the Alfabet user interface in the header of the configured report in a single line under the report caption and the **Description** field for the configured report in the table of all views listing configured reports, like the **Configured Reports** views of the **Search** functionalities. If the configured report is assigned to an object view as a page view, the text will be displayed under the page view caption as short description in the object view.

  

  In the configured report, the description will be truncated if it is longer than one line on the screen. Therefore, the description should be short to ensure complete display in the configured report header.

- **Usage Guideline**: Provide information that helps users to execute and interpret the configured report. This information will not be displayed directly on the user interface. The user can access the information using the following mechanisms:
  - If the user moves the cursor over the description provided for the configured report with the attribute **Description**, a tooltip opens that includes both the description and the usage guideline.
  - The **Options** button will be displayed on the upper right with an option **Help On Filter Fields** to open a new window displaying the usage guideline in addition to any filter field hints, if configured.

    For views that have filters defined, the **Options** button will only be displayed if the filter panel either allows batch clearing of filter fields or collapsing and expanding of the filter panel. For more information about the configuration of these functionalities, see Configuring the Complete Filter Area to be Collapsible and Allowing the User to Clear the Filter Area.

- **Technical Comment**: Provide information that is useful for solution designers working with Alfabet Expand in order to better understand the configured report from a technical perspective. The **Technical Comment** will not be displayed in the user interface. Nevertheless, you can configure the interface to display the information in, For example, the attribute section of the configured report's object profile in the **Reports Administration** functionality.
- **Template**: Select one of the following:
  - `BranchingDiagramReport` to create a report with multiple levels of objects connected via lines.
  - `BusinessChartReport` to create a pie chart, bar chart, radar chart or line chart.
  - `CircularRoadMap` to create a report that displays object icons distributed in a circle divided into shells and circles.
  - `CustomPivotTable` to create a configured report that allows to analyse a cube in a Pivot table layout.
  - `DataTableReport` to create a configured report that allows users to sort, filter and layout a dataset at runtime.
  - `DynamicLaneReport` to create a dynamic lane report displaying relations between objects as connections between the object in different columns, whereby the number of columns depends on the results in the dataset.
  - `GalleryReport` to create a configured report displaying a gallery of object boxes with informations about objects.
  - `GanttReport` to create a Gantt chart.
  - `GaugeReport` to create a linear or circular gauge report.
  - `GridReport` to create a grid report displaying one or multiple configured reports in a cluster or tree structure.

- `LaneReport` to create a lane report displaying relations between objects as connections between the objects in different columns, whereby the number of columns is fixed.
- `MatrixMapReport` to create a matrix report.
- `MatrixMapReport_Ex` to create a matrix with enhanced functionalities.
- `NodeArcReport` to create a configured report that displays objects and connections between objects in the diagram styles available for standard Alfabet diagrams designed with the Alfabet Diagram Designer.
- `NodeArcReportWithBundling` to create a configured report that displays objects and connections between objects in the `Spring Layout` of standard Alfabet diagrams designed with the Alfabet Diagram Designer with the additional ability to bundle connections to provide a better overview in diagrams with a high number of objects and connections.
- `PercentageDistributionReport` to create a configured report that displays percentage distributions of objects in a bar or half-circle diagram.
- `PortfolioReport` to create a portfolio.
- `AugmentedAIReport` to create a portfolio diagnostics report.
- `TreeMapReport` to create a tree map or layered diagram report.

For HTML reports displaying indicator values in an HTML based table, no template is available and the attribute must be empty to define the configured report.

The templates `CaptureApplications`, `CaptureComponents`, `CaptureDevices`, `CaptureICTObjects`, `CapturePeripherals` and `CaptureServiceProducts` cannot be used in configured reports of the **Type** `Custom`. They are for exclusive use with tabular datasets defined in configured reports of the **Type** `Query` or `NativeSQL`.

- **Report State**: The **Report State** attribute is view only and is set to `Plan` for new configured reports. The configured report can only be edited when the **Report State** attribute is set to `Plan`. After finishing all configuration steps described in the following, the **Report State** attribute must be set to `Active` as described in the section General Guidelines for Creating Configured Reports. The configured report is then visible to users in the Alfabet user interface.
- **Help Index**: Specify the location of the external Help file using the following syntax:(For example,:). The external help file will be displayed when the user clicks the context-sensitive Help link in the standardHelp menu.

Server variables can be used in the Help links. Server variables allow you to define all or part of the URL definition in the server alias configuration of the Alfabet Server instead of directly defining it in the configuration in Alfabet Expand. Use of server variables is useful, For example, in order to change a Web server name defined in multiple URL definitions in Alfabet Expand. Instead of changing all URL definitions, only the variable value in the server alias configuration must be updated. The use of server variables is described in the section Using Server Variables in Web Link and Database Server-Related Specifications in the chapter Configuring Reports.

- **Apply to Class**: When the configured report is applied to a class, a base object can be selected for the configured report. A filter for selection of a base object will automatically be set on top of the configured report. When configuring queries for the configured report, you can use the Alfabet parameter `BASE` to refer to the object selected in the filter and define search conditions dependent on the base object. To apply the configured report to a base object class or object class stereotype, click the **Browse** button to open a dialog box and select the object class or object class stereotype to which you want to apply the configured report and click **OK**.

  Note the following:

  - This attribute is mandatory for configured reports displaying an HTML report about indicators. It is optional for all other configured reports of the type `Custom`.
  - If the configured report is applied to an object class stereotype, the filter field for selection of the base object will use the caption of the object class stereotype as caption of the filter field and the selector defined in the class settings for the object class stereotype for selection of the base object.
  - If the configured report is assigned to the object view for the relevant object class, the configured report will automatically open with the current object selected as the base object even if the **Apply to Class** attribute is not set.
  - Alternatively, the base object of a configured report can be set with the **Base Query** attribute. Whereas the **Apply to Class** attribute enables the user to determine the current base object by setting a filter, the **Base Query** attribute evaluates the base object by executing a query when the configured report is opened. A filter field is not available and the user cannot change the base object.
  - The **Apply to Class** attribute also influences the availability of the configured report in the Alfabet interface. Select a class to make the configured report available in the **Configured Reports** page view in the object view for the selected object class. If you do not set the attribute, the configured report will only be available in the **Configured Reports** functionality. The configured report can be assigned to object views and wizards independent of the attribute.

- **Base Object Query**: If a base object query is defined for the configured report, a base object will be evaluated for the configured report at runtime. When configuring the other queries for the configured report, you can use the Alfabet parameter `BASE` to refer to the object returned by the base object query and define search conditions dependent on the base object. To apply the configured report to a base class, click the **Browse** button to open a text editor, define either a native SQL query or an Alfabet query that returns a single object, and click **OK**.

  Note the following:

  - Alternatively, the base object of a configured report can be set by means of the **Apply To Class** attribute. Whereas the setting of the **Base Object Query** attribute triggers the evaluation of the base object by executing a query when the configured report t is opened, the **Apply to Class** attribute enables

the user to determine the current base object by setting of an automatically-generated filter.

- The query defined for the base object query is executed when the user opens the configured report to evaluate the base object at runtime. Parameters referring to the current working environment can be used in the query to find a base object dependent on the user opening the configured report or the user profile used for login, For example,. A base object query may also find, For example, the ICT object that a specific application is currently assigned to.
- If the **Base Object Query** attribute is set and the configured report is assigned as a view to an object profile, the Alfabet parameter `BASE` referring to the `REFSTR` of the object that the user is working with when the configured report is opened can be used in the base object query.

- **Execute on Enter**: Set to `True` to execute the configured report with empty filter settings when the user opens the configured report on the Alfabet interface. Set to `False` to open the configured report without execution of the Alfabet query with empty filter settings. By default, this attribute is set to `True`. It should only be set to `False` when a configured report would result in an exceedingly big dataset when executed with empty filter settings.

  

  When you set **Execute on Enter** to `False`, you must make sure that the **Submit** button is available in the custom report view of the configured report. If the **Submit** button is deleted from the custom report view, the configured report cannot be displayed. The setting and execution of the **Execute on Enter** attribute is independent from the definition of filters for a configured report. A configured report without filters must nevertheless have a **Submit** button when **Execute on Enter** is set to `False`.

- **Selector Behavior**: The attribute can be used to exclude configured reports that are defined for special purposes, like For example, triggering of data export via the RESTful API, from being selectable in the **Configured Reports** table. By default, the attribute is set to `Visible` and the configured report is visible in the selector for adding configured reports to the **Configured Reports** table if all other conditions for access to the configured report apply. If the attribute is set to `NotVisible`, the configured report is excluded from the selector for adding configured reports to the **Configured Reports** functionality. Please note however, that this setting is not excluding the configured report from any standard views or customer configured views and selectors, but exclusively from the standard selector for configured reports implemented in Alfabet.

The attribute cannot be edited in the attribute window directly. To change the setting, right-click the configured report and select **Set Report Selector Behavior to 'Not Visible'** or **Set Report Selector Behavior to 'Visible'** respectively.

- **Applicable for AlfaBot**: Specify whether the configured report is accessible via the AlfaBot. By default, the attribute will be set to `True` for new reports. Set the attribute to `False` if the configured report should not be opened outside of a specific context. For example, this may be relevant for reports that are specifically designed to be embedded in an object cockpit.

  

  This attribute is only relevant if the AlfaBot is implemented. For information about the implementation of the AlfaBot, see Implementing the AlfaBot for Navigation via a Full-Text Command.

- **Business Problem Statement**: Optionally enter a description that will help users to search for the configured report in the AlfaBot. The text is not displayed in the user interface, but it is of special relevance for the search mechanisms implemented for the AlfaBot. If the report caption entered by the user in the AlfaBot for a request to open a configured report does not match the caption of one of the available configured reports, the AlfaBot will split the caption entered by the user into keywords and will perform a keyword search on the **Caption**, **Description** and the **Business Problem Statement** attributes of the configured reports that are accessible via the AlfaBot. In addition to a keyword search, a synonym search is performed on the text provided in the **Business Problem Statement** attribute.

  This attribute is only relevant if the AlfaBot is implemented. For information about the implementation of the AlfaBot, see Implementing the AlfaBot for Navigation via a Full-Text Command.

- **Base Classes**: Define the object classes that must be available to run the configured report. If this attribute is set, the Alfabet Server checks whether the object classes specified as base classes are excluded from the view scheme used to access the configured report. If the user does not have access permissions to one of the base classes, the configured report will be disabled. To set the attribute, click the **Browse** button to select the object classes that are required to run the configured report and click **OK**.

- **Can Create Express View**: Select `True` if an express view may be created for the report. Select `False` if an express view may not be created for the report. Please note that for reports that have a custom report view, the setting must be consistent with the setting of the attribute **Can Create Express View** of the custom report view.

  An express view is a link to a specific Alfabet view displaying data that allows individuals inside or outside of the user community to view information in Alfabet. When the express view is created, an email notification is automatically mailed to a specified recipient. The recipient receives a URL that allows him/her to access the current page view in Alfabet. For more information, see the section *Sending and Receiving Express Views* in the reference manual *Getting Started with Alfabet*.

4) In the explorer, right-click the configured report and select **Create Configured Report View**. The view editor opens. In the explorer, the custom report view is displayed as a subordinate object of the configured report. The attributes for the custom report view are displayed in the attribute window. You can optionally edit the following attributes:

   - **Name**: Optionally you can change the name for the custom report view. The **Name** must be unique for custom report views.

   - **Can Create Bookmark**: Select `True` if a bookmark may be created for the configured report. Select `False` if a bookmark may not be created for the configured report.

   - **Can Create Express View**: Select `True` if an express view may be created for the configured report. Select `False` if an express view may not be created for the configured report. Please note that the setting must be consistent with the setting of the attribute **Can Create Express View** of the configured report.

     An express view is a link to a specific Alfabet view displaying data that allows individuals inside or outside of the user community to view Alfabet information. When the express view is created, an e-mail notification is automatically mailed to the specified recipient who receives a URL that allows him/her to access the current

page view in Alfabet. For more information, see *Sending and Receiving Express Views* in the reference manual *Getting Started with Alfabet*.

The custom report view initiates the **Report Assistant**. A custom report view shall never be deleted from the configured report after the **Report Assistant** was already used to configure the configured report. When you delete the custom report view of an existing template-based configured report and create a new one, the **Report Assistant** is reset to the example specified by default and your configuration is lost.

5) In the explorer, right-click the configured report and select **Start Alfabet Report Assistant**. The **Report Assistant** opens.

The **Report Assistant** is not available for HTML reports displaying indicator values in an HTML-based table. The configured report is defined in an XML object in the attributes of the configured report. For more information, see Defining HTML Reports. After defining the configured report in the XML object, proceed with step 7.

6) Define the configured report as described below in the sections for the configuration of the different configured report types. For general information about working with the **Report Assistant**, see Configuring the Report with the Report Assistant.

- Defining Branching Diagram Reports
- Defining Chart Reports
- Defining a Circular Roadmap Report
- Defining Reports to Analyse Data Cubes
- Defining a Gallery Report
- Defining Gantt Chart Reports
- Defining a Grid Report
- Defining Lane Reports
- Defining a Matrix Report
- Defining Node Arc Reports or Node Arc Reports With Edge Bundling
- Defining Portfolio Reports
- Defining Portfolio Diagnostics Reports
- Defining a Treemap Report
- Defining a Rectangular Treemap Report
- Defining a Layered Diagram Report
- Defining Widget Reports

7) Delete or edit the parameter panel for the configured report. For more information, see Defining Filters for Configured Reports and Selectors.

For most configured reports, the parameter panel only contains a **Submit** button. If you do not define own filters for the configured report, the filter panel can then be deleted. For configured reports based on the template `NodeArcReport`, filter fields for the

definition of a diagram layout are automatically added. If these filter fields are deleted, the default filter settings defined in the configured report are applied to the node arc report and the user cannot select a different layout. Customer configured filters can be added to the node arc report on demand in addition to the automatically created layout filters.

8) Click **OK** to save the configuration.

9) In the toolbar, click the **Save**  button to save your changes.

10) In the explorer, right-click the configured report and select **Review Report**. The configured report opens in a web browser. If the results are not as expected, you can edit the configured report until the output of the configured report meets your expectations.

Configuring the Report with the Report Assistant

The **Report Assistant** is available to help you to define a template-based report. The **Report Assistant** allows you to define the content of the report and to design the graphic display. Most graphic reports show object dependencies in a structured layout. .

The **Report Assistant** for these reports is similar and the general method to add and configure layers is described in this section. This knowledge is assumed in the sections providing information about the configurations required for each individual report. If the use of the **Report Assistant** deviates for a report type, this will be described separately in the section addressing the report's configuration.

The **Report Assistant** displays an explorer and an attribute window on the right of the explorer. The name of the explorer root node is identical to the name of the report you are currently designing. The attribute window displays the attributes of the selected element in the explorer. The attributes allow to define the look and content of elements of the report.

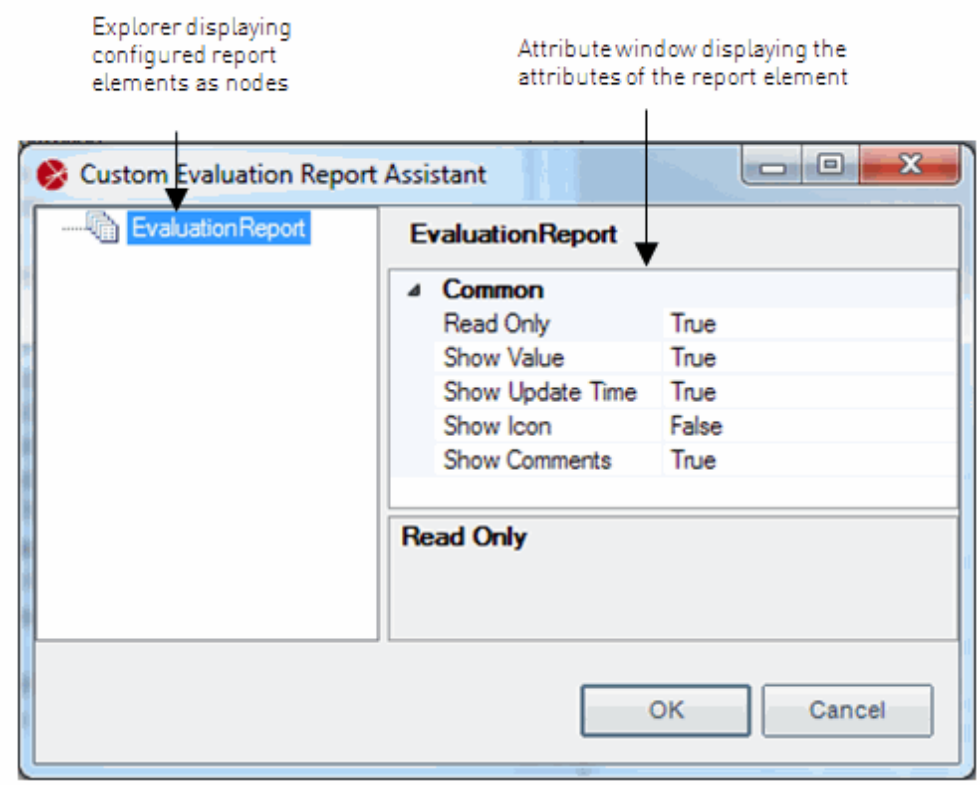

FIGURE: Interface of the Report Assistant for an evaluation report

Defining Elements of the Report

When you right-click a node in the explorer, the context menu of the selected element opens and allows you to add new elements as child elements of the current element, if applicable.

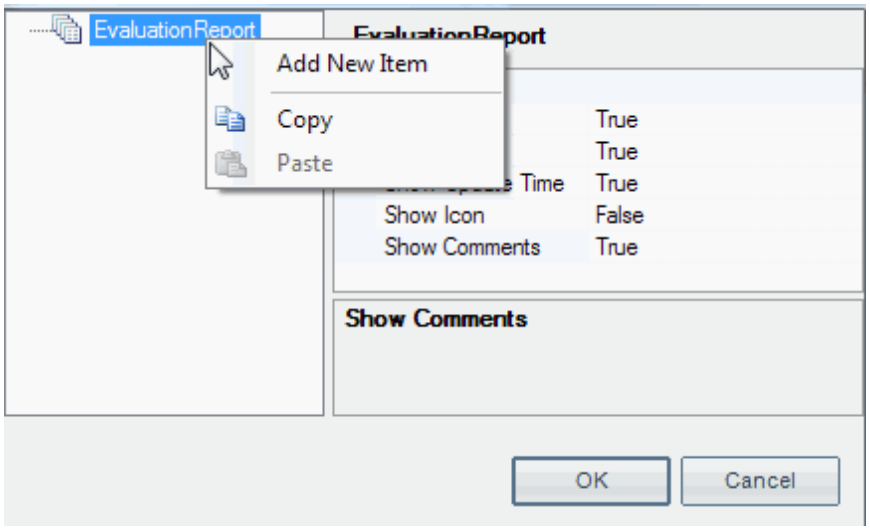

FIGURE: The context menu of the explorer root node of an evaluation report

The context menu also offers a copy and paste functionality to support the re-use of elements within a report or between reports.

If you copy an element, the element, its attributes and all child elements will be copied. You can paste the copied element into another element of the same report or a parallel report using the paste functionality.

Configuring the Attributes of Report Elements

The attribute window of the **Report Assistant** allows you to define the layout of the report. When you click an element node in the explorer, the attribute window of the element opens and displays the default settings for the configuration. Depending on the attribute you want to edit, you can either directly overwrite the default setting with a string, select a new value from a drop-down menu, or open a selector or text editor to define your settings. If a **Browse** button is displayed when you click the value field of an attribute, you cannot change settings directly within the value field but instead must open the text editor or selector via the **Browse** button to edit the attribute.

Defining Color Attributes

Colors can be defined either by writing the RGB or hexadecimal color code into the attribute or by using a color selector.

To define the color directly in the field, delete the text for the default color definition and enter the color either as hexadecimal code (For example, `#336699`) or as RGB values (For example, `52,104,168`). Click into another attribute field to submit the value. Hexadecimal values will be changed to the corresponding RGB values automatically and the colored field on the left of the attribute will show the new color.

When you click the **Drop-Down** button in an attribute field in order to define a color, a color selector opens that allows you to select colors from a **Custom**, **Web** or **System** palette.

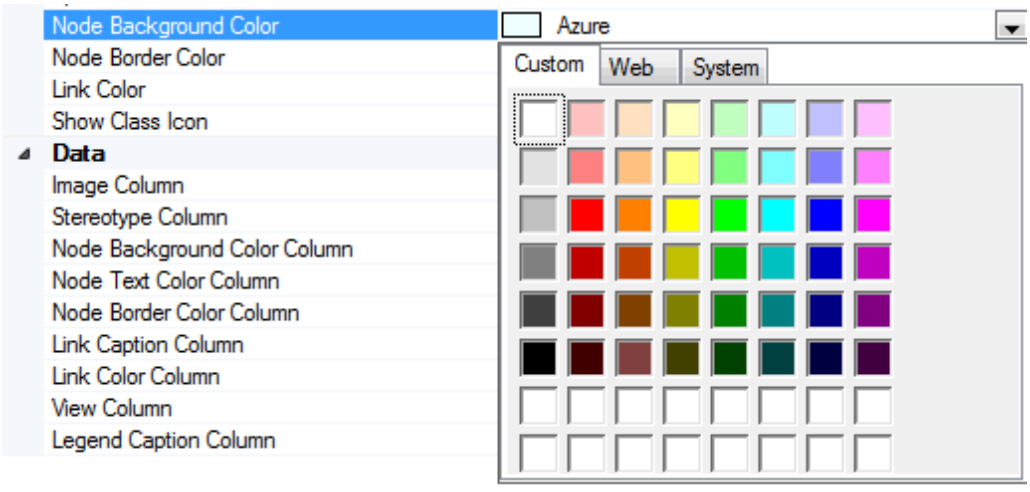

FIGURE: The color selector of the Report Assistant

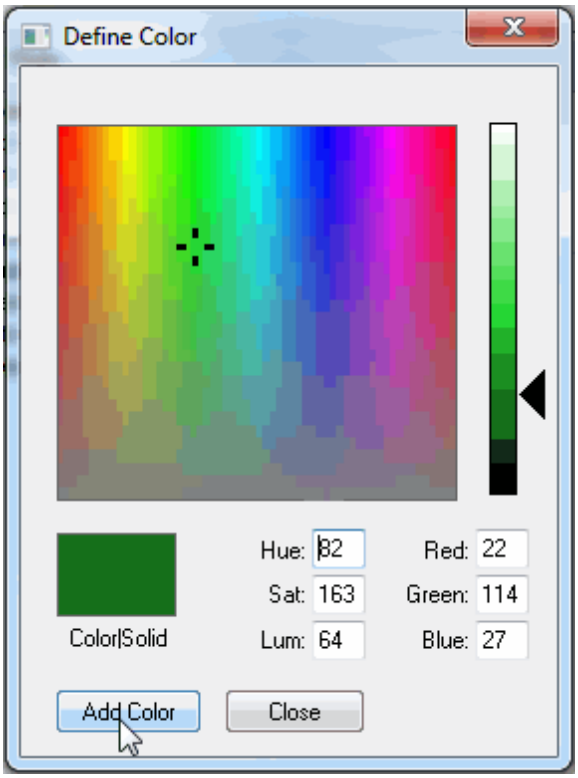
You can either click a color in the palette in one of the tabs and click **OK** to select it, or you can add a new color to the **Custom** tab.

To add a new color to the **Custom** tab of the color selector:

1) In the **Custom** tab of the color selector, right-click one of the empty white fields. A new window opens.

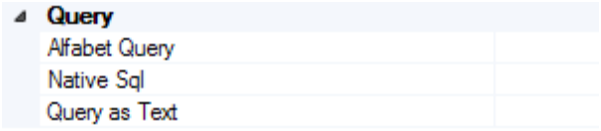
2) Select a color either from the palette fields in the upper part of the selector window or by defining the Red/Green/Blue and Hue/Saturation/Luminescence values for the color.



3) Click **Add Color** to add the new color to the palette. The color will be available in the **Custom** palette of all color selectors for all users working with the **Report Assistant** in Alfabet Expand.

Defining Query Attributes

If a query needs to be specified for a report element, the attribute window will display a separate section labeled **Query** with different attributes for the specification of a native SQL query or Alfabet query:



To define an Alfabet query in the **Alfabet Query Builder**, click the **Browse** button in the **Alfabet Query** field to select a `FIND` class and open the **Alfabet Query Builder**.

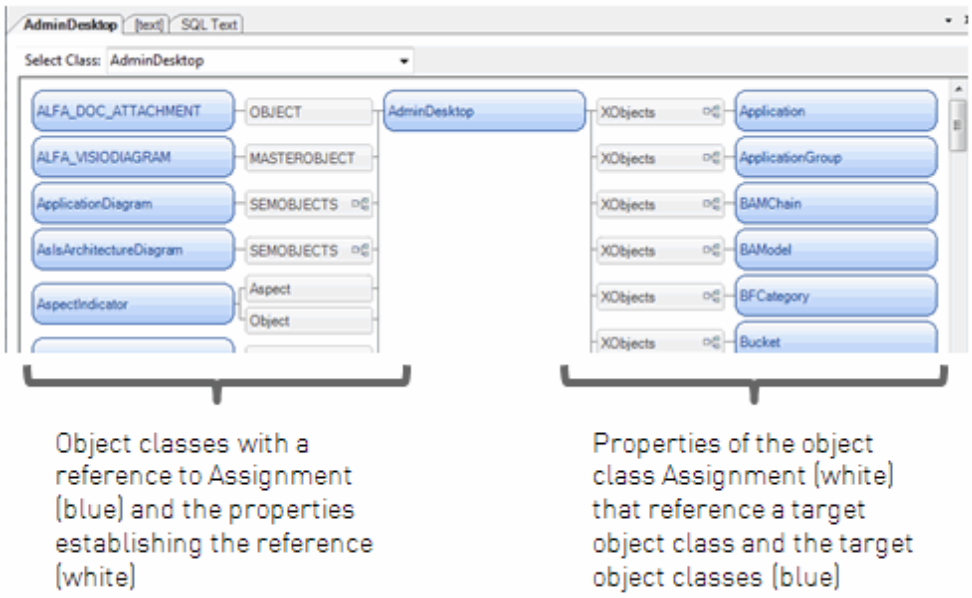
To define an Alfabet query in a text editor, click the the **Browse** button in the **Query as Text** field to open a text editor.

To define a native SQL query, click the **Browse** button in the **Native Sql** field to open a text editor for the definition of native SQL. The text editor has a separate tab for the definition of instructions. The text editor for the definition of SQL queries offers help for the definition of the SQL query in separate tabs:

- References to other object classes:

When you first open the text editor, the **AdminDesktop** tab is displayed. The object class `AdminDesktop` is the first class in alphabetical order in the Alfabet meta-model. In the **Select Class** field, you can select the object class whose references to other object classes that you want to see. A new tab with the name of the selected object class will open that displays the relation of the selected object class to other object classes in a graphic.

The selected object class is displayed in the upper middle of the graphic. On the left, all object classes referencing the selected object class via one or multiple of their object class properties are listed in blue boxes. The object class property that establishes the reference is displayed in a white box between the classes. On the right, all object class properties of the selected object class that store references to other object classes are listed. The target classes are listed in the blue boxes on the right.



If you double-click a referenced object class in the graphic, a new tab will open that displays the references of this class to other object classes.

- Object class documentation

When you open the **[text]** tab and select an object class in the **Select Class** field, the help document provided for the object class is displayed. The documentation includes a description of the purpose of the object class and all the object class properties of the object class and lists all relevant attributes in a table. Additionally, information is provided about class dependencies based on database triggers. All rules that define which dependent objects are deleted when an object of the selected class is deleted and vice versa are described in the documentation.

Once you have defined either a native SQL query or an Alfabet query, the attribute fields that are not used will no longer be displayed.

For information about defining Alfabet queries, see the chapter Defining Queries.

For information about the rules that apply to the definition of native SQL queries when used in Alfabet configurations, see Defining Native SQL Queries in the chapter Defining Queries.

Note the following when defining the query:

- If the configured report is applied to an object class with the attribute **Apply to Class**, you must configure the query to show results for the current object that is selected by the user when opening the configured report only. To refer to the current object, use the Alfabet parameter "`BASE`". For example, a configured report with the base class `Application` with a `WHERE` clause "`WHERE Application.REFSTR=@BASE`" will show results for the application that the user is currently working with only. A selector is added automatically to each configured report that is applied to an object class by means of the attribute **Apply to Class** . The selector allows the user to display other base objects in the configured report. If you do not specify a `WHERE` clause with the Alfabet parameter `BASE`, the selector will still be present, but it will not have any impact on the resulting configured report.
- You can define filters for a configured report to allow the users to specify the range of results in the configured report. You can generate a filter from any `WHERE` clause of the configured report by defining the value of the `WHERE` condition as Alfabet parameter. For more information about configuring filters, see Defining Filters for Configured Reports and Selectors in the chapter Defining Queries.
- You can combine the native SQL query as well as Alfabet query with Alfabet instructions written in Alfabet query language. For native SQL, the Alfabet instructions are defined separately in the tab **Instructions**. Alfabet instructions allow you For example, to define the output format for date and time information or to rename columns. For information about configuring Alfabet instructions, see Using Instructions to Format the Results of an Alfabet or Native SQL Query in the chapter Defining Queries .

  To check whether the syntax and the use of Alfabet parameters is correct in the native SQL query, click **Check**. The **Check** button checks the query for Alfabet conformance. Database-vendor specific SQL constructs, requirements, or dialects are not taken into account for this check.

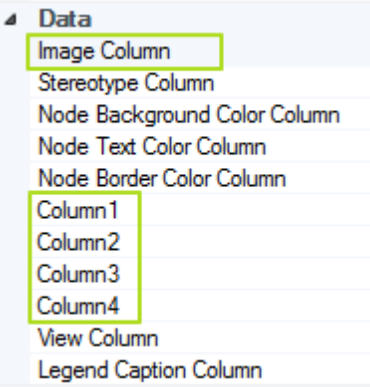
Mapping of Query Data to Attributes

Many of the data that is displayed in graphic reports is taken over directly from the result dataset of the query defined for the configured report or for a specific part of the configured report. For example, the definition of a tooltip that is displayed in a graphic report when the user moves the mouse over a box representing an object can be defined per object in the query results. With this mechanism it is possible to display individual tooltips for each object box.

The column name of the result dataset column containing the data must be defined in an attribute of the configured report in the report assistant to enable the use of the data for building of the graphic. Attributes that refer to data in the result dataset are displayed in the section **Data** of the root node of the report assistant or of a subnode thereof, depending on the report type.

For detailed information about the way column names are defined in Alfabet queries and native SQL queries, see Defining Column Names and Captions.

For example, for configured gallery reports, the central text displayed in the graphic for an object is defined with an attribute **Image Column** in the section **Data** of the attributes of the root node of the report while text displayed in the corners of the object boxes can be defined with the attributes **Column 1** - **Column 4**:



In a configured gallery report, applications in a selected application group shall be displayed together with the start date, end date, release status and object state of the application. In the middle of the object box, the name and version number of the application shall be displayed. All information about the applications is added to the Alfabet query defined for the configured gallery report:

```
ALFABET_QUERY_500

FIND Application

WHERE Application.ApplicationGroups CONTAINS:BASE

Instructions

   JoinColumns("Application.Name,Application.Version","Application.N
   ame", " v. ");

EndOfInstructions

QUERY_XML

<QueryDef>

   <ShowProperty Type="Property" ClassName="Application" Name="Name"
   />

   <ShowProperty Type="Property" ClassName="Application"
   Name="Version" />

   <ShowProperty Type="Property" ClassName="Application"
   Name="StartDate" />

   <ShowProperty Type="Property" ClassName="Application"
   Name="EndDate" />

   <ShowProperty Type="Property" ClassName="Application"
   Name="ObjectState" />

   <ShowProperty Type="Property" ClassName="Application"
   Name="Status" />

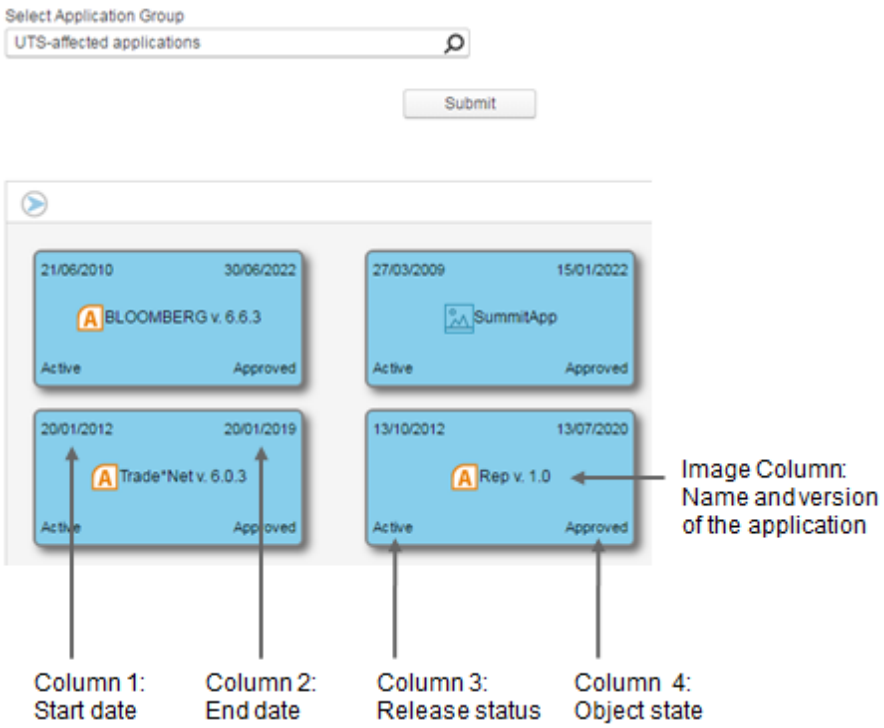
</QueryDef>
```

Name and version of the applications shall be displayed as text in the gallery report. Therefore, a `JoinColumns` instruction was used to write the information about the name and version number of the applications into one column that can than be referenced in the attributes of the root node of the configured report.

In the attribute section **Data** of the root node of the report, the names of the columns in the query are filled into the respective attributes:

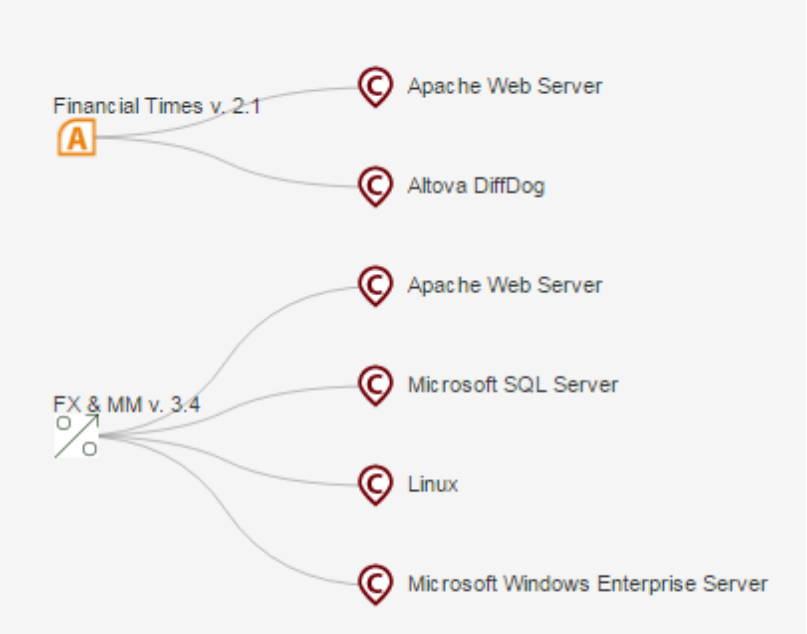
Data	
Image Column	Application.Name
Stereotype Column	
Node Background Color Column	
Node Text Color Column	
Node Border Color Column	
Column1	Application.StartDate
Column2	Application.EndDate
Column3	Application.Status
Column4	Application.ObjectState
View Column	

As a result, the report displays the object boxes with the defined data:



In some reports, multiple queries can be defined but only the root node includes the mapping in the attribute section **Data**. Other reports only include one query but the query defines a grouped dataset with multiple levels of objects that shall all refer to the same attribute of the section **Data**. In these cases the columns that define the same property, For example, the background color of object boxes or the text to be displayed in the object boxes must have the same name. In grouped dataset this requires the definition of a grouped dataset joining information about objects from different levels in a single query.

For example, a configured branching diagram report displays applications and local components thereof and the name of the applications and local components shall be displayed on the nodes of the report:



The text to be displayed on the nodes of the configured report is defined with one single attribute in the section **Data** of the root node attributes: **Image Column**. Therefore, only one column name can be defined for display of the text. The query the configured report is based on must not only group the dataset to display application on the first and local component on the second level, but it must also contain a `JoinColumns` instruction that joins the columns into one single column.

In the example this is the column `app.Name`. First the information about the application name and application version is joined in this column to display all required information about the application. In a second step, the information to display for applications is joined with the information to display about the local components:

```
SELECT app.REFSTR, app.REFSTR AS 'app.REFSTR', app.NAME AS
'app.Name', app.VERSION AS 'app.Version', lcom.REFSTR AS
'lcom.REFSTR', lcom.NAME AS 'lcom.Name'

FROM APPLICATION app, LOCALCOMPONENT lcom

WHERE app.REFSTR = lcom.OWNER

   AND app.NAME LIKE 'F%'

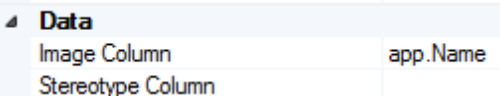
/* Alfabet Instructions */

GroupBy_Ex("app.REFSTR","lcom.REFSTR","app",0);

JoinColumns("app.Name,app.Version","app.Name", " v. ");

JoinColumns("app.Name,lcom.Name","app.Name", "");
```

The column `app.Name` is then defined in the **Image Column** attribute in the root node of the configured report:



A column in the result dataset can be defined in multiple attributes in the section **Data**. If the configured report has an attribute for the definition of a label text and one for the definition of a legend item text and you want the label text to be identical to the text that shall be displayed in the legend, you can enter the same column name in both attributes.

The design of the configured report via data from the result dataset of a query is limited for Alfabet queries. Alfabet queries can only return data from the Alfabet database. For example, if you want to include a color definition in a result dataset, the color definition can only be taken over from a color definition stored for an object in the Alfabet database. It is not possible to define the color as string directly in the Alfabet query.

Some features of configured reports are limited to configured reports defined with native SQL. This applies For example, to the definition of a link target to open an Alfabet view when the user clicks the object in the report. It is Therefore, recommended to define configured graphic reports via native SQL queries.

Defining Navigation from the Report to Alfabet Views

By default, the object profile of the object represented by the node opens when the user double-clicks a node or object box in the report or uses the **Navigate** button in the toolbar of the report. Alternatively, many configured graphic reports can be configured to open another configured report, an object profile or a standard Alfabet view with the object represented by the node or object box as base object. For configured reports with multiple levels of nodes or object boxes, you can define an alternative navigation target for all or only for a subset of levels in the configured report. If no navigation target is defined for one level, the default is used and the object profile of the object opens.

Navigation to a defined view from the configured report can only be configured via native SQL queries and requires the following configurations:

1) In the native SQL query defined for the report, a column must be added for the definition of the navigation target. If the configured report is based on a grouped dataset, and you want to define the navigation target for all grouping levels of the report, you must specify one column for each level, containing the navigation target definition for the objects of the respective level, and then combine the columns into one column with a `JoinColumns` instruction.

   The syntax required for definition of the view is the following:

   `View=`*`ViewType`*`:`*`ViewName`*

   The `ViewType` can be one of the following:

   - ***Report*** for a configured report
   - ***GraphicView*** for a standard Alfabet view
   - ***ObjectView*** for an object profile

   `ViewName` is the name of the view.

   If the navigation target is a configured report, parameters values can be handed over to the view that opens.

   The query of the report must contain each parameter definition as a variable defined as

   `@`*`ParameterName`*

   Please note that the old syntax of the Alfabet query language defining parameters as:`ParameterName` is not supported.

   The parameters can be used in `WHERE` clauses of the query without defining a filter for the report, because the parameter values are already defined in the navigation link.

Optionally, filters can be defined for the report to allow the user opening the report to alter the parameter values. In this case the parameter values in the navigation link are used as default values for the filter when opening the report. The filter settings are also stored in the user context settings for the report. That means, when the user first opens the report via drilldown from a chart report and then afterwards opens the report in any other context, For example, via the **Reports** functionality, the report will open with the last filter settings derived from the drill-down.

For each parameter the following string must be added to the navigation target definition:

```
&ParameterName=ParameterValue
```

The setting of three parameters would result in the following navigation link:

```
View=ViewType:ViewName&ParameterName1=ParameterValue1&ParameterName2=Para
meterValue2&ParameterName1=ParameterValue2
```

2) In the attributes of the root node of the report assistant, enter the name of the column containing the navigation target specification into the attribute defined to store the navigation target view definition.

For all configured reports that allow specification of the navigation target via a query, a base object for the view that opens has to be specified. For some configured reports the base object for the link is automatically identical with the object represented by the graphic element containing the link. For other configured reports, the navigation target object must be defined in a separate column of the configured report. If the navigation target is defined separately, or the graphic element is not representing a single object anyway, there are two ways to define the navigation target object:

- To define the link to open a configured report independent from a base object via the following specification of the link target:
  - Configured reports are objects of the object class `ALFA_REPORT`. Define the configured report's REFSTR as REFSTR of the navigation target object.
  - Define the navigation link to open the report defined as navigation target object.
  - If the titel of the configured report shows the name instead of the caption of the configured report when opening the configured report via the link, define class settings for the class `ALFA_REPORT` with a format string returning the caption. For more information about defining class settings, see Configuring Class Settings for Object Classes and Object Class Stereotypes.
- To define the link to open for multiple objects of the same object class:
- Define the object of the object class `ALFA_MM_CLASS_INFO` representing the object class the objects belong to as navigation target object. If the graphic element containing the link is styled via the class settings of an object class, the class settings of the object class the `ALFA_MM_CLASS_INFO` object represents will be used for styling of the graphic element.

Defining Rules for Display of Objects In Reports Dependent on Object Property Values

To enhance the visibility of important aspects for the objects displayed in a report, customer graphic reports for Alfabet can be configured to change the size, color or icons dependent on the value of a defined object property.

In many reports this can be achived by mapping data from the result dataset of the query finding the objects to specific attributes in the report assistant. For more information see Mapping of Query Data to Attributes.

For other reports, rules can be defined that find objects with a defined property value or property value range via a query and apply the formatting defined in the rule to the object. For example, objects with a critical value for an indicator can be marked in red while all other objects can be displayed in green.

The following design can be configured to be dependent on object property values via rules:

Rule	Report Type	Description
Color Rules	Treemap Report Layered Diagram Grid Report Matrix Map Lane Report Gantt Charts	Color rules allow colors to be assigned to object boxes in a report dependent on the object class or on the availability or value of a property of the object class. For more information, see Defining Color Rules.
Indicator Rule	Treemap Report Rectangular Treemap Report Layered Diagram Grid Report Matrix Map Lane Report Dynamic Lane Report Node Arc Reports	Indicator rules allow an indicator icon to be displayed in the object boxes of all objects specified in the indicator rule. For more information, see Defining Indicator Rules.
Size Rule	Treemap Report Layered Diagram	Size rules can be defined to display the object boxes in a report with different heights dependent on an object property values. For more information, see Displaying Evaluation Criteria By Size or Color Variation or Addition of Indicator Icons in the description of how to define a treemap report.

Defining Color Rules

The colors of graphic reports are normally specified per object class. Either the colors defined in the **Background Color** and **Foreground Color** attributes for the relevant class setting are used or the color of an object class can be defined in the attributes of the element nodes defined for the report.

For a subset of reports, coloring can be defined via color rules. Color rules allow coloring to be defined not only per object class, but also on the basis of a query that specifies a subset of objects of a class the color shall be applied to.

You can specify various color rules for a report that allow you to display objects with different attribute values in different colors. For example, you can display objects that are in the object state **Plan** in one color and objects in the object state **Active** in another color.

Color rules are available for the following reports:

- TreeMap Reports
- Layered Diagram Reports
- Grid Reports
- Matrix Maps
- Lane Reports

Color rules are valid for all objects found by the query defined for the color rule independent of the level configuration of the report. For example, if you define a layered diagram report that displays domains in the first layer and sub-domains in the second layer, you can define a color rule that colors all domains in all layers that have a defined indicator value below a specified value.

For tree maps, layered diagrams, lane reports and matrix maps, color rules are defined as sub-nodes of the report's root node. For grid reports, color rules are defined as sub-nodes of the **Cell** nodes of the report. Different coloring can be applied to all cells of the report.

The specification of color rules is optional. If no color rules are specified and no other attributes of the report allow definition of a default color, all objects will be displayed in the background and foreground color specified in the class settings defined for the respective object class and the border color defined in the attributes of the element nodes defined for the report.

Depending on the values you want to analyze, you can define as many color rules as required. When defining the color rules, you must ensure that each object can be explicitly assigned to one of the color rules. Objects that cannot be assigned to any of the color rules are displayed in the default color. Objects that can be assigned to more than one color rule are displayed in the color of the last rule they apply to.

You must take this behaviour into account if you want to use For example, the foreground color and the border color to highlight different object properties in a report. this scenario requires to define a different rule for each combination of property values.

A report shall highlight an indicator value of the object via the foreground color while the border color changes according to the release status of the objects. The objects can be in the release status **Plan**, **Active**, or **Retired**. The indicator value can be either low or high. Therefore, 6 color rules must be defined, one for each combination of release status and indicator value. The rules must find objects matching the following conditions and apply the appropriate combination of background color and border color:

Rule Number	Indicator Value	Release Status	Coloring
1	high	Plan	

2	high	Activ	
3	high	Retired	
4	low	Plan	
5	low	Active	
6	low	Retired	

To change the default color in a report, two different types of color rules can be defined:

- `ObjectQuery`: The query defined for the color rule returns the `REFSTR` of the object that the color shall be applied to. The colors that shall be applied to the object boxes are defined separately via attributes of the color rule.

  When defining an Alfabet query, no Show property definition is required. The `REFSTR` of the `FIND` object class is returned.

  When defining a native SQL query, the `SELECT` statement of the query must have the `REFSTR` of the relevant object class defined as the first argument. No further arguments are required in the `SELECT` statement.

- `ColorQuery`: The query defined for the color rule not only returns the `REFSTR` of the objects that the color shall be applied to but also the HTML-compliant specification of the colors to be applied to the object boxes.

  Color queries require the specification of a native SQL query.

  The `SELECT` statement of the SQL query must return the following in the given order:

  - the `REFSTR` of the current object
  - a string that is used as the caption for the color assignment in the legend of the report
  - a string that defines the background color of the object boxes of objects matching the query conditions in HTML-compliant color coding
  - a string that defines the foreground color of the object boxes of objects matching the query conditions in HTML-compliant color coding

- a string that defines the border color of the object boxes of objects matching the query conditions in HTML-compiant color coding

For example,:

```
SELECT DOMAIN.REFSTR, "Legend text", "#336699", "white",
"black"
```

The definition of a color query in a color rule has the following advantages as compared to an object query:

- The number of overall color rules required for a report can be reduced. For example, if you want to apply a different color to an application in a different object state, you can define the color coding for all object states in one query while a separate color rule for each object state would be required when using object queries.
- Dynamic color assignment can be applied to a report. You can, For example, define a query that colors object boxes according to the indicator values assigned to the objects. In the report, you can define a filter that allows the user viewing the report to choose an indicator type. The coloring of object boxes is then reassigned according to the values for the selected indicator (see the example below).

For example, in a report displaying applications a filter is defined that allows the user to select an indicator type for which the indicator values shall be used for coloring the object boxes of the applications in the report. Indicators are selected in a filter field named `@AppColorType`. The query defined for the color rule finds the indicator for the selected object that is based on the selected indicator type and assigns different colors for each value that may be defined for the indicator. The values for all indicators are in the range of 0 - 4.

```
SELECT obj.REFSTR,'Very Low','#80ff80','Black'
FROM APPLICATION obj, INDICATOR ind
WHERE (ind.INDICATORTYPE = @AppColorType OR 1 = 2)
AND ind.OBJECT = obj.REFSTR
AND ind.VALUE = 0
UNION ALL
SELECT obj.REFSTR,'Low','#b0ff80','Black'
FROM APPLICATION obj, INDICATOR ind
WHERE (ind.INDICATORTYPE = @AppColorType OR 1 = 2)
AND ind.OBJECT = obj.REFSTR
AND ind.VALUE = 1
UNION ALL
SELECT obj.REFSTR,'Moderate','#ffff80','Black', 'Black'
FROM APPLICATION obj, INDICATOR ind
WHERE (ind.INDICATORTYPE = @AppColorType OR 1 = 2)
AND ind.OBJECT = obj.REFSTR
```

```
AND ind.VALUE = 2
UNION ALL
SELECT obj.REFSTR,'High','#ffb080','Black', 'Black'
FROM APPLICATION obj, INDICATOR ind
WHERE (ind.INDICATORTYPE = @AppColorType OR 1 = 2)
AND ind.OBJECT = obj.REFSTR
AND ind.VALUE = 3
UNION ALL
SELECT obj.REFSTR,'Very High','#ff8080','Black', 'Black'
FROM APPLICATION obj, INDICATOR ind
WHERE (ind.INDICATORTYPE = @AppColorType OR 1 = 2)
AND ind.OBJECT = obj.REFSTR
AND ind.VALUE = 4
```

The condition for the indicator type in the query above takes into account that a user may submit the report without selecting an indicator type. In this case, the condition will be deleted from the query before execution. This would result in a query applying colors according to the first setting of an indicator of any type for the application because only the indicator object and value are then defined in the `WHERE` clause. To deactivate the color rule when no indicator type is defined, a condition that cannot be fulfilled (like 1 = 2) is added as alternative text if no indicator type is defined.

If a legend is displayed for the report, all color rules of the type `ObjectQuery` form one legend group with the caption **Colors** . Each color rule of the type `ColorQuery` forms a separate legend group with the **Name** of the color rule displayed as a caption of the legend group.

The legend lists all coloring options defined as small boxes with a background color and border color as defined in the color rule and the character "x" displayed in the box in the color defined as foreground color.

The table below lists all available attributes in the **Color Rule** element.

Attribute	Description
Name	Defines the title displayed for the color in the legend. The **Name** is also displayed as the name of the color rule node in the explorer of the **Report Assistant**. **NOTE**: The attribute **Show Legend** of the report's root node element must be set to `True` to display the legend.
Type	Select `ObjectQuery` to define the objects that the color rule shall apply to in either a native SQL query or Alfabet query and define the colors assigned to the objects with the attributes **Background Color** and **Foreground Color** of the color rule. Select `ColorQuery` to define both the objects and the colors assigned to the object in a native SQL query.

Attribute	Description
Background Color	Only if the attribute **Type** is set to `ObjectQuery`: Defines the color of the boxes representing the objects in the report.
Foreground Color	Only if the attribute **Type** is set to `ObjectQuery`: Defines the color of the text in the boxes representing the objects in the report. **NOTE**: In color rules defining coloring of links in a lane report, the **Foreground Color** defines the color of the text in the link label.
Border Color	Only if the attribute **Type** is set to `ObjectQuery`: Defines the color of the border of the boxes representing the objects in the report.
Native Sql/ Alfabet Query/ Query as Text	Define the objects to which this color rule applies. A valid Alfabet query or native SQL query has to be written into the parameter that finds the relevant objects. If the **Type** of the color rule is `ObjectQuery`, define a native SQL query or Alfabet query that returns the `REFSTR` of the objects that the color rule shall apply to. If the **Type** of the color rule is `ColorQuery`, define a native SQL query that returns: • the `REFSTR` of the current object • a string that is used as the caption for the color assignment in the legend of the report • a string that defines the background color of the object boxes of objects matching the query conditions in HTML-compliant color coding • a string that defines the foreground color of the object boxes of objects matching the query conditions in HTML-compliant color coding
Legend Row Item Count	Defines the number of color rules displayed in one row of the legend of the report on export of the report via the **Export** button. This setting is only evaluated on export of the report. In the Alfabet user interface, the legend displays one entry per row independent of this setting. For color rules of the type `ObjectQuery`, only the value defined in the first color rule of the type `ObjectQuery` of the report is applied to the group. By default, 4 items are displayed in a row of the legend.

Defining Indicator Rules

You can define that an indicator should be displayed in the report for each object of an object class. This allows an additional dimension of evaluation for the objects in the report. Indicator rules add icons to the boxes representing the object. Multiple icons can be assigned to each object box via multiple different indicator rules, or single rules of a subtype that permit definition of multiple indicators.

You can define one of the following:

- Indicators defined for the object that are represented by an icon can be displayed to visualize the object evaluation. Multiple icons can be placed into one object box.

  Note the following:

  - An indicator can only be displayed in the report if the indicator type has been configured to display icons rather than numerical values. Indicator types are specified in the **Evaluations and Portfolios** functionality of Alfabet. For information about the configuration of indicator types and the icon gallery used to visualize their values, see the section *Configuring Indicator Types for an Evaluation Type* in the reference manual *Configuring Evaluation and Reference Data in Alfabet*.
  - The indicator icon is only displayed in the object boxes of objects that the indicator is set for.

- Icons can be assigned independent form indicator settings via a query. For example, the object boxes representing applications can contain an icon for each domain the application is assigned to or associated with. The user can navigate from the icon to the object view of the object represented by the icon. Multiple icons can be assigned to an object box.

You can specify various indicator rules for a report that allow you to display a different indicator per object class or for objects matching defined conditions. It is also possible to display multiple indicators per object.

Indicator rules are available for the following reports:

- TreeMap Reports
- Rectangular Treemap Reports
- Layered Diagram Reports
- Grid Reports
- Matrix Maps
- Lane Reports
- Dynamic Lane Reports
- Node Arc Reports (only indicator rules of the type `IconQuery` are supported)

Indicator rules are valid for all objects defined within the attributes of the indicator rule independent of the level of configuration of the report. For example, if you define a layered diagram report that displays domains in the first layer and sub-domains in the second layer, you can define an indicator rule that displays an indicator for all domains in all layers.

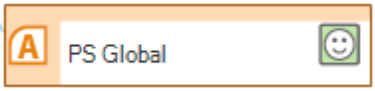
For tree maps, layered diagrams, node arc reports, lane reports, dynamic lane reports and matrix maps, indicator rules are defined as sub-nodes of the report's root node. For grid reports, indicator rules are defined as sub-nodes of the **Cell** nodes of the report. Different indicator rules can be applied to cells of the report.

The specification of indicator rules is optional. If no indicator rules are specified, all objects will be displayed without an indicator icon in the object box. Depending on the values you want to analyze, you can define as many indicator rules as required. The configured report can then be configured to display one or multiple icons per object box: Whether one or multiple indicators are displayed per object is defined with the

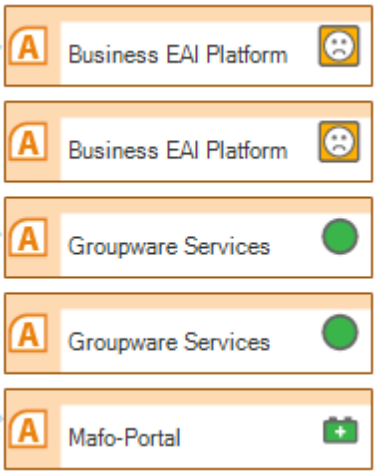
attribute **Show Multiple Indicators** of the configured report. The attribute is available in the root node of the configured reports displaying a treemap, layered diagram, rectangular treemap, matrix map, or lane report, in the **Item** element of grid reports, and in the **Node** element of lane reports.

- **Displaying one icon** (**Show Multiple Indicators** is set to `False`):

The icon is displayed on the right of the object box:



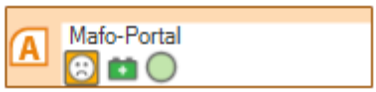
When defining the indicator rules, you must ensure that each object can be explicitly assigned to one of the indicator rules. Objects that cannot be assigned to any of the indicator rules are displayed without indicator icons. Objects that can be assigned to more than one indicator rule are displayed with the indicator icon of the last rule they apply to. If a single indicator rule is defined for the assignment of multiple icons, the last icon returned in the result dataset of the indicator rule query is displayed. For example, if three indicator rules all assign an icon to the object boxes of applications, and none of the indicators represented by the icon is set for all applications, the icon from the last indicator rule returning an indicator for that application is displayed for each application, returning a configured report:



This method is not available for node arc reports.

- **Displaying multipe icons** (**Show Multiple Indicators** is set to `True`):

The icons are displayed on the bottom of the white sector of the object box from left to right:

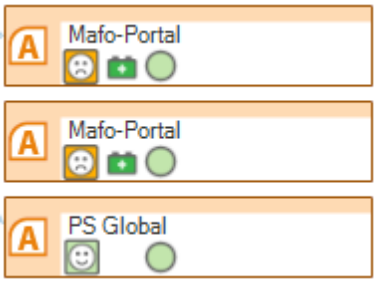


If the space is not sufficient to display all defined indicators, the last indicators will be dropped. The object box width is not changed if more indicators are displayed.

The position of the indicators depends on the setting of the attribute **Indicator Fill Policy**. The attribute is available in the root node of the configured reports displaying a treemap, layered diagram, rectangular treemap, matrix map, node arc or lane report, in the **Cell** element of grid reports, and in the **Node** element of lane reports. The **Indicator Fill Policy** can be one of the following:

- `ByIndex`: This setting shall be used if multiple indicators are defined via multiple indicator rules, each returning a single icon. The position of the icon resulting from each indicator rule

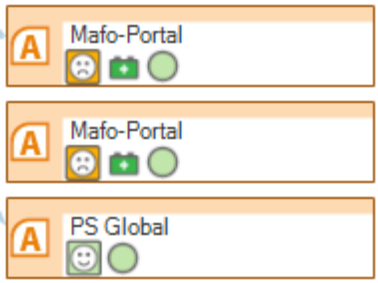
is defined by means of the attribute **Indicator Index** of the respective indicator rule that must be set to an unsigned integer starting with 0 for the left most position. If an **Indicator Index** attribute has been defined for each indicator rule and an indicator is not set for a specific object, the position of this indicator icon in the box will be left empty and the position of all other indicator icons will not be changed:



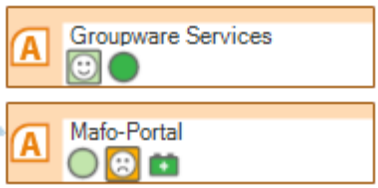
If the order of the **Indicator Index** attribute is not defined, the placement of indicators will be arbitrary.

This method is designed for positioning only one icon per indicator rule. If an indicator rule returns multiple icons, only one of the icons is displayed.

- `LeftAlign`: This setting shall be used if a single indicator rule is defined that returns multiple icons. It can also be applied when multiple indicator rules each return a single icon, but the position and order of icons is not important to understand the report. The Icons are displayed in the order of occurence within the indicator rule(s) from left to right. If a different number of indicator icons is returned, the remaining icons are moved to the left:



If the indicator icons are all found by a single indicator rule, the order of icons depends on the order of results in the result dataset of the query of the indicator rule and may be different for different objects:



To display indicators in object boxes of a report, you can define four different types of indicator rules:

- `ClassName`: This indicator rule type returns a single icon representing an indicator. An indicator icon is assigned to all objects of a defined object class for that the indicator is set. All indicator icons represent the same indicator type.
- `ObjectQuery`: This indicator rule type returns a single icon representing an indicator. An indicator icon is assigned to all objects found via a query. All indicator icons represent the same indicator type.

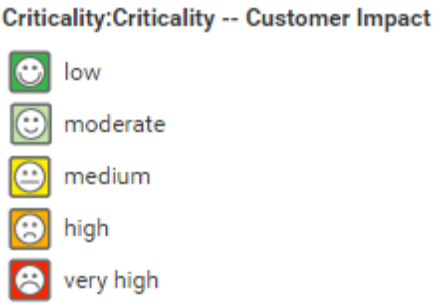
- `TypeQuery`: This indicator rule type returns one or multiple icons representing indicators. One or multiple indicator icons are assigned to all objects found via a query. The indicator icons can represent different indicator types.

  The definition of a `TypeQuery` in an indicator rule has the following advantages as compared to an object query:

  - The number of overall indicator rules required for a report can be reduced. For example, if you want to display a different indicator for objects in a different object state, you can define the indicators for all object states in one query while a separate indicator rule for each object state would be required when using object queries.
  - Dynamic indicator assignment can be applied to a report. For example, you can define a filter for the report that allows the user viewing the report to choose an indicator type. The indicator icon of the selected value is then displayed in the report (see the example below).

- `IconQuery`: This indicator rule type returns one or multiple icons that represent information not related to an indicator. One or multiple icons are assigned to all objects found via a query. The icons can For example, represent related objecs or highlight the setting of a property of the object, like the release status or object state. Navigation to any Alfabet view related to the information can be activated.

If icons are added to object boxes, the icons are explained in a legend. For icons found via an indicator rule of the type `IconQuery` or `TypeQuery`, the legend header and legend texts for the icons are defined via the query. For icons representing a fixed indicator via an icon rule of the type `ClassName` or `ObjectQuery`, the heading of the legend group displaying the indicator icons returns the name of the evaluation type and indicator type of the indicator by default. If a legend caption is defined in the indicator rule, the default caption is substituted with the defined caption. For each icon, the semantic value of the indicator is displayed:



The following sections inform about the attribute settings in the indicator rule node for the different types of indicator rules:

- Creating an Indicator Rule of the Type ClassName
- Creating an Indicator Rule of the Type ObjectQuery
- Creating an Indicator Rule of the Type TypeQuery
- Creating an Indicator Rule of the Type IconQuery

Creating an Indicator Rule of the Type ClassName

This indicator rule type assignes an indicator icon for a defined indicator type and evaluation type to all objects of a defined class.

Set the following attributes of the indicator rule node:

Attribute	Description
Name	Defines the name of the indicator rule node in the explorer of the **Report Assistant**.
Type	Select `ClassName`.
Class Name	Defines the object class for which the indicator shall be displayed. For the object classes that allow stereotype specifications (For example, `Project` and `Domain`), the XML attribute `ClassName` can specify an object of a specific stereotype. To define an XML element ***Query*** for a stereotype, the XML attribute `ClassName` must be *`ClassName`*`:`*`StereotypeName`* For example,: *`Project`*`:`*`StatementOfWork`*
Evaluation Type	Defines the name of the evaluation type for which the indicator type is specified. **NOTE:** The evaluation type must be assigned to the object class specified with the attribute **ClassName**. This is done in the **Class Configuration** functionality in the **Configuration** module. For more information, see the section *Assigning Evaluations Types to an Object Class* in the reference manual *Configuring Evaluation and Reference Data in Alfabet*.
Indicator Type	Defines the name of the indicator type that shall be displayed in the report. **Note**: The indicator type must be configured to use an icon gallery to display its value in evaluations. This is done in the **Evaluations and Portfolios** functionality in Alfabet. For more information, see the section *Configuring Indicator Types for an Evaluation Type* in the reference manual *Configuring Evaluation and Reference Data in Alfabet*.
Legend Row Item Count	Defines the number of indicator values displayed in one row of the legend of the report. By default, 4 items are displayed in a row of the legend.
Indicator Index	If multiple indicator rules are defined, and the attribute **Indicator Fill Policy** of the configured report is set to `ByIndex`, define the position of the icon displayed for the current indicator rule. Enter 0 for the first position on the left and ascending integers for the next positions from left to right.

Attribute	Description
Legend Caption	Defines a heading for the legend group that explains the indicator icons for the indicator found by this indicator rule. If no Legend Caption is defined, the name of the evaluation type and indicator type of the indicator are displayed as heading of hte legend group.

Creating an Indicator Rule of the Type ObjectQuery

This indicator rule type assignes an indicator icon for a defined indicator type and evaluation type to a sub-set of objects of a defined class. The objects are found by a query.

Set the following attributes of the indicator rule node:

Attribute	Description
Name	Defines the name of the indicator rule node in the explorer of the **Report Assistant**.
Type	Select `ObjectQuery`.
Class Name	Defines the object class for which the indicator shall be displayed. The query defined in the attributes **Native Sql** / **Alfabet Query** / **Query as Text** must be defined to return objects of the specified class only. For the object classes that allow stereotype specifications (For example, `Project` and `Domain`), the XML attribute `ClassName` can specify an object of a specific stereotype. To define an XML element ***Query*** for a stereotype, the XML attribute `ClassName` must be *`ClassName:StereotypeName`* For example,: *`Project:StatementOfWork`*
Evaluation Type	Defines the name of the evaluation type for which the indicator type is specified. **NOTE:** The evaluation type must be assigned to the object class specified with the attribute **ClassName**. This is done in the **Class Configuration** functionality in the **Configuration** module. For more information, see the section *Assigning Evaluations Types to an Object Class* in the reference manual *Configuring Evaluation and Reference Data in Alfabet*.
Indicator Type	Defines the name of the indicator type that shall be displayed in the report. **Note**: The indicator type must be configured to use an icon gallery to display its value in evaluations. This is done in the **Evaluations and Portfolios** functionality in Alfabet. For

Attribute	Description
	more information, see the section *Configuring Indicator Types for an Evaluation Type* in the reference manual *Configuring Evaluation and Reference Data in Alfabet*.
Native Sql / Alfabet Query / Query as Text	Defines the objects to which this indicator rule applies. A valid Alfabet query or native SQL query has to be written in the parameter that finds the relevant objects. Define a native SQL query or Alfabet query that returns the `REFSTR` of the objects that the indicator rule shall apply to. Objects must belong to the object class defined with the attribute **Class Name**. When defining an Alfabet query, no Show property definition is required. The `REFSTR` of the `FIND` object class is returned. When defining a native SQL query, the `SELECT` statement of the query must have the `REFSTR` of the relevant object class defined as first argument. No further arguments are required in the `SELECT` statement.
Legend Row Item Count	Defines the number of indicator values displayed in one row of the legend of the report. By default, 4 items are displayed in a row of the legend.
Indicator Index	If multiple indicator rules are defined, and the attribute **Indicator Fill Policy** of the configured report is set to `ByIndex`, define the position of the icon displayed for the current indicator rule. Enter 0 for the first position on the left and ascending integers for the next positions from left to right.
Legend Caption	Defines a heading for the legend group that explains the indicator icons for the indicator found by this indicator rule. If no Legend Caption is defined, the name of the evaluation type and indicator type of the indicator are displayed as heading of hte legend group.

Creating an Indicator Rule of the Type TypeQuery

The query defined for the indicator rule not only returns the `REFSTR` of the objects that the indicator shall be displayed for but also a reference to the indicator.

Set the following attributes of the indicator rule node:

Attribute	Description
Name	Defines the name of the indicator rule node in the explorer of the **Report Assistant**.
Type	Select `TypeQuery`.

Attribute	Description
Native Sql/ Alfabet Query/ Query as Text	Defines the objects to which this indicator rule applies. A valid Alfabet query or native SQL query has to be written in the parameter that finds the relevant objects. Define a native SQL query or Alfabet query. When defining an Alfabet query, the `REFSTR` of the `FIND` object class is returned to find the relevant objects. The **Show Properties** must return the following: • the `REFSTR` property of the indicator type of the indicator that shall be displayed. • the `Value` property of the indicator. This specification is optional. When defining a native SQL query, the `SELECT` statement of the SQL query must return the following: • the `REFSTR` of the current object (as first SELECT argument not visible in the result dataset when displayed as table) • the `REFSTR` property of the indicator type of the indicator that shall be displayed. • the `Value` property of the indicator. This specification is optional. The return dataset must either return the values listed above as first columns in the result dataset in the order specified above, or, if the position of columns is changed, the name of the columns defining the `REFSTR` of the indicator type and the value of the indicator must be entered into the attributes **Indicator Reference Column** and **Indicator Value Column**.
Legend Caption Column	Enter the name of the column in the query result dataset returning a string to be used as headline of the legend group for the indicators icons in the legend of the configured report. If not defined, the name of the evaluation type and indicator type of the indicator are used as group caption. Please note that the number of groups is identical to the number of indicators and not derived from the text returned via the dataset. If For example, the same text is returned for each indicator, the icons are still listed with one group per indicator with all groups returning the same name.
Indicator Reference Column	Enter the name of the column in the query results returning the `REFSTR` property of the indicator type of the indicator that shall be displayed. This specification is optional. If the `REFSTR` property of the indicator type is returned as first column in the tabular result dataset of the query, the information is read from the query without defining the column in the **Indicator Reference Column**.
Indicator Value Column	Enter the name of the column in the query results returning the `Value` property of the indicator.

Attribute	Description
	This specification is optional. If the `Value` property of the indicator is returned as second column in the tabular result dataset of the query, the information is read from the query without defining the column in the **Indicator Value Column** attribute.
Legend Row Item Count	Defines the number of indicator values displayed in one row of the legend of the report. By default, 4 items are displayed in a row of the legend.
Indicator Index	If multiple indicator rules are defined, and the attribute **Indicator Fill Policy** of the configured report is set to `ByIndex`, define the position of the icon displayed for the current indicator rule. Enter 0 for the first position on the left and ascending integers for the next positions from left to right. Please note that positioning `ByIndex` only displays one icon per indicator rule. If you defined a query returning multiple icons per object box, the **Indicator Fill Policy** of the configured report should be set to `LeftAlign`. This attribute is then ignored for positioning.

For example, in a report displaying applications a filter is defined that allows the user to select an indicator type that the indicator icons shall be displayed for in the object boxes of the applications in the report. Indicators are selected in a filter field named:`AppIndicatorType`. The Alfabet query defined for the indicator rule finds the indicator for the selected object that is based on the indicator type selected in the filter.

```
ALFABET_QUERY_500

FIND

Application

INNERJOIN Indicator ON Indicator.Object=Application.REFSTR

INNERJOIN IndicatorType ON
Indicator.IndicatorType=IndicatorType.REFSTR

WHERE

    (OR IndicatorType.REFSTR =:AppIndicatorType

    IndicatorType.REFSTR = 'xxx')

QUERY_XML

<QueryDef>

    <ShowProperty Type="Property" ClassName="IndicatorType"
    Name="REFSTR" />

    <ShowProperty Type="Property" ClassName="Indicator" Name="Value"
    />

</QueryDef>
```

The condition for the indicator type in the query above takes into account that a user may submit the report without selecting an indicator type. In this case, the condition is deleted from the query before execution. This would result in a query applying indicator icons according to the

first setting of an indicator of any type for the application. To deactivate the display of indicator icons when no indicator type is defined, a condition that cannot be fulfilled (like `IndicatorType.REFSTR` = 'xxx') is added as an alternative text if no indicator type is defined.

Creating an Indicator Rule of the Type IconQuery

For indicator rules of the the type `IconQuery`, all relevant information has to be derived from a query.

Although it is possible to define an Alfabet query for an indicator rule of the type `IconQuery`, the possibilities to define the query in Alfabet query language are very limited. It is recommended to use native SQL to define the query.

The query must return at least the the name of an icon from the icon gallery and the REFSTR of the object represented by the object box the icon shall be placed in. Optionally, the query can also couple the icon to an object in the Alfabet database, which enables navigation from the icon to the object view of the assigned object or to any other view related to that object if the view is defined in the query as navigation target. Tooltip and legend texts are also defined via the query.

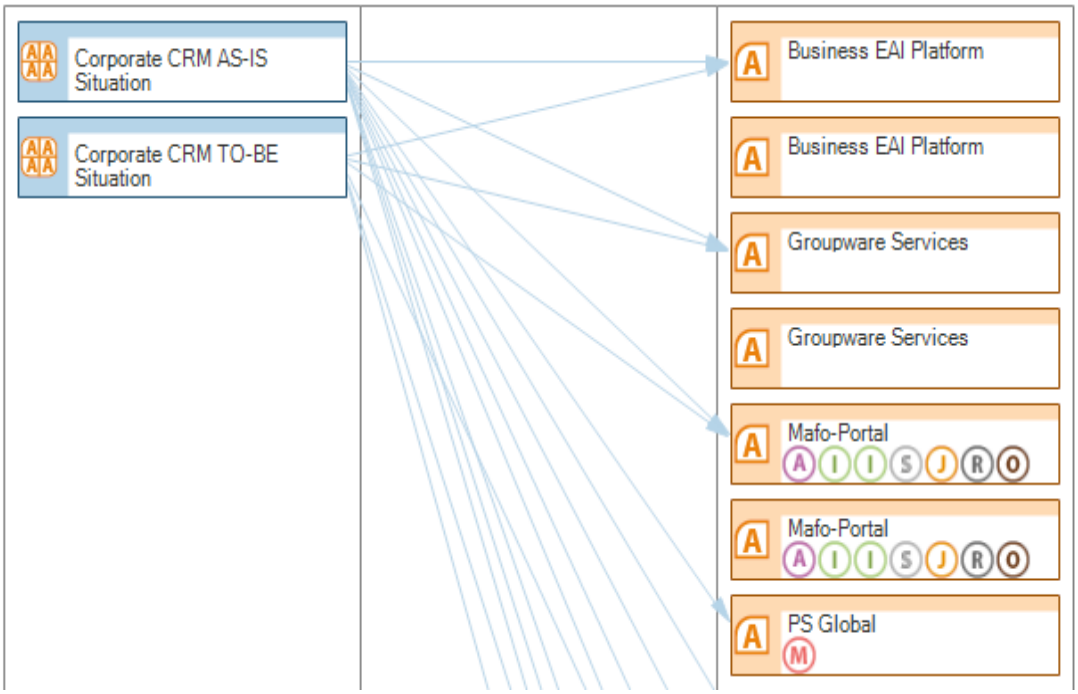
Set the following attributes of the indicator rule node:

Attribute	Description
Name	Defines the name of the indicator rule node in the explorer of the **Report Assistant**.
Type	Select `IconQuery`.
Native Sql/ Alfabet Query/ Query as Text	Defines all information about the icon assignment. Define a query that returns at least: • The `REFSTR` of the current object. This definition must be included in the `SELECT` statement of native SQL query in a visible column, that means that the first argument of the `SELECT` statement cannot be used to define this information. For Alfabet queries, the `REFSTR` of the objects found by the query must be defined in the Show properties. • The name of the icon that shall be displayed. Only icons uploaded as 22 x 22 icon to the icon gallery can be used for display via an icon query. For information about uploading icons to the icon gallery, see the section Adding and Maintaining Icons for the Alfabet Interface. Optionally, the query can contain columns returning the following information: • A string to be displayed as tooltip for the icon. • A string to be displayed as legend text for the icon.

Attribute	Description
	• A string to be displayed as legend group header for the legend group the icon shall be explained in. This information is required to add the icon explanation to the legend. • The REFSTR of an object that shall be coupled with the icon as navigation target. If this information is provided, and a view definition is not given, the object view of the object opens when the user double-clicks the icon. • A view definition that specifies a view related to the object represented by the icon. The view opens instead of the object view if the user double-clicks the icon. Navigation is only activated if the REFSTR of a navigation target object is also defined in the query. The navigation target must be specified in the syntax described in the section Defining Navigation from the Report to Alfabet Views.
Icon Column	Enter the name of the column in the query results returning the name of the icon that shall be displayed.
Object Column	Enter the name of the column in the query results returning the REFSTR of the object the icons shall be assigned to in the configured report.
Tooltip Column	Enter the name of the column in the query results returning the string that shall be displayed as tooltip if the user moves the mouse over the icon.
View Column	Enter the name of the column in the query results returning the view that shall open as a navigation target instead of the object view of the object assigned to the icon with the column defined in the attribute **Navigation Object Column**. The view opens for the assigned object. Navigation is not provided if the attribute **Navigation Object Column** is not defined. The navigation target must be specified in the query using the syntax described in the section Defining Navigation from the Report to Alfabet Views.
Navigation Object Column	Enter the name of the column in the query results returning the REFSTR of the object that shall be assigned to the icon. If an object is assigned to an icon, navigation to the object view of the object or to the alternative navigation view defined with the attribute **View Column** is enabled.
Legend Group Column	Enter the name of the column in the query results returning a string to be used as headline of the legend icon group the icons in the legend of the configured report. If no **Legend Group Column** is defined, the icon is not added to the legend, even if a **Legend Entry Column** is defined.
Legend Entry Column	Enter the name of the column in the query results returning a string that shall be displayed next to the icon in the legend of the configured report. If no **Legend Entry Column** is defined, but **Legend Group Column** is defined, the icons are displayed in the legend with the icon name as legend text.

Attribute	Description
Legend Row Item Count	Defines the number of indicator values displayed in one row of the legend of the report. By default, 4 items are displayed in a row of the legend.
Indicator Index	If multiple indicator rules are defined, and the attribute **Indicator Fill Policy** of the configured report is set to `ByIndex`, define the position of the icon displayed for the current indicator rule. Enter 0 for the first position on the left and ascending integers for the next positions from left to right. Please note that positioning `ByIndex` only displays one icon per indicator rule. If you defined a query returning multiple icons per object box, the **Indicator Fill Policy** of the configured report should be set to `LeftAlign`. This attribute is then ignored for positioning.

For example, a lane report displaying applications in application groups and sub-groups shall display local components defined for the applications as icons in the application. The icons used for this example are bubbles with a letter that shall display the start letter of the name of the local component.



If a user double-clicks an icon, the Evaluations page view shall open for the selected local component. The tooltip text and the legend text shall both return the name of the local component.

The following query is defined for the indicator rule:

```
SELECT NULL AS 'REFSTR', app.REFSTR AS 'Object',
'Contoured_Circle_Color_'+UPPER(LEFT(loco.NAME,1)) AS 'Icon',
loco.NAME AS 'Tooltip', 'View=GraphicView:ObjectEvaluation' AS
```

```
'View', loco.REFSTR AS 'Navigation', 'Local Components' AS
'LegendGroup'

FROM APPLICATION app

INNER JOIN LOCALCOMPONENT loco ON loco.OWNER = app.REFSTR

INNER JOIN RELATIONS rel ON rel.FROMREF = app.REFSTR

INNER JOIN APPLICATIONGROUP appg ON appg.REFSTR = rel.TOREF

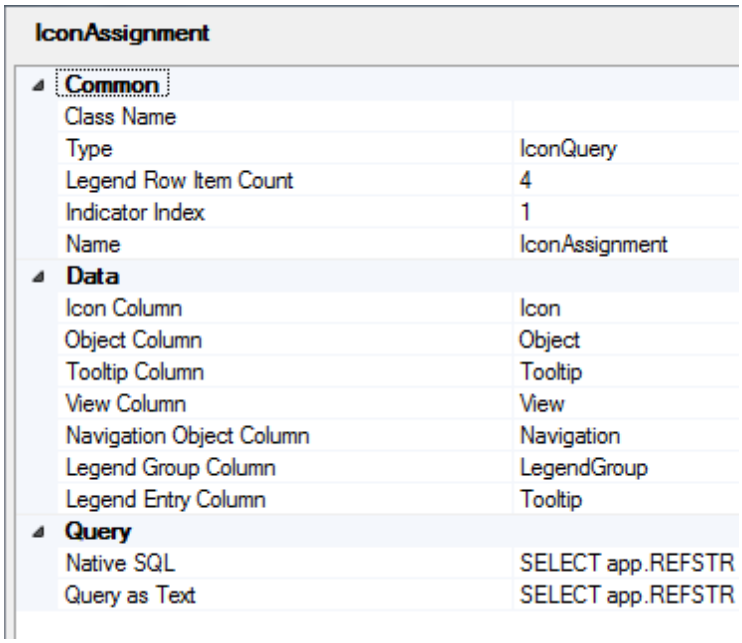
WHERE rel.PROPERTY = 'ApplicationGroups'

AND appg.BELONGSTO = @BASE
```

The mandatory information is added to the query with the following arguments of the SELECT statement:

- The first argument of the SELECT statement is not required, because a base object is not evaluated for the result dataset. It is set to NULL. The object the icon shall be assigned to is defined in the column `Object`, that returns the REFSTR of the application the local component is assigned to. The `JOIN`s and `WHERE` conditions in the query reduce the number of applications to applications that are displayed in the lane report.
- The name of the icon is defined in the column `Icon` of the result dataset. The name of the icons are identical except for the letter they display. This enables the query of the configured report to return the icon name on basis of a fixed string combined with an object related information, which is the first letter of the local component's name.

The columns in the report dataset are then mapped to the respective attributes of the indicator rule of the type `IconQuery`:



The attributes **Tooltip Column** and **Legend Entry Column** are both mapped to the same column in the query result dataset, because the information shall be identical in the tooltip and the legend.

Defining the General Display of Object Boxes in Treemap, Diagram, Lane and Layered Diagram Reports

By default, object boxes in treemap, diagram matrix, lane and layered diagram reports are displayed as a colored box with a white inner field containing the text:

This design can be changed to fully colored object boxes with the text displayed in the colored area:

To change the coloring of object boxes in the XML object ***SolutionOptions***:

1) Click the **Presentation** tab in the tab bar and expand the **XML Objects** folder by clicking the + symbol. You will see all XML objects that can be edited.
2) Right-click the XML object ***SolutionOptions*** and select **Edit XML**. The **XML Editor** is displayed in the center pane. For general information about editing XML objects in Alfabet Expand, see Working with XML Objects.
3) If not already included, add the XML attribute `CustomReportUserItemStyle` to the XML element `SolutionOptions`. Enter one of the following values for the XML attribute:
   - `WhiteFace`: The object boxes are rendered in the standard design with text displayed with a white background within the colored box.
   - `FullFace`: The object boxes are rendered with a fully colored background with the text directly displayed in the colored area.
4) In the toolbar, click the **Save** button to save the XML definition.

Defining Branching Diagram Reports

Branching diagram reports are designed in the **Report Assistant**. For information about how to open the **Report Assistant**, see Creating a New Graphic Report. For more information about how to work with the **Report Assistant**, see Configuring the Report with the Report Assistant.

The content and layout of a branching diagram report is defined by adding elements to the explorer of the **Report Assistant** and setting the attributes in the attribute pane of the **Report Assistant** window.

The following table lists the types of explorer node elements that can be added to the report configuration to specify the content of the report. Information is provided in the table about the purpose of each explorer node element:

Explorer Node Element	Required to Configure:
Root Node	General layout of the report
Root Queries	Container for **Query** elements that define the content of the report.
Query	Definition of all or part of the content of the report. This node is a sub-node of the **Root Queries** node. A **Root Queries** node can have multiple **Query** sub-nodes.

The content of the report is defined via one or multiple native SQL queries.

A simple version of the report can also be build using Alfabet query language. But many of the functionalities that are implemented like color definitions and definition of an alternative navigation target for objects in the report are only available via native SQL queries.

Defining the Basic Design of the Branching Diagram Report

The basic design of the report is designed directly in the attributes of the root node element of the **Report Assistant** explorer:

Attribute	Description
Rendering Type	Set to `Label_as_Node` to render nodes as a box with the label text in the box. Set to `Circular_Node_with_Separate_Label` to render nodes as bubbles, or class icons with the label text outside the bubble or class icon. Whether nodes are rendered as bubbles or class icons depend on the setting of the **Show Class Icon** attribute.
Show Class Icon	If the **Rendering Type** attribute is set to `Label_as_Node`, and this attribute is set to `True`, object class icons are displayed in front of the label text within the boxes representing the nodes. If the **Rendering Type** attribute is set to `Label As Node`, nodes are rendered as class icons if this attribute is set to `True` and as bubbles if this attribute is set to `False`. The class icon is defined in the class settings of the relevant object class.
Report Background Color	Defines the background color for the branching diagram report.

Attribute	Description
Margin	Defines the space between the branching diagram nodes and the border of the presentation object in pixel.
Node Radius	Defines the radius of each node in pixel. This setting is only relevant if the **Rendering Type** attribute is set to `Circular_Node_with_Separate_Label`.
Node Max Width	Defines the maximum width of boxes representing object nodes. This setting is only relevant if the **Rendering Type** attribute is set to `Label_as_Node`. Note the following about the sizing of object node boxes: The object boxes will all have an identical size. The size is the size required to display the longest label text with the limitation that the boxes will not be bigger than defined with the **Node Max Width** and **Node Max Height** attributes. If the maximum size of the box is not sufficient to display the complete label text, the text will be truncated and will end with three dots. If no tooltip is defined for the object node, the complete label text will be displayed as tooltip if the user moves the cursor over a truncated label text.
Node Max Height	Defines the maximum height of boxes representing object nodes. This setting is only relevant if the **Rendering Type** attribute is set to `Label_as_Node`. Note the following about the sizing of object node boxes: The object boxes will all have an identical size. The size is the size required to display the longest label text with the limitation that the boxes will not be bigger than defined with the **Node Max Width** and **Node Max Height** attributes. If the maximum size of the box is not sufficient to display the complete label text, the text will be truncated and will end with three dots. If no tooltip is defined for the object node, the complete label text will be displayed as tooltip if the user moves the cursor over a truncated label text.
Space Between Nodes Vertical	Defines the vertical spacing between the nodes in pixel.
Space Between Nodes Horizontal	Defines the horizontal spacing between the nodes in pixel.
Node Background Color	Defines the default coloring of the bubbles or boxes representing the objects in the branching diagram. The attribute is not relevant if nodes are rendered as object class icons. The color is applied to all nodes for that no color is defined via the native SQL query for the report.
Node Border Color	Defines the default coloring of the border of bubbles or boxes representing the objects in the branching diagram. The attribute is not relevant if nodes are rendered as object class

Attribute	Description
	icons. The color is applied to all nodes for that no color is defined via the native SQL query for the report.
Node Border Width	Defines the border width for the object nodes in pixel.
Node Border Weight	Defines the border styple for the object nodes. Lines can be solid, dashed or dotted.
Link Color	Defines the default coloring of the links between the object nodes in the branching diagram. The color is applied to all links for that no color is defined via the native SQL query for the report.
Link Weight	Defines the width of the links between the object nodes in pixel.
Link Style	Defines the line style of the links between the object nodes. Lines can be solid, dashed or dotted.
Draw Vertical	Defines the direction of the branching diagram. If set to `True`, the different grouping levels are placed beneath each other in vertical direction with the nodes in the same grouping level displayed next to each other in horizontal direction. If set to `False`, the different grouping levels are displayed horizontally with the nodes in the same grouping displayed next ot each other in vertical direction.
Captions Vertical	Defines the direction of the captions in the reports. This attribute is only available if the attribute **Draw Vertical** is set to `True`. By default, captions are written in horizontal direction. Setting this attribute to `True` changes the display of the caption text. Text is then displayed vertically with the text direction from bottom to top.

Defining Display of Objects and Links via the Query of the Report

The display of object nodes and the links between the different levels of object nodes are specified via a native SQL query or an Alfabet query defined in an element node `Query/Alfabet Query/Query As Text` as sub-node of the `RootQueries` node. The query must define a grouped dataset via definition of Alfabet query language instructions. The grouping levels in the query correspond to the levels in the branching diagram report.

For information about how to define a grouped dataset using Alfabet query language instructions see the section Grouping Query Results in Expandable Reports in the chapter Defining Queries.

The query defined for a configured branching diagram report can be very complex. To make sure that your query corresponds to the above mentioned requirements without taking the configuration of the report into account, you can first define a configured report of the **Type** `NativeSQL` or `Query` and control that the output is a grouped table with the columns joined in the correct way. When the output is as expected, paste the query into the rectangular treemap report and set the required attributes in the report assistant.

Multiple Query elements can be defined within the Root Queries node. If you define multiple Query elements, the objects found by each query are displayed in the same level in the order of queries.

After having defined the query, the name of the column containing the respective information must be defined in the attributes of the root node of the report assistant. The defined column must contain data in a given format. The following table lists the attributes to be filled with the column names and the data format required in the result dataset:

Attribute	Description	Expected Query Output
Image Column	Defines the name of the column containing the text to be displayed in the boxes.	Any string to display under the nodes.
Stereotype Column	Defines the name of the column containing the name of the stereotype of the current object.	The value of the Stereotype attribute of the object.
Node Background Color Column	Defines the name of the column containing a HTML compliant color definition for coloring of the background of the nodes.	An HTML compliant color code, like For example,: `#11A6D0`
Node Text Color Column	Defines the name of the column containing a HTML compliant color definition for coloring of the text under the nodes.	An HTML compliant color code, like For example,: `#11A6D0`
Node Border Color Column	Defines the name of the column containing a HTML compliant color definition for coloring of the border of the nodes.	An HTML compliant color code, like For example,: `#11A6D0`
Link Caption Column	Defines the name of the column containing a text to display under the links connecting the nodes.	Any string to display under the links.
Link Color Column	Defines the name of the column containing a HTML compliant color definition for	An HTML compliant color code, like For example,: `#11A6D0`

Attribute	Description	Expected Query Output
	coloring of the links connecting the nodes.	
View Column	Defines the name of the column containing the definition of an alternative link target for the double click action on the object nodes. By default, the standard object profile of the object opens when a user double clicks on a node or clicks a node and then clicks the **Navigate** button.	`View=`*`ViewType`*`:`*`ViewName`* The `ViewType` can be one of the following: • ***Report*** for a configured report • ***GraphicView*** for a standard Alfabet view • ***ObjectView*** for an object profile `ViewName` is the name of the view. For more information about defining navigation to a target view, see Defining Navigation from the Report to Alfabet Views.
Legend Caption Column	Defines the text to be displayed in the legend for the given node type. The legend gives information about each different node. If the class icons are displayed, each class icon displayed is added to the legend. If bubbles are displayed, each differently colored bubble is explained.	Any string to display in the legend.

In the attributes of the root node of the report assistant, only one column can be defined for a type of information. For example, only one column can be defined to display the text of the object boxes. Therefore, the native SQL query must be defined to display information about all levels in the grouped dataset in the same column. This can be achived with `JoinColumn` instructions of the Alfabet query language.

For detailed information about the mapping of columns in the result dataset to attributes of the root node of the configured report, see Mapping of Query Data to Attribute.

Configuring Bubble Cloud Reports

Bubble cloud reports are designed in the **Report Assistant**. For information about how to open the **Report Assistant**, see Creating a New Graphic Report. For more information about how to work with the **Report Assistant**, see Configuring the Report with the Report Assistant.

The report assistant has a single node in the explorer with the attributes displayed in the area on the right.

The content of the bubble cloud report is defined via a query that returns the data in the required formats. The names of the columns in the dataset resulting from the query must then be mapped to the attributes in the **Report Assistant** to define which information required to build the report is returned in which column of the query.

It is recommended to use native SQL for creating bubble cloud reports. Alfabet query language does not provide the ability to include anything else than data from the tables in the Alfabet database into the search results, and the data is usually not corresponding to meaningful text size or text orientation values for the words cloud report.

The following table lists the attributes available to define the query and the mapping of data from the query to the respective functionality. The description informs about the data type to return in the column mapped to the respective attribute:

Attribute	Description
Native SQL / **Query as Text** / **Alfabet Query**	Define a native SQL query in either the attribute **Native SQL** or **Query as Text**, or define an Alfabet query in either the attribute **Alfabet Query** or **Query as Text**. Details about the required output of the query are given below with the description of the column mapping attributes.
Text Column Name	The name of the database column in the query that returns the text to be displayed. This attribute is mandatory.
Font Size Column Name	The name of the database column in the query that returns the font size for the text in pixel. This attribute is mandatory.
Rotation Column Name	The name of the database column in the query that returns the text orientation. Allowed values are 0 - 180. 0 will display the text in normal horizantal orientation, while 180 will display the text upside down. the text is turned clockwise. This attribute is mandatory.
Tooltip Column Name	The name of the database column in the query that returns a string to be displayed as tooltip on mouseover on the text. This attribute is optional. By default, no tooltip is displayed.
Text Color Column Name	The name of the database column in the query that returns the color of the text in HTML compatible format. This attribute is optional. The default text color is black (#000000).
Legend Group Column Name	If the **Show Legend** attribute is set to `True` and both the **Legend Caption Column Name** attribute and the **Text Color Column Name** attribute are defined, legend will be displayed for the text coloring in the words cloud report. Optionally, the legend can be grouped in sections. This can be useful For example, in case coloring has a different impact for different font sizes. The legend will be grouped in sections if the **Legend Group Column Name** attribute is set to the name of the database column in the query that returns the caption of the legend group that the text color returned in the same row shall be displayed in.

Attribute	Description
	If **Legend Group Column Name** is not set, all coloring will be listed under the heading **Legend** without grouping.
Legend Caption Column Name	A legend is available for the text coloring in the words cloud report. To display the legend, **Legend Caption Column Name** must be set to the name of the database column in the query that returns an explanatory string for the text color returned in the same row.
Reference Column Name	The column in the return dataset returning the REFSTR of the object for that navigation should be activated for the bubble in the report. This attribute is mandatory to define navigation. By default, navigation will open the object profile of the object. This behavior can be changed with the attribute **View Column Name**.
View Column Name	The column in the return dataset returning the navigation target for navigation from bubbles in the report. By default, navigation will open the object profile of the object. the column must return the navigation target in the format <ViewType>:<ViewName>. Allowed view types are `GraphicView`, `Report`, and `ObjectView`. Form ore information about the defintion of a link target, see Defining Navigation from the Report to Alfabet Views.

In addition to the dynamic content, static formatting can be applied to the report with the following attributes. All these attributes are optional.

Attribute	Description
Width	Defines the width of the area that can be filled with text in pixel. The default value is 800 pixel.
Height	Defines the height of the area that can be filled with text in pixel. The default value is 600 pixel.
Background Color	Defines the background color of the area reserved for the report. By default, the background is white. The color can be changed via the color picker. For more information about working with the color picker, see Defining Color Attributes.
Border Color	Defines the color of the border drawn around the report area. By default, the border color is white. As the default for the background color is also white, no border will be visible per default for the report. The color can be changed via the color picker. For more information about working with the color picker, see Defining Color Attributes.

Attribute	Description
Border Thickness	Defines the thickness of the border drawn around the report area. The default value is 1 pixel. Please note that the border is drawn within the area filled with text by the report algorithm. Therefore, if the report shows a very high number of results, the text may overlap the border.
Padding	Defines the space between texts in the report. The default is 2 pixel.

Defining Chart Reports

The **Report Assistant** has four tabs:

- **Data Source Definition**: The **Data Source Definition** tab allows the query to define the objects displayed in the chart to be specified.
  - **To define an Alfabet query**: Write the complete Alfabet query, including instructions, if required, into the **Query for Rows** field or click the Browse  button to open the **Alfabet Query Builder** to specify your Alfabet query.
  - **To define a native SQL query**: Write the native SQL query into the **Query for Rows** field. If you need to define Alfabet query language instructions in combination with the native SQL query, For example, to create expandable rows or columns, define the instructions separately in the **Query Instructions (for native SQL only)** field.

More information about the specification of the data source is given in the section Defining the Display of the Data Source in a Chart.

- **Data Source Result**: The data source result displays the result of the query defined in the **Data Source Definition** tab in a tabular report. The report is generated when clicking the **Check Data Source** button on the upper right corner of the **Data Source Result** tab and on opening of the **Report Assistant**. The query definition should be checked prior to proceeding with the next configuration steps.
- **Business Graphic Definition**: This tab allows you to specify the type and content of the chart on basis of the data source definition.
- **Additional Attributes**: This tab allows you to specify additional formatting options for the chart defined in the **Business Graphic Definition** tab.

Specification of the Data Source

A chart report is a graphic representation of the influence of a property (x value) on a numerical value (y value).

A chart can display For example,

- costs per year

- indicator values per indicator type
- the number of applications per application group
- the number of applications in a specific lifecycle status.

Pie charts, doughnut charts and waterfall charts can only display this two-dimensional relationship, while in line, area, spline, spline area and bar charts, the relationship creates one line, spline, spline area, area or bar and a third dimension can be added by displaying multiple lines, splines, spline areas, areas or bars in the chart (series).

Radar charts are more complex representations of the influence of multiple properties on numeric values. Each radius defines a property with a scale for the numeric value for the property. For each series of data, the value of the object on the respective radius is displayed by a colored bubble on the radius. The bubbles for an object are connected by lines and optionally the net span by the connected bubbles can be colored.

Multi-level pie charts display a two-dimensional relationship on two related levels. For example, the applications in an application group sized by the value of an indicator and on a second level, for each application the local component sized by the same indicator are displayed. The relative sizing of object can either be accurate on the outer or the inner part of the multi-level pie chart.

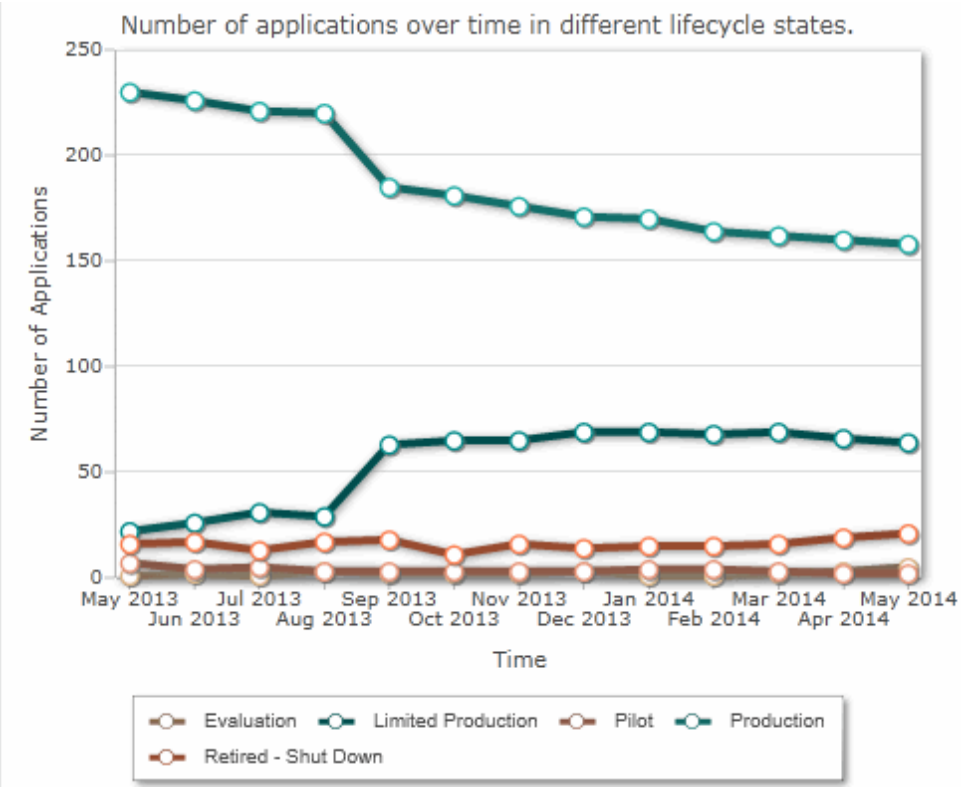
The data source definition specifies which objects and which properties are displayed in the chart report based on a query. Depending on the type of chart that is being designed, the query must result in a table providing the data required to built the respective chart.

The x and y-axis of a report can be defined in two different ways:

- The dataset contains two columns, one for the values on the x-axis and one for the corresponding values on the y-axis. For radar charts, each values in the x-axis column correspond to a radius in the radar chart. The values in the y-axis column must be of the type integer or double. You can either specify an object's property of the type integer, or a `COUNT` on the results for a property of any other data type. For line, spline, bar, area, spline area and radar charts, y values in columns that are identical in the x value and the serie value are summed up and the total of all rows is displayed as y value for the x value and series. For waterfall charts each row in a result dataset is displayed as a separate column, even if the x value and any other value except for the y value is identical. The results are added to the chart in the order that they are specified in the result dataset.

For radar charts, a third column must define the object that the x and y definition in the respective row belongs to. For bar, area, spline area, spline and line charts, the definition of a third row defining which line, spline, spline area, area, or bar series in the chart the data belongs to is optional. For pie charts, multiple pie charts and waterfall charts the third dimension is not applicable.

For example, a line charts displays how many applications are in which lifecycle phase for each month of the next twelve month:



The line chart is based on an SQL query that calculates the time scale and reads the number of applications in each lifecycle status for the calculated time values:

Query for Data Source

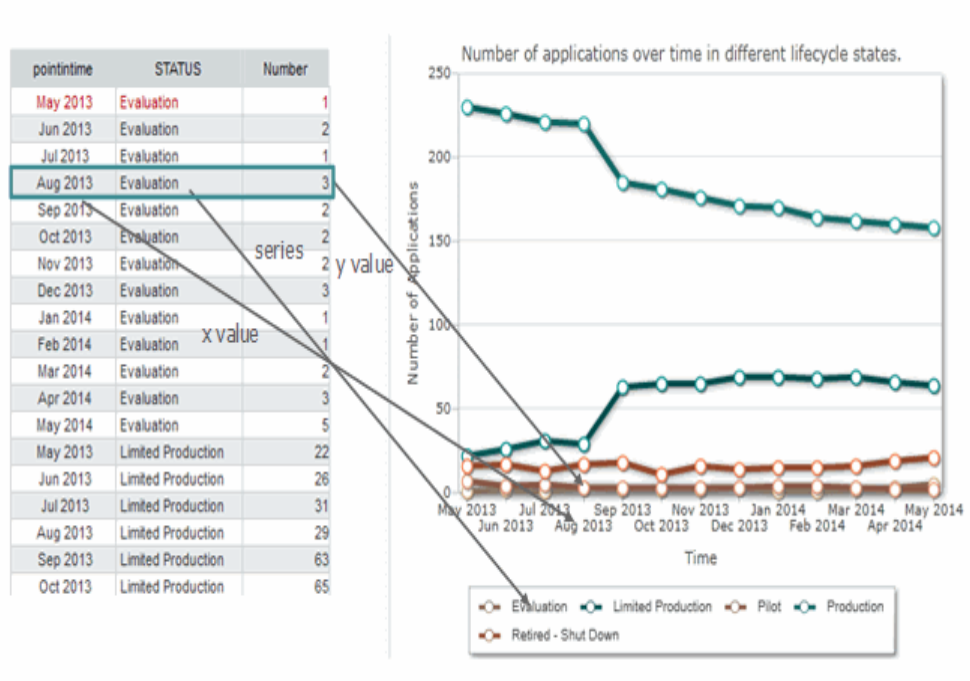
```
WITH tmp(pointintime, monthcount) AS (
  SELECT CURRENT_TIMESTAMP - DAY(CURRENT_TIMESTAMP) + 1, 0
  UNION ALL
  SELECT DATEADD(month, 1, tmp.pointintime), monthcount + 1
  FROM   tmp
  WHERE  tmp.monthcount < 12
)
SELECT NULL, tmp.pointintime, ts.STATUS, COUNT(*) AS Number
FROM   tmp, APPLICATION app, TIMESTATUS ts
WHERE  ts.OWNER = app.REFSTR
  AND  ts.STARTDATE <= tmp.pointintime
  AND  ts.ENDDATE >= tmp.pointintime
GROUP BY tmp.pointintime, ts.STATUS
```

Query Instructions (for native SQL only)

```
SETCOLUMNFORMAT("pointintime", "MMM yyyy");
```

The resulting dataset has three columns. The column `pointintime` contains the x-values, the column `Number` contains the y values and the column `Status` defines wich series a value belongs to. Each row of the dataset defines one point in the line chart. The x

values, y values and the title of the series are all written from the dataset in the respective row.



- The dataset contains multiple columns each corresponding to one x value on the x-axis. The values in the column are the y values for the x value represented by the column. The values in the x-axis column must be of the type integer or double. You can either specify an object's property of the type integer, or a `COUNT` on the results for a property of any other data type.

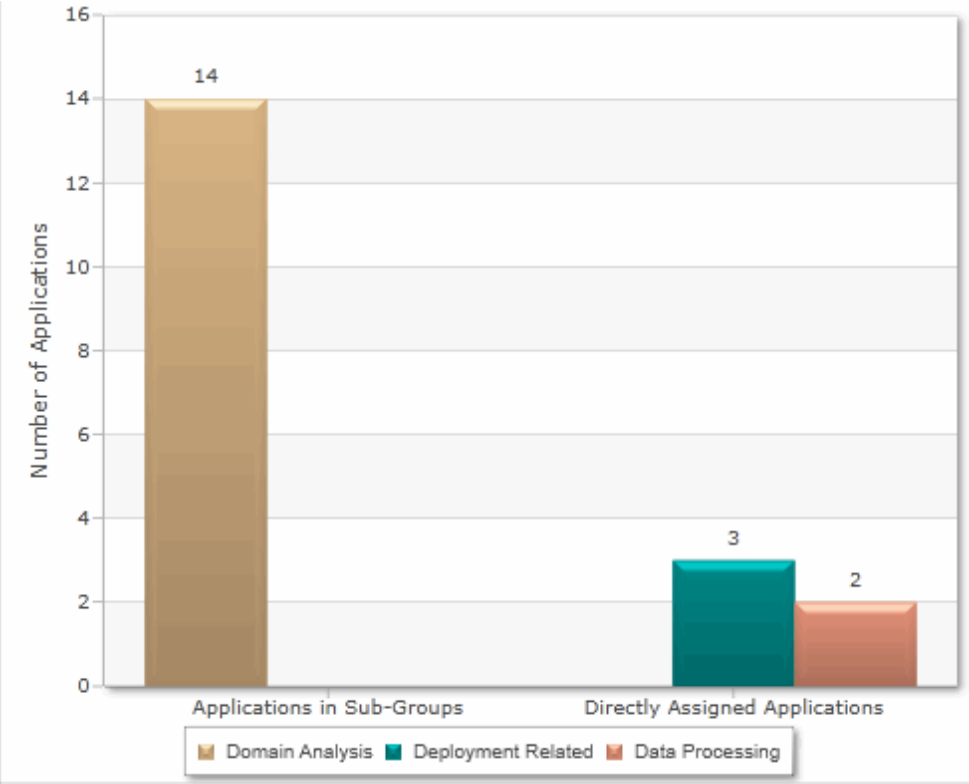
For radar charts, a third column must define the object net that the x and y definition in the respective row belongs to. For bar, area, spline area, waterfall, spline, and line charts, the definition of a third row defining which line or bar series in the chart the data belongs to is optional. For pie, doughnut and multi level pie charts, the definition of a third row is not applicable.

If the dataset contains more than one row and no series is defined, the y value is the total of all values in the rows of the x column. If the dataset contains a column for the series definition, the numerical value in a row is displayed for the series specified in the series column. If multiple rows contain results for the same serie, the total of the numerical values of all rows belonging to the series are displayed as y value for the series.

The text displayed on the x-axis for each x value is identical to the name of the respective column. To change the name of the column, a `RenameColumn` instruction can be used in Alfabet queries and an alias can be defined in native SQL queries. The `SetColumnShowName` instruction and the alias definition in Alfabet queries change the caption of the column without changing the column name and are Therefore, not suitable to define x values in charts. For information about the `RenameColumn` instruction, see the section Defining Column Names and Captions in the chapter Defining Queries.

For example, a bar chart displays the number of applications that are directly assigned to application groups of a first level in the hierarchy and the number of applications that are assigned to the application groups that are assigned as sub-groups to the first level application groups. The number of applications are displayed on the y-axis and the x-axis has two values: directly assigned and indirectly assigned. The first level application groups are defined as series, which means that multiple bars with different coloring are

displayed for each x value and a legend informs about the application group represented by each different color.



The data source query for the bar chart finds application groups and the directly subordinate application groups thereof as well as the number of applications that are directly assigned to the application group and the number of applications assigned to one of the subordinate application groups:

```
ALFABET_QUERY_500

FIND ApplicationGroup AS parent

LeftJoin ApplicationGroup AS child ON child.BelongsTo =
parent.REFSTR

LeftJoin Application AS capp ON child.Applications =
capp.REFSTR

LeftJoin Application ON parent.Applications =
Application.REFSTR

WHERE parent.Name LIKE 'D%'

Instructions

RenameColumn("Application.REFSTR","Directly Assigned
Applications");

RenameColumn("capp.REFSTR","Applications in Sub-Groups");

EndOfInstructions

QUERY_XML

<QueryDef>

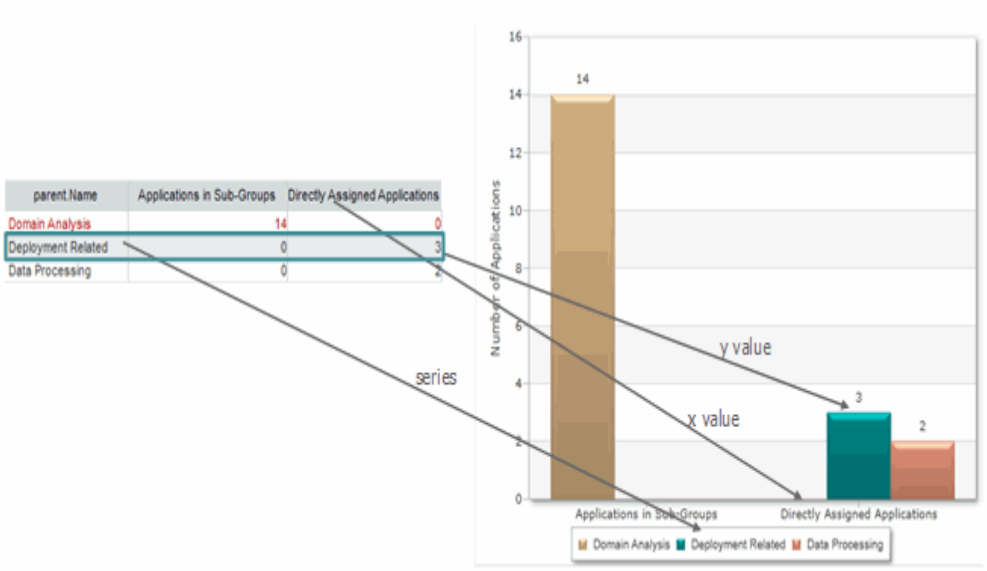
<ShowProperty Type="Property" ClassName="ApplicationGroup"
ClassAlias="parent" Name="Name" />
```

```
<ShowProperty Type="Property" ClassName="Application"
ClassAlias="capp" Name="REFSTR" Function="COUNT" />

<ShowProperty Type="Property" ClassName="Application"
Name="REFSTR" Function="COUNT" />

</QueryDef>
```

The resulting dataset has three columns. The column `parent.Name` is the series column that defines which bar the data in the following two columns belongs to. The other two columns both correspond to one x value, that means that the name of the column is identical to a value on the x-axis. Therefore, a `RenameColumn` instruction was used in the query to give the x values in the graphic a meaningful name. The numerical vlaues in the columns are the y values displayed for the bar for the respective x value of the column.



For multi level pie chart reports, the definition of the x and y-axis must be provided multiple times, that means a separate definition of x and y-axis values must be provided per level. The query must Therefore, return a grouped dataset with each grouping level defining one circle of the multi-level pie chart. The x and y-axis values must be available in a single column. The dataset must Therefore, not only grouped by using a `GroupBy_Ex` instruction, but the columns containing the respective x and y values must be joined using a `JoinColumns` instruction.

For detailed information about how to define a grouped dataset with the **GroupBy_Ex** and **JoinColumns** instructions, see Grouping Query Results in Expandable Reports in the chapter Defining Queries.

A multi-level pie chart shall display applications owned by a selected organization in the first level and the applications that are connected to these applications via information flows in the second level. The sizing of objects shall depend on the value of the indicator "Incidence Rate".

The query defined for the multi-level pie chart returns the name and `REFSTR` of the application and the value of the indicator for both the first level applications (parent) and the second level applications (child).

```
SELECT parent.REFSTR, parent.REFSTR AS 'parent.REFSTR', parent.NAME
AS 'parent.Name', parentind.VALUE As 'parent.Indicator',
child.REFSTR AS 'child.REFSTR', child.NAME AS 'child.Name',
childind.VALUE AS 'child.Indicator'

FROM APPLICATION parent

INNER JOIN RELATIONS rel

   ON rel.PROPERTY = 'ApplicationGroups' AND
   rel.FROMREF=parent.REFSTR

INNER JOIN APPLICATIONGROUP appg

   ON appg.REFSTR = rel.TOREF

INNER JOIN INFORMATIONFLOW inf

   ON inf.A_TO=parent.REFSTR OR inf.A_FROM=parent.REFSTR OR
   inf.FROMOWNER=parent.REFSTR OR inf.TOOWNER=parent.REFSTR

INNER JOIN APPLICATION child

   ON inf.A_TO=child.REFSTR OR inf.A_FROM=child.REFSTR OR
   inf.FROMOWNER=child.REFSTR OR inf.TOOWNER=child.REFSTR

INNER JOIN INDICATOR parentind

   ON parentind.OBJECT=parent.REFSTR

INNER JOIN INDICATOR childind

   ON childind.OBJECT=child.REFSTR

WHERE appg.REFSTR = @BASE

   AND parent.REFSTR != child.REFSTR

   AND parentind.NAME = 'Incidence Rate:Incidence Rate'

   AND parentind.VALUE >= 1

   AND childind.VALUE >= 1

   AND childind.NAME = 'Incidence Rate:Incidence Rate'
```

A `GroupBy_Ex` instruction is used to group the result dataset into the parent and child level. The columns returning the `REFSTR` of the parent and child applications, that were included for grouping only, are removed from the result dataset. The name columns and indicator value columns are joined with `JoinColumns` instructions into one column.

```
GroupBy_Ex("parent.REFSTR","child.REFSTR","parent",0);

RemoveColumns("parent.REFSTR,child.REFSTR");

JoinColumns("parent.Name,child.Name","parent.Name", "");

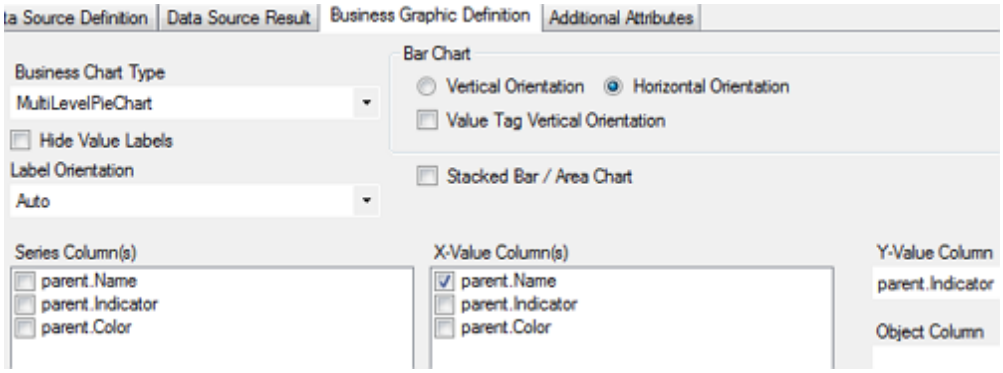
JoinColumns("parent.Indicator,child.Indicator","parent.Indicator",
"");
```

The resulting dataset displays two columns only: One returning the name of the applications of both levels (`parent.Name`) and one returning the indicator value for both levels (`parent.Indicator`):

	parent.Name	parent.Indicator
1	Eurex Bonds	3.00
2	Summit	3.00
3	Marketview	2.00
4	Eurex Repo	2.00
5	Summit	3.00

First level Second level

In the **Business Graphic Definition** tab, the column `parent.Name` is selected as **X-Value Column(s)** and the column `parent.Indicator` is selected as **Y-Value Column**.

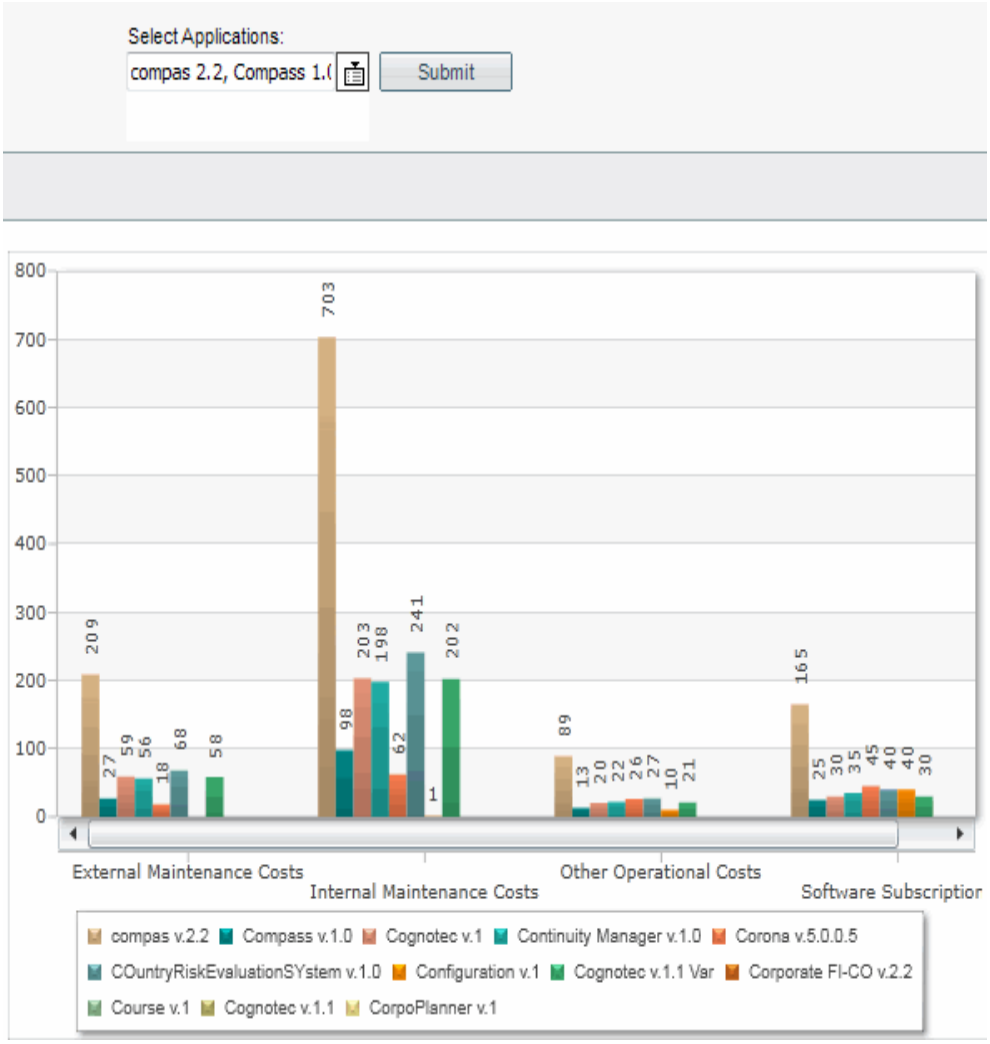


Note the following about the definition of the query the report is based on:

- The attribute `BASE` can be used in the query to generate a report in dependency of the object the user is currently working with. A filter is than generated on top of the report that allows other objects of the base object class to be selected.
- In Alfabet queries, the definition of indicators with a `ShowProperty` element of the type `Indicator` is not supported. Indicators can only be added to the result dataset by joining the respective object classes to the report and adding normal `ShowProperty` elements for property values of the object classes related to indicator definition.

- If a bar, area, spline, spline area or line chart has series defined, a legend is added to the report that relates the series name with the color used for display of the series in the report. If the report contains only one series, the legend is not displayed. For both methods of chart definition described above, the series are read from the values in a column of the report. If a report is defined to display data from multiple series, but at the time the report is used only object data for one of the series is available, the legend will not be shown. If you want to make sure that the report displays a legend even if some of the series are currently not displayed, define a native SQL query that returns at least one empty value for each series.

A report displays budget costs for a group of applications. For each application, all costs are displayed in the same color and a legend is displayed that matches the colors with the application names:



The report is based on the following native SQL query:

```
SELECT NULL As 'REFSTR', app.NAME As 'Application',
app.VERSION As 'Version', COSTTYPE.NAME As 'CostType',
budget.VALUE As 'Budget'

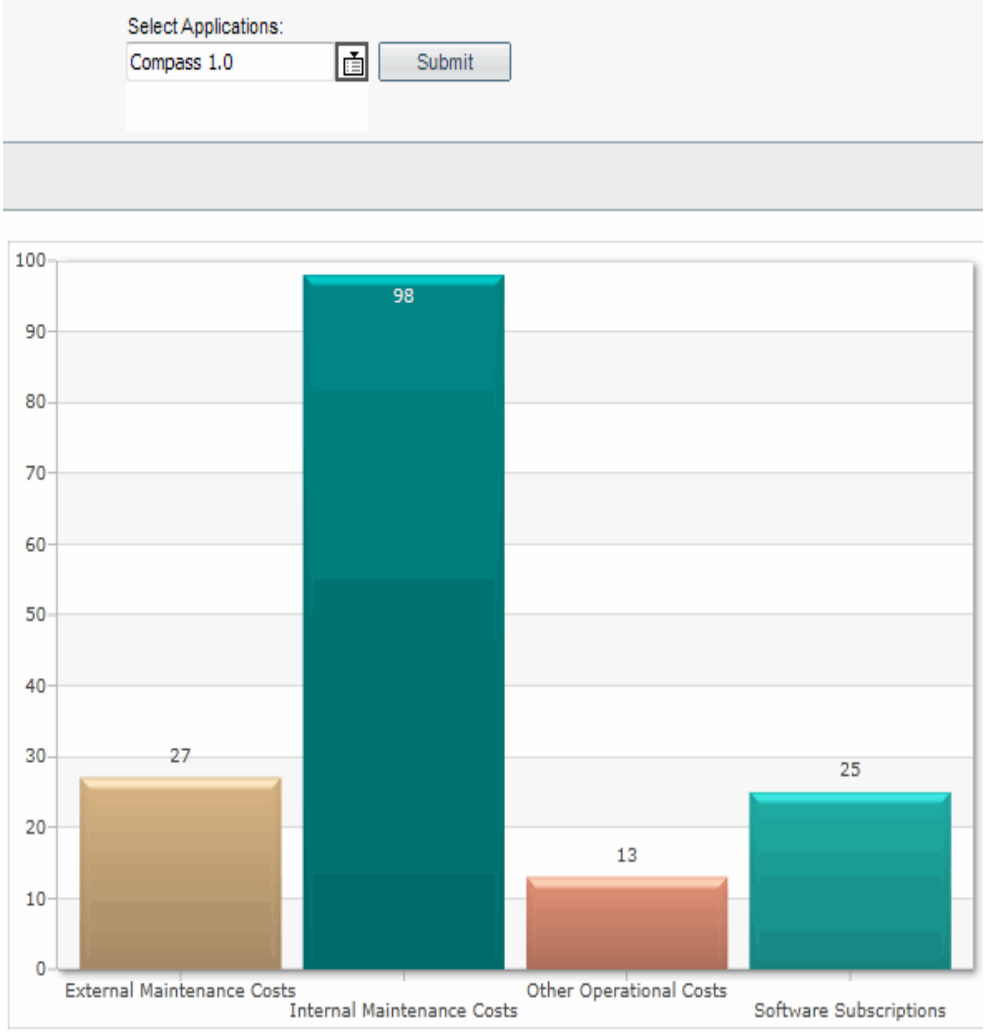
FROM APPLICATION app

INNER JOIN BUDGETVALUE budget

    ON budget.OWNER = app.REFSTR
```

```
INNER JOIN COSTTYPE
    ON COSTTYPE.REFSTR = budget.MONETARYTYPE
WHERE budget.YEAR='2012'
    AND app.NAME LIKE 'Co%'
    AND app.REFSTR IN (@apps)
    AND budget.MONETARYCODEID = 'Current'
```

A filter field on top of the report allows the user to restrict the display to a subset of the applications in the report. If the user selects only one application, the legend is not displayed and the coloring is different for each cost type, although all costs are assigned to the same application:

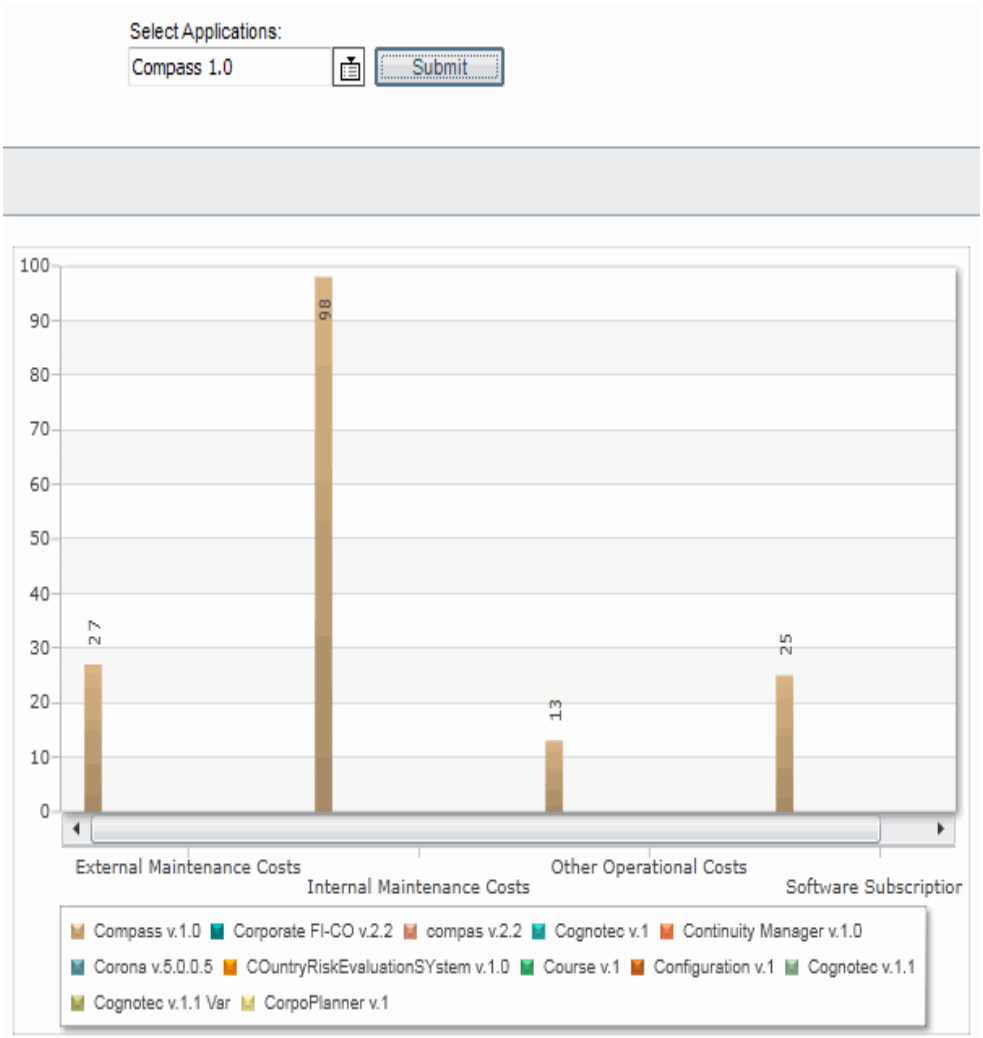


To maintain the constant coloring per application and the display of the language, a UNION ALL is added to the query that adds one row for each application not selected in the filter with the cost type and budget value set to NULL:

```
SELECT NULL As 'REFSTR', app.NAME As 'Application',
app.VERSION As 'Version', COSTTYPE.NAME As 'CostType',
budget.VALUE As 'Budget'
FROM APPLICATION app
INNER JOIN BUDGETVALUE budget
```

```
    ON budget.OWNER = app.REFSTR
INNER JOIN COSTTYPE
    ON COSTTYPE.REFSTR = budget.MONETARYTYPE
WHERE budget.YEAR='2012'
    AND app.NAME LIKE 'Co%'
    AND app.REFSTR IN (@apps)
    AND budget.MONETARYCODEID = 'Current'
UNION ALL
SELECT NULL As 'REFSTR', app.NAME As 'Application',
app.VERSION As 'Version', NULL As 'CostType', NULL As
'Budget'
FROM APPLICATION app
WHERE app.NAME LIKE 'Co%'
    AND app.REFSTR NOT IN (@apps)
```

With this change in the query, the report will look as follows when displaying results for one application only:



Defining the Display of the Data Source in a Chart

The type of chart and the display of data defined in the **Data Source Definition** tab is defined in the **Business Graphic Definition** and **Additional Attributes** tabs:

Do the following to define the chart:

1) Define the data source in the **Data Source Definition** tab.
2) Click the **Check Data Source** button in the **Data Source Result** tab. The result of the test is displayed in the **Data Source Errors** field. The next step can only be performed when the query passes the test without errors.

This step must also be executed if an existing chart is altered, even if the **Data Source Definition** itself is not changed.

3) Define the following fields in the **Business Graphic Definition** tab:
   - **Business Chart Type**: Select the chart type from the drop down list.
   - **Bar Chart**: For bar charts, the following options can also be selected:
     - **Vertical Orientation** / **Horizontal Orientation**: Select the checkbox for the orientation of the bars in the report.
     - **Value Tag Vertical Orientation:** By default, value tags on bars are displayed horizontally. If the required space for complete display of the value tags is not available, you can change the orientation to vertical by selecting the checkbox to allow display of value tags vertically on top of small bars.
   - **Stacked Bar / Area Chart**: For bar and area charts, select the checkbox if you want the results for multiple series in the report to be displayed stacked (each bar or area starting above the previous one with the end of the previous bar or area as starting point). If the checkbox is not selected, the bars or areas of each series will be displayed next to each other starting with the x-axis level.
   - **Hide Value Labels**: The values displayed in chart reports within the graphic can be hidden to enhance readability of charts that contain much data and Therefore, may result in overlap of displayed values. If the checkbox **Hide Value Labels** is selected, values are not displayed within the graphic. To see a value, the user can move the cursor on a point or bar in the graphic to see a tooltip that displays the value.
   - **Label Orientation**: For bar, waterfall, area, spline area, spline and line charts, this parameter defines the text orientation on the x-axis of the report. You can select the following options:
     - `Auto`: The text orientation is automatically determined according to the label text size and the size of the chart.
     - `Vertical`: The text is displayed in a vertical line.
     - `Diagonal`: The text is displayed in a slanted line from bottom left to top right.
   - **Serie Column(s)**: Define the column in the result table of the data source that defines which data belongs to which dataset in a line, spline, radar, area, spline area, bar, or combination chart.

Note the following about the definition of series:

- The number of datasets in a line, spline, waterfall, area, spline area, radar or bar chart should be small to enhance readability. If your data source returns an exceedingly high number of series, you can restrict the display to a maximal number of series by setting the parameter **Max Series Count** in the **Data Source Definition** tab to the maximal allowed number of series. Note however, that this option will hide results from display. Instead of defining the maximal number of series, you should redefine the data source query to return a low number of series values.
- If multiple rows in the dataset match the criteria for the same x-value and serie, the sum of the values in the respective rows are displayed as y-value for the x-value/serie combination.

- **X Value Column(s)**: Select the checkbox of the data source report column(s) that define the x-axis values of the line, spline, spline area, area, or bar chart or the sections in the pie chart, doughnut chart or multi-level pie chart. For radar charts, the x-axes correspond to the radii of the radar chart. For waterfall charts, the x values are used as labels on the x-axis.

Depending on the dataset the report is based on, you can select one or multiple x value columns:

dataset	X value definition	Y value definition
Each combination of x and y value is read from one row in the report. The report contains one column for the x-axis value and one for the y value definition. The data in the y value column must be numerical, the data in the x-axis column can have any data type.	Only one x value column can be selected.	The y value column must be defined with the attribute **Y Value Column**.
For each x-axis value there is a column in the report. The name of the columns are the values displayed on the x-axis. All x-axis columns must contain numerical data.	Multiple x value columns must be selected.	Specification of an y value column is not allowed.

- **Y Value Column**: Select the data source report column that defines the values for the y-axis of the line, spline, area, spline area, waterfall or bar chart or the size of the sectors of the pie chart, doughnut chart or multi-level pie chart. This definition is not required for reports that are based on a dataset where each x value is defined by a separate column in the dataset. For multi-level pie chart, this definition is also not required. All sectors of the pie chart are equally sized if no y-axis is defined.
- **Object Column**: Select the data source report column that define the object that is related to the displayed results. The column must contain the `REFSTR` of the objects. If you select `RowReference`, the `REFSTR` of the `FIND` class of the Alfabet query or the `REFSTR` defined as the first `SELECT` argument in the native SQL query will be used to identify objects. Setting the **Object Column** activates the following functionality:
  - Objects are displayed in different colors and the **Colors** button is activated. The button allows users to change the color for the display of single objects. For more

information about the configuration of coloring based on the **Object Column** attribute see the section Configuring Color Definition per Alfabet Object. If the **Color Column** attribute is set, it supersedes the **Object Column** setting for color definition.

- Navigation from report results to the object profile of the object defined with the **Object Column** attribute is activated. Navigation is only performed if the **Navigate** button is activated for the configured report. If you want to define coloring without defining navigation to the object, you can set the **Object Column** attribute without activating the **Navigate** button. The complete configuration required for navigation based on the setting of the **Object Column** attribute is described in detail in the section Configuring Navigation to the Object's Profile. If the **Navigation Column** attribute is set, it supersedes the **Object Column** setting for color definition.

- **Color Column**: Select the data source column that define the color to be used in the chart for the respective results. The color must be defined in HTML compliant color codes.

  The configuration required to define the color of graphic elements within the dataset is described in detail in the section Configuring Color Definition per Graphic Element.

- **Navigation View Column**: If the **Navigate** button is activated for the report, the user can navigate from graphic parts of the report to an Alfabet view that is defined in the result dataset of the query for the chart report. The link target must be defined in the data source of the report in a special syntax. Select the data source column that defines the Alfabet view that shall open if a user clicks a part of the graphic in the report.

  The required syntax of the link definition and the complete configuration to define the navigation within the dataset is described in detail in the section Configuring Navigation to a Defined View.

- **Use Default Sorting**: Select the check box if you want objects in the report to be sorted by name in alpha-numeric order. If you do not select the checkbox, the sorting order defined in the query in the **Data Source Definition** tab will be used.

- **Graphic Title**: Optionally enter a title that will be displayed on top of the chart.

- **X Title**: For line, spline, waterfall or bar charts, enter the title of the x-axis.

Pie charts and radar charts do not have an x-axis title. The elements in the pie and the radii of the radar chart are labelled with the strings defined as x-axis values.

- **X Value Format**: This field is only relevant if a property of the type date/time is used on the x-axis and a `SetColumnFormat` instruction was used in the data source specification for the property. Enter the format specification specified in the `SetColumnFormat` instruction into the **X-Value Format** field.

- **Y Title**: For line, spline, waterfall, area, spline area and bar charts, enter the title of the y-axis.

Pie charts, multi-level pie charts and radar charts do not have an y-axis title. The size of the elements in the pie and the position of the value bubbles on the radii of the radar chart represent the y values.

- **Width**: Define the width of the graphic by defining the width in pixel. Allowed values are between 1 and 1000. The default value is 500.
- **Height**: Define the height of the graphic by defining the height in pixel. Allowed values are between 1 and 1000. The default value is 400.

  Note the following recommendations for the definition of the **Width** and **Height** attributes:

  - The graphic is displayed in the defined size independent from the size of the client device's screen. If the screen size is not sufficient to display the whole graphic, scroll bars are added to the graphic. In order to ensure that business graphics can be adequately viewed on a variety of devices, it is recommended that graphic reports and object cockpits are designed for a low screen resolution (such as 1280 x 800 or 1280 x 1024).
  - For small display sizes, the graphic views embedded in object cockpits and console reports should be vertically positioned rather than horizontally.
  - For configured reports displaying a pie chart: The dimensions for width to height should be 1:3, whereby the width should be a minimum of 500 pixel. If the pie chart is embedded in an object cockpit, an additional 60 pixel should be added to the height if navigation is supported in the pie chart. An additional 40 pixel should be added to the height if navigation is not supported.
  - For configured reports displaying a radar chart: The dimensions for width to height should be 1:2, whereby the width should be a minimum of 500 pixel. If the pie chart is embedded in an object cockpit, an additional 60 pixel should be added to the height if navigation is supported in the pie chart. An additional 40 pixel should be added to the height if navigation is not supported.
  - For configured reports displaying a bar, stacked bar, waterfall, area, spline area, spline, or line chart: The dimensions will depend on the displayed content. If a bar, stacked bar, waterfall, area, spline area, spline, or line chart is embedded in an object cockpit, an additional 60 pixel should be added to the height if navigation is supported in the chart. An additional 40 pixel should be added to the height if navigation is not supported.

4) In the **Additional Attributes** tab, define the following attributes:

   You will only see the attributes that apply to the type of chart that you selected in the **Business Graphic Definition** tab.

- **Show Tootips**: Defines whether tooltips are displayed when the user moves the mouse over a graphic element in the chart.
- **Show Legend**: Defines whether a legend is available directly beneath the chart. The availability of a legend in the floating toolbar is not affected by this setting. For waterfall charts, a legend is meaningless, and the floating toolbar will not show a legend.
- **Decimals**: An integer that defines the maximum number of decimal values that are displayed for numbers in the chart.

- **Number Prefix**: A string that will be displayed in front of all numbers in the chart. This value can be set to display values For example, with a currency symbol in front without converting the numbers into a string on the SQL layer.
- **Number Suffix**: A string that will be displayed behind all numbers in the chart. This value can be set to display values For example, with a currency symbol behind them without converting the numbers into a string on the SQL layer. If you want number and text to be separated by a whitespace, the whitespace must be added to the string definition.
- **Value Tag Color**: Values can be displayed as label on graphic elements. Depending on the coloring of the graphic, text in the default color for text on the Alfabet interface may not be readable in the graphic elements of the chart. Therefore, for all charts except pie charts and doughnut charts the text color for the labels can be changed by selecting a color with this attribute.
- **Maximum Value**: For all charts except pie charts, doughnut charts and multi-level pie charts, a maximum value can be assigned to the y-axis of the chart. If no maximum value is defined, the maximum value of the y-axis is derived from the highest y value in the dataset. Definition of a fixed maximum value can For example, be used to streamline the y-axis definitions of multiple charts for comparison reasons. If an y value in the result dataset of the report exceeds the defined maximum value, the defined maximum is ignored and the y-axis is extended to display all values in the dataset.
- **Minimum Value**: For all charts except pie charts, doughnut charts and multi-level pie charts, a minimum value can be assigned to the y-axis of the chart. If no minimum value is defined, the minimum value of the y-axis is 0 or, if negative values are displayed, derived from the lowest y value in the dataset. Definition of a fixed minimum value can For example, be used to highlight differences if values are all in a high range and differences would not be clearly visible if values are displayed on a scale starting from 0. If an y value in the result dataset of the report is lower than the defined minimum value, the defined minimum is ignored and the y-axis is extended to display all values in the dataset.

For bar, line, area, spline, spline area and combination reports only:

- **Canvas Background Color**: The color used instead of light grey for coloring of the background of the business chart graphic. The coloring of the canvas is done in differently shaped stripes to highlight the y-axis scale. The selected color will be used in combination with a lighter shade of the same color.
- **Canvas Background Opacity**: The opacity of the background color defined as integer between 0 and 100 to specify the percentage of opacity that shall be applied to the coloring defined with **Canvas Background Color**. By default, **Canvas Background Opacity** is 100%.
- **X-Axis Color**: The color used for display of the x-axis if **X-Axis Thickness** is set to a value higher than zero.
- **X-Axis Thickness**: The width of the line drawn on the x-axis. By default, **X-Axis Thickness** is set to zero and no line is drawn.
- **Y-Axis Color**: The color used for display of the y-axis if **Y-Axis Thickness** is set to a value higher than zero.
- **Y-Axis Thickness**: The width of the line drawn on the y-axis. By default, **Y-Axis Thickness** is set to zero and no line is drawn.

For bar, area, spline area and combination reports only:

- **Plot Border Color**: The color used for display of the border of bars or areas if **Plot Border Thickness** is set to a value higher than zero.
- **Plot Border Thickness**: Define the width of the line drawn around areas or bars. By default, **Plot Border Thickness** is set to 1 and the bars or areas are having a thin border.

For waterfall charts only:

- **Negative Color**: The color used for display of bars representing negative values in the waterfall chart. This attribute is only valid if the attribute **Color Column** in the **Business Graphic Definition** tab is not set.
- **Positive Color**: The color used for display of bars representing positive values in the waterfall chart. This attribute is only valid if the attribute **Color Column** in the **Business Graphic Definition** tab is not set.
- **Show Connectors**: If set to `True`, a dotted line is displayed as connector between the end of a bar and the start of the next bar.
- **Connector Color**: The color used for display of the dotted line between bars.
- **Sum Info Column**: The name of the column in the dataset that contains the information whether this column is a normal column representing results, or a `SUM` column that displays the sum of all columns to the left of it up to the last `SUM` column, or a `CUMSUM` column that displays the sum of al columns representing data left to it no matter how many `SUM` colums are located left of it. The column in the dataset must return the string `SUM` for `SUM` columns, `CUMSUM` for `CUMSUM` columns and must be either empty or set to any other value for result columns. For more information, see Configuring Display of the Sum of Multiple Columns in Waterfall Chart Reports.

For pie charts and doughnut charts only: A sum of the amounts represented by the slices in the pie chart can be calculated and displayed as subheading beneath the graphic title. The subtitle is a string that is concatenated from the text defined with the following attributes and the calculated value in the following way:

<Total Prefix> <calculated value> <Total Unit of Measure> <Total Suffix>

A whitespace is added automatically between the defined parts of the text. The text is only displayed if at least one of the following values is defined:

- **Total Prefix**: A text to be displayed preceeding the calculated sum.
- **Total Suffix**: A text to be displayed following the **Total Unit of Measure**.
- **Total Unit of Measure**: The unit that is applicable to the sum. The **Total Unit of Measure** is displayed following the calculated sum.

For pie charts, doughnut charts and multi-level pie charts:

- **Show Percent Values**: If set to `True`, the percentage of the value for the element on the overall amount of values displayed in the circle is displayed on the element instead of the value the element represents. The value represented by the element is then displayed in the tooltip. If set to `False`, the value that the element represents is displayed on the element and the percentage value is displayed in the tooltip.

- **Pie Radius**: Defines the outer radius of the pie chart, doughnut chart or multi-level pie chart in pixel. If set to zero, the chart is automatically sized to fit into the size defined for the graphic.
- **Doughnut Radius**: For dougnut charts only, the inner radius of the circle, that means the radius of the hole in the center of the chart can also be defined in pixel.

For multi-level pie charts only:

- **Pie Border Color**: The color used for display of the borders of the elements of the multi-level pie chart.
- **Pie Border Thickness**: An integer to define the width of the borders of the elements in the multi-level pie chart. The standard width is 1.

5) Click **OK** to save your settings.

6) In the toolbar, click the **Save** button to save your changes.

An example for the configuration of a bar chart based on Alfabet query language is provided in the section Configuring Color Definition per Alfabet Object. An example for the configuration of a bar chart based on native SQL is provided in the section Configuring Navigation to a Defined View.

An example for the configuration of a pie chart based on native SQL is provided in the section Configuring Color Definition per Graphic Element.

An example for the configuration of a radar chart based on Alfabet query language is provided in the section Configuring Navigation to the Object's Profile.

Configuring Fixed Color Assignment

In configured chart reports, colors are by default assigned randomly to the objects in the report. There are two methods to influence the color coding used in chart reports:

- The report can be defined to use object colors. If a color is assigned to an object, this object is then displayed in the defined color in all standard chart and portfolio reports on the Alfabet interface and in all configured business chart reports that are configured to use object specific coloring. The color of individual objects can be changed by the user if the **Colors** button of the report is enabled.
- Colors for the graphic objects in the chart report can be defined within the result dataset. This method allows to streamline the coloring of all chart reports displayed For example, in the same object cockpit or to assign fixed colors to graphic elements not representing Alfabet objects.

For waterfall reports only, a third method for applying color is available. Two colors can be defined for the waterfall charts, one for positive and one for negative values. The report will then show all negative values, independent from the series they belong to, in the color defined for negative values and all positive values in the color defined for positive values. The color definition is done in the tab **Additional Attributes** with the attributes **Negative Color** and **Positive Color**. The defined positive and negative colors are only used if the **Color Column** attribute is not set.

The color definitions can be activated or deactivated per configured chart report:

Configuring Color Definition per Alfabet Object

A color can be assigned to single objects of any object class with a property ***Color***. If a color is assigned to an object, this color is used for the object in all standard portfolio and chart reports in Alfabet. Whether the object color is used in configured chart reports depend on the configuration of the report.

The assignment of colors to objects can be performed on the Alfabet interface by two different methods:

- The color can be assigned via a color selector in a custom editor for the respective object class. The color may than be assigned to the object by a user with Read/Write access to the object and access to the custom editor.
- The color can be assigned by any user opening a report via the the **Colors** button in the toolbar of the report. Whether a **Colors** button is available in the toolbar of a standard report or configured report and whether the button is active or disabled, depends on the configuration of the Alfabet Server and the view scheme assigned to the user profile used when opening the report.

For information about the configuration required to activate color setting per object, see *Allowing Users to Change the Color Assigned to Objects in Business Graphics* in the reference manual *System Administration*.

When color setting is activated, the colors assigned to objects are only used in a configured chart report if the graphic elements in the report can be assigned to an object and the report is configured to identify the object behind the graphic.

The following configuration is required:

- In the data source of the chart report, each column in the dataset must be related with an object.

When the report is based on an Alfabet query, each column of the dataset is automatically assigned to the respective object of the `FIND` class of the Alfabet query.

For native SQL queries, the first SELECT argument of the query must return the REFSTR property of an object class. This column is removed from display of the result dataset but nevertheless associates the dataset with an object class.

> When configuring chart reports, it is possible to define `NULL` as `REFSTR` in the first `SELECT` argument. For an example, see Configuring Color Definition per Graphic Element. Therefore, in native SQL queries the graphic elements in a chart are not necessarily related with an object.

The assignment of an object to each row in the report can also be performed by adding an additional row to the dataset that returns the `REFSTR` of an object related to the displayed results.

- The attribute **Object Column** is set in the **Business Graphic Definition** tab of the **Report Assistant** and specifies the column containing the `REFSTR` of the differently colored objects. When you select `Row Reference` in the drop-down list of the **Object Column** attribute, the `REFSTR` of the `FIND` class

of the Alfabet query or the first `SELECT` argument in the native SQL query are used to assign an object to the graphic.

- The attribute **Color Column** is NOT set in the **Business Graphic Definition** tab of the **Report Assistant**. This attribute activates coloring according to a color specification in the result dataset of the query. It supersedes an **Object Column** setting.

For example, a bar chart is configured to display applications in a selected application group on the x-axis and the number of local components assigned to each application on the y-axis. The configured report is assigned to the object class Application Group with the **Apply To Class** attribute to allow selection of the application group. The following Alfabet query is defined as data source:

```
ALFABET_QUERY_500

FIND Application

InnerJoin LocalComponent ON LocalComponent.Owner = Application.REFSTR

WHERE Application.ApplicationGroups CONTAINS:BASE

Instructions

JoinColumns("Application.Name,Application.Version","Application.Name",
" v.");

EndOfInstructions

QUERY_XML

<QueryDef>

<ShowProperty Type="Property" ClassName="Application" Name="Name" />

<ShowProperty Type="Property" ClassName="Application" Name="Version"
/>

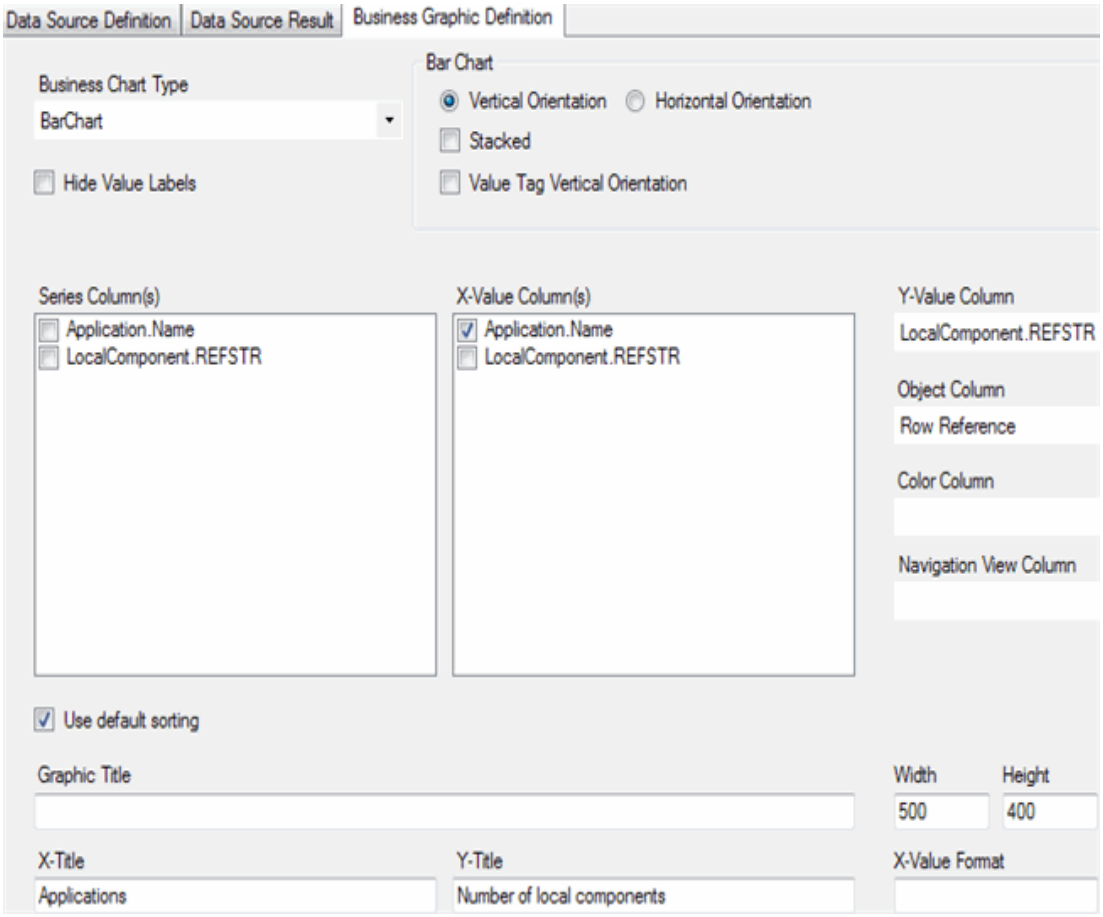
<ShowProperty Type="Property" ClassName="LocalComponent" Name="REFSTR"
Function="COUNT" />

</QueryDef>
```

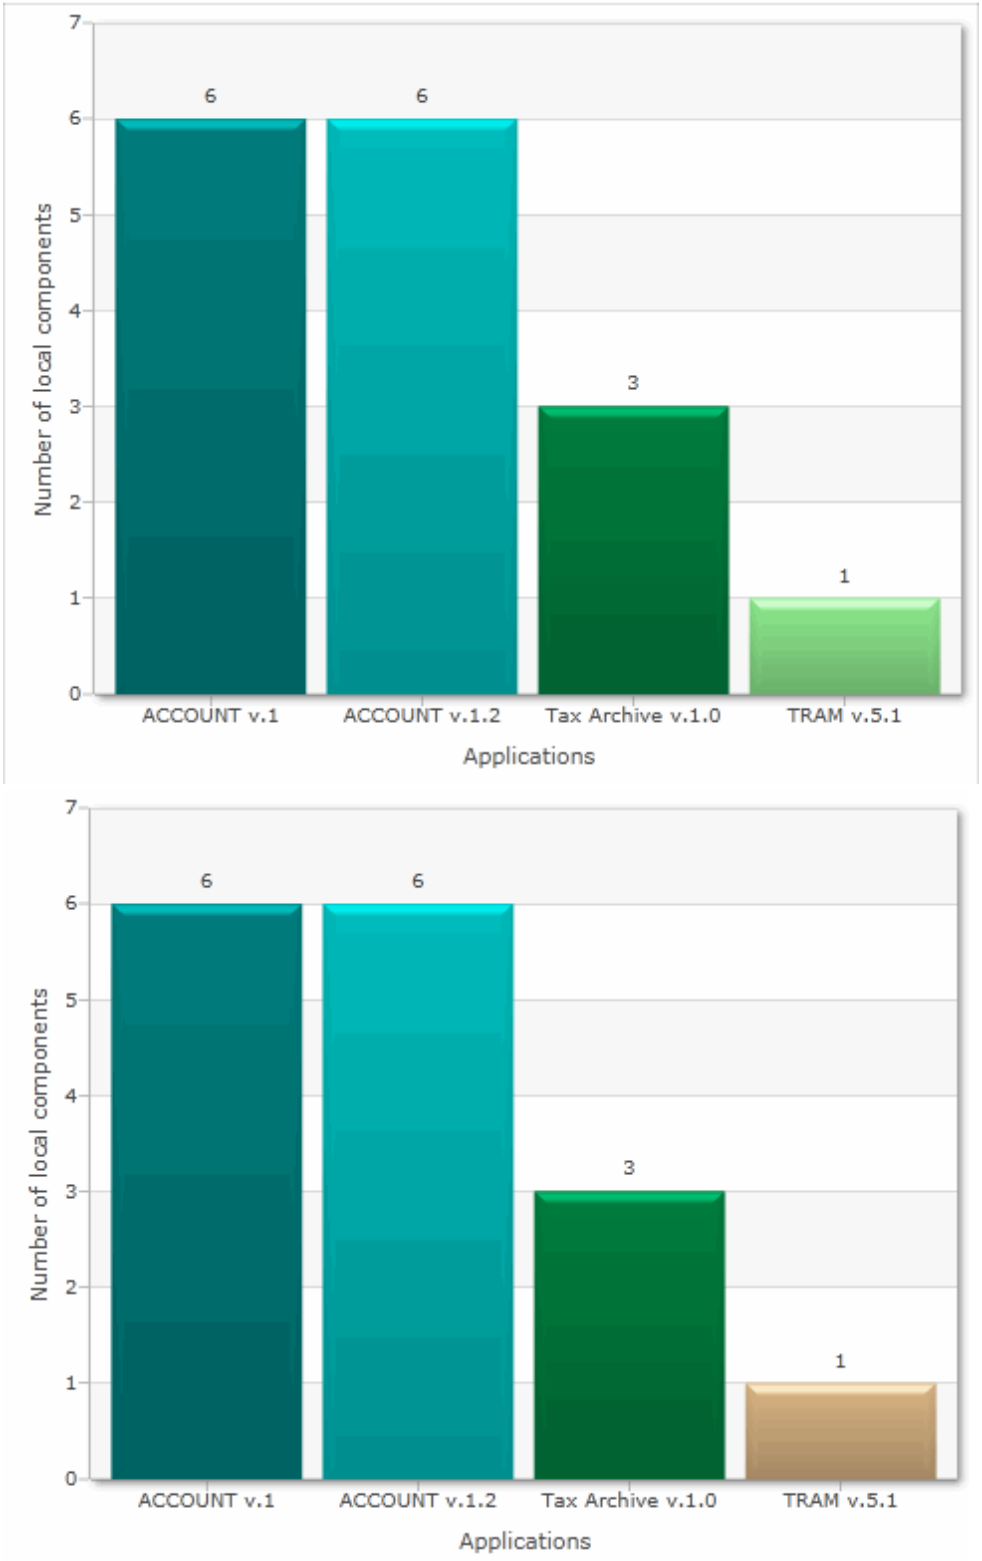
The result dataset has two columns. One column returning the name and version number of the application (column `Application.Name`) and one that returns the number of local components assigned to the respective application (column `LocalComponent.REFSTR`):

Application.Name	LocalComponent.REFSTR
Business EAI Platform v.2.2	1
Groupware Services v.2.2	1
Mafo-Portal v.2.6	12
PS Global v.2.5	1
ALLFinance PISA v.2.9	2
SAP@OptiRetail v.2.0	2
SAP@AI v.4.0	25
BookIT v.2.9	2
Corporate FI-CO v.2.2	29

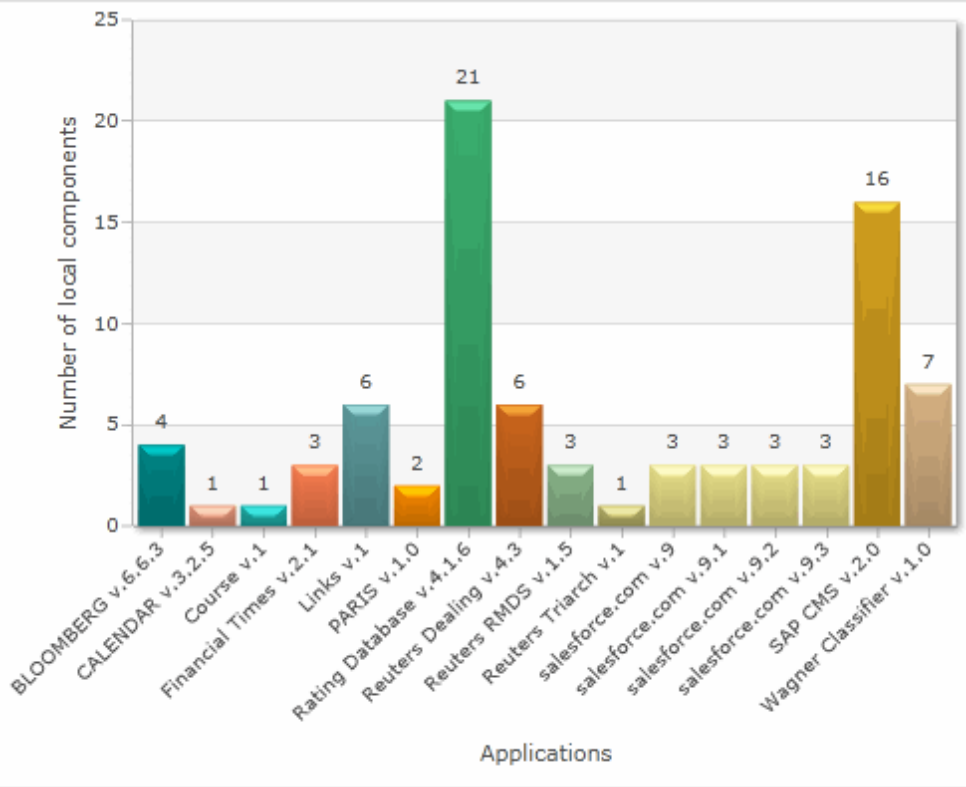
The color defined for single applications shall be applied to the bar chart. The object class Application is the `FIND` class of the data source query and must be set in the **Object Column** definition of the **Business Graphic Definition** of the report to identify the application assigned to each graphic element:



In the resulting report, applications that have a color defined are displayed in the same color in each result dataset while the color of applications with no color defined is assigned randomly at each opening of the report. In the following example, a color is defined for all application except for the application TRAM v. 5.1. Therefore, when the report is opened a second time, the bars representing the applications with a color assigned are displayed with the assigned color while the color of the bar representing the application without color assignment is selected randomly.



Alternatively, a new dimension of information can be added to the report by coloring all applications that are assigned to the same ICT object with the same color. In the example below, all application versions named `salesforce.com` are assigned to the same ICT object and are Therefore, displayed with the same color:



To configure the report to assign the color to the columns depending on the ICT object the applications are assigned to, the query must be extended to find the ICT object the application is assigned to and return the `REFSTR` of the ICT object in the result dataset:

```
ALFABET_QUERY_500

FIND Application

InnerJoin LocalComponent ON LocalComponent.Owner = Application.REFSTR

InnerJoin ICTObject ON Application.ICTObject = ICTObject.REFSTR

WHERE Application.ApplicationGroups CONTAINS:BASE

Instructions

JoinColumns("Application.Name,Application.Version","Application.Name",
" v.");

EndOfInstructions

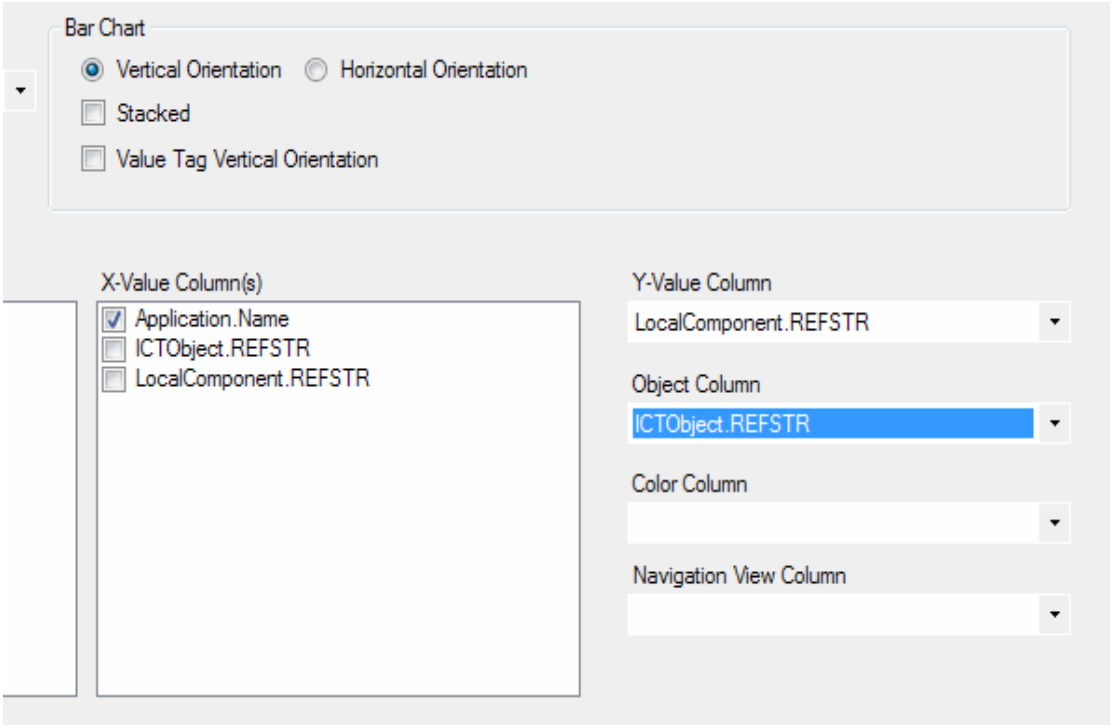
SAP International v.2.8	26-43-0	11
compas v.2.2	26-14-0	6

The **Object Column** attribute is set to the column containing the `REFSTR` of the ICT object:



Configuring Color Definition per Graphic Element

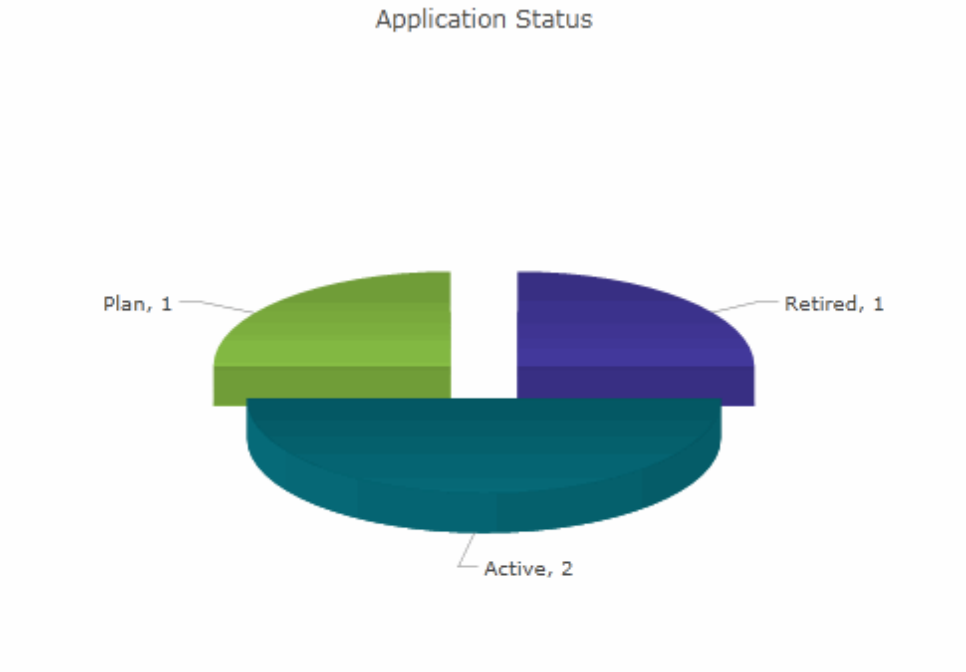
The colors used to display the elements in a configured chart report can be defined within the dataset of the data source query for the chart report.

This requires the following configuration:

- The data source query must be defined to return a dataset with a column containing a color specification in HTML compliant color coding.
- The column containing the color definitions must be selected in the attribute **Color Column** of the **Business Graphic Definition** tab of the **Report Assistant**.

When both a **Color Column** and an **Object Column** are defined, the color coding defined by the **Color Column** definition is used for color definition.

For example, a configured pie chart report report displays the number of applications assigned to an ICT object that are in the object state **Active**, **Plan**, or **Retired** and the coloring of the pie elements shall match a given color scheme.



The configured report is applied to the object class ICT object as base class with the attribute **Apply to Class**.

The data source query of the configured report is a native SQL query that combines three datasets, each counting applications assigned to the base ICT object that are in one of the given object states. Each `SELECT` statement results in one row in the result dataset.

The rows in the result dataset are not related to a single Alfabet object, and Therefore, the first argument in each `SELECT` statement, that has to return the `REFSTR` of the current object, is set to `NULL`.

```
SELECT NULL As 'REFSTR', 'Active' As 'ObjectState', COUNT(*) As
'Applications', '#076D7B' As 'Color'

FROM APPLICATION app

WHERE app.OBJECTSTATE = 'Active'

AND app.ICTOBJECT=@BASE

UNION ALL

SELECT NULL As 'REFSTR', 'Plan' As 'ObjectState', COUNT(*) As
'Applications', '#8AC145' As 'Color'

FROM APPLICATION app

WHERE app.OBJECTSTATE = 'Plan'

AND app.ICTOBJECT=@BASE

UNION ALL
```

```
SELECT NULL As 'REFSTR', 'Retired' As 'ObjectState', COUNT(*) As
'Applications', '#453AA1' As 'Color'

FROM APPLICATION app

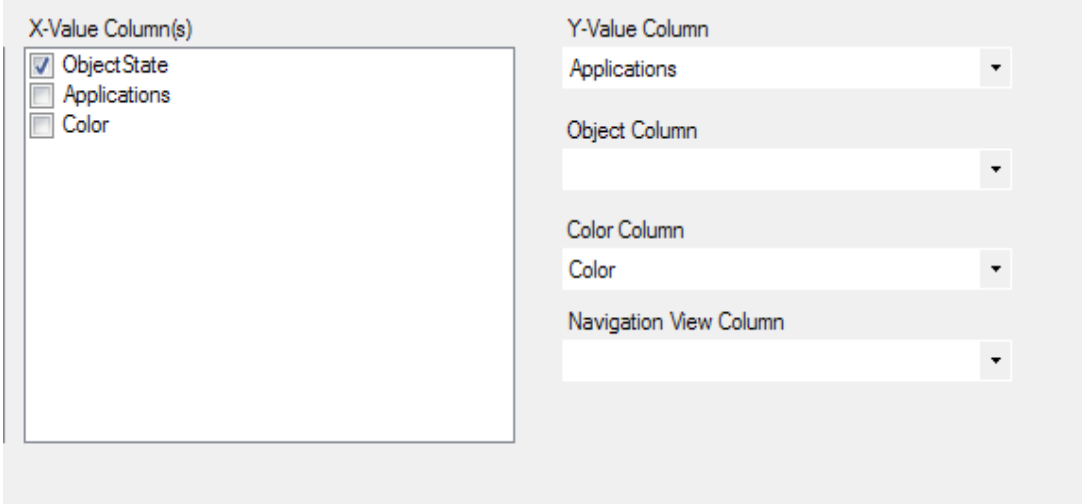
WHERE app.OBJECTSTATE = 'Retired'

AND app.ICTOBJECT=@BASE;
```

The result dataset contains three columns:

ObjectState	Applications	Color
Active	266	#076D7B
Plan	15	#8AC145
Retired	53	#453AA1

- ***ObjectState:*** This column contains the name of the object state, defined as string in the `SELECT` statement. In the **Business Graphic Definition** tab, the column is selected as **X-Value Column** of the pie chart.
- ***Applications:*** This column contains the count of applications in the Alfabet database matching the search criteria. The column is selected as **Y-Value Column** of the pie chart.
- ***Color:*** This column contains a color code, defined as string in the `SELECT` statement. Each element in the graphic shall be colored in the defined color code. The column is selected as **Color Column** of the pie chart.



Configuring Navigation from a Chart Report

Configured busines chart reports can provide navigation from a graphic element in the report. When the user clicks the graphic element, a preview window opens with a button **Show Details**. Clicking on the button can open one of the following, according to the configuration of the configured report:

- If the graphic elements in the chart represent Alfabet objects, the user can navigate to the object profile of the objects represented in the report.

- Navigation targets for the graphic objects in the chart report can be defined within the result dataset. This method allows to open any object profile, configured report or standard Alfabet view from a graphic report. Parameters can be defined in the target definition to pre-set filters in the report that opens.

These functionalities can be activated or deactivated per configured chart report via the following configurations:

- Configuring Navigation to the Object's Profile
- Configuring Navigation to a Defined View

Configuring Navigation to the Object's Profile

Navigation to the object's profile from the report requires the following configurations:

- In the data source of the chart report, each column in the dataset must be related with an object.

When the report is based on an Alfabet query, each column of the dataset is automatically assigned to the respective object of the `FIND` class of the Alfabet query.

For native SQL queries, the first `SELECT` argument of the query must return the `REFSTR` property of an object class. This column is removed from display of the result dataset but nevertheless associates the dataset with an object class.

When configuring chart reports, it is possible to define `NULL` as `REFSTR` in the first `SELECT` argument. For an example, see Configuring Color Definition per Graphic Element. Therefore, in native SQL queries the graphic elements in a chart are not necessarily related with an object.

The assignment of an object to each row in the report can also be performed by adding an additional row to the dataset that returns the `REFSTR` of an object related to the displayed results.

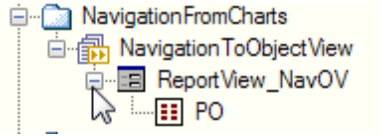
- The attribute **Object Column** is set in the **Business Graphic Definition** tab of the **Report Assistant** and specifies the column containing the `REFSTR` of the objects for which the object profile shall be the navigation target. When you select `Row Reference` in the drop-down list of the **Object Column** attribute, the `REFSTR` of the `FIND` class of the Alfabet query or the first `SELECT` argument in the native SQL query are used to assign an object to the graphic.
- The attribute **Navigation View Column** is NOT set in the **Business Graphic Definition** tab of the **Report Assistant**. This attribute activates navigation to a target view defined in the result dataset of the query. It supersedes an **Object Column** setting.
- The **Navigate**  button is activated for the report. By default, the **Navigate**  button is deactivated for a new configured report. Activation of the button is required for technical reasons to activate the navigation functionality. In the report, the button is not displayed in the toolbar, but navigation can be performed by clicking a graphic element in the chart.

Note the following about the **Navigate**  button:

- If you hide the inactivated **Navigate** button in the toolbar via configuration of the view scheme used for the user's profile, the hyperlinks to navigate to objects are not displayed any longer.
- The setting of the **Object Column** attribute is also required to use coloring defined for single objects in the graphic. If you want to define coloring without defining navigation to the object, you can set the **Object Column** attribute without activating the **Navigate** button.

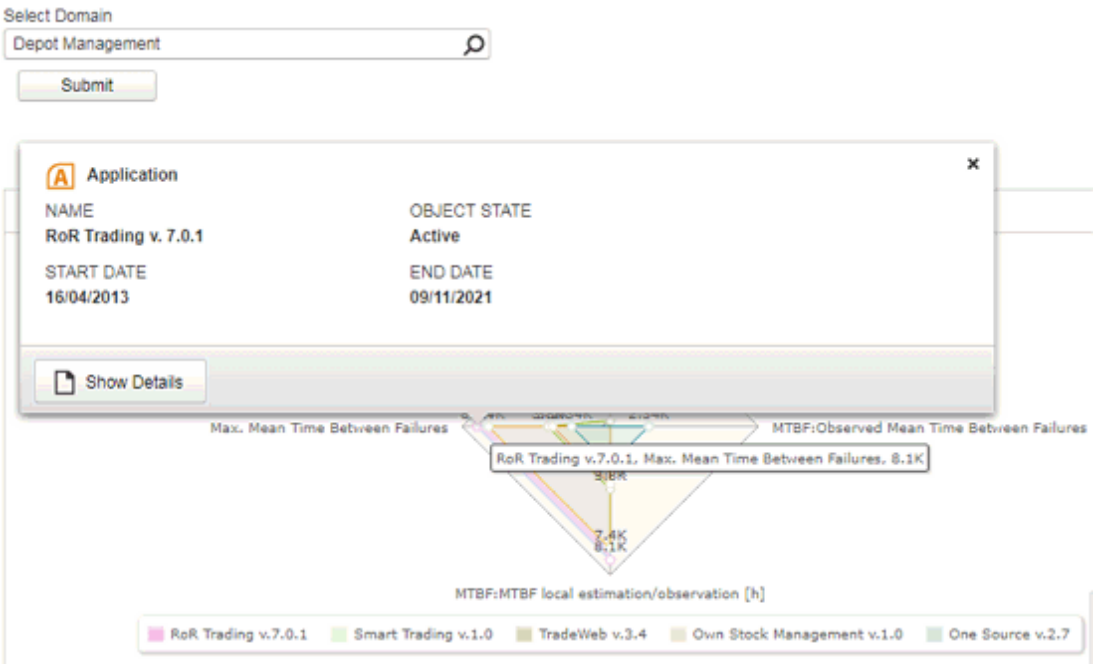
Do the following to activate the navigate button:

1) In the explorer of the Reports tab of Alfabet Expand, expand the Custom Report View's Node of the chart report for that you want to activate the **Navigate** button.



2) Click the `PO` element under the Custom Report View's Node. The attributes of the `PO`-element are displayed in the attribute window.
3) In the **Buttons** section of the attribute window, set the attribute **Has Navigate Button** to `True`.

For example, a radar chart is configured to show the indicators regarding failure times for applications assigned to a domain selected as base class of the report. clicking a node in the report not only shows the value for the selected indicator for the selected application as a tooltip, but also leads to display of a preview window. Clicking on the button **Show Details** in the preview opens the application's object view.



The report is based on the following Alfabet query:

```
ALFABET_QUERY_500

FIND Application

InnerJoin Indicator ON Indicator.Object = Application.REFSTR

InnerJoin EvaluationType ON EvaluationType.REFSTR =
Indicator.EvaluationType

WHERE (AND

Application.Domain CONTAINS:BASE

EvaluationType.Name LIKE 'MTBF%')

Instructions

JoinColumns("Application.Name,Application.Version","Application.Name
", " v.");

EndOfInstructions

QUERY_XML

<QueryDef>

<ShowProperty Type="Property" ClassName="Application" Name="Name" />

<ShowProperty Type="Property" ClassName="Application" Name="Version"
/>

<ShowProperty Type="Property" ClassName="Indicator" Name="Value" />

<ShowProperty Type="Property" ClassName="Indicator" Name="Name" />

<ShowProperty Type="Property" ClassName="EvaluationType" Name="Name"
/>

</QueryDef>
```

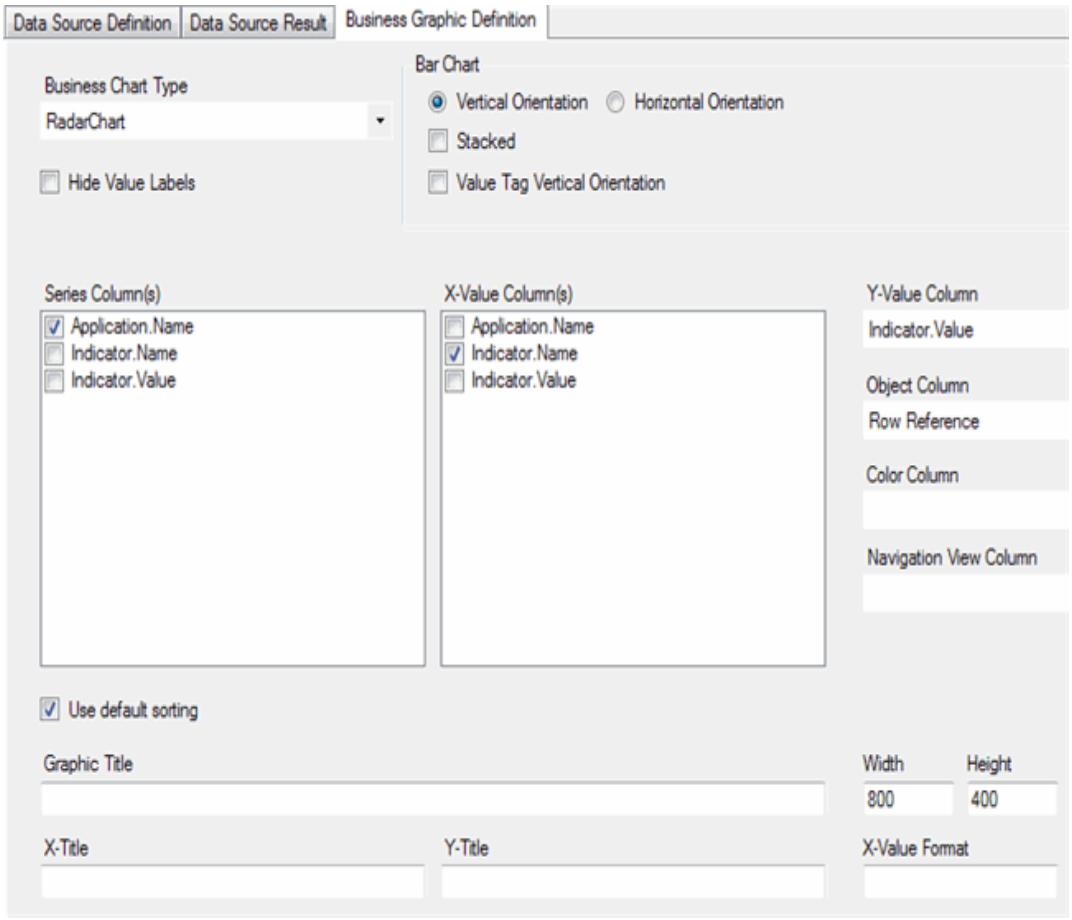
The query results in the following dataset:

Application.Name	Indicator.Name	Indicator.Value
Business EAI Platform v.2.2	Max. Mean Time Between Failures	5,700.00
Business EAI Platform v.2.2	MTBF:MTBF local estimation/observation [h]	5,700.00
Groupware Services v.2.2	Aggregated Mean Time Between Failures [h]	6,300.00
Groupware Services v.2.2	Max. Mean Time Between Failures	6,300.00
Mafo-Portal v.2.6	Aggregated Mean Time Between Failures [h]	1,577.33
Mafo-Portal v.2.6	Max. Mean Time Between Failures	1,577.33
PS Global v.2.5	Max. Mean Time Between Failures	7,600.00
PS Global v.2.5	MTBF:MTBF local estimation/observation [h]	7,600.00
ALLFinance PISA v.2.9	Max. Mean Time Between Failures	8,500.00
ALLFinance PISA v.2.9	MTBF:MTBF local estimation/observation [h]	8,500.00
SAP@OptiRetail v.2.0	Aggregated Mean Time Between Failures [h]	123.53
SAP@OptiRetail v.2.0	Max. Mean Time Between Failures	123.53
SAP@AI v.4.0	Max. Mean Time Between Failures	1,000.00
SAP@AI v.4.0	MTBF:MTBF local estimation/observation [h]	1,000.00
BookIT v.2.9	Max. Mean Time Between Failures	5,600.00
BookIT v.2.9	MTBF:MTBF local estimation/observation [h]	5,600.00

The radar chart has three dimensions.

- The x-axis corresponds to the radii of the radar chart. There is one radius per indicator. The column `Indicator.Name` defines the radii and which result is applicable to which radius.
- The y-axis corresponds to the values on the radii. The values are defined in the column `Indicator.Value`.
- The report displays indicator values for multiple applications. The application are the third dimension that defines which indicator value belongs to which graphic net element within the radar chart. The `Application.Name` column is Therefore, selected as series column.

The report shall also trigger the navigation to the application's profile. Application is the `FIND` class of the Alfabet query the report is based on and Therefore, the attribute **Object Column** of the report can be set to `RowReference` to identify the application that is associated with the value the user clicks on to display the navigation link.



In addition to the configuration in the **Business Graphic Definition** tab of the **Report Assistant**, the navigation to the object's profile is activated in the report by activation of the **Navigate** button in the attributes of the `PO` node of the Custom Report View.

Configuring Navigation to a Defined View

Navigation to a defined standard view, configured report or object profile from the configured chart report requires the following configurations:

- In the data source of the chart report, a column must be added for the definition of the navigation target.

The syntax required for definition of the view is the following:

```
View=ViewType:ViewName
```

The `ViewType` can be one of the following:

- ***Report*** for a configured report
- ***GraphicView*** for a standard Alfabet view
- ***ObjectView*** for an object profile

`ViewName` is the name of the view.

If the navigation target is a configured report, parameters values can be handed over to the view that opens.

The query of the report must contain each parameter definition as a variable defined as

```
@ParameterName
```

Please note that the old syntax of the Alfabet query language defining parameters as:`ParameterName` is not supported.

The parameter @BASE that refer to the base object for that the link is opened cannot be changed via parameter settings.

The parameters can be used in WHERE clauses of the query without defining a filter for the report, because the parameter values are already defined in the navigation link.

Optionally, filters can be defined for the report to allow the user opening the report to alter the parameter values. In this case the parameter values in the navigation link are used as default values for the filter when opening the report. The filter settings are also stored in the user context settings for the report. That means, when the user first opens the report via drilldown from a chart report and then afterwards opens the report in any other context, For example, via the **Reports** functionality, the report will open with the last filter settings derived from the drill-down.

For each parameter the following string must be added to the navigation target definition:

```
&ParameterName=ParameterValue
```

The setting of three parameters would result in the following navigation link:

```
View=ViewType:ViewName&ParameterName1=ParameterValue1&ParameterName2=Para
meterValue2&ParameterName1=ParameterValue2
```

.

The assignment of an object to each row in the report can also be performed by adding an additional row to the dataset that returns the `REFSTR` of an object related to the displayed results.

- The attribute **Navigation View Column** is set in the **Business Graphic Definition** tab of the **Report Assistant** and specifies the column containing the navigation target definition.

The **Navigation View Column** supersedes the navigation setting of the **Object Column** attribute that can be set both to trigger navigation to the object view of objects represented by the graphic elements in the chart and to trigger coloring according to the fixed colors defined for single objects in the report. You can define reports that use coloring based on object colors and at the same time navigate to defined views in the report.

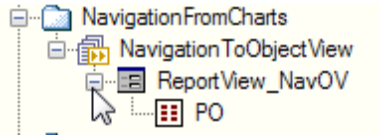
When **Object Column** is defined in parallel with **Navigation View Column**, the `REFSTR` in the **Object Column** is handed over to the navigation target defined in the **Navigation View Column** as base object that can be referred to by the parameter `BASE`.

- The **Navigate** button is activated for the report. By default, the **Navigate** button is deactivated for a new configured report. Activation of the button is required for technical reasons to activate the navigation functionality. In the report, the button remains inactive in the toolbar.

  If you hide the inactivated **Navigate** button in the toolbar via configuration of the view scheme used for the user's profile, the hyperlinks to navigate to objects are not displayed any longer.

Do the following to activate the navigate button:

1) In the explorer of the Reports tab of Alfabet Expand, expand the Custom Report View Node of the chart report for that you want to activate the **Navigate** button.



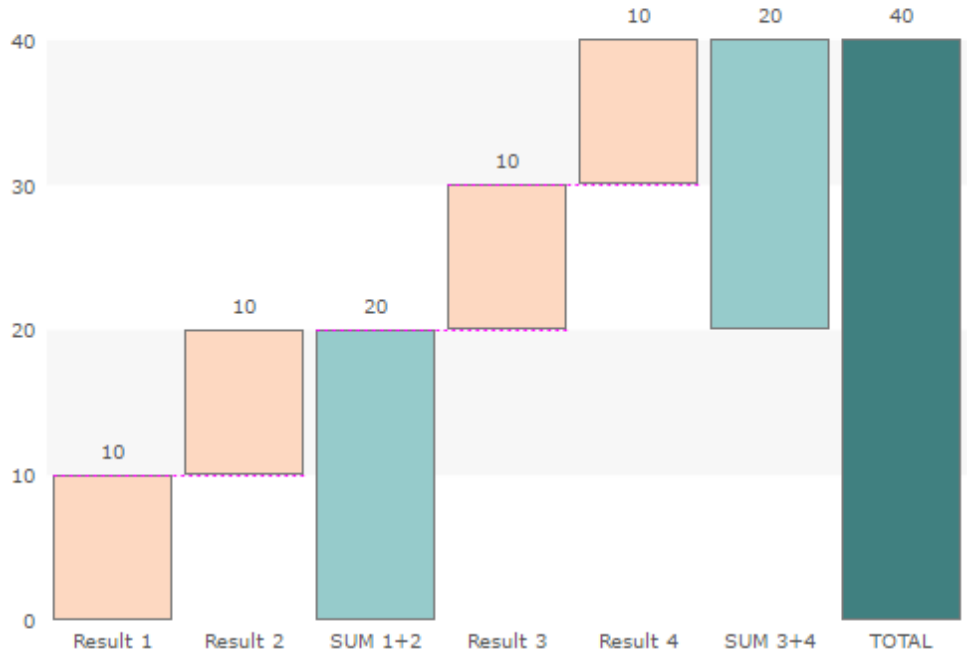
2) Click the PO element under the Custom Report View Node. The attributes of the PO-element are displayed in the attribute window.
3) In the **Buttons** section of the attribute window, set the attribute **Has Navigate Button** to `True`.

Configuring Display of the Sum of Multiple Columns in Waterfall Chart Reports

In waterfall charts, columns can be integrated into the report that sum up the values of all columns displayed left of them. There are two types of sum columns:

- `SUM` columns sum up all results starting at the last integrated `SUM` column.
- `CUMSUM` columns sum up all results independent of the number of `SUM` or `CUMSUM` columns that are integrated in the result dataset left to them.

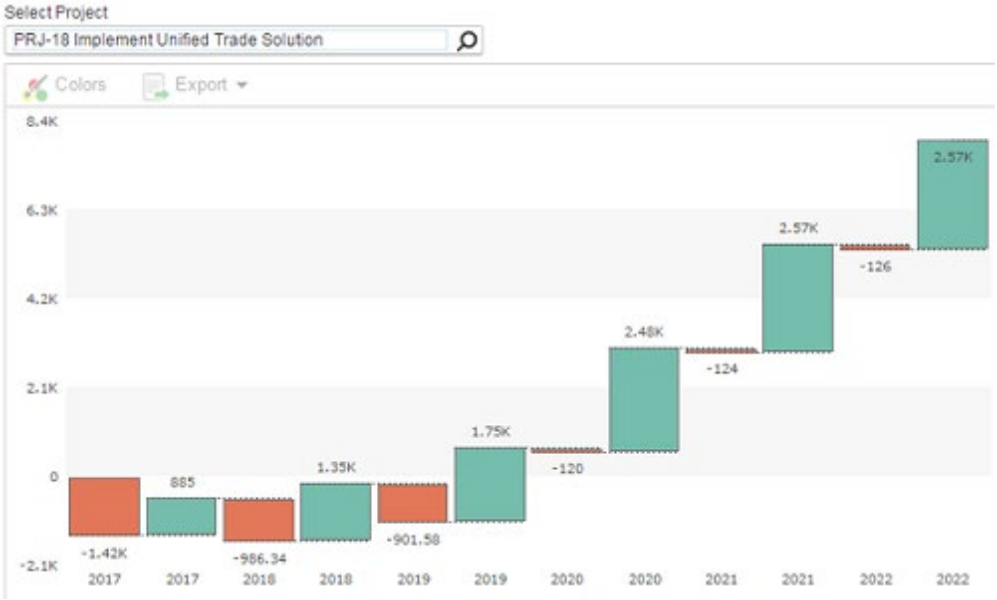
IN the following example this is demonstrated with easy result values of ten for each result column. The light green `SUM` columns added to the report sum up two result colums each, while the dark green `CUMSUM` column at the end of the report displays the sum of all values in the result columns of the report:



The inclusion of `SUM` or `CUMSUM` columns requires a change in the query definition of the configured waterfall chart report:

1) Add a new column to the result dataset of the configured report that is empty for result columns, returns `SUM` for `SUM` columns and `CUMSUM` for `CUMSUM` columns.
2) In the tab **Additional Attributes** of the business chart report assistant, enter the name of that column into the **Sum Info Column** attribute.
3) For each `SUM` or `CUMSUM` column, enter a new row to your result dataset at the position that the `SUM` or `CUMSUM` column is supposed to be displayed.

A configured waterfall chart report displays the costs and incomes resulting from a project over time. For each year two columns are displayed: one for costs and one for incomes.



The waterfall chart is based on the following query:

```
SELECT REFSTR,CLASS, YEAR, CASE WHEN CLASS = 'CostType' THEN -
(SUM(VALUE))ELSE SUM(VALUE)END AS Value, COLOR

FROM (

   SELECT NULL AS REFSTR, dbo.SCF_GetClassName(bv.MONETARYTYPE) AS
   CLASS, bv.YEAR, bv.VALUE, CASE WHEN
   dbo.SCF_GetClassName(bv.MONETARYTYPE) = 'CostType' THEN '#F99E68'
   ELSE '#33C0C0' END AS COLOR

   FROM BUSINESSCASE bc, BUDGETVALUE bv

   WHERE bc.OWNER = @BASE

   AND bv.OWNER = bc.REFSTR

) x

GROUP BY REFSTR, CLASS, YEAR,COLOR

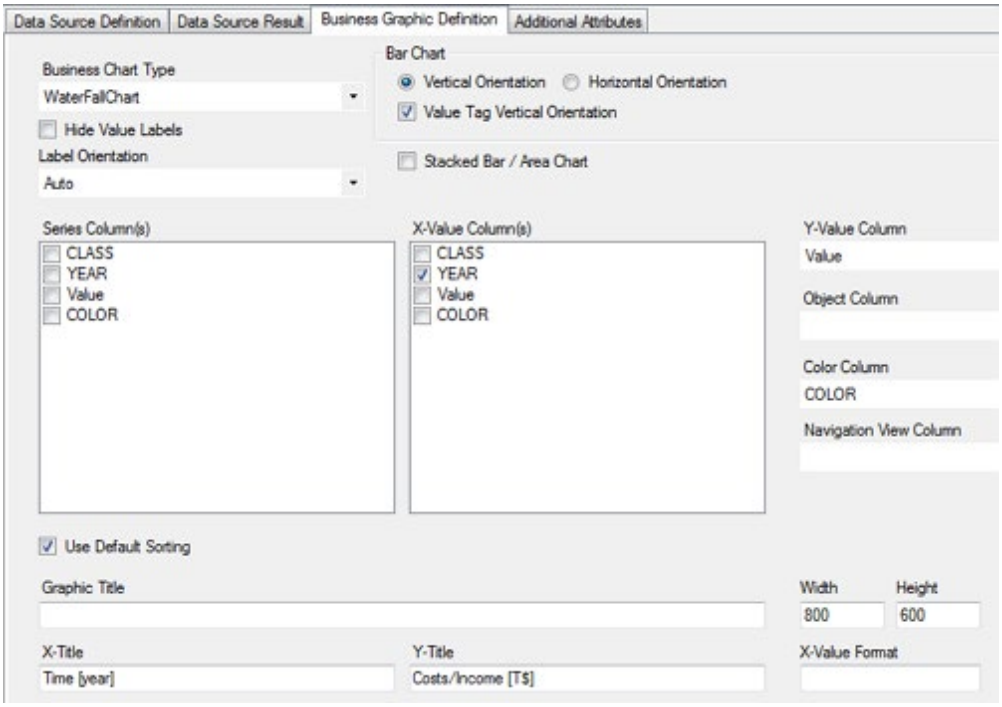
ORDER BY YEAR, CLASS
```

In the Alfabet database, the values for cost types and income types are both stored as positive values. The display of costs in the negative range of the graphic is performed in the query with a CASE expression based on the monetary type of the budget value. Coloring is also depending on the monetary type. Grouping is performed to sum the values of all costs for the same object, monetary type and year. The results are ordered by year and monetary type to view the costs and incomes in the order that they will occure in the project.

The query results in the following dataset:

	CLASS	YEAR	Value	COLOR
1	CostType	2017	-1,420.31	#F99E68
2	IncomeType	2017	885.00	#33C0C0
3	CostType	2018	-986.34	#F99E68
4	IncomeType	2018	1,350.00	#33C0C0
5	CostType	2019	-901.58	#F99E68
6	IncomeType	2019	1,750.00	#33C0C0
7	CostType	2020	-120.00	#F99E68
8	IncomeType	2020	2,480.00	#33C0C0
9	CostType	2021	-124.00	#F99E68
10	IncomeType	2021	2,570.00	#33C0C0
11	CostType	2022	-126.00	#F99E68
12	IncomeType	2022	2,570.00	#33C0C0

In the **Business Graphic Definition** tab of the report assistant, the `Value` column is defined as `Y Value Column`, The `COLOR` column is defined as **Color Column** to provide coloring of the bars, and the `YEAR` column is defined as **X-Value Column(s)** . It would also be possible to use the `CLASS` column as **X-Value Column(s)**. This would change the labels on the x-axis, but the outlook of the bars would be the same.



To add `SUM` columns to the report that sum up the costs and incomes of each year and to add a cumulative sum at the end of the report, the following changes have to be performed on the query:

- An additional column must be added to the dataset resulting from the query. The column can return an empty string for the columns containing data. In the example the column is named `SUMCOL`. In the example, the string returned for the column `CLASS` is also changed to return meaningful wording because the `CLASS` definition will be used instead of the `YEAR` definition for labels on the x-axis of the waterfall chart.
- Additional rows must be added to the dataset using a `UNION ALL` command to add a `SUM` column for each year. The same query specification that is used to find the budget values

for each year is also used to add the sum columns. This method ensures that SUM columns are returned for all years for that the dataset contains budget values. In the column named SUMCOL the value SUM is returned to specify that this is a SUM column. The Value of the budget is ignored for these rows and set to '1' for all results. The CLASS column returns the string SUM together with the current year. It is important that in alphabetical sorting, the CLASS defined for the SUM column is having a higher position than the CLASS definitions for the data columns because the SUM column must be added to the end of each year.

- An additional row must be added to the dataset using a UNION ALL command to add a CUMSUM column at the end of the report. This row must return CUMSUM for the column named SUMCOL and returns the string 'TOTAL' for the column CLASS and for the column YEAR, a year that is higher than the last possible end date of a project is specified, to display the column at the end of the report. The values in all other columns are technically not taken into account.
- A sorting is performed on the top level, that means that all results gathered via UNION ALL are sorted by YEAR and then by CLASS.

This results in the following query:

```
SELECT REFSTR, CLASS, YEAR, Value, COLOR, SUMCOL

FROM (

    SELECT REFSTR,CASE WHEN CLASS = 'CostType' THEN 'Costs'ELSE
    'Profits' END AS CLASS, YEAR, CASE WHEN CLASS = 'CostType' THEN -
    (SUM(VALUE)) ELSE SUM(VALUE)END AS Value, COLOR,SUMCOL FROM (

        SELECT NULL AS REFSTR, dbo.SCF_GetClassName(bv.MONETARYTYPE)
        AS CLASS, bv.YEAR, bv.VALUE, CASE WHEN
        dbo.SCF_GetClassName(bv.MONETARYTYPE) = 'CostType' THEN
        '#F99E68' ELSE '#33C0C0' END AS COLOR,'1' AS SUMCOL

        FROM BUSINESSCASE bc, BUDGETVALUE bv

        WHERE bc.OWNER = @BASE

        AND bv.OWNER = bc.REFSTR

    ) x

    GROUP BY REFSTR, CLASS, YEAR,COLOR,SUMCOL

    UNION ALL

    SELECT REFSTR, CLASS, YEAR, '1' AS Value, COLOR,SUMCOL

    FROM (

        SELECT NULL AS REFSTR, 'SUM ' + CAST (bv.YEAR AS varchar) AS
        CLASS, bv.YEAR, '1' AS VALUE, '#C0C0C0' AS COLOR, 'SUM' AS
        SUMCOL FROM BUSINESSCASE bc, BUDGETVALUE bv

        WHERE bc.OWNER = @BASE

        AND bv.OWNER = bc.REFSTR

    ) x

    GROUP BY REFSTR, CLASS, YEAR, COLOR,SUMCOL

    UNION ALL

    SELECT NULL AS REFSTR, 'TOTAL ' AS CLASS, '2030' As YEAR, '1' As
    Value, '#408080' AS COLOR, 'CUMSUM' AS SUMCOL
```

```
) x
ORDER BY YEAR, CLASS
```

The query returns the following dataset:

	CLASS	YEAR	Value	COLOR	SUMCOL
1	Costs	2017	-1,420.31	#F99E68	1
2	Profits	2017	885.00	#33C0C0	1
3	SUM 2017	2017	1.00	#C0C0C0	SUM
4	Costs	2018	-986.34	#F99E68	1
5	Profits	2018	1,350.00	#33C0C0	1
6	SUM 2018	2018	1.00	#C0C0C0	SUM
7	Costs	2019	-901.58	#F99E68	1
8	Profits	2019	1,750.00	#33C0C0	1
9	SUM 2019	2019	1.00	#C0C0C0	SUM
10	Costs	2020	-120.00	#F99E68	1
11	Profits	2020	2,480.00	#33C0C0	1
12	SUM 2020	2020	1.00	#C0C0C0	SUM
13	Costs	2021	-124.00	#F99E68	1
14	Profits	2021	2,570.00	#33C0C0	1
15	SUM 2021	2021	1.00	#C0C0C0	SUM
16	Costs	2022	-126.00	#F99E68	1
17	Profits	2022	2,570.00	#33C0C0	1
18	SUM 2022	2022	1.00	#C0C0C0	SUM
19	TOTAL	2030	1.00	#408080	CUMSUM

In the settings of the **Business Graphic Definition** tab of the report assistant, the **X-Value Column(s)** definition is changed to `CLASS`.

The configured report now includes sums of values for all years and a total at the end of the report:

Combining Multiple Chart Types in One Chart

Line, area, and bar charts can be combined in a combination chart. The combination chart offers the following features for display of different kind of charts in the same graphic:

- Business charts of two different chart types can be combined, For example, some series can be displayed as a bar and some as a line.
- Two different y axes can be defined, For example, to combine charts that require a different scale because the series are having different ranges of values or units of measure.
- For a better graphic display of the combined chart types, 3D effects can be added to the configured report.

This section informs about the additional configuration required to implement a combination chart. The data displayed in each series is defined as described for individual chart types.

The following information is available:

- Combining Two Different Chart Types
- Implementing a Second Y-Axis
- Implementing Three-Dimensional Display

Combining Two Different Chart Types

Bar, area and line charts can be displayed next to each other in a single graphic with the following restriction:

- Stacked bars or stacked areas cannot be displayed in a combination chart.

To display different series in different chart types, add the following configuration to your basic chart definition returning all series in one chart type:

1) In the **Data Source Definition** tab, add an additional column to your dataset that returns the chart type for each series. The chart type can be one of the following:
   - bar
   - line
   - area

   Please note the following about the definition of the chart type:
   - All data belonging to the same series must return the same value.
   - If no data or any other than the allowed values are returned, the series will be displayed as bar chart.
2) Click the **Check Data Source** button in the **Data Source Result** tab. The result of the test is displayed in the **Data Source Errors** field. The next step can only be performed when the query passes the test without errors.
3) Define the following attributes in the **Business Graphic Definition** tab in addition to the basic configurations for display of the series:
   - **Business Chart Type**: Select `CombinationChart`.
   - **Chart Type Column**: Select the column in the dataset of the query defined in the **Data Source Definition** tab that returns the chart type.
   - **Stacked Bar / Area Chart**: Make sure that the checkbox is deselected. Stacked bars or stacked areas cannot be displayed in a combination chart.

Implementing a Second Y-Axis

The use of a secondary y-axis for some series is not limited to a combination report displaying more than one chart type:

- For bar charts, you can follow the steps described below without any additional configuration.
- For line and area charts and charts displaying multiple chart types, you must define the chart type for each series as described in the section Combining Two Different Chart Types. If all series return the same chart type, only one chart type is displayed.

Add the following configuration to your chart definition to use a secondary y-axis:

1) In the **Data Source Definition** tab, add an additional column to your dataset that returns `Secondary` for all data belonging to the series that shall use the secondary y-axis. If any other value is returned, the primary y-axis is used.

   Please note that for any chart type other than bar chart you must also define the chart type in a separate column as described in the section Combining Two Different Chart Types.

2) Click the **Check Data Source** button in the **Data Source Result** tab. The result of the test is displayed in the **Data Source Errors** field. The next step can only be performed when the query passes the test without errors.

3) Define the following attributes in the **Business Graphic Definition** tab in addition to the basic configurations for display of the series:

   - **Business Chart Type**: Select `CombinationChart`.
   - **Show Secondary Y-Axis**: Select the checkbox.
   - **Secondary Y-Title**: Optionally define a caption to be displayed on the secondary y-axis.
   - **Y-Axis Selection Column**:

4) Optionally define the following attributes in the **Additional Attributes** tab:

   - **Secondary Y Maximum Value**: Enter a maximum value for the secondary y-axis. If no maximum value is defined, the maximum value of the y-axis is derived from the highest y value in the dataset. Definition of a fixed maximum value can For example, be used to streamline the y-axis definitions of multiple charts for comparison reasons. If an y value in the result dataset of the report exceeds the defined maximum value, the defined maximum is ignored and the y-axis is extended to display all values in the dataset.
   - **Secondary Y Minimum Value**: Enter a minimum value for the secondary y-aaxis. If no minimum value is defined, the minimum value of the y-axis is 0 or, if negative values are displayed, derived from the lowest y value in the dataset. Definition of a fixed minimum value can For example, be used to highlight differences if values are all in a high range and differences would not be clearly visible if values are displayed on a scale starting from 0. If an y value in the result dataset of the report is lower than the defined minimum value, the defined minimum is ignored and the y-axis is extended to display all values in the dataset.
   - **Secondary Y Number Prefix**: Enter a string that will be displayed in front of all numbers on the secondary y-axis and in front of all label numbers in the chart that are referring to the secondary y-axis . This value can be set to display values For example, with a currency symbol in front without converting the numbers into a string on the SQL layer.
   - **Secondary Y-Axis Color**: The color used for display of the secondary y-axis if **Secondary Y-Axis Thickness** is set to a value higher than zero.
   - **Secondary Y-Axis Thickness**: The width of the line drawn on the secondary y-axis. By default, **Secondary Y-Axis Thickness** is set to zero and no line is drawn.

Implementing Three-Dimensional Display

Three dimensional display is only available for a subset of combination charts:

- **Bars** are fully supported. Bars can be either displayed with a three-dimensional effect on the bar only, or as fully three-dimensional cubes.
- **Lines** can be added to three-dimensional combination charts, but they are nevertheless displayed two-dimensional. Please note that the display of lines requires the configuration described in the section Combining Two Different Chart Types in addition to the configuration described below.
- **Areas** are not supported. If the combination chart includes area charts, these will be displayed as bars instead.

The three-dimensional display requires the following settings for the configured report:

1) Click the **Check Data Source** button in the **Data Source Result** tab. The result of the test is displayed in the **Data Source Errors** field. The next step can only be performed when the query passes the test without errors.
2) Define the following attributes in the **Business Graphic Definition** tab in addition to the basic configurations for display of the series:
   - **Business Chart Type**: Select `CombinationChart`.
3) Define the following attributes in the **Additional Attributes** tab:
   1) **3D Effect on Bar**: Select True if you want to display a 3D effect inside the two-dimensional bars.
   2) **Chart Appearance**: Select 3D from the drop-down list to display bars as cubes.

Defining a Circular Roadmap Report

Circular roadmap reports are designed in the **Report Assistant**. For information about how to open the **Report Assistant**, see Creating a New Graphic Report. For basic information about how to work with the **Report Assistant**, see Configuring the Report with the Report Assistant.

The content and layout of a circular roadmap report is defined by adding elements to the explorer of the **Report Assistant** and setting the attributes in the attribute pane of the **Report Assistant** window.

It is recommended to use native SQL for creating circular roadmap reports. Alfabet query language does not provide the ability to include anything else than data from the tables in the Alfabet database into the search results, which excludes some of the features of the report.

The following table lists the types of explorer node elements that can be added to the report configuration to specify the content of the report. Information is provided in the table about the purpose of each explorer node element:

Explorer Node Element	Required to Configure:
Root Node	General layout of the report.

Explorer Node Element	Required to Configure:
Item Query	Definition of the objects that are displayed as items in the shells and sectors of the circular roadmap report.
Sector Query	Definition of the sectors of the circular roadmap report.
Shell Query	Definition of the shells of the circular roadmap report.

Defining the Content of the Circular Roadmap Report

The circular roadmap report defines the relationship of objects to the following two dimensions in a circular graphic:

- The distance of the object elements from the center of the circle is derived from a date or a numeric value like a date or an indicator.
- The circle is devided into sectors, that typically represent objects. An object element is placed into the sector representing a related object.

To define a circular roadmap, three queries must be provided:

- A **Shell Query** that defines a numeric or time scale from the center to the border of the circle. The scale devides the circle into shells that can be highlighted with different colors.
- A **Sector Query** that defines the division of the circle into sectors.
- An **Item Query** that finds the objects to be displayed in the circle and their position within the shells and sectors.

Optionally, a **Connections Query** can be specified to display connecting arrows between items in the circular roadmap.

The content, design and navigation behaviour of the configured report is mainly directly defined within the three queries the circular roadmap report is based on. The data from the query is taken over if the name of the column in the query output that contain the data is added to the respective attribute in one of the sections **Common**, **Data**, **Special Item Data** and **Special Sector Data** of the report.

Some of the attributes in the section **Data** are valid for all mandatory queries. That means that the column in the result dataset that contains For example, the specification of the label for shells, sectors and items must be identical in all queries or the circular roadmap report.

Basic information about taking over data from queries by defining attributes of the root node of the report is given in the section Mapping of Query Data to Attributes.

The query parameter `BASE` can be used in all three queries to refer to the base object if the attribute **Apply to Class** of the configured report is set.

The report can only be displayed if all three queries are available, valid and combined in the correct way. This is a very complex configuration and Therefore, it is recommended to define all queries separately in configured reports of the **Type** `Query` or `NativeSQL` to check whether the result of each query results in the required dataset prior to combining the data in the report.

In the following the basic requirements for combining the queries is described in detail:

- Defining the Shells
- Defining the Sectors
- Defining the Items
  - Defining the Design of the Items in the Circular Roadmap Report
- Defining Connections Between Items

Defining the Shells

The shells of the circular roadmap are the graphic representation of a scale that either covers a range of dates or a range of numbers. The **Shell Query** must either define dates or numbers. The first row of the dataset defines the starting point of the scale. Each following row defines the end point of the respective shell on the scale. Object elements in the report are located on the axis of the scale according to their defined value. For example, if a scale has the shells 0-1, 1-2, 2-3, and 3-4, an object with the y value 3.5 is positions in the middle of the shell 3-4.

The query definition must at least contain one column that returns the numeric value or date. The name of that column must be specified in the attribute **Value Column** in the section **Data** of the root node of the circular roadmap report. Additional columns of the dataset can provide the following data:

Attribute	Column must return:	Mandatory	Exclusive use of attribute for this query
Value Column	A date or numerical value that marks the end of the shell on the scale. (The value defined in the first row of the dataset defines the start of the scale).	Yes	No, attribute is used by all queries of the circular roadmap report.
Label Column	A string that shall be displayed as label of the shell. Labels are displayed from the center of the cirlce to the right if **Label Column** is defined.	No, if not defined, no labels are displayed.	No, attribute is used by all queries of the circular roadmap report.

Attribute	Column must return:	Mandatory	Exclusive use of attribute for this query
Color Column	A HTML compliant color definition for coloring of the shell.	No, if not defined, no legend is displayed for shell coloring.	No, attribute is also used for **Item Query**.
Legend Group Column	A string that shall be displayed as heading for the legend entry defined with **Legend Entry Column** in the same row of the dataset. All legend entries that have the same **Legend Group Column** are grouped and displayed under the heading defined with **Legend Group Column**.	No, if the attribute is not defined, the legend does not display entries for shell coloring.	No, attribute is also used for **Item Query**. Please note that
Legend Entry Column	A string that shall be displayed next to the color of the shell in the legend of the report.	No, if not defined, and **Legend Group** Column is defined, the legend displays entries for shell coloring with the color followed by the value.	No, attribute is also used for **Item Query**.

The color and label defined defined for the first row in the dataset define the center point of the circle and are not visible in the report. But the color defined for the center point is included into the legend, if a legend group for shells is defined.

For example, a time scale is defined for the shell definition. The time scale covers a range of 5 years starting from the current date. That means that the y-axis is representing dates with each shell covering one year, that means 365 days. The following native SQL query is defined as **Shell Query**. A color and a label are also assigned to each shell.

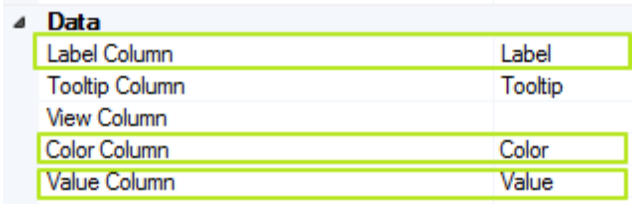
```
SELECT NULL AS REFSTR, '#ffffff' AS Color, 'today' AS Label,
CURRENT_TIMESTAMP AS Value UNION ALL SELECT NULL AS REFSTR,
'#d8d8ff' AS Color, '1. yr' AS Label,
DATEADD(YEAR,1,CURRENT_TIMESTAMP) AS Value UNION ALL SELECT NULL AS
REFSTR, '#e0e0ff' AS Color, '2. yr' AS Label,
DATEADD(YEAR,2,CURRENT_TIMESTAMP) AS Value UNION ALL SELECT NULL AS
REFSTR, '#e8e8ff' AS Color, '3. yr' AS Label,
DATEADD(YEAR,3,CURRENT_TIMESTAMP) AS Value UNION ALL SELECT NULL AS
REFSTR, '#f0f0ff' AS Color, '4. yr' AS Label,
DATEADD(YEAR,4,CURRENT_TIMESTAMP) AS Value UNION ALL SELECT NULL AS
REFSTR, '#f8f8ff' AS Color, '5. yr' AS Label,
DATEADD(YEAR,5,CURRENT_TIMESTAMP) AS Value
```

The query results in the following dataset:

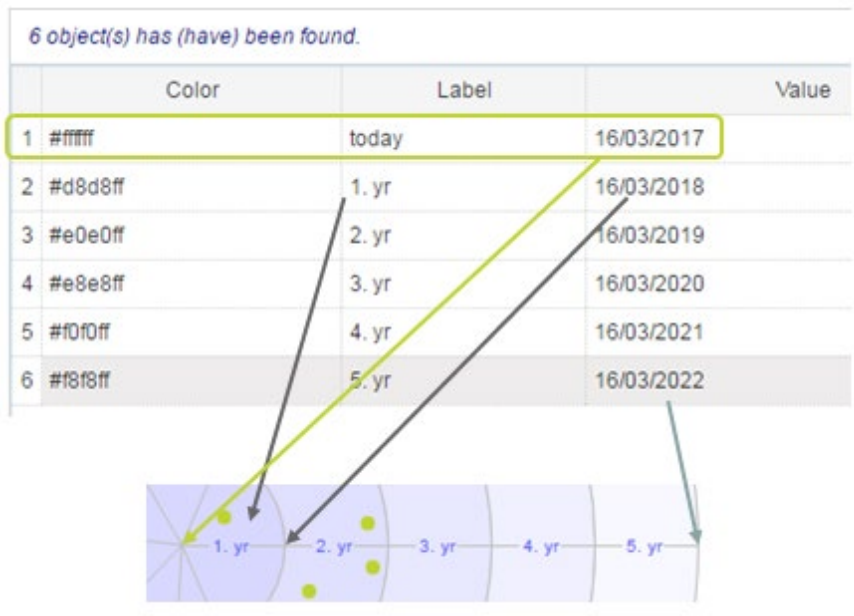
6 object(s) has (have) been found.

	Color	Label	Value
1	#ffffff	today	16/03/2017
2	#d8d8ff	1. yr	16/03/2018
3	#e0e0ff	2. yr	16/03/2019
4	#e8e8ff	3. yr	16/03/2020
5	#f0f0ff	4. yr	16/03/2021
6	#f8f8ff	5. yr	16/03/2022

In the root node of the report, the data is mapped to the attributes Value Column, Label Column and Color Column:



In the report, each `Value` returned in the dataset represents the border of a shell. The `Value` of the first row is the starting point of the scale. The `Label` and `Color` defined in that row are ignored. The `Value` in the following rows each define the endpoint of a shell. The `Label` and `Color` defined for a `Value` are used for the shell for that the `Value` marks the end point:



The object elements in the report are displayed along the shell according to the date defined for them as y value.

The shell query does not have to be related to the item query by refering to the same objects, but you must ensure that all possible values for placement on the shell axis that are returned for item objects fall into the defined range or the scale.

For example, the **Shell Query** definition for a circular roadmap report with the shells representing indicator values can be defined completely unrelated to the indicator values:

```
SELECT NULL As REFSTR, '0' As Value, 'very low' AS Label, '#E6EDD6'
As Color

UNION ALL

SELECT NULL As REFSTR, '1' As Value, 'very low' AS Label, '#E6EDD6'
As Color

UNION ALL

SELECT NULL As REFSTR, '2' As Value, 'low' AS Label, '#DBDBDB' As
Color

UNION ALL

SELECT NULL As REFSTR, '3' As Value, 'middle' AS Label, '#FCC8A9' As
Color

UNION ALL SELECT NULL As REFSTR, '4' As Value, 'high' AS Label,
'#FA9558' As Color

UNION ALL

SELECT NULL As REFSTR, '5' As Value, 'very high' AS Label, '#E15806'
As Color
```

or, if you are not sure which range is defined for the indicator as:

```
SELECT DISTINCT NULL As REFSTR,

CASE WHEN ind.VALUE <=1 THEN '0' ELSE CAST(ind.VALUE AS INT) END AS
Value,

CASE WHEN ind.VALUE > 1 AND CAST(ind.VALUE AS INT)= 1 THEN 'very
low' WHEN ind.VALUE > 1 AND CAST(ind.VALUE AS INT)= 2 THEN 'low'
WHEN ind.VALUE >1 AND CAST(ind.VALUE AS INT)=3 THEN 'middle'WHEN
ind.VALUE >1 AND CAST(ind.VALUE AS INT)= 4 THEN 'high' ELSE 'very
high' END AS Label,

CASE WHEN ind.VALUE > 1 AND CAST(ind.VALUE AS INT)= 1 THEN '#E6EDD6'
WHEN ind.VALUE > 1 AND CAST(ind.VALUE AS INT)= 2 THEN '#DBDBDB' WHEN
ind.VALUE >1 AND CAST(ind.VALUE AS INT)=3 THEN '#FCC8A9'WHEN
ind.VALUE >1 AND CAST(ind.VALUE AS INT)= 4 THEN '#FA9558' ELSE
'#E15806' END As Color

FROM INDICATOR ind

WHERE ind.NAME LIKE 'Criticality (aggr.)'
```

Both queries result in the same result dataset:

	Value	Label	Color
1	0	very high	#E6EDD6
2	1	very low	#C0C0C0
3	2	low	#FCC8A9
4	3	middle	#FA9558
5	4	high	#E15806
6	5	very high	#E15806

But the second query provides security that all values defined for the indicator are included into the shell definition. It also reduces the shell definition to the subset of shells that are required. If only indicator values between 0 and 3 are defined for the objects in the Alfabet database, the report will display only three instead of 5 shells and the sizing is optimized for display of differences between indicator settings.

The design of the shells can be further specified with attributes of the root node of the circular roadmap report assistant. For more information see Defining the Basic Design of the Circular Roadmap Report.

Defining the Sectors

The **Sector Query** typically returns objects from the Alfabet database, but this is not a requirement. The **Sector Query** must return a dataset with a key property that is different for each result in the return dataset and can be used to map the object elements unambiguously to a sector. The column of the dataset that returns the key property must be defined in the attribute **Sector Id Column** of the root node of the circular roadmap. If the sector query returns objects of the Alfabet database, and the result returns only one row per object, the `FIND` class of the Alfabet query or the `REFSTR` returned via the first definition in the `SELECT` clause of a native SQL query can be used to identify the sector. In this case, **Sector Id Column** does not need to be defined.

The columns of the result dataset can return information about the sectors that is used for display of the sectors in the circular roadmap report. The following attributes of the root node of the circular roadmap report can be mapped to columns in the result dataset:

Attribute	Column must return:	Mandatory	Exclusive use of attribute for this query
Section **Special Sector Data**			
Sector Id Column	A key property that is different in each row of the result dataset and that can be related	No, if the `FIND` class of the Alfabet query or the `REFSTR` returned via the first definition in the `SELECT` clause of a	Yes

Attribute	Column must return:	Mandatory	Exclusive use of attribute for this query
	with the object items in the circular roadmap report.	native SQL query is used to identify the sector, the setting is not required.	
Section **Data**			
Value Column	A numerical value that is used to calculate the size of the sectors. The circle size of a sector equals the share of its value on the overall sum of values. The numeric value is also used to calculate the horizontal deviation of the position of items to the middle axis of a sector, that means how far left or right of the middle axis an item is displayed. This calculation depend on the **Value Column** value of the sector definition and the **Axial Value Column** value of the item definition.	Yes. This attribute is required for calculating the position of items within a sector. To define equally sized sectors, the **Value Column** in the result dataset can be defined to return the same value in each row.	No, also used by **Shell Query** and **Item Query**.
Label Column	The text displayed as label of each sector outside the circle.	No, if not set, no labels are displayed.	No, also used by **Shell Query** and **Item Query**.
Tooltip Column	The text displayed as tooltip when the user moves the mouse over a sector.	No, if not set, no tooltips are displayed.	No, also used by **Item Query**.
Legend Group Column	A string that shall be displayed as heading for the legend entry defined with **Legend Entry Column** in the same row of the dataset. All legend entries that have the same **Legend Group Column** are grouped and displayed under the heading defined with **Legend Group Column**.	No, if not set, sectors are not included into the legend.	No, also used by **Shell Query** and **Item Query**.
Legend Entry Column	A string that shall be displayed for the sectors in the legend. The string is displayed as is, that means that if you would For example, explain the abbreviations used as labels for	No, if not defined, but **Legend Group Column** is defined, sector labels are listed in the legend group.	No, also used by **Shell Query** and

Attribute	Column must return:	Mandatory	Exclusive use of attribute for this query
	sectors, the column must return both the abbreviation and the full name with a separator.		**Item Query**.

The following example is a **Sector Query** that returns organisations subordinate to a selected base organisation. This **Sector Query** will be used in the description of the **Item Query** in combination with the indicator scale example for a **Shell Query** to explain mapping of object elements to shells and queries.

```
SELECT REFSTR, SectorId, Tooltip, Label, ThisGroup, Entry,
COUNT(ICTO) As Value

FROM(

   SELECT org.REFSTR as REFSTR, org.NAME As SectorId, org.SHORTNAME
   As Label, org.NAME As Tooltip, 'Sectors' As ThisGroup,
   org.SHORTNAME + ' = ' + org.NAME As Entry, icto.REFSTR As ICTO

   FROM ORGAUNIT org

   INNER JOIN ICTOBJECT icto ON icto.OWNER=org.REFSTR

   WHERE org.BELONGSTO = @BASE

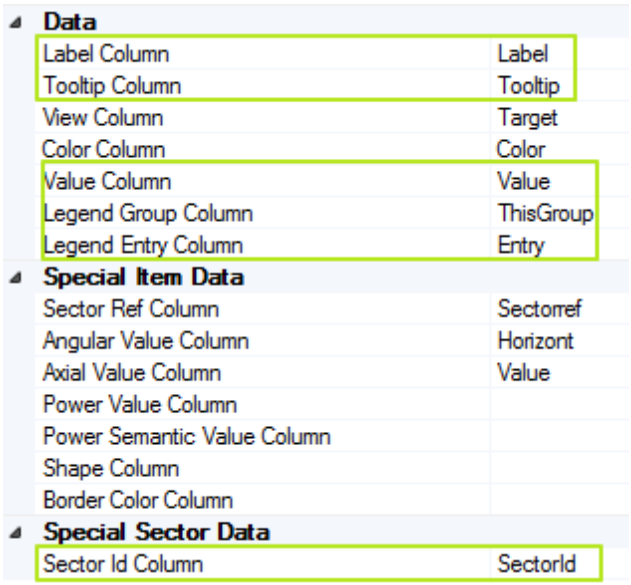
)x

GROUP BY REFSTR, SectorId, Label, Tooltip, ThisGroup, Entry
```

The column `Value` is defined in the attribute **Value Column** of the root node attributes. It returns the number of ICT Objects assigned to the organization. When rendering the graphic, this value will be used both for sizing of the sectors representing the organizations and for calculating how much left or right of the middle axis of the sector an items is displayed. The column SectorId returns the name of the organization, that is used to identify the sector for placing of the items. The column SectorId is define in the attribute Sector Id Column in the root node attributes.

The label of the sectors displays the short name of the organization. To provide the user with the full name of the organization, a tooltip column is added that displays the name of the organization when a user places the mouse in a sector and a legend group has been defined with a string concatenated from the shortname of the organization, an equal sign and the name of the organization.

The columns are mapped as follows:



The design of the shells can be further specified with attributes of the root node of the circular roadmap report assistant. For more information see Defining the Basic Design of the Circular Roadmap Report.

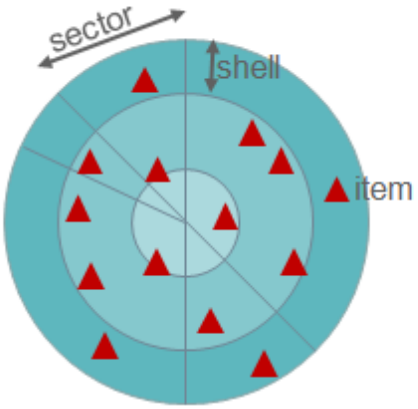
Defining the Items

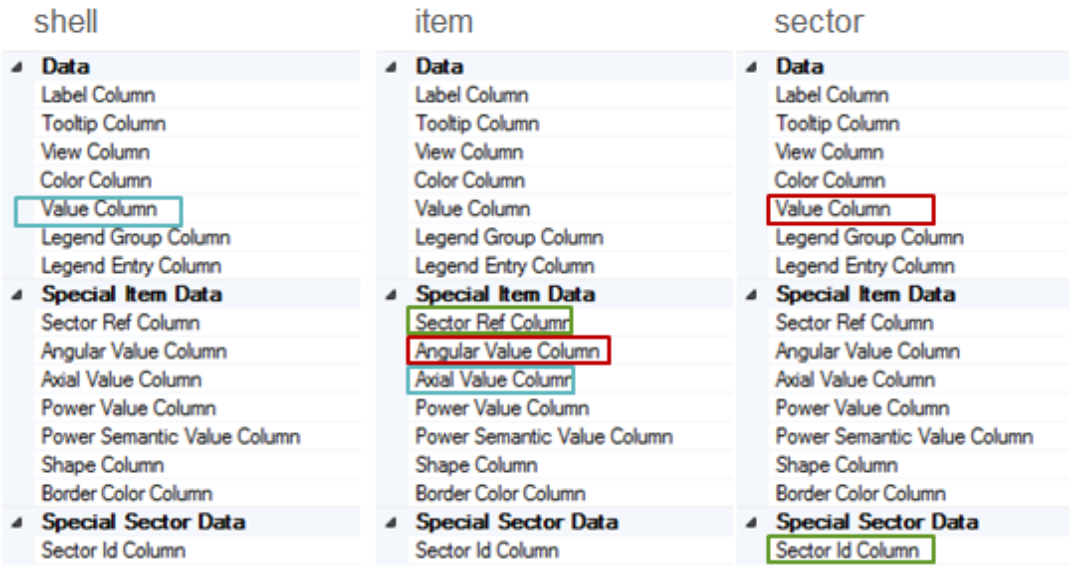
The items of the circular roadmap have two dimension of configuration. First, the positioning of the items in the report must be defined. You can then optionally define the items to be colored, sized and formed differently.

The positioning of items includes three mappings:

- The position relative to the shell axis must be defined.
- The mapping to a sector must be defined.
- The position of the item relative to the middle axis of the sector must be defined to avoid multiple items with the same shell axis value and sector mapping to be placed on top of each other.

To position the items, the columns in the result dataset of the Sector Query, Shell Query and Item Query must be set in relation to each other. This is performed by defining the columns in the result datasets to be related with each other and to map the related column to attributes in the root node of the circular roadmap report. The following columns of the result datasets are involved:





The **Value Column** defined for the **Shell Query** defines a scale either as date format or numerical value. The **Axial Value Column** of the **Item Query** must contain values that are in the range of this scale. For example, if the **Shell Query** defines the range of a year per shell for 2015 to 2025, and the **Axial Value Column** for an item returns July 1st, 2016, the item is placed in the middle of the shell for 2016.

The **Sector Id Column** of the **Sector Query** must return a unique value for each sector. The **Sector Ref Column** of the **Item Query** must return values that are identical to the values of the **Sector Id Column** to map each item to one of the defined sectors. For example, of the sectors display domains and the **Sector Id Column** contains the names of the domains, the **Sector Ref Column** of the **Item Query** must return a domain name for each item in the **Sector Ref Column**.

The **Value Column** of the **Sector Query** defines the size of the sectors in the graphic, but also the size of the sector for placement of the items left and right of the middle axis of the sector. The **Angular Value Column** defined for the item in the **Item Query** is used together with the **Value Column** of the **Sector Query** to define the exact placement of the item in the sector. For example, if the number of items in a sector is used to define the sector size, a row count for

items returned for the same sector in the result dataset can be used to specify a different number for each item within the range of the overall number of items in the sector.

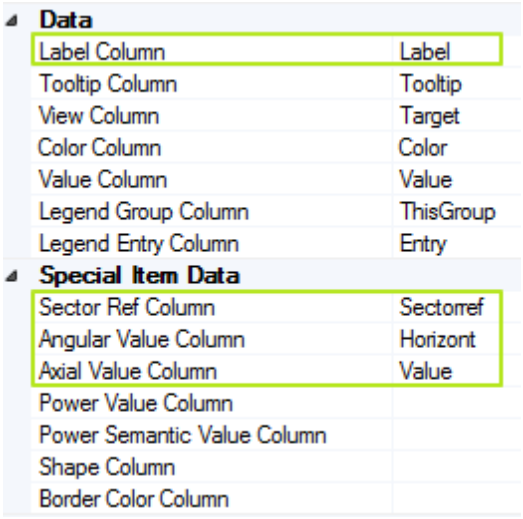
The **Item Query** to be used with the **Shell Query** and the **Sector Query** in the examples in the sectons above defines applications owned by the organizations displayed as sectors. The placment in the shells depends on an indicator value:

```
SELECT REFSTR, Label, Sectorref, Value, ROW_NUMBER() OVER (PARTITION
BY Sectorref ORDER BY Label) - 0.5 As Horizont

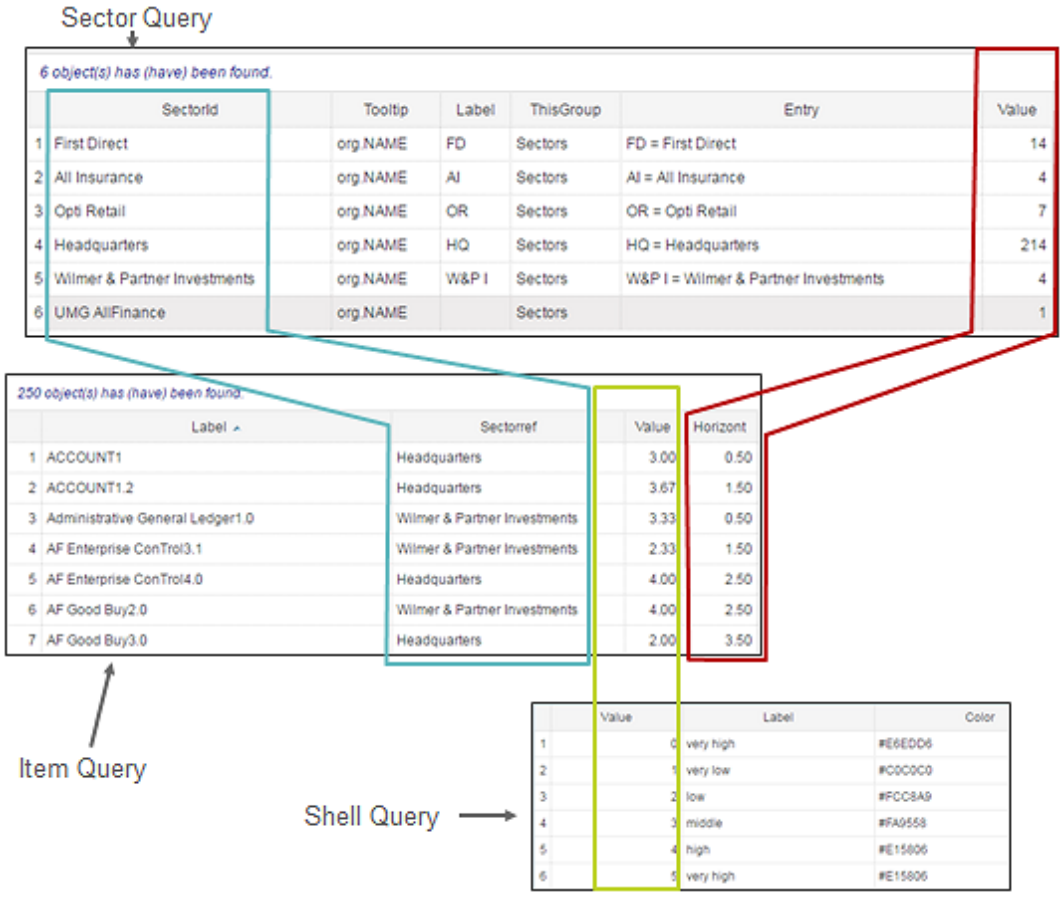
FROM(

SELECT app.REFSTR as REFSTR, app.NAME + app.VERSION As Label,
org.NAME AS Sectorref, ind.VALUE As Value, NULL As Horizont FROM
APPLICATION app INNER JOIN ICTOBJECT icto ON app.ICTOBJECT =
icto.REFSTR INNER JOIN ORGAUNIT org ON icto.OWNER=org.REFSTR INNER
JOIN INDICATOR ind ON ind.OBJECT = app.REFSTR WHERE org.BELONGSTO =
@BASE AND ind.NAME LIKE 'Criticality (aggr.)')x
```

The columns for the result dataset are mapped to the attributes in the root node of the circular roadmap as follows:



The result dataset of the **Item Query** is mapped to the result dataset of the **Shell Query** and the **Sector Query** to render the report:



The indicator that is used to define the position of the items in the shells is a calculated indicator that is returned in the `Value` column if the **Item Query**. The position of the items is Therefore, within the shells and not always exactly on the borders of the shells.

The names of the organisations returned in the `Sectorref` column of the **Item Query** each match a name of an organisation returned in the `SectorId` column of the **Sector Query**, mapping the items to a defined sector. Within the sector, the value defined for `Horizont` is used together with the number defined in the **Sector Query** in the column `Value` to define the relative position of the items with regard to the middle axis of the sector. In the example above, the sector `Wilmer & Partner Investments` has a `Value` of 4. Three of the results for items mapped to the sector are included into the example graphic. They have `Horizont` values 0.50, 1.50 and 2.50. The values are calculated as the row number within the result set of the sector minus 0.5 to make sure that the items number 4 is not placed directly on the border. These values are all different and are all in the range of 4.

Items that are defined for a circular roadmap can be presented as geometric shape that may differ in different size, shape and coloring for each item. Alternatively, items can be represented by icons. In the **Item Query**, you can define the design of the items per item. The column of the result is then defined in the attributes of the root node of the circular roadmap report. The following attributes of the root node of the circular roadmap report can be mapped to columns in the result dataset:

Attribute	Column must return:	Mandatory	Exclusive use of attribute for this query
Section **Special Item Data**			
Sector Ref Column	Each value returned in this column must match a value returned in the column **Sector Id Column** of the **Sector Query** to map the item to a sector. If no **Sector Id Column** is defined for the Sector Query, but sectors represent objects of the objet class that is the `FIND` class of the Alfabet query or for that `REFSTR` values are returned in the first argument of the `SELECT` clause of the **Sector Query**, the column must return the `REFSTR` value of one of the sectors.	Yes	Yes
Angular Value Column	The **Angular Value Column** must return a number that is used together with the **Value Column** of the **Sector Query** to define the exact placement of the item in the sector.	Yes	Yes
Axial Value Column	The **Value Column** defined for the **Shell Query** defines a scale either as date format or numerical value. The **Axial Value Column** of the **Item Query** must contain values that are in the range of this scale.	Yes	Yes
Power Value Column	A numeric value that is used to calculate the size of the item. The higher the value in the **Power Value Column**, the bigger the size of the item. The absolute size range for sizing of objects is defined with the attributes **Min Item Size** and **Max item Size** in the section **Common**.	No, if not set, all items are equally sized. If items are represented by icons, this setting is ignored.	Yes
Power Semantic Value Column	If **Power Value Column** is defined to size items differently and the attribute **Add Power To Tooltip** in the section **Common** is set to `True`, the value in the **Power Value Column** is added in parantheses to the tooltip text at the end of the string defined with **Tooltip Column**. If you would like to display a string explaining the power value instead of the numeric value, you can define a string in the dataset of the **Item Query** and set **Power Semantic Value Column** to the name of the respective	No, if not set, the numerical vaule will be added to the tooltip if the attribute **Add Power To Tooltip** in the section **Common** is set to `True`	Yes

Attribute	Column must return:	Mandatory	Exclusive use of attribute for this query
	column. The string defined in that column will be added to the tooltip instead of the numerical value.		
Border Color Column	A HTML compliant color definition for coloring of the item border if the item is displayed as geometric shape.	No, if items are displayed as geometric shapes and this attribute is not set, the item border is transparent. If items are represented by icons, this setting is ignored.	Yes
Section **Data**			
Label Column	The text displayed as label next to the item. Labels are only displayed if the attribute **Show Item Label** in the section **Common** is set to **True**.	No, if not set, no labels are displayed.	No, also used by **Shell Query** and **Sector Query**.
Tooltip Column	The text displayed as tooltip when the user moves the mouse over an item.	No, if not set, the label is displayed as tooltip.	No, also used by **Sector Query**.
View Column	Definition of a link target that shall open if a user double-clicks on an item. The format is `View=ViewType:ViewName` The `ViewType` can be one of the following: • ***Report*** for a configured report • ***GraphicView*** for a standard Alfabet view • ***ObjectView*** for an object profile `ViewName` is the name of the view.	No, if not set, navigation is deactivated.	Yes

Attribute	Column must return:	Mandatory	Exclusive use of attribute for this query
	For detailed information about the required configuration to activate navigation, see Defining Navigation from the Report to Alfabet Views.		
Color Column	A HTML compliant color definition for coloring of the item, if the item is displayed as geometric shape..	No, if items are displayed as geometric shape and this attribute is not set, a color is assigned randomly. All items are equally colored. If items are represented by icons, this setting is ignored.	No, als used by **Shell Query**.
Legend Group Column	A string that shall be displayed as heading for the legend entry defined with **Legend Entry Column** in the same row of the dataset. All legend entries that have the same **Legend Group Column** are grouped and displayed under the heading defined with **Legend Group Column**.	No, if not set, no legend for items is displayed.	No, als used by **Shell Query** and **Sector Query**.
Legend Entry Column	A string that shall be displayed for the items in the legend. If set, the string is displayed after a graphic combining all design options except the size defined for the item. If the same string is defined for multiple design options, the first design option found for the string is displayed for the entry.	No, if not set and **Legend Group Column** is set, a separate legend entry will be added for each item.	No, als used by **Shell Query** and **Sector Query**.
Common Section			
Shape Source > **Shape Name Column**	The column defined with this attribute must return one of the following values to define a shape for the item: `Rectangle`, `Triangle`, `Circle`, `Diamond` or `FlippedTriangle`. Please note that this attribute is only available in the context of specific settings for Shape Source that are described in detail in the section Defining the Design of the Items in the Circular Roadmap Report.	No, by default items are displayed as circles. This setting is only required if items shall be displayed in different geometric shapes. If items are all represented by the same geometric shape or	Yes

Attribute	Column must return:	Mandatory	Exclusive use of attribute for this query
		by an icon, this setting is not required.	
Shape Source > Shape Name Column	The column defined with this attribute must return the name of an icon from the 22x22 icon gallery. Please note that this attribute is only available in the context of specific settings for Shape Source that are described in detail in the section Defining the Design of the Items in the Circular Roadmap Report.	No, by default items are displayed as circles. This setting is only required if items shall be displayed in different geometric shapes. If items are all represented by the same geometric shape or by an icon, this setting is not required.	Yes

The complete settings for the various options to represent items either via geometric shapes or via icons and either static or via the query are described below.

The design of the shells can be further specified with attributes of the root node of the circular roadmap report assistant. For more information see Defining the Basic Design of the Circular Roadmap Report.

Defining the Design of the Items in the Circular Roadmap Report

The items in the circular roadmap can be represented either by icons or by geometric shapes. The following options are available:

- A geometric shape is assigned per item via the **Item Query**.
- The same geometric shape is used for all items. This is the default behaviour. The default shape is a circle.
- An icon from the 22x22 icon gallery is assigned per item via the **Item Query**.
- The icon of the object represented by the item is used to display the item. The following applies:
  - All objects that have an icon assigned are represented by the object's icon.
  - If no icon is assigned to the object, the object class icon defined in the relevant class settings is used.
  - If the item is not representing an object, items are displayed as rectangles.

The display of items is mainly configured with the attribute **Shape Source** in the section **Common** of the attributes of the root node of the report assistant. The attribute is expandable and different settings are required for each type of graphic item representation. In addition, other attributes or results from the **Item**

Query might be required. The required configurations are listed in the following separately for each type of graphic item representation.

To display all items with the same geometric shape:

1) In the root node attributes of the report assistant, expand the **Shape Source** attribute.
2) Set the following attributes in the order they are listed here:
   - **Shape Type**: Select `GeometricShape`.
   - **Shape Source**: Select `ReportDefinition`.
   - **Fixed Shape**: Select a shape from the drop-down list.
3) By default, all items are displayed in the same, randomly selected color. Optionally, you can define the background color and border color of the items per item in the query defined with the element **Item Query**. Colors must be returned as HTML compliant color code. The name of the columns returning the color definitions must be entered into the attributes **Color Column** and **Border Color Column** in the root node of the report assistant.
4) Optionally, change the size of your items with one of the following settings:
   - If all items shall be displayed with the same size, you can change the size of the item by changing the atribute **Min. Item Size** in the root node of the report assistant.
   - If items shall be differently sized, the query defined for the Item Query element must include a column that returns a numeric value that is used to calculate the size of the item. The higher the value in the column, the bigger the size of the item. The name of the column must be entered into the attribute **Power Value Column** in the root node of the report assistant. The absolute size range for sizing of objects is defined with the attributes **Min. Item Size** and **Max. Item Size** in the root node of the report assistant.

To display items with different geometric shapes:

1) In the **Item Query**, add a column that returns one of the following values to define a shape for each item: `Rectangle`, `Triangle`, `Circle`, `Diamond` or `FlippedTriangle`.
2) In the root node attributes of the report assistant, expand the **Shape Source** attribute.
3) Set the following attributes in the order they are listed here:
   - **Shape Type**: Select `GeometricShape`.
   - **Shape Source**: Select `Query`.
   - **Shape Name Column**: Enter the name of the column in the **Item Query** that returns the shape definition.
4) By default, all items are displayed in the same, randomly selected color. Optionally, you can define the background color and border color of the items per item in the **Item Query**. Colors must be returned as HTML compliant color code. The name of the columns returning the color definitions must be entered into the attributes **Color Column** and **Border Color Column** in the root node of the report assistant.
5) Optionally, change the size of your items with one of the following settings:
   - If all items shall be displayed with the same size, you can change the size of the item by changing the atribute **Min. Item Size** in the root node of the report assistant.

- If items shall be differently sized, the query defined for the Item Query element must include a column that returns a numeric value that is used to calculate the size of the item. The higher the value in the column, the bigger the size of the item. The name of the column must be entered into the attribute **Power Value Column** in the root node of the report assistant. The absolute size range for sizing of objects is defined with the attributes **Min. Item Size** and **Max. Item Size** in the root node of the report assistant.

To display the object icon as item:

1) In the root node attributes of the report assistant, expand the **Shape Source** attribute.
2) Set the following attributes in the order they are listed here:
   - **Shape Type**: Select `Icon`.
   - **Shape Source**: Select `Object`.

To display items with different icons selected from the 22x22 icon gallery:

1) In the **Item Query**, add a column that returns the name of an icon from the 22x22 icon gallery.
2) In the root node attributes of the report assistant, expand the **Shape Source** attribute.
3) Set the following attributes in the order they are listed here:
   - **Shape Type**: Select `Icon`.
   - **Icon Source**: Select `Query`.
   - **Icon Name Column**: Enter the name of the column in the query defined with the element **Item Query** that returns the icon name.

Defining Connections Between Items

To display connections between items in the report, all relevant data for rendering the connections must be provided via th optional **Connections Query**. The **Connection Query** must at least return the `REFSTR` of the object that is represented by the item the connection is coming from and the `REFSTR` of the object represented by the item the connection is ending at. That means that both values must be identical to a `REFSTR` returned with the first `SELECT` statement of the native SQL query for definition of the **ItemQuery**.

The columns in the result dataset of the **Connections Query** must then be mapped to attributes in the root node of the report assistant that are available when expanding the attribute **Connection Query Columns** in the section **Data**.

In addition to the mandatory definition of the start item and end item of the connection, the query can return styling parameters, legend texts and a link target to activate navigation from the connection to an Alfabet view. The columns must be mapped to the following sub-attributes of the attribute **Connection Query Columns**:

Attribute	Column must return:	Mandatory
Start Ref Column	The `REFSTR` of the object represented with by the item the connection is starting at. The `REFSTR` must be identical to a `REFSTR` returned in the first `SELECT` argument in the **Item Query** when written in native SQL or the `FIND` class in an Alfabet query.	Yes
End Ref Column	The `REFSTR` of the object represented with by the item the connection is ending at. The `REFSTR` must be identical to a `REFSTR` returned in the first `SELECT` argument in the **Item Query** when written in native SQL or the `FIND` class in an Alfabet query.	Yes
Line Style Column	The style of the connecting line. Allowed values are `Solid`, `Dash`, `DashDot`, `DashDotDot` and `Dot`.	No, by default connections are displayed as solid lines (`Solid`).
Line Weight Column	The width of the connecting line as integer.	No, the default value is 1.
Line color Column	The color of the connecting line as HTML compliant color code.	No, by default connections are displayed as black lines.
Start Arrow Style Column	The style of the start point of the connection. Allowed values are `None`, `Angle`, `Triangle`, `Square`, `Circle` and `Rhomb`. Navigation from a connection and display of a tooltip is only available if the user points to either the start or end point of the connection. If you would like to activate navigation or the display of a tooltip, definition of a start arrow style will make it easier for the user to find the connection start.	No, by default connections are displayed with no extra decoration at the start point (`None`).
End Arrow Style Column	The style of the end point of the connection. Allowed values are `None`, `Angle`, `Triangle`, `Square`, `Circle` and `Rhomb`. Navigation from a connection and display of a tooltip is only available if the user points to either the start or end point of the connection. If you would like to activate navigation or the display of a tooltip, definition of an end arrow style will make it easier for the user to find the connection end.	No, by default connections are displayed with no extra decoration at the end point (`None`).
Tooltip Column	A string that is displayed as tooltip when the user moves the cursor over the start or end point of the connection.	No, by default no tooltips are displayed.

Attribute	Column must return:	Mandatory
Link Ref Column	The `REFSTR` of an object. If this column is specified, navigation from the start and end point of the connection is activated. When the user clicks and holds the end point, a preview of the object with the `REFSTR` returned in the **Link Ref Column** opens. The user can navigate to the object profile or object cockpit of the object by clicking the **Show Details** button in the preview. If **View Column** is defined, the defined navigation target opens instead of the object profile or object cockpit of the object.	No, if not set, navigation is deactivated.
View Column	Definition of a link target that shall open if a user double-clicks on an item. The format is `View=`*`ViewType`*`:`*`ViewName`* The `ViewType` can be one of the following: • ***Report*** for a configured report • ***GraphicView*** for a standard Alfabet view • ***ObjectView*** for an object profile `ViewName` is the name of the view. For detailed information about the required configuration to activate navigation, see Defining Navigation from the Report to Alfabet Views.	No, if not set, but **Link Ref Column** is set, navigation is opening the object profile or object cockpit of the object defined with **Link Ref Column**.
Legend Group Column	A string that shall be displayed as heading for the legend entry defined with **Legend Text Column** in the same row of the dataset. All legend entries that have the same **Legend Group Column** are grouped and displayed under the heading defined with **Legend Group Column**. A legend is only displayed for connections if both **Legend Group Column** and **Legend Text Column** are defined.	No, if the attribute is not defined, the legend does not display entries for connection styles.
Legend Text Column	A string that shall be displayed next to the style of the connection in the legend of the report. A legend is only displayed for connections if both **Legend Group Column** and **Legend Text Column** are defined.	No, if the attribute is not defined, the legend does not display entries for connection styles.

Defining the Basic Design of the Circular Roadmap Report

The basic design of the report is designed directly in the attributes of the root node element of the **Report Assistant** explorer in the section **Common**:

Attribute	Description
Width	Defines the overall width of the resulting report in mm (1 mm = 4 pixel).
Height	Defines the overall height of the resulting report in mm (1 mm = 4 pixel).
Add Power To Tooltip	If set to `True`, the value defined in the column of the **Item Query** dataset defined as **Power Semantic Value Column** in the section **Special Item Data** is written in parentheses to the end of the tooltip. If **Power Semantic Value Column** is not defined, the numerical value from the column of the **Item Query** dataset defined as **Power Value Column** is written in parentheses to the end of the tooltip.
Left Item - Left Label	If set to `False`, all item labels are displayed on the right of the item. If set to `True`, the labels of the items on the left side of the graphic are displayed left of the corresponding item. Defines the color of the item labels. This setting is only relevant if **Show Item Label** is set to `True`.
Draw Shell Grid	If set to `True`, shells are separated with lines.
Draw Sector Grid	If set to `True`, sectors are separated with lines.
Show Item Label	If set to `True`, labels are displayed for items.
Plot Area Background Color	Defines the background color of the circular roadmap report, that means the color of the area surrounding the circle.
Plot Area Border Color	Defines the border color of the area surrounding the circular roadmap report.
Default Shell Color	Defines the coloring that shall be applied to shells if no color is defined in the **Shell Query**.
Sector Label Color	Defines the color of the sector labels.

Attribute	Description
Shell Label Color	Defines the color of the shell labels.
Item Label Color	Defines the color of the item labels. This setting is only relevant if **Show Item Label** is set to `True`.
Grid Color	Defines the color of grid lines in the report. Defines the color of the item labels. This setting is only relevant if **Draw Sector Grid** and/or **Draw Shell Grid** is set to `True`.
Plot Sector Line Extension	If set to `False`, grid lines for sectors end at the border of the circle. If set to `True`, the grid lines for sectors are extending the border of the circle. This setting is only relevant if **Draw Sector Grid** is set to `True`.
Min Item Size	The minimum size of items in the report. If the attribute **Power Value Column** in the section **Special Item Data** is not set, this is the size of all items in the report.
Max Item Size	The maximum size of items in the report if sizing is performed according ot the values in the column of the **Item Query** dataset that is defined with the attribute **Power Value Column** in the section **Special Item Data**.

Defining Reports to Analyse Data Cubes

Cubes are multi-dimensional blocks of facts that are structured by dimensions. A dimension is a facet of your enterprise relevant for analysis, whereas a fact is a measurement related to the elements within each dimensions.

For example, if you want to analyse the cost of applications in the organizations of your enterprise, typical dimensions are Application, Organization, Time, and Cost Types. Each organization of the enterprise is an element of the dimension "Organization". Elements of the dimension Time may be For example, month, or year.

The costs are the facts that are stored in the cube in relation to the dimensions.

A cube allows to aggregate data along the dimensions. The dimensions can be structured hierarchically, and the facts can be aggregated on the various levels of the hierarchy. Each element of a dimension can also have various attributes, and aggregation can be performed by aggregating elements wich are identical in a defined attribute.

Cubes are defined outside of Alfabet in the Microsoft® Business Analysis Services that are part of the distribution of Microsoft SQL Server. The definition of data cubes is independent from the Alfabet database. Data in a cube can be defined independent of any data source or can take over data from one or multiple databases. Therefore, cubes can be build on data from the Alfabet database in combination with data from any other data source or with data that is added manually to the cube.

The data in the cube represents a snapshot of the data in the source databases and must be updated in regular intervals to reflect changes made in the underlying source database. Regular update intervals can be configured for a cube in the Microsoft® Business Analysis Services.

Alfabet provides an interface for the analysis and graphical display of data in the cube. The analysis is done with the embedded third party components DevExpress®. Data in a cube can be displayed in a table as well as in a chart or a portfolio and the data can easily be structured by dimensions and aggregated along the axes of the report. The user can drill-down from the analysis view to the object profile of Alfabet objects.

To analyse the data that is created and maintained by the Alfabet users via the user interface in a cube, you must mainly work in third-party components either outside or embedded to the Alfabet components:

- The cube is created and updated in the Microsoft® Business Analysis Services that is a component of Microsoft SQL Server. For information about the creation and management of cubes, see the documentation of the Microsoft® Business Analysis Services version you are working with.

  The cube can take over data from any external source. The Alfabet database on Oracle database servers can also be used as a data source.

- The analysis of data is performed within a Pivot grid analysis view based on the embedded component DevExpress®embedded into the Alfabet components. The Alfabet Web Application must be configured to allow PivotTable handling. For more information about the required settings, see *Prerequisits for Using DevExpress®* in the *Technical Requirements*.

To analyse the cube designed with Microsoft® Business Analysis Services with one of the third party components based Pivot grid analysis views on the Alfabet interface, a configured report must be defined in Alfabet Expand that fetches the data from one or multiple cubes of a cube project for analysis.

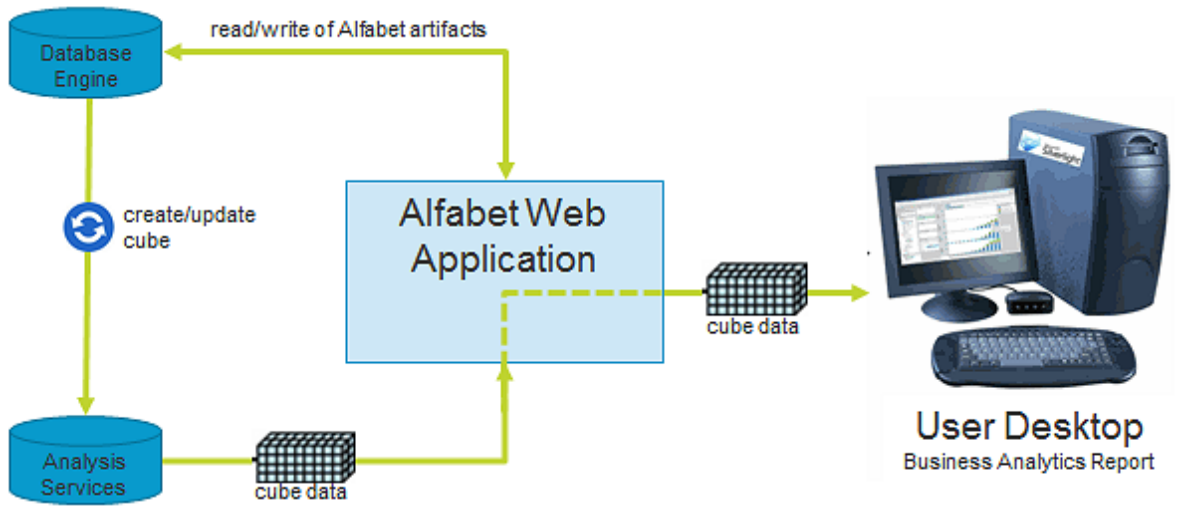


FIGURE: Overview of the components involved in cube reporting

Cube reports are designed in the **Report Assistant**. For information about how to open the **Report Assistant**, see Creating a New Graphic Report. For general information about how to work with the **Report Assistant**, see Configuring the Report with the Report Assistant.

Defining the Access to the Cube Data in the Report

In the **Report Assistant**, set the following attributes to define access of the Alfabet Web Application to the cube that shall be analysed.

Attribute	Description
Data Source	Enter the name of the Microsoft® SQL Server hosting the cube in the Microsoft® Business Analysis Services. All or part of the specification can be defined as server variable. Server variables are substituted with the value defined for the server variable in the server alias configuration of the Alfabet Web Application. This enables the same configuration of the report to be used in different environments with a different Microsoft® SQL Server hosting the cube in the Microsoft® Business Analysis Services. For information about how to define server variables, see Using Server Variables in Configurations in the chapter Getting Started with Alfabet Expand.
Extended Parameters	Optionally, you can define a string to add parameters required for connecting to the database to the default connection string used for database connection.
Roles	In the Microsoft® Business Analysis Services, you can restrict access to cube data based on roles. If you have used roles when defining the cube, you can specify the role that shall be used by the Alfabet Server to access the cube in this attribute.
Initial Catalog	Enter the name of the project containing the cube or cubes that shall be analysed.
Cube	Enter the name of the cube that shall be available via the report.
Alfabet Ref Fields	To activate navigation from the Pivot grid analysis to the object profile of Alfabet objects, the REFSTR of the object class must be available as field in the dimension of the cube. The field referencing the object in the cube must be specified fully qualified in the **Alfabet Ref Fields** attribute. The qualifiers must be written in squlare brackets. Dimension fields must start with $. For example,: `[$Application].[REFSTR]` Multiple fields can be specified as comma separated list.

Providing Context Sensitive Online Help for the Pivot Grid Analysis View of the Cube Based Report

If you would like the user to be informed about the functionality of the Pivot grid analysis view via the context sensitive help, you can do the following:

- An Alfabet specific standard help file is available. To display the standard help, enter `PivotTableAnalysis.html` in the **Help Index** attribute.
- A customer specific help can be opened. The method for defining customer specific help is described in the section Specifying Custom Help for a Configured Report.

Defining Dynamic Lane Reports

Dynamic lane reports are designed in the **Report Assistant**. For information about how to open the **Report Assistant**, see Creating a New Graphic Report. For more information about how to work with the **Report Assistant**, see Configuring the Report with the Report Assistant.

The content and layout of a dynamic lane report is defined by adding elements to the explorer of the **Report Assistant** and setting the attributes in the attribute pane of the **Report Assistant** window.

The content and layout of a lane report is defined in the root node element.

The following table lists the explorer node elements that can be configured to specify the content of the report as well as provides information about the purpose of each sub-element:

Explorer Node Element	Required to Configure:
Root Node of the report	Definition of the layout of the report.
Lane	Definition of a new lane added to the report. A lane consists of a row of objects and optionally a definition of a link to the next lane in the report. The next lane is the lane right of the current lane.
Node	Definition of the layout of the object row of the lane. The Node element is a child of the Lane element.
Link	Definition of the layout of the connections between this object row and the object row right of this object row. The Link element is a child of the Lane element.
Query	If defined as child of the Node element, the Query element defines the objects displayed in the object row of the lane. If defined as child of the Link element, the Query element defines the kind of connections displayed in the diagram between the object rows.

Explorer Node Element	Required to Configure:
Color Rule	Definition of the colors used in the current cell of the grid report and the rules that define which objects are displayed in which color. For more information about the definition of color rules, see Defining Color Rules.
Indicator Rule	Definition of one or multiple icons displayed in the boxes representing the objects in the current cell of the lane report. The icons can either represent an indicator or any aspect defined via a query. For more information, see the section Defining Indicator Rules.

UKA new dynamic lane report is available in which the number of lanes is not fixed but dynamically specified via the query. The configured report is of the type Custom and based on the new template DynamicLaneReport. Please note the following: • In the report assistant, a Query node must be added to the explorer to define the content of the configured dynamic lane report via either Alfabet query language or native SQL. The query must return a grouped dataset. The first grouping level defines the lanes, the second grouping level defines the nodes on the lane and the third grouping level defines connections between the lanes where one of the columns of the dataset must return the REFSTR of one of the objects in the next lane for that the connection is to be established. • The respective column must be mapped to the attribute Link To Column in the root node of the dynamic lane report. Connections can also be re-directed to the previous lane. In this case, a dataset column returning the value PREV for all connections that shall be redirected to the previous lane must be included into the query result table and the column must be mapped to the Link Direction Column attribute in the root node of the dynamic lane report. • The root node of the report assistant provides attributes to configure the look of the lane report, the coloring and line styles either by mapping data from the query to attributes or by direct definition in the attribute. • Drill-down to the object profile of the object represented in the lanes is provided. Drill-down from connections is provided if the connection represents an object is defined for the connection. • This functionality will be documented with a future patch release.

Defining a Gallery Report

Gallery reports are designed in the **Report Assistant**. For information about how to open the **Report Assistant**, see Creating a New Graphic Report. For more information about how to work with the **Report Assistant**, see Configuring the Report with the Report Assistant.

The report assistant of the gallery report does not have an explorer. All attributes are on the root level and are displayed as a list of attribute fields for defining the configured report.

The following information is available:

- Defining the Basic Design of the Gallery Report
- Defining the Content of the Gallery Report

Defining the Basic Design of the Gallery Report

The basic design of the gallery report, like For example, the background color and any design that applies to all content independent from the displayed data is defined in the section **Common**:

Attribute	Description
Report Background Color	Select a color for the background between object boxes for the configured report from the color selector. For information about how to select colors, see Defining Color Attributes.
Area Margin	Define the spacing between the border of the graphic and the object boxes in the report in pixel.
Rows	Define how many rows shall be displayed for the gallery report. The object boxes resulting from the result dataset of the query of the report are distributed equally among the rows. if the graphic size exceeds the screen size in length or in width, scrolling might be required to view all objects of the report.
Node Width	Define the width of the individual object boxes in pixel.
Node Height	Define the height of the individual object boxes in pixel.
Node Radius	Define how much the edges of the object boxes are rounded off. If you define 0, the object boxes are displayed as squares.
Space Between Nodes Vertical	Define the vertical spacing between the object boxes in pixel.
Space Between Nodes Horizontal	Define the horizontal spacing between the object boxes in pixel.
Node Background Color	Select a default color for coloring of the object boxes for which no object specific coloring is defined via the query of the configured report. For information about how to select colors, see Defining Color Attributes.
Node Text Color	Select a default text color for coloring of the object boxes for which no object specific text coloring is defined via the query of the configured report. For information about how to select colors, see Defining Color Attributes.

Attribute	Description
Node Border Color	Select a default border color for coloring of the object boxes for which no object specific border coloring is defined via the query of the configured report. For information about how to select colors, see Defining Color Attributes.
Show Class Icon	Set to `True` if you want to display a class specific icon in front of the text in the middle of the object boxes. Please note the following: • If no text is defined for the boxes via the query of the configured report and the attribute **Image Column**, icons are not displayed, even if **Show Class Icon** is set to `True`. • If the report is based on a native SQL query and the query results are not referencing an object class either by returing the `REFSTR` of objects as first argument of the `SELECT` statement or via a `SetRowReference` instruction, icons are not displayed, even if **Show Class Icon** is set to `True`. • If object specific icons are defined for single objects in the result dataset, these icons are displayed instead of the class icon. • If a stereotype is defined via the query and the attribute Stereotype Column is set, the icons defined for the object class stereotypes are displayed instead of the icon for the object class.
Shadow	Set to `True` if you want to display object boxes with a shadow.

Defining the Content of the Gallery Report

The content of the gallery report and all object specific design and information is defined in a native SQL or Alfabet query in the section **Query** of the gallery report attributes. The content is then mapped to attributes in the section **Data** of the gallery report attributes to map the information to specific parts of the gallery report design. For general information about how to map the query result dataset to attributes of a configured report, see Mapping of Query Data to Attributes.

For each row in the result dataset a box is added to the report. The underlying technology assigns the box to the object that is the `FIND` class of the Alfabet query or the class for the the first argument of the `SELECT` statement returns a `REFSTR`. That means that For example, the assignment of a class icon to the text in the boxes is derived from this object and the default navigation by double-clicking on an object box opens the object profile of this object.

The following special cases may apply:

- The Alfabet query language instruction `SetRowReference` can be used in both Alfabet queries and native SQL queries to specify any other object class for that data is included into the result dataset to the referenced object class represented in the object boxes of the report.
- If the first argument of the `SELECT` statement returns the `REFSTR` values for multiple object classes, class icons and navigation is set according to the correct object class for each object box.

Additional information can be displayed in each corner of the object box. The information has to be added to the query results and the column of the result dataset mapped to the respective attribute **Column 1** - **Column 4** of the gallery report.

Each box corner can be regarded as a cell in a tabular report, that means that color assignment and picture assignment via Alfabet query language instructions can be used to design the box corners. The column names defined for the box corners are displayed as tooltip when the user moves the cursor over the information displayed in the corner.

The following data can be defined via the query of the configured report and mapped to the following attributes of the configured report to be used for the design of the gallery report:

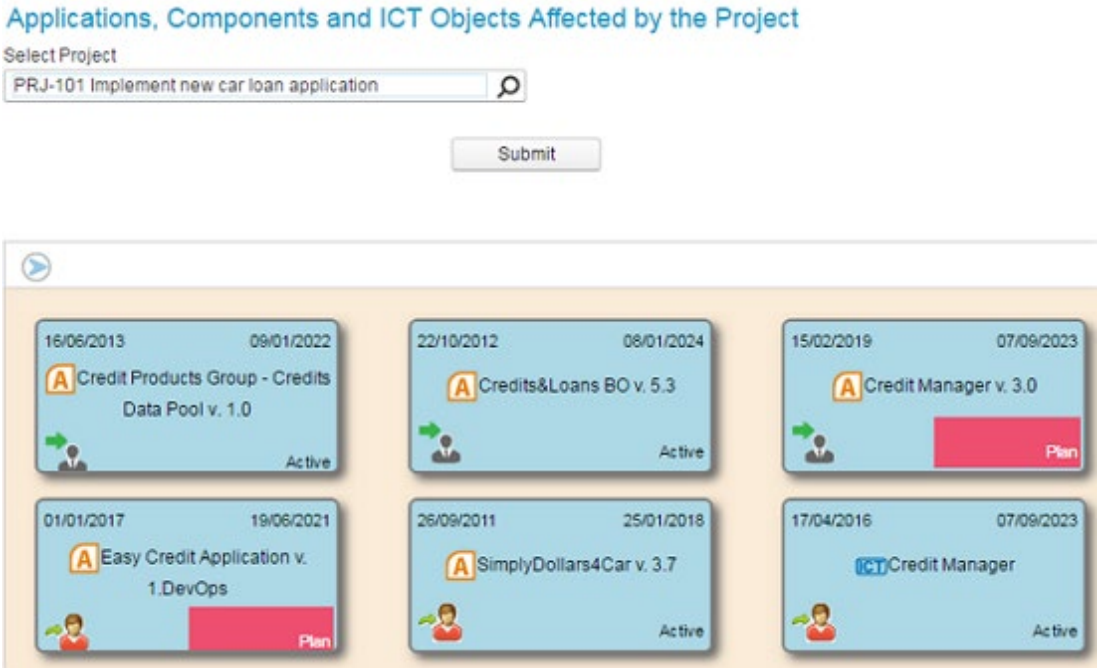
Attribute	Description	Expected Query Output
Image Column	Defines the name of the column containing the text to be displayed in the center of the object boxes.	A string.
Stereotype Column	Defines the name of the column containing the name of the stereotype of the current object. If this attribute is defined, and the attribute Show Class Icon is set to True, the stereotype icon is displayed instead of the object class icon left to the text in the center of the object boxes.	The value of the **Stereotype** attribute of the object.
Node Background Color Column	Defines the name of the column containing a HTML compliant color definition for coloring of the background of the object boxes. If this attribute is not set, all object boxes are displayed with the background color defined with the attribute **Node Background Color**.	An HTML compliant color code, like For example,: `#11A6D0`
Node Text Color Column	Defines the name of the column containing a HTML compliant color definition for coloring of the text in the object boxes. If this attribute is not set, the color defined with the attribute **Node Text Color** is used	An HTML compliant color code, like For example,: `#11A6D0`

Attribute	Description	Expected Query Output
	for the text in all object boxes.	
Node Border Color Column	Defines the name of the column containing a HTML compliant color definition for coloring of the border of the object boxes. If this attribute is not set, the color defined with the attribute **Node Border Color** is used for the text in all object boxes.	An HTML compliant color code, like For example,: `#11A6D0`
Column 1	Defines the information to be displayed in the upper left corner.	Any string to display.
Column 2	Defines the information to be displayed in the upper right corner.	Any string to display.
Column 3	Defines the information to be displayed in the lower left corner.	Any string to display.
Column 4	Defines the information to be displayed in the lower right corner.	Any string to display.
View Column	Defines the name of the column containing the definition of an alternative link target for the double click action on the object boxes. By default, the standard object profile of the object opens when a user double clicks on an object box.	`View=`*`ViewType`*`:`*`ViewName`* The `ViewType` can be one of the following: • ***Report*** for a configured report • ***GraphicView*** for a standard Alfabet view • ***ObjectView*** for an object profile `ViewName` is the name of the view. Please note that the link target only opens if each result in the query is returning a base class. In Alfabet queries this is the `FIND` class. In native SQL queries, the first argument of the `SELECT` statement must return the `REFSTR` of an object

Attribute	Description	Expected Query Output
		in the Alfabet database. This is also required if the link target does not refer to an object as base object. For more information about defining navigation to a target view, see Defining Navigation from the Report to Alfabet Views.
Legend Caption Column	Defines the text to be displayed in the legend for the given node type. The legend gives information about each different node. If the class icons are displayed, each class icon displayed is added to the legend. If bubbles are displayed, each differently colored bubble is explained.	Any string to display in the legend.

A simple example for a gallery report configuration is available in the section Mapping of Query Data to Attributes.

In the following example, a gallery report is configured to display objects of different object classes and information as icons or with a colored background. The report gives a user an overview about the applications and ICT Objects assigned as affected architecture to a project. The user can see from an image displayed in the lower left corner, whether he/she is responsible for the object. If he/she is responsible, the person icon is displayed in red. In the lower right corner, the report displays the information about the object state of the application or ICT object. If hte application is planned, the object state is displayed with a red background, because it is likely that the current user is currently involved in the implementation and action is required. In the upper corner of the boxes, the start date and end date of the application or ICT object is displayed to give a hint about the time frame for actions:



Defining Gantt Chart Reports

The general design of the report is defined via the attributes of the root node element of the explorer in the **Report Assistant**. The root node element can contain one or multiple elements **Item** to define the objects for which a row is added to the report and to configure the data displayed for the object in the gantt, For example, whether start and end date and/or a lifecycle is displayed. **Item** elements can be hierarchically structured in the report.

Defining the General Layout and Time Scale of the Gantt Chart

The general layout of the report is defined with the attributes of the root node element.

To edit the attributes of the root node, click the root node in the explorer and edit the attributes described below in the attribute window:

Attribute	Description
Caption	The x-axis field on top of the y-axis displays the caption text as a headline for the objects displayed in the report.

Attribute	Description
	
Caption Width	Defines the width of the y-axis fields in mm (1 mm = 4 pixel).
Calendar Step	Defines the default scaling of the time information on the x-axis. The time line can have one field for each year or one for each quarter or month or week of the year with the information about the year on top.  *FIGURE: Yearly scale*  *FIGURE: Quarterly scale*  *FIGURE: Monthly scale*  *FIGURE: Weekly scale* The user can change between the scaling options at runtime using the zoom in and zoom out options of the floating toolbar.
Today Based	Defines how the start and end year of the time scale is calculated. If set to `False`, the time scale will start with the year defined with the parameter **Start Year** and will end with the year defined with the parameter **End Year**. Or, if those parameters are not defined, all years for which objects in the report have a lifecycle defined will be displayed.

Attribute	Description
	If set to `True`, the time scale will start with the current year minus the number of years defined with the parameter **Start Year** and will end with the current year plus the number of years defined with the parameter **End Year.** **NOTE**: **Today Based** influences both the start and end year of the time scale. If **Today Based** is set to `"true"` and you do not set the parameters **Start Year** and **End Year**, the time scale will be limited to the current year.
Start Year	Defines the start year for the time scale of the Gantt report. The definition of the start year depends on the setting for the parameter **Today Based**. If **Today Based** is set to `False`, a year must be defined with ***StartYear*** to start the time scale of the report with the defined year. If ***TodayBased*** is set to `True`, an integer or -1 must be defined with ***StartYear***. The time scale starts with the year matching the current year minus the number of years defined with ***StartYear*** or, if ***StartYear*** is set to -1 or not defined at all, with the current year.
End Year	Defines the end year for the time scale of the Gantt report. The definition of the end year depends on the setting for the parameter **Today Based**. If **Today Based** is set to false, a year must be defined with **End Year** to end the time scale of the report with the defined year. If **Today Based** is set to true, an integer or -1 must be defined with **End Year**. The time scale ends with the year matching the current year plus the number of years defined with **End Year** or, if **End Year** is set to -1 or not defined at all, with the current year.
Show Legend	When set to `True`, a legend is shown for the lifecycle phases and the object classes in the report. 
Show Enterprise Milestones	When set to `True`, enterprise milestones are displayed in a separate row on top of the object lifecycles in the report. The target date of the enterprise milestone is displayed as vertical line. When you move the cursor over a milestone, a tooltip displays the name and dates of the milestone. double-clicking on a milestone symbol opens the enterprise milestones object view. 

Attribute	Description
Show Project Milestones	When set to `True`, project milestones are displayed in the row representing the project. When you move the cursor over a milestone, a tooltip displays the name and dates of the milestone. All Columns As Caption	If set to `True`, the y-axis of the report shows one single object box that contains all information about the current object in the dataset resulting from the query in the **Item** element. If set to `False`, the y-axis displays the dataset resulting from the query in the **Item** element as a table. **NOTE**: The information included into the dataset for technical reasons, like the start and end date of the object included in the dataset, is not diplayed in the object information.
dataset Width	This attribute is only relevant if the attribute **All Columns As Captions** is set to `False`. Define the width of the dataset in the report in pixel to restrict the space used for display of the additional information. The first row of the dataset is regarded as basic object information. The configured width is the width of the additional dataset rows only.

Defining the Hierarchy of the Objects Displayed in the Report

The root node element can contain one or multiple **Item** elements. These first level **Item** elements must have a query definition in their attribute specifications in order to find the objects displayed in the report. The query can either be a native SQL query or an Alfabet query.

If you are not familiar with Alfabet queries, see the chpater Defining Queries.

For special rules that apply to the definition of native SQL queries in the context of configurations for Alfabet, see the section Defining Native SQL Queries.

The information displayed on the y-axis of the Gantt report is identical to the column values that would result from a tabular output of the defined query.

Report columns that are defined for technical reasons are not displayed in the object information in the report. This includes:

- The first column of the output of a native SQL query. This column must specify the `REFSTR` of the object for technical reasons and is ignored for the visible output.
- The **Start Date** and **End Date** property of an object. The start date and end date are instead displayed on top or instead of the lifecycle information for the object. See below for details of the configuration.

The information about the object in each row provided in the dataset resulting from the query can be displayed in two ways dependent on the attribute **All Columns As Caption** of the report:

- If **All Columns As Caption** is set to `True`, all information is displayed in a single object box prior to the lifecycle information.

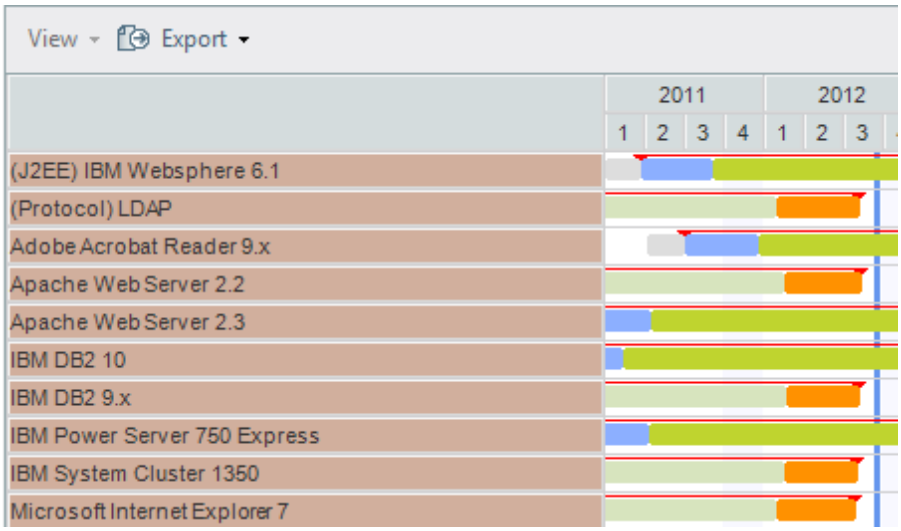

FIGURE: Name and Version of each Application are displayed in a single box

- If **All Columns As Caption** is set to `False`, a column is displayed for each column of the dataset. The first column is regarded as object box and has the title defined in the attribute **Caption** of the root node of the report. All other columns are regarded as additional information and have a header title that is identical to the header title of the dataset table:

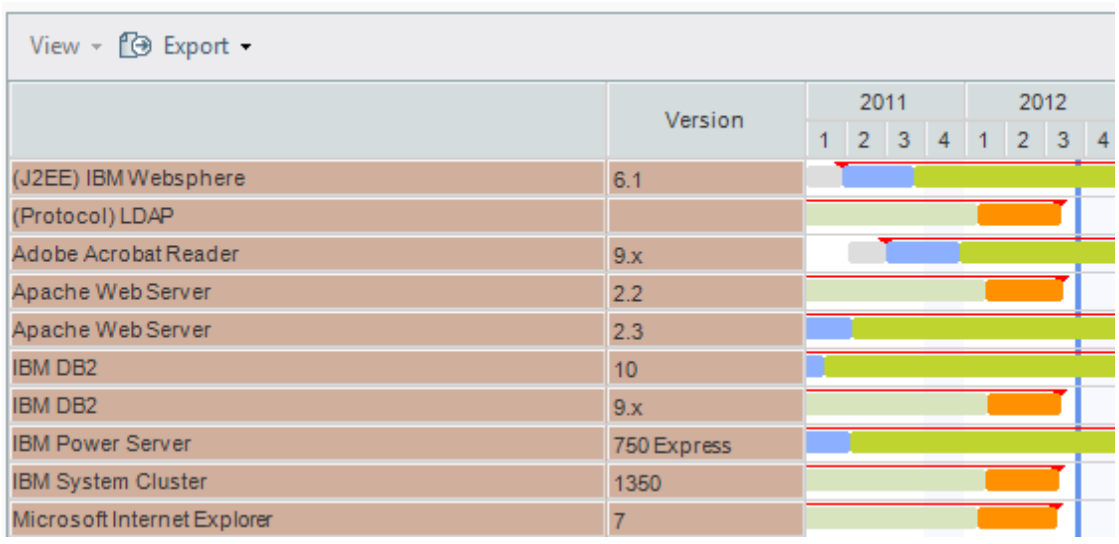

FIGURE: Name and Version of each Application are displayed in a separate column

The attribute **dataset Width** can be used to restrict the size of the dataset containing the additional information.

If the attribute **All Columns as Caption** is set to `False`, indicators can be displayed as icons in the report. If the information displayed about an object includes an indicator

value, and the indicator type is configured to display icons representing values, the icon is displayed in the gantt report instead of the value of the indicator.

The report can either display a flat list of objects and their lifecycle, or a grouped report can be configured. There are two methods to configure a grouped report:

- The complete content of the report is defined in one query resulting in a grouped dataset.

  If the attribute **All Columns as Caption** is set to `False` the information about each grouping level is displayed in separate columns of the dataset. The header titles are identical to the header titles resulting from the query.

- A separate query is added to the report configuration for each object class added to one of the levels of the report.

  When separate queries are defined, a high number of queries must be executed by the database to display the report. This can lead to performance issues. Therefore, it is recommended to base the report on a grouped dataset defined in a single query. Nevertheless for some use cases, like For example, defining different indicators for objects assigned to the same level, it is required to define multiple queries for the report.

  If the attribute **All Columns as Caption** is set to `False` the dataset is build from the first level. The header titles are identical to the header titles resulting from that query. The information of the subordinate datasets is written in the resulting columns in the order of their specification without regard of the correctness of the header titles. Therefore, it is recommended to base the report on a grouped dataset defined in a single query when displaying information about objects in a dataset.

Defining a Grouped Report Based on a Single Query

By default, the color of the boxes and text in the boxes on the y-axis is identical to the background color and foreground color defined for the object class or the object class stereotype in the relevant class settings for the object class. The coloring can be changed by defining color rules for the report. The object boxes are then colored according to the defined color rules. Boxes representing objects of the same object class may then have different colors assigned because of a color rule defined to color objects For example, dependent on their object state. For more information about the configuration of color rules, see Defining Color Rules.

The report can either display a flat list of objects and their lifecycles, or a grouped report can be configured with the query. For a grouped report, the y-axis of the Gantt report displays the information defined for the column headers of the respective group.

Grouped reports are defined via `GroupBy_Ex` instructions defined in Alfabet query language. Alfabet query language instructions can also be combined with native SQL queries.

A detailed description about how to define a grouped report using the `GroupBy_Ex` command is given in the section Grouping Query Results in Expandable Reports in the chapter Defining Queries.

Report columns that are defined for technical reasons are not displayed in the object boxes in the report. This includes:

- The first column of the output of a native SQL query. This column must specify the `REFSTR` of the object for technical reasons and is ignored in the visible output.
- `StartDate` and `EndDate` property of an object. The start date and end date are instead displayed on top or instead of the lifecycle information for the object. See below for details of the configuration.

If the query output results in a grouped report, an **Item** element without a query specification must be added to the explorer tree for each grouping level in a hierarchical structure, that means each subordinate level **Item** element as child of the superordinate **Item** element. The hierarchy of **Item** elements correspond to the grouping levels. To enhance the overview over the report structure, an attribute **Name** is available for the item elements that allow to rename the **Item** explorer nodes.

The attribute **Visible** of the **Item** element allows you to define rows that are not displayed in the report. This is useful to display the Gantt charts of objects that are related via an intermediate object without displaying the information about the intermediate object class.

For each element **Item** the display of the lifecycle and/or the start and end dates of the objects can be defined by setting different attributes of the **Item** element.

Item elements are not defined per object class but per grouping level. You can define grouped datasets with more than one object class per level. In this case, however, the settings in the **Item** element for the level are valid for all object classes displayed in the level.

Defining a Grouped Report on Basis of One Query Per Object Class

Item elements can be structured hierarchically. If an element **Item** contains a child element **Item**, for each row added to the report on basis of the definition in the parent **Item** element, subordinate rows are added to the report on basis of the definition in the child element **Item**. To enhance the overview over the report structure, an attribute **Name** is available for the item elements that allow the **Item** explorer nodes to be renamed.

For each element ***Item*** an Alfabet query or a native SQL query can be specified that defines for which objects rows are added to the report.

Note the following for the definition of the query for the **Items Query** attribute:

- If an element ***Item*** is child of a parent **Item** element, the query defined for the **Item** element must contain the parameter `BASE` in a `WHERE` clause to map the objects of this layer to the objects in the parent layer. `BASE` is identical to the `REFSTR` of the object in the parent layer.

  This specification is not mandatory for the top layer objects. The attribute `BASE` can only be used in the Alfabet query or native SQL query defining the top layer objects if the report is assigned to an object class with the attribute **Apply To Class**.

- For each **Item** element you can specify an attribute **Param Name** that allows a name to be defined that can be used as a parameter in queries of other **Item** elements in order to refer to the class found by the query in the selected **Item** element. In the queries of other **Item** elements, the

parameter returns the `REFSTR` of the `FIND` class of the current Alfabet query or the `REFSTR` defined as first `SELECT` argument in the native SQL query.

For information about the use of parameters in Alfabet queries, see Referring to the Current Alfabet Context in a WHERE Condition. For information about the use of parameters in native SQL queries, see Using Alfabet Parameters in the section Defining Native SQL Queries.

- The information displayed in the boxes on the y-axis of the Gantt chart report is identical to the column headers that would result from a tabular output of the defined query.

Report columns that are defined for technical reasons are not displayed in the object boxes in the report. This includes:

- `StartDate` and `EndDate` property of an object. The start date and end date are instead displayed on top or instead of the lifecycle information for the object. See below for details of the configuration.
- The first column of the output of a native SQL query. This column must specify the `REFSTR` of the object for technical reasons and is ignored in the visible output.

By default the color of the boxes on the y-axis and the color of the text in the boxes is identical to the background and foreground colors defined for the object class or the object class stereotype in the relevant class settings for the object class. For more information, see Configuring Class Settings for Object Classes and Object Class Stereotypes. The coloring can be changed by defining color rules for the report. The object boxes are then colored according to the defined color rules. Boxes representing objects of the same object class may then have different colors assigned because of a color rule defined to color objects For example, dependent on their object state. For more information about the configuration of color rules, see Defining Color Rules.

The attribute **Visible** of the **Item** element allows you to define rows that are not displayed in the report. This is useful to display the Gantt charts of objects that are related via an intermediate object without displaying the information about the intermediate object class.

For each element **Item** the display of the lifecycle and/or the start and end dates of the objects can be defined by setting different attributes of the **Item** element.

Defining the Attributes of the Item Element

The table below lists all attributes of the ***Item*** element. This also includes elements that define the display of lifecycles and start and end dates. A detailed description on how to specify those parameters to configure the chart is given in the sections Defining the Display of Lifecycles and Defining the Display of Start and End Dates..

Attribute	Description
Param Name	The **Param Name** attribute allows a parameter name to be defined that can be used in all queries defined for the report in order to refer to the `REFSTR` of the current object of the **Item** level that the attribute is defined for.

Attribute	Description
LC Query	Defines the object's lifecycle displayed in the report. If the parameter is set to `Default` and a lifecycle is defined for the object, all lifecycle states are displayed automatically in the chart. If you want to display any other lifecycle information, you must define the lifecycle that shall be displayed via an Alfabet query or a native SQL query. For more information about how to define the query see Defining the Display of Lifecycles.
Gantt Item Type	Defines the display mode of the start and end date of the object. For more information about the different modes to display the start and end date, see Defining the Display of Start and End Dates.
Color	Defines the color for the display of the start and end date information for the object class.
Visible	Defines whether information about the object class is visible in the report.
Name	Defines a name for the ***Item*** element. The name is used in the explorer tree as name for the ***Item*** node.
Alfabet Query/ Query as Text/ Native Sql	Defines the objects displayed in the report via an Alfabet query or a native SQL query. For each object found by the Alfabet query a line is added to the report. If you want to define an Alfabet query, you can either use the **Alfabet Query Builder** available via the **Alfabet Query** attribute or write the Alfabet query in a text editor available via the **Query as Text** attribute. If you want to define a native SQL query, use the text editor available via the **Native Sql** attribute. The text editor has separate tabs for the definition of the native SQL query and the definition of Alfabet query language instructions that can be used in combination with native SQL queries to built a grouped dataset. To open an editor, click in the respective attribute field to display the **Browse**  button and click the button.

Defining the Display of Lifecycles

The lifecycle of an object defined in an element **Item** of the report is displayed if:

- A lifecycle is defined that is related to the object and
- The attribute **LC Query** is defined in the **Item** element that contains the query finding the objects for that the lifecycledefinition is valid. If the report is based on a single query returning a grouped dataset, the **LCQuery** attribute must be defined for the **Item** element containing the object query only and must return lifecycle definitions for all objects in the report.

If a lifecycle is directly defined for the object, the attribute **LC Query** can be set to `Default`. All lifecycle states defined for the object are then displayed.

If you want to display only a subset of the lifecycle states or the lifecycle an object assigned to the object found by the report's query for the **Item**, you must define a query in the `LCQuery` attribute. The query must match the following conditions:

- The object found by the query must be of the object class `TimeStatus`.
- The query must be assigned to the object found for the **Item** element by using the parameter `BASE` in a `WHERE` clause of the query. The parameter `BASE` equals the `REFSTR` of the current object found by the query defined in the **Item** element.
- For Alfabet queries: the Show properties of the report must specify the following attributes of the object class `TimeStatus`: `Owner`, `Status`, `StartDate` and `EndDate`
- For native SQL queries: The `SELECT` clause of the query must define the `REFSTR` of the object class TimeStatus as first property followed by the definition of the properties `Owner`, `Status`, `StartDate` and `EndDate`. All other properties defined in the `SELECT` clause are ignored.
- the query must return a dataset with the column headers named `Owner`, `Status`, `StartDate` and `EndDate`.

The following example is a simple native SQL query finding the lifecycle elements of the object found for the **Item**:

```
SELECT ts.REFSTR, ts.OWNER AS 'Owner', ts.STATUS AS 'Status',
ts.STARTDATE AS 'StartDate', ts.ENDDATE AS 'EndDate'

FROM TIMESTATUS ts

WHERE ts.OWNER = @BASE
```

Defining the Display of Start and End Dates

The start and end date of an object defined in an element **Item** of the report is displayed if:

- The object has a start and end date defined and
- the query defining the **Item** content includes both the `StartDate` and `EndDate` property of the object class in the **Show Properties** of the Alfabet query or in the `SELECT` statement of the native SQL query.

For grouped reports, the columns for the `StartDate` and `EndDate` properties of the basic find class of the report are relevant for the display of start and end dates of all levels of the report. To define a report with start and end dates in various levels:

- Add all `StartDate` and `EndDate` properties for all object classes in all levels to the **Show Properties** of the Alfabet query or the `SELECT` clause of the native SQL query.
- Use the `JOINCOLUMNS` command of the Alfabet query language to join all `EndDate` properties in the `EndDate` column the basic find class and all `StartDate` properties in the `StartDate` column for the basic find class.

By default, the start and end dates are displayed as triangles connected by a line. You can change the display mode of the start and end dates by setting the **Gantt Item Type** attribute of the **Item** element. The following display modes are available:

Gantt Item Type	Display	Example
`Rectangle`	A rectangle with rounded edges is displayed between start and end date.	
`StartEndLine`	A line starting and ending with a triangle is displayed in the upper part of the cell for the gantt chart. This representation can be used to display lifecycle and start and end time information in parallel.	
`Milestone`	A rectangle with sharp edges is displayed at the start date of the object.	`IconLine`	A rectangle with sharp edges is displayed at the start date of the object. A vertical line is drawn from the rectangle to the lower border of the diagram. The line is displayed behind the other objects in the Gantt chart. When the start and end date information is displayed in parallel to the lifecycle of the object, the rectangle is displayed on top of the lifecycle.	
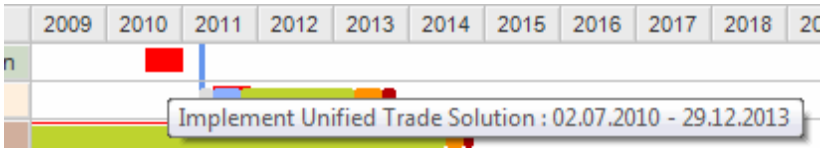
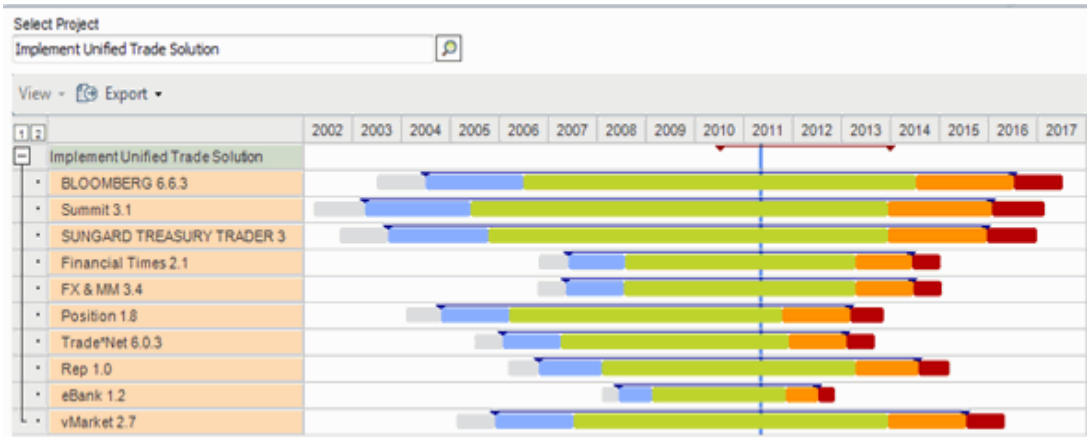
If both start and end date and the lifecycle of an object shall be displayed, you must select the default **Gantt Item Type** `StartEndLine` that is displayed on top of the lifecycle or IconLine, that is displayed in front of the lifecycle. For Milestone and IconLine, the start and end date information is displayed behind the lifecycle information and is Therefore, not visible.

The color of all start and end date representations can be changed by setting the attribute **Color** of the **Item** element. By default, all start and end date information is displayed in red.

When you move the cursor over the start and end date information, a tooltip is displayed that shows the object's name as well as the start and end date of the object:



The following example displays the lifecycles of applications assigned to the project architecture of a selected project. The start and end dates of both the project and the applications is also displayed in the report:



The report can For example, be created on basis of the following Alfabet query:

```
ALFABET_QUERY_500

FIND Project

    InnerJoin ProjectArch ON ProjectArch.Project = Project.REFSTR

    InnerJoin Application ON ProjectArch.Object = Application.REFSTR

WHEREProject.REFSTR =:BASE

Instructions

    GROUPBY_EX("Project.REFSTR","Application.REFSTR","Project",0);

    REMOVECOLUMNS("Project.REFSTR,Application.REFSTR");

    JOINCOLUMNS("Project.StartDate,Application.StartDate","Project.St
    artDate", "");

    JOINCOLUMNS("Project.EndDate,Application.EndDate","Project.EndDat
    e","");

EndOfInstructions

QUERY_XML

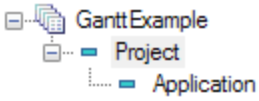
<QueryDef>

    <ShowProperty Type="Property" ClassName="Project" Name="REFSTR"
    />
```

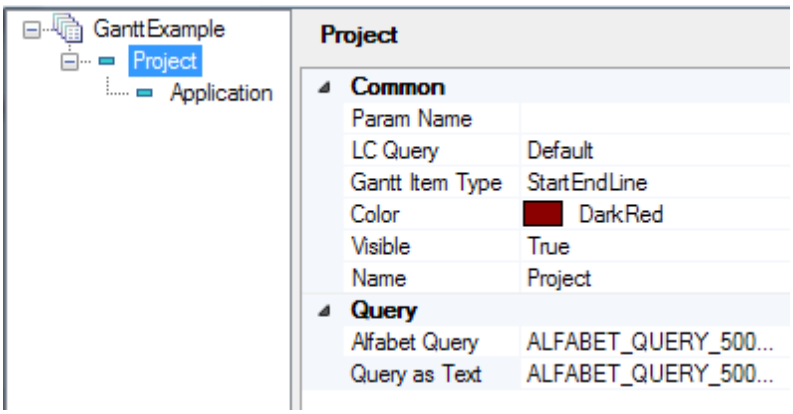
```
        <ShowProperty Type="Property" ClassName="Project" Name="Name" />
        <ShowProperty Type="Property" ClassName="Project"
        Name="StartDate" />
        <ShowProperty Type="Property" ClassName="Project" Name="EndDate"
        />
        <ShowProperty Type="Property" ClassName="Application"
        Name="REFSTR" />
        <ShowProperty Type="Property" ClassName="Application" Name="Name"
        />
        <ShowProperty Type="Property" ClassName="Application"
        Name="Version" />
        <ShowProperty Type="Property" ClassName="Application"
        Name="StartDate" />
        <ShowProperty Type="Property" ClassName="Application"
        Name="EndDate" />
        <SortProperty Type="Property" ClassName="Project" Name="REFSTR"
        />
        <SortProperty Type="Property" ClassName="Application"
        Name="REFSTR" />
    </QueryDef>
```

The query results in a grouped report. The `StartDate` and `EndDate` properties of both project and applications are added to the Show properties. The instructions join the `StartDate` values and the `EndDate` values respectively to allow display of start and end date information in all levels of the report.

In the **Report Assistant** of the report, one **Item** element must be added to the root node for the definition of the first level. The first level Item element contains a second level **Item** element:

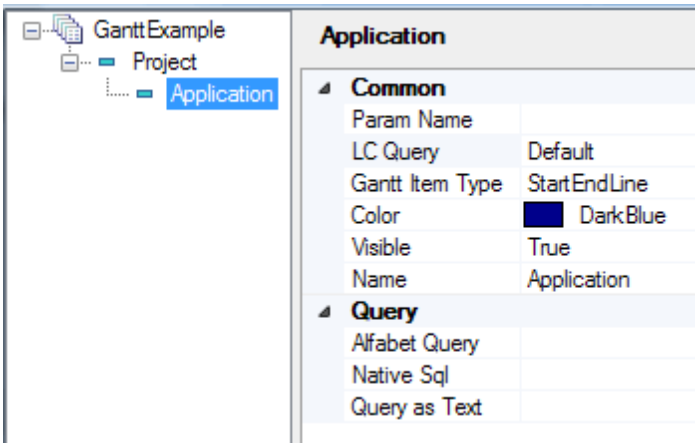


The Alfabet query defining the grouped dataset is defined in the attributes of the first level **Item** element. The first level element also contains the definition of the display of start and end date information for the projects displayed as first level. Projects have no lifecycle defined and Therefore, the `LCQuery` attribute is not considered for this **Item**.



The second grouping level of the report displays information about the objects of the object class Application. The attributes of the **Item** element define the display of the lifecycle and start and

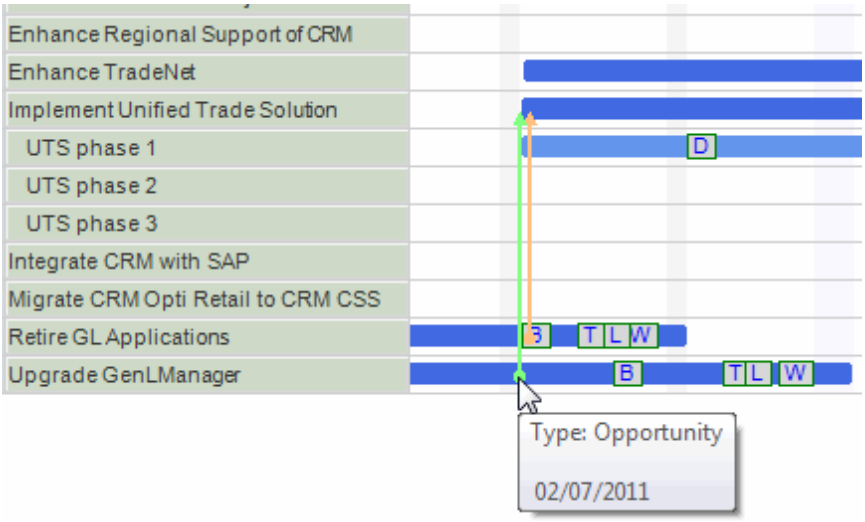
end date information for the applications assigned to the project. Applications are found via the query defined for the first level Item element, Therefore, no query definition to find objects is defined in the **Item** attributes:



Displaying Connections between Objects

Gantt charts can include information about relations between objects displayed in the Gantt chart, For example, migration links that indicate the time when an object is substituted by another one in the chart or project dependencies that indate the dependency of one project from the progress of another project.

Connections are displayed as an arrow pointing from one object to another at a given time in the timescale of the lifecycle diagram:



When an object that is connected to another object via a connection is included multiple times in the report, the connection will only be displayed for the first occurence of the object in the report.

Different types of connections can be implemented that can be destinguished by color and by name. When moving the cursor over the connection, a tooltip is displayed. The tooltip informs either about the name of the objects that are connected or displays additional information about the connection defined in the query the connection is based on. The date of the connection is always displayed in the tooltip.

Customer configured connections are not included into the legend. Instead, the tooltip can be used to give the required information to destinguish between different kind of connections.

Connections are based on a customer defined query that must result in a dataset with at least three columns returning the following values:

- The `REFSTR` property of the object that the connection is starting at.
- The `REFSTR` property of the object that the connection is ending at.
- The time in the time scale of the gantt diagram at that the connection shall be displayed.

Optinally, additional columns can be defined for the resulting dataset. If the resulting dataset includes additional columns, the content of the respective columns in a row is displayed as tooltip for the connection. If no additional columns are defined, the tooltip displays the information of the object boxes of the connected rows in the report. The date of the connection is added to the tooltip in both cases.

For each row in the resulting dataset, a connection is displayed in the diagram.

Connections are defined as sub-nodes of the report's root node. Right-click the report's root node in the **Report Assistant** and select **Add New Connection** to add a connection element to the report and define the connection with the following attributes:

Attribute	Description
From Column	Defines the name of the column returning the REFSTR of the object in the report that the connection starts with.
To Column	Defines the name of the column returning the REFSTR of the object in the report that the connection ends with.
Date Column	Defines the name of the column returning the date at which the connection is displayed in the diagram.
Color	Defines the color for the display of the connection in the gantt diagram.
Name	Defines a name for the connection. The name is used in the explorer tree of the **Report Assistant** as name for the **Connection** node.
Alfabet Query/ Query as Text/ Native Sql	Defines the objects that are to be connected and the date at which the connection is displayed in the report via an Alfabet query or a native SQL query. The query must result in a dataset with at least three columns returning the REFSTR of the start and end objects and the date of the connection. The output of any additional column is displayed in the tooltip for the connection in the diagram. If you want to define an Alfabet query, you can either use the **Alfabet Query Builder** available via the **Alfabet Query** attribute or write the Alfabet query in a text editor available via the **Query as Text** attribute.

Attribute	Description
	If you want to define a native SQL query, use the text editor available via the **Native Sql** attribute. The text editor has separate tabs for the definition of the native SQL query and the definition of Alfabet query language instructions that can be used in combination with native SQL queries to built a grouped dataset. To open an editor, click in the respective attribute field to display the **Browse** button and click the button.

A gantt report displays the lifecycle of all applications that are part of the affected architecture of a selected project. If a migration is defined for the project, the migration rules affecting the applications displayed in the gantt chart shall be displayed as connections.

A connection is defined for the report with the following Alfabet query finding migration rules (=MigrationLink) defined for migrations of the current project and returning the From object, To object and completion date of the migration rule:

```
ALFABET_QUERY_500

FIND

MigrationLink

InnerJoin Migration ON MigrationLink.Migration = Migration.REFSTR

InnerJoin Project ON Project.Migrations = Migration.REFSTR

WHERE

    Project.REFSTR =:BASE

AUTODSINFO

QUERY_XML

<QueryDef>

    <ShowProperty Type="Property" ClassName="MigrationLink"
    Name="From" />

    <ShowProperty Type="Property" ClassName="MigrationLink" Name="To"
    />

    <ShowProperty Type="Property" ClassName="MigrationLink"
    Name="CompletionDate" />

    <SortProperty Type="Property" ClassName="MigrationLink"
    Name="From" />

    <SortProperty Type="Property" ClassName="MigrationLink" Name="To"
    />

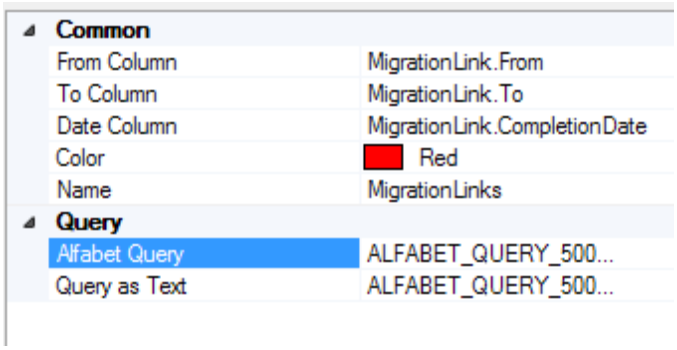
    <SortProperty Type="Property" ClassName="MigrationLink"
    Name="CompletionDate" />

</QueryDef>
```

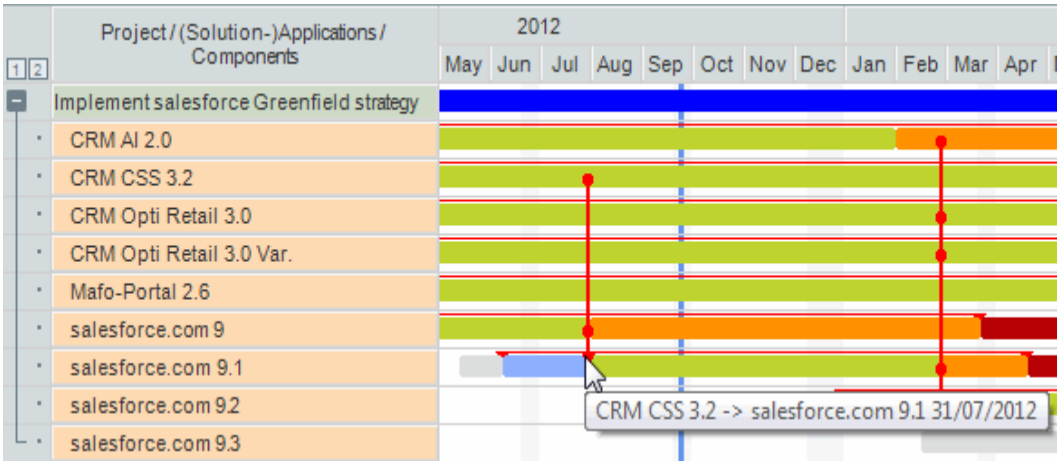
The dataset resulting from the query returns three columns:

Migration Rule Source	Migration Rule Target	Migration Rule Completion Date
26-200-0	26-620-0	30/03/2014
26-514-0	26-620-0	28/11/2014
26-516-0	26-620-0	28/11/2014
26-590-0	26-620-0	30/03/2014
26-591-0	26-620-0	30/09/2012
26-592-0	26-620-0	30/03/2014
26-593-0	26-620-0	30/09/2012
26-597-0	26-620-0	30/03/2014
26-598-0	26-620-0	30/09/2012

In the attributes of the connection element in the report, the technical name of the columns in the dataset, that is the ClassName and Name attribute of the respective Show property separated with a dot are defined as From Column, To Column and Date Column:



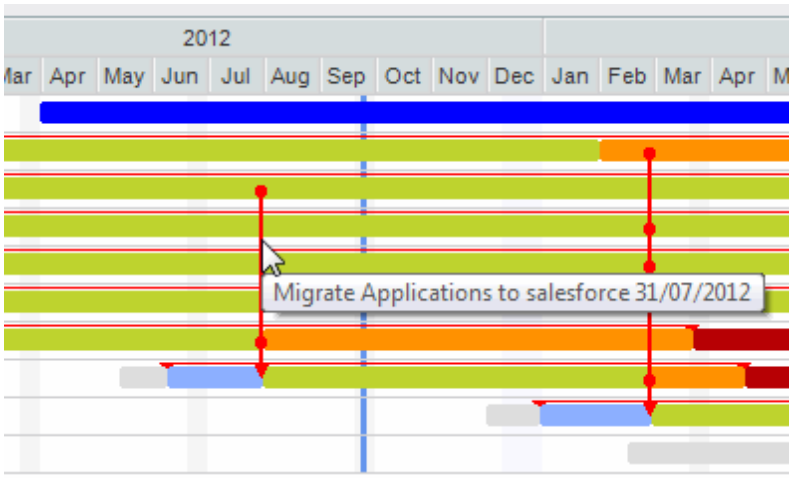
The resulting report shows the connections as red arrows between objects. In the example, multiple migrations are overlapping, because their completion date and target object is identical. You can see a red dot at each lifecycle where there is a start point for the migration rule.



If you want the report to display the name of the migration for which the migration rule is defined in the tooltip, the name of the Migration must be added as additional Show property to the query defined for the connection, resulting in a dataset with four columns:

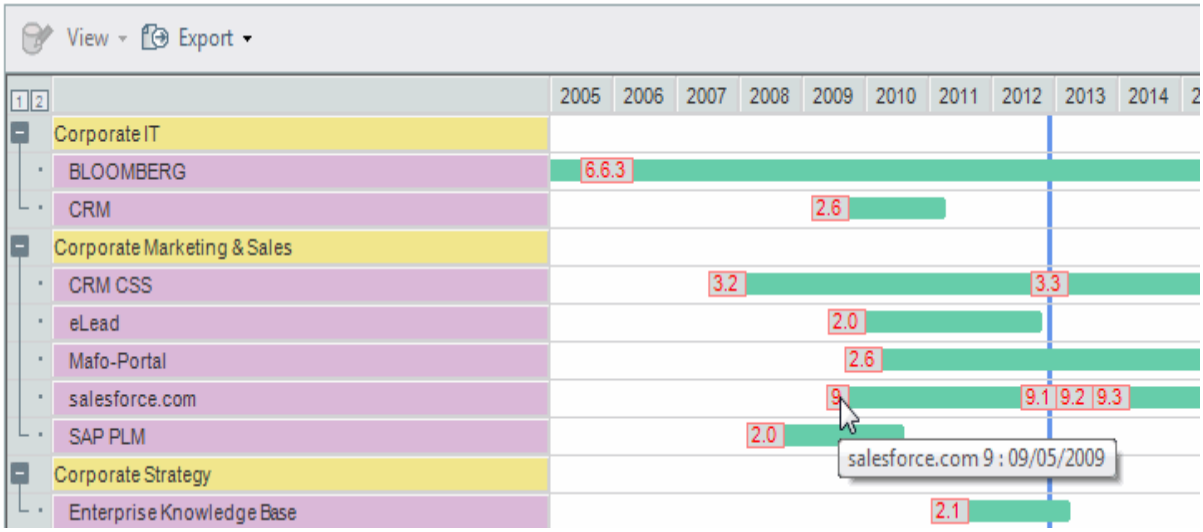
Migration Rule Source	Migration Rule Target	Migration Rule Completion Date	Migration Name
76-2694-0	76-3331-0	31/07/2012	Migrate Applications to salesforce
76-2694-0	76-3333-0	31/10/2013	Migrate Applications to salesforce
76-2760-0	76-3332-0	28/02/2013	Migrate Applications to salesforce

The tooltip is then changed to display the name of the migration:



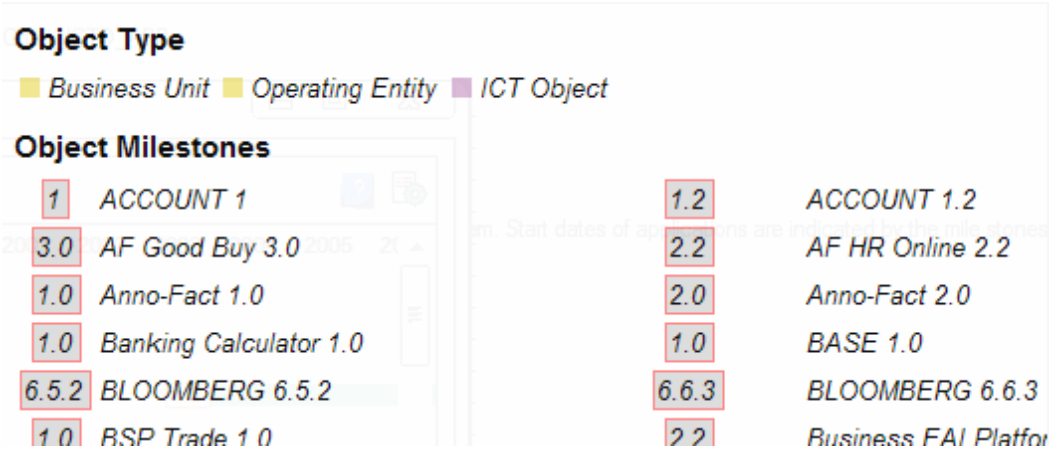
Displaying Customer Defined Milestones In the Lifecycle

Relevant events can be defined as milestones for the lifecycle of objects in the Gantt chart. For example, the assignment of new versions of an application to an ICT object can be displayed on the lifecycle of the ICT object to give information about software updates.



The customer configured milestones are displayed as a rectangle diplaying a customer defined label text in the lifecycle of the objects in the report. If the user moves the cursor over the milestone, a tooltip is displayed giving customer defined information and information about the exact date of the milestone.

In the legend of the report, milestones are listed with the information displayed in the tooltip as explanatory text.



The milestone definition is based on a customer defined native SQL or Alfabet query that returns the information about the location of the milestone in the time scale and for the lifecycle of which object the milestone shall be displayed. The query can also return the information displayed in the label and in the tooltip and legend for the milestone. Alternatively, the tooltip and label text can be a static text used for all milestones that is defined in the attributes of the milestone configuration.

The query defined for the milestone must return at least two columns:

- The `REFSTR` of the object for that the milestone shall be displayed in the lifecycle. If the query returns results for objects that are not displayed in the Gantt chart report, the respective row in the result dataset is ignored.
- A date that defines the time on the time scale of the Gantt Chart that the milestone is displayed at. If the query returns results for a time that is not displayed in the Gantt chart report, the respective row in the result dataset is ignored.

The query defined for the milestone can optionally return columns to display individual information for each milestone:

- A string that shall be displayed as a label in the milestone. The string should be short because the length of the milestone is matching the length of the string.
- A string that is displayed in a tooltip if the user moves the cursor over the milestone. The string is displayed together with the date information, that is automatically added to the string.

If you do not want an individual label and tooltip text to be displayed for a milestone, you can alternatively define a fixed label and/or tolltip text in the milestone definition in the **Report Assistant**.

Milestones are defined as sub-nodes of the first level **Item** element of the Gantt report.

Right-click the **Item** element in the **Report Assistant** and select **Add New Milestone** to add a milestone element to the report and define the milestone with the following attributes:

For technical reasons, the option **Add New Milestone** is available in the context menu of all **Item** elements in the hierarchy. Nevertheless, only milestones defined for first level **Item** elements are displayed in the report.

Attribute	Description
Background Color	Defines the background color of the milestones in the Gantt Chart.
Foreground Color	Defines the text color of the milestones in the Gantt Chart.
Border Color	Defines the color of the border of the milestones in the Gantt Chart.
Label	Defines the text to be displayed in all milestones displayed as a result of the query defined with the attribute **Alfabet Query/ Query as Text/ Native Sql**. Alternatively, an individual label text for each displayed milestone can be derived from the query result dataset. The text specified with the attribute **Label** is ignored if the **Label Column** attribute is defined.
Hint	Defines the text to be displayed in the tooltip of all milestones displayed as a result of the query defined with the attribute **Alfabet Query/ Query as Text/ Native Sql**. Alternatively, an individual tooltip text for each displayed milestone can be derived from the query result dataset. The text specified with the attribute **Hint** is ignored if the **Hint Column** attribute is defined.
Name	Defines a name for the milestone. The name is used in the explorer tree of the **Report Assistant** as name for the ***Milestone*** node.
Row Object Column	The name of the column in the result dataset of the query defined with the attribute **Alfabet Query/ Query as Text/ Native Sql** that returns the REFSTR of the object the milestone is valid for. For information about column name specifications, see Defining Column Names and Captions in the chapter Defining Queries.
Date Column	The name of the column in the result dataset of the query defined with the attribute **Alfabet Query/ Query as Text/ Native Sql** that returns the date in the time scale of the Gantt Chart the milestone shall be displayed at. For information about column name specifications, see Defining Column Names and Captions in the chapter Defining Queries.
Label Column	The name of the column in the result dataset that contains the string to be displayed as label in the milestones. Alternatively, you can use the attribute **Hint** to define a static hint displayed for all milestones in the Gantt chart.

Attribute	Description
	For information about column name specifications, see Defining Column Names and Captions in the chapter Defining Queries.
Hint Column	The name of the column in the result dataset that contains the string to be displayed in the tooltip of the milestones. Alternatively, you can use the attribute **Label** to define a static label displayed in all milestones in the Gantt chart. For information about column name specifications, see Defining Column Names and Captions in the chapter Defining Queries.
Alfabet Query/ Query as Text/ Native Sql	Defines the milestones to be displayed in the report. The query must return a dataset with at least 2 columns defining the location of the milestone in the Gantt Chart. One column must return a date to define the location of the milestone in the time scale, the other column must return the `REFSTR` of the object for that the milestone shall be added to the lifecycle information. Optionally, information about the label and tooltip of the milestone can also be derived from columns of the query result dataset. If you want to define an Alfabet query, you can either use the **Alfabet Query Builder** available via the **Alfabet Query** attribute or write the Alfabet query in a text editor available via the **Query as Text** attribute. If you want to define a native SQL query, use the text editor available via the **Native Sql** attribute. The text editor has separate tabs for the definition of the native SQL query and the definition of Alfabet query language instructions that can be used in combination with native SQL queries. To open an editor, click in the respective attribute field to display the **Browse** button and click the button.

For example, a report that displays the lifecycle of ICT Objects that are grouped by the organization they are owned by, shall display the start date of applications assigned to the ICT object as milestones.

The native SQL query in the milestone definition finds all applications that are assigned to ICT objects owned by organizations.

```
SELECT app.REFSTR, icto.REFSTR AS ICTO, app.STARTDATE, app.VERSION,
app.NAME + ISNULL(' ' + app.VERSION, '') AS NAME

FROM ORGAUNIT ou, ICTOBJECT icto, APPLICATION app

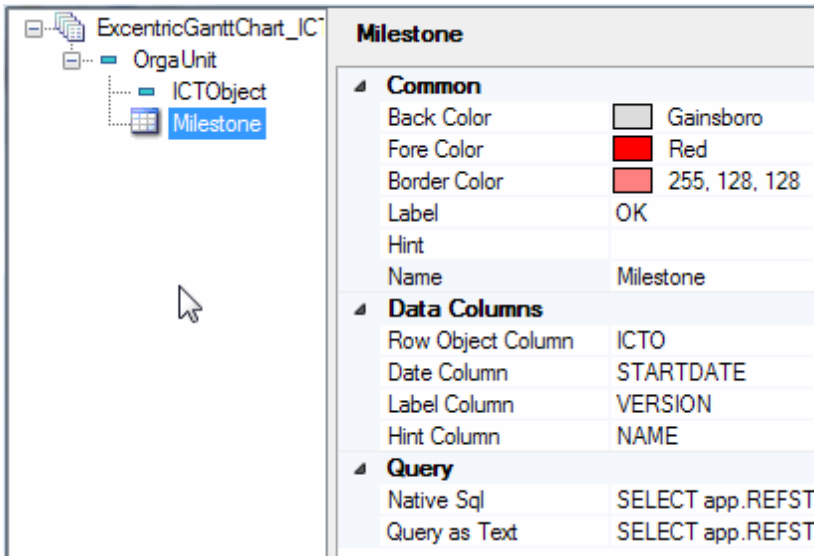
WHERE icto.OWNER = ou.REFSTR

AND app.ICTOBJECT = icto.REFSTR
```

The query returns the REFSTR of the ICT Object, the start date of the application, the version number of the application and the name of the application. The dataset that would result from the query displays one row for each milestone that are added to the Gantt chart if both the start date is within the time scale displayed in the report and the REFSTR of the ICT object is identical with the REFSTR of an ICT object in the report.

	ICTO	STARTDATE	VERSION	NAME
1	26-126-0	14/11/2009 00:00:00 000	2.2	Business EAI Platform 2.2
2	26-129-0	12/02/2009 00:00:00 000	2.2	Groupware Services 2.2
3	26-68-0	25/08/2009 00:00:00 000	2.6	Mafo-Portal 2.6
4	26-94-0	24/03/2010 00:00:00 000	2.5	PS Global 2.5
5	26-105-0	24/01/2009 00:00:00 000	2.9	ALLFiance PISA 2.9
6	26-21-0	10/07/2009 00:00:00 000	2.0	SAP@OptiRetail 2.0
7	26-23-0	17/04/2003 00:00:00 000	4.0	SAP@AI 4.0
8	26-27-0	03/02/2009 00:00:00 000	2.9	BookIT 2.9
9	26-41-0	27/03/2009 00:00:00 000	2.2	Corporate FI-CO 2.2
10	26-43-0	19/01/2011 00:00:00 000	2.8	SAP International 2.8

In the definition of the milestone, the names of the columns from the result dataset are defined in the attributes Row Object Column, Date Column, Label Column and Hint Column to enable the creation of milestone objects from the query results.



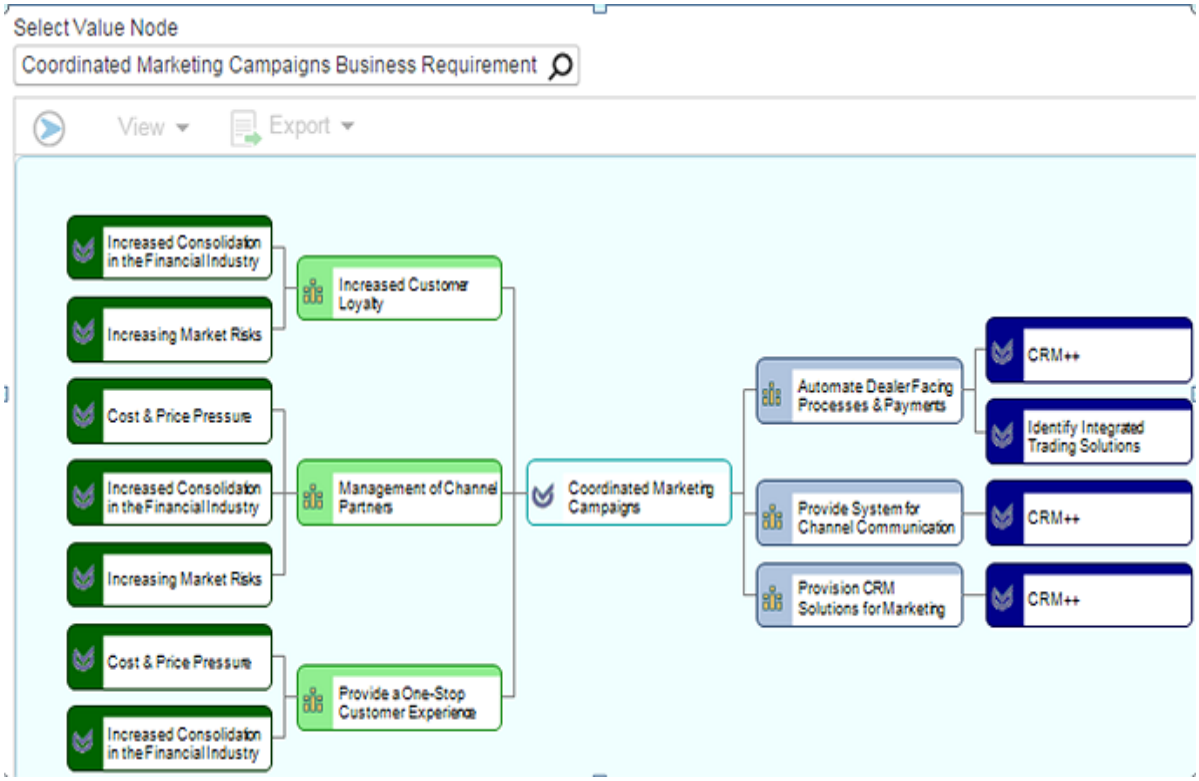
Defining a Grid Report

Grid reports are designed in the **Report Assistant**. For information about how to open the **Report Assistant**, see Creating a New Graphic Report. For more information about how to work with the **Report Assistant**, see Configuring the Report with the Report Assistant.

The content and layout of a grid report is defined by adding elements to the explorer of the **Report Assistant** and setting the attributes in the attribute pane of the **Report Assistant** window. The general design of the grid and the number of cells that contain graphics is defined via the attributes of the root node element.

A grid report is like a table that contains graphic reports in every table cell. For each cell, an element **Cell** defines the location of the cell in the table and the content of the cell. In the cells, objects are displayed as boxes and the relationship between the boxes is displayed as one of the following:

- A tree where related objects are connected with the branches of the tree. The tree can span in one or two directions. Whether the tree spans horizontally or vertically depends on the configuration of the report.



- A cluster map where boxes representing objects are stacked in each other hierarchically. If multiple objects are displayed in the box of a subordinate object, the boxes can be displayed on top of each other or next to each other.

For each type of cell content, the size, coloring and text attributes of the objects in a cell can be individually configured. A default for all cells can be defined in **Default Attribute Item** elements that can be defined as a sub-element of the ***Default Attribute Items*** node below the root node.

The design of the boxes representing objects in the configured report can be changed from the standard design with a white rectangle as background for text within the colored object box to fully colored object boxes. For more information see Defining the General Display of Object Boxes in Treemap, Diagram, Lane and Layered Diagram Reports.

The following table lists all elements that can be configured to specify the content of the report and provides information about the purpose of each sub-element:

XML Element	Purpose
Root Node	General layout of the report and number of rows and columns containing grid cells.
Cell	Definition of a cell in the report. The attributes of this element specify the general layout of the cell and its location in the grid table. The content is specified by the child elements **Item**. One element **Cell** must be defined as a child of the **Grid Report Def** element for each cell of the grid table. For example, if the **Grid Report Def** element defines that the grid table has two columns and three rows, the number of `Cell` elements in the report is 2 x 3 = 6.
Item	Definition of the objects to be displayed in the report. *For reports displaying a tree:* Definition of the content of one layer of the graphic tree. The tree is built starting with the `Item` element that is a child of the `Cell` element. This element can then contain one or two other `Item` elements as child elements and define the second layers. The third layer is defined by the child element of the second layer `Item` elements, and so on. *For reports displaying a cluster map:* Definition of one level of boxes in the hierarchy. The upper level boxes are defined as child element of the `Cell` element. This element can then contain one or multiple other `Item` elements as a child element to define the second layer. The third layer is defined by the child element(s) of the second layer, and so on.
Query	Definition of the content of either the current layer of the report or of all layers of the report in a grouped dataset.
Default Attribute Items	Container for the definition of **Default Attribute Item** elements.

XML Element	Purpose
Default Attribute Item	Definition of the default box layout for a single object class for all cells in the report.
Color Rule	Definition of the colors used in the current cell of the grid report and the rules that define which objects are displayed in which color. For more information about the definition of color rules, see Defining Color Rules.
Indicator Rule	Definition of one or multiple indicator or object related icons displayed in the boxes representing the objects in the current cell of the grid report. For more information about the definition of indicator rules, see .

Defining the Cells of the Grid Report

The basic design of the report and the number of cells in the report is configured directly in the attributes of the root node element of the report. For each cell of the report, the element **Cell** must be added as a child element to the root node.

A grid report can be regarded as an invisible table with each element **Cell** of the report configuring a cell in the table. The number of rows and columns in the report table is defined with the attributes **Rows** and **Columns** of the root node element. Each column and row is assigned a number. Columns are numbered from left to right, starting with zero and rows are numbered from top to bottom starting with zero. Therefore, a cell can be specified by the column and row number of the cell.

	Column 0	Column 1	Column 2	Column 3
Row 0	0,0	1,0	2,0	3,0
Row 1	0,1	1,1	2,1	3,1
Row 2	0,2	1,2	2,2	3,2
Row 3	0,3	1,3	2,3	3,3
Row 4	0,4	1,4	2,4	3,4
Row 5	0,5	1,5	2,5	3,5

FIGURE: Grid report table with naming of the table cells as "column number, row number"

The position of the cell within the report is defined by means of the attribute **Rectangle** of the **Cell** element. The attribute **Rectangle** specifies four numbers:

- The column number of the cell

- The row number of the cell
- The number of columns a cell spans
- The number of rows a cell spans

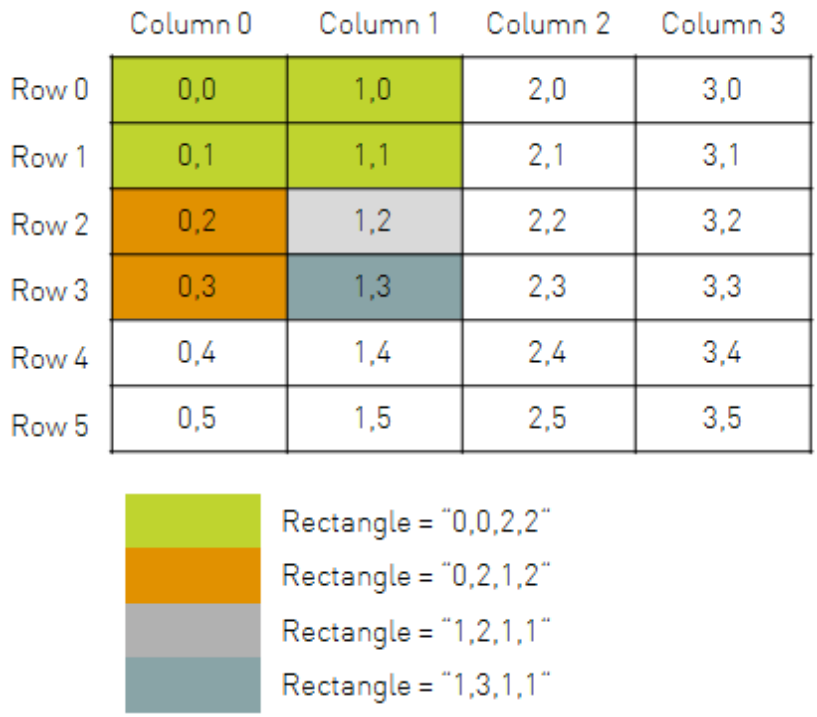


FIGURE: Grid report table with specification of the location of four different grid report cells

The following table lists all attributes of the root node element and the element **Cell** that are used to define the table layout.

The layout of object boxes is in general defined in the elements specifying the content of the objects in the report. Only a few attributes of the **Cell** element define the layout of items in the report. These attributes depend on the type of graphic display in the report and are described in separate sections in the table.

Attribute	Description
Root Node	
Rows	Defines the number of rows that the report will have.
Columns	Defines the number of columns that the report will have.
Row Height	Defines the height of the table rows in the grid report in mm (1 mm = 4 pixel). In the menu of the grid report, the option **View** > **Definition Size** allows the view mode to be defined:

Attribute	Description
	• If **Definition Size** is selected, the height and width of the table cells will be displayed as specified with the attributes **Row Height** and **Column Width**. If the content of the cell does not fit into the specified size, the handling of cell content will depend on the setting of the attribute **Auto Fit** of the **Cell** node. If **Auto Fit** is set to `true`, the content of the cells is drawn to a smaller scale to fit to the defined size. If **Auto Fit** is set to `False`, the content is not scaled and only part of the content is visible. • If **Definition Size** is deselected, the grid will be displayed in a full size view, whereby the cell sizes of the grid table will be computed based on the space required by the content of the cell.
Column Width	Defines the width of the table columns in the grid report in mm (1 mm = 4 pixel). In the menu of the grid report, the option **View** > **Definition Size** allows the view mode to be defined: • If **Definition Size** is selected, the height and width of the table cells will be displayed as specified with the attributes **Row Height** and **Column Width** . If the content of the cell does not fit into the specified size, the handling of cell content will depend on the setting of the attribute `Auto Fit` of the `Cell` node. If **Auto Fit** is set to `true`, the content of the cells is drawn to a smaller scale to fit to the defined size. If **Auto Fit** is set to `False`, the content is not scaled and only part of the content is visible. • If **Definition Size** is deselected, the grid will be displayed in a full size view, whereby the cell sizes of the grid table will be computed based on the space required by the content of the cell.
Cell Background Color	Defines the default background color of the grid cells in the report. This value can be overwritten by the **Background Color** attribute in the **Cell** element that defines a single cell.
Cell Border Color	Defines the default border color of the grid cells in the report. This value can be overwritten by the **Border Color** attribute in the **Cell** element that defines a single cell.
Cell Foreground Color	Defines the default cell text color of the grid cells in the report. This value can be overwritten by the **Foreground Color** attribute in the **Cell** element that defines a single cell.
Cell Caption Height	Defines the default height of the cell captions of the report in mm (= 4 pixel). This value can be overwritten by the **Caption Height** attribute in the **Cell** element that defines a single cell.
Show Legend	Defines whether a legend is shown for the color coding of the objects in the report.

Attribute	Description
Item Border Width	Defines the width of the border of the boxes in the report. the default value is 1 point. when using the border color as object property indicator via a color rule, it is recommended to set the border width to a higher value.
Cell	
Name	Defines the name of the **Cell** node in the explorer.
Layout Type	Defines the graphic design of the cell content. Currently, only three options can be selected: • `TreeHorizontal` displays a tree in a horizontal direction. • `TreeVertical` displays a tree in a vertical direction. • Cluster displays a cluster map. Whether boxes in the cluster are displayed a in horizontal or vertical direction is defined in the **Item Layout Type** attribute of the **Cell** element.
Rectangle	Defines the position and size of the cell. The first two numbers define the position of the cell in the table by specifying the number of the column from the left and the number of the row from top. Please note that the first row/column has the number "0". The next two numbers specify the width and height of the cell. **NOTE**: To define the attribute, click the rectangle in front of the attribute to expand it and define the values for the cell position and size in the respective sub-attributes.
Caption	Defines the caption of the cell in the grid report. **Note**: The caption is displayed in the color defined with the attribute **Foreground Color**. If **Foreground Color** is set to transparent, the caption will not be displayed.
Caption Height	Defines the height of the cell caption in mm (= 4 pixel)
Background Color	Defines the background color of the grid cell.
Foreground Color	Defines the text color of the grid cell.

Attribute	Description
Border Color	Defines the border color of the grid cell.
Auto Fit	Defines the handling of cell content if **View** > **Definition Size** is selected by the user in the toolbar of the report.: If **Definition Size** is selected, the height and width of the table cells will be displayed as specified in the attributes **Row Height** and **Column Width**. If the content of the cell does not fit into the specified size, the handling of cell content will depend on the setting of the attribute **Auto Fit** of the **Cell** node. If **Auto Fit** is set to true, the content of the cells will be drawn to a smaller scale to fit to the defined size. If **Auto Fit** is set to **False**, the content will not be not scaled and only part of the content is visible.
Item Spacing	Defines the spacing between items (object boxes) in the grid in mm (1 mm = 4 pixel). Click the rectangle in front of the attribute to expand it and define the horizontal spacing with the sub-attribute **Horizontal** and the vertical spacing with the sub-attribute **Vertical**. If you want to define identical values for horizontal and vertical spacing, you can enter the value in the sub-attribute **All** to set it simultaneously for all sub-attributes. **All** is defined as -1 if Horizontal and Vertical are different.
Item Padding	Defines the spacing between items (object boxes) and the border of the grid cell in mm (1 mm = 4 pixel). Click the rectangle in front of the attribute to expand it and define the spacing for the different sides of the cell with the sub-attributes **Left**, **Top**, **Right**, and **Bottom**. If you want to define equal values for all cell border spacings, you can enter the value in the sub-attribute **All** to set it simultaneously for all sub-attributes. **All** is defined as -1 if different values are defined for sub-attributes.
Hor. Align	Defines the horizontal alignment of the cell content.
Ver. Align	Defines the vertical alignment of the cell content.

Attributes for trees only:

Direction	Defines the direction of display of objects. Select Bidirectional to display object in two directions. Whether objects are displayed in horizontal (left and right) or vertical (top and bottom) directions is specified with the attribute **Layout Type**. Select Regular to display objects in one direction only, from left to right or from top to bottom, depending on the setting for **Layout Type**. Select Invers to display objects in one direction only, from right to left or from bottom to top, depending on the setting for **Layout Type**.

Attribute	Description
Tree Color	Defines the color of the tree displayed in the grid cell.
Attributes for clusters only:	
Item Layout Type	Defines the direction of object boxes in the first level of the report. Select Vertical to display objects next to each other from top to bottom or Horizontal to display object boxes next to each other from the left to the right.
Line Count	If many objects are found by a query that defines the objects in one layer of the reports, the defined space of the box can be too small to display all items next to each other. The **Line Count** element allows you to define how many objects are displayed next to each other (in horizontal or vertical direction, according to the **Layout Type** and **Item Layout Type** attributes of the **Cell** element). If the number of objects specified with the attribute **Line Count** is reached, the next boxes are displayed in a new row in reports with horizontal direction or in a new column in reports with vertical directions. **Note**: If the ***Line Count*** attribute is set to 1, the orientation specified in the **Item Layout Type** attribute is reversed.
Equal Width	Select `"true"` to display all boxes of the first layer of the report in equal width. For more information about the sizing of object boxes in cluster maps, see the section Defining the Size of Object Boxes in the Report.
Equal Height	Select `"true"` to display all boxes of the first layer of the report with equal height. For more information about the sizing of object boxes in cluster maps, see the section Defining the Size of Object Boxes in the Report.

Defining the Items Displayed in a Cell of a Grid Report

A cell in a grid report can either display object relationships in a tree structure or as nested boxes. For both types of reports, each level of the object boxes is defined with an Item element . An Item element triggers the display of objects of a single object class. The object class is defined with the attribute **Class Name** of the **Item** element.

The first level of the cell content is defined by an Item element that is a sub-node of the **Cell** node in the explorer. A **Cell** element can contain only one Item element to define the first level of the report. The first level **Item** element contains one or multiple child Item elements that define the next level of the tree or cluster map. The number of child elements to be defined for the root Item element depends on the type of report:

- For unidirectional trees:

Each **Item** element can have one child element defining the next level of the tree.

- For bidirectional trees:

The root **Item** element of a tree spanning in two directions can contain two Item elements, each defining a direction of the tree. All other **Item** elements of the report can have one child element defining the next level of the tree.

- For cluster maps:

Each **Item** element can have multiple child elements defining the next level of nested object boxes. This allows relationships to multiple objects to be displayed in one level of a report.

For cluster maps the attribute **Class Name** of the **Item** element can be left blank. In that case, all objects in the level are displayed in object boxes with the design defined in the **Item** element regardless of the object class the object belongs to.

The last level in the report is defined by an **Item** element without a child Item element.

The objects displayed in the levels of the report are found on via queries defined for the **Item** elements of the report. The queries can either be native SQL queries or Alfabet queries.

If you are not familiar with Alfabet queries, see the chapter Defining Queries.

For special rules that apply to the definition of native SQL queries in the context of configurations for Alfabet, see the section Defining Native SQL Queries.

The information displayed in the object boxes of the report is identical to the column headers that would result from a tabular output of the defined query.

Report columns that are defined for technical reasons are not displayed in the object boxes in the report. This includes the first column of the output of a native SQL query. This column must specify the `REFSTR` of the object for technical reasons and is ignored in the visible output.

There are two methods to define the content of the grid report:

- The complete content of the report is defined in one query resulting in a grouped dataset.
- A separate query is added to the report configuration to find the objects in a level of the report.

When separate queries are defined, a high number of queries must be executed by the database to display the report. This can lead to performance issues. Therefore, it is recommended to base the report on a grouped dataset defined in a single query.

Defining a Grid Report With a Single Query

The content of all level of the report is defined via an Alfabet query or a native SQL query in a Query element node. The **Query** node is a sub-node of the root **Item** node in a **Cell** element. The query finds the objects that are displayed in the report and determines the information that is displayed about the objects in the object boxes of the report. The query must return a grouped dataset. Each grouping level corresponds to a level in the report.

All other **Item** elements in the cell may not contain a sub-element **Query**.

The query must find objects of the object classes defined with the attribute **Class Name** of the **Item** elements of the corresponding level. Otherwise objects found by the query are not displayed in the report. For **Item** elements in cluster maps that does not have a **Class Name** defined, the report displays all objects found by the query without restrictions and a query can return objects from multiple classes.

Defining a Grid Report With One Query Per Item

The content displayed for each **Item** element in the report is defined via an Alfabet query or a native SQL query in a **Query** element node. The **Query** node is a sub-node of the respective **Item** element. The query must find objects of the object class defined with the attribute **Class Name** of the **Item** element. Otherwise objects found by the query are not displayed in the report. For **Item** elements in cluster maps that does not have a **Class Name** defined, the report displays all objects found by the query without restrictions and a query can return objects from multiple classes.

The object class defined for a level of the report is the same as the base class for the objects displayed in the next level. The Alfabet query or native SQL query defining the object class displayed in the next level must contain the parameter `BASE` in a `WHERE` clause to map the objects to the objects of the current layer. The parameter `BASE` is identical to the `REFSTR` of the objects in the current layer.

This specification is not mandatory for the top layer objects. The attribute `BASE` can only be used in the Alfabet query or native SQL query defining the top layer objects if the report is assigned to an object class with the attribute **Apply To Class**.

The use of the parameter `BASE` depends on the setting of the Cascading attribute in the Query element:

- If **Cascading** is set to `True`, a query in a layer cannot only refer to an object of the directly superordinate layer, but can also refer to objects of all other superordinate layers. The parameters to refer to objects of the superordinate layers are then specified as `BASE0` to refer to the directly superordinate layer, `BASE1` to refer to the layer above the directly superordinate layer and so on.
- If `Cascading` is set to False, a query in a layer can only refer to an object of the directly superordinate layer using the parameter `BASE`.

The layout of the object boxes in the level defined by an **Item** element are configured via attributes of the following elements:

- The attributes of the **Item** element for the current level define the layout of each single object box.
- The attributes of the **Item** element of the superordinate level define how boxes are displayed in the level. This includes, For example, the spacing between boxes. The `Cell` element contains the specification for the level layout display of the first level of the report.
- The attributes of the **Default Attribute Item** elements in the **Default Attribute Items** sub-node of the explorer allow a default layout of object boxes to be defined for a specified class. This default layout will be implemented if no layout specifications are specified in an **Item** element in any of the cells of the report that trigger the display of objects of the specified object class. The **Default Attribute Item** element allows you to define a consistent layout for multiple trees or cluster maps displayed in a grid report.

  The specifications in a **Default Attribute Item** element for an object class are overwritten with the specifications in an **Item** element for the object class with the following exceptions:

- When a tree is displayed in the cell, the **Item Size** setting in the **Default Attribute Item** element supersedes the **Item Size** specification in the root **Item** element of the cell.
- Values for **Text Attributes** in the **Default Attributes Item** element are ignored and must always be defined the **Item** element.

The table below lists all available attributes in the **Item** element and the allowed child Query element as well as the attributes of the **Default Attributes Item** element.

The attributes of the `Item` element defining the layout of the current level can be configured in the **Common** section of the property grid for the **Item** element. The attributes defining the subordinate level are listed in the **Layout section**. For the definition of the first level layout, see the description of attributes of the **Cell** element in Defining the Cells of the Grid Report.

Elements (Bold) and Attributes	Description
Item	
Section Common (Attributes configuring the current level)	
Name	Defines the name of the **Item** node in the explorer of the **Report Assistant**.

Class Name	Defines the object class specified in this **Item** element.
	
	NOTE: For object classes allowing stereotype specification (For example, Project and Domain), the **Class Name** can specify an object of a specific stereotype. To define an **Item** element for a stereotype, the **Class Name** must be written with the following syntax:
	
	`ClassName:StereotypeName`
	
	For example,:
	
	`Project:StatementOfWork`

Background Color	Defines the color of the boxes representing the objects in the report. If no value is specified, the value specified in the **Default Attributes Item** element for the object class defined with the **Class Name** attribute will be used. For more information about color selection, see Defining Color Rules.
Foreground Color	Defines the color of the text in the boxes representing the objects in the report. If no value is specified, the value specified in the ***Default Attributes Item*** element for the object class defined with the **Class Name** attribute will be used.

Elements (Bold) and Attributes	Description
	For more information about color selection, see Defining Color Rules.
Border Color	Defines the border color of the boxes representing the objects in the report. If no value is specified, the value specified in the **Default Attributes Item** element for the object class defined with the **Class Name** attribute will be used. For more information about color selection, see Defining Color Rules.
Icon	Defines the icon displayed for the object class in the report. The icon must be an icon that has already been added to Alfabet Expand. For more information, see the section Adding and Maintaining Icons for the Alfabet Interface. If no value is specified, the value specified in the **Default Attributes Item** element for the object class defined with the **Class Name** attribute is used. If this value is also undefined, the icon defined in the class settings for the object class will be used. **NOTE**: If object class stereotypes are defined for an object class and an icon is not defined in the **Item** element or a **Default Attributes Item** element for the object class, the icon defined for the object class stereotype of the object displayed in a box is used per default. Therefore, different icons can be used for objects in the same level. **Default Attributes Item** elements can also be defined per object class stereotype to define a stereotype-based default icon for the report.
Rounded	Defines whether the edges of the object boxes are rounded.
Show Class Icon	Defines whether an icon is displayed for the object class in the report. If not otherwise specified via the Picture attribute, the icon implemented is that defined in the **Icon** attribute of the relevant class setting.
Show Indicator	Defines whether icons can be displayed in the boxes representing the objects in the current level of the report. The icons can either represent an indicator or any other aspect of the object data, like For example, objects associated with the current object. Icons are displayed for objects defined in the **Indicator Rule** elements in the report, independent of the level of the tree they are assigned to. The attribute **Show Indicators** allows the display of indicators to be limited to only the specified levels. For information about defining indicator rules, see the section Defining Indicator Rules.
Show Multiple Indicators	Defines whether display of icons defined via indicator rules is limited to one icon per object box or whether multiple icons can be assigned to an object box. If **Show Multiple Indicators** is set to `False`, a single icon can be displayed on the right of the object box. If multiple icons are found by indicator rules, the first icon found is assigned and all other icons are ignored.

Elements (Bold) and Attributes	Description
	If **Show Multiple Indicators** is set to `True`, one or multiple icons are displayed from left to right at the bottom of the object box. If the number of icons that are assigned to the object box via indicator rules exceeds the space available for display of icons in a single row, the first icons found are displayed and, if the object box space is exceeded, any other icons are ignored. The way icons are placed in the object box also depends on the attribute **Indicator Fill Policy** of the **Item** node. For more information about the placement of icons assigned via indicator rules, see the section Defining Indicator Rules.
Indicator Fill Policy	If **Show Multiple Indicators** is set to `True`, this attribute defines how icons assigned to an object box are placed in the row on the bottom of the object box: • `ByIndex`: This setting shall be used if multiple indicators are defined via multiple indicator rules, each returning a single icon. The position of the icon resulting from each indicator rule is defined by means of the attribute **Indicator Index** of the respective indicator rule that must be set to an unsigned integer starting with 0 for the left most position. If an **Indicator Index** attribute has been defined for each indicator rule and an indicator is not set for a specific object, the position of this indicator icon in the box will be left empty and the position of all other indicator icons will not be changed:  If the order of the **Indicator Index** attribute is not defined, the placement of indicators will be arbitrary. This method is designed for positioning only one icon per indicator rule. If an indicator rule returns multiple icons, only one of the icons is displayed. • `LeftAlign`: This setting shall be used if a single indicator rule is defined that returns multiple icons. It can also be applied when multiple indicator rules each return a single icon, but the position and order of icons is not important to understand the report. The Icons are displayed in the order of occurence within the indicator rule(s) from left to right. If a different number of indicator icons is returned, the remaining icons are moved to the left:

Elements (Bold) and Attributes	Description
	 If the indicator icons are all found by a single indicator rule, the order of icons depends on the order of results in the result dataset of the query of the indicator rule and may be different for different objects if no sort order is defined in the query.
Item Size	Click the rectangle in front of the **Item Size** attribute to expand it and define the width and height of the items (object boxes) of the current level in mm (1 mm = 4 pixel) by setting the sub-attributes **Width** and **Height**. If you define -1, the sub-attribute is undefined. For more information about the specification of object box sizes, see Defining the Size of Object Boxes in the Report.
Text Attributes	Click the rectangle in front if the **Text Attributes** attribute to define how text is displayed in the object boxes of the current level. If no specification is made, the **Text Attributes** defined in the **Default Attributes Item** element for the object class defined with **Class Name** will be used. **NOTE**: To allow line breaks in the text of the object box, set the sub-attribute **Word Wrap** to `true`.
Format	Allows static text to be added to the information displayed about an object in the object box. A string can be defined that contains place holders for the information added from the query results for the current object. The place holder is the column name for the property that would result from a tabular output of the report written in curly brackets. For example, the name and the version number of applications is to be displayed with the string " Version " between the name and version number. The report is based on an Alfabet query with `Application.Name` and `Application.Version` as Show properties. The string defined for the attribute Format resulting in the required output is: `{Application.Name} Version {Application.Version}` **NOTE**: The name and not the caption of the column of the tabular output of the query must be defined in the curly brackets. When the query is an Alfabet query, the correct syntax is ClassName.PropertyName or, if an alias is defined for the class, ClassAlias.PropertyName. A defined show name for the column in the report is ignored. When you define a native SQL query, setting an alias in the `SELECT` clause does not only change the caption but also the name of the database column.

Elements (Bold) and Attributes	Description
Attributes configuring the next level for trees:	
Direction	Defines the direction in that the tree starting with the item spans. This attribute is only allowed in the level under the root level if the attribute Direction of the **Cell** element is set to Bidirectional. Select Regular to display objects from left to right or from top to bottom, depending on the setting of the attribute **LayoutType** of the **Cell** element. Select Invers to display objects from right to left or from bottom to top, depending on the setting of the attribute **LayoutType** of the **Cell** element.
Attributes configuring the next level for cluster maps	
Hor. Align	Defines the horizontal alignment of the object boxes of the next level in object boxes of this level.
Ver. Align	Defines the vertical alignment of the object boxes of the next level in object boxes of this level.
Item Layout Type	Defines the direction of object boxes in the next level of the report. Select Vertical to display objects next to each other from top to bottom or Horizontal to display object boxes next to each other from the left to the right.
Line Count	If many objects are found by a query that defines the objects in one level of the report, the defined space of the box can be too small to display all items next to each other. The **Line Count** element allows you to define how many objects are displayed next to each other (in horizontal or vertical direction, according to the **Layout Type** and **Item Layout Type** attributes of the **Cell** element). If the number of objects specified with the attribute LineCount is reached, the next boxes will be displayed in a new row in reports with horizontal direction or in a new column in reports with vertical directions. **Note**: If the **Line Count** element is set to 1, the orientation specified in the **Item Layout Type** attribute will be reversed.
Equal Width	Select `true` to display all boxes of the next level of the report in equal width. **Note:** This parameter is ignored for the last level of boxes in the report. The last level contains no boxes inside and Therefore, all boxes are displayed with equal width anyway.
Equal Height	Select `true` to display all boxes of the next level of the report with equal height.

Elements (Bold) and Attributes	Description
	Note: This parameter is ignored for the last level of boxes in the report. The last level contains no boxes inside and Therefore, all boxes are displayed with equal height anyway.
Item Spacing	Defines the spacing between object boxes in the next level in mm (1 mm = 4 pixel).
Item Padding	Defines the spacing between object boxes of the next level and the border of the superordinate object box of this level in mm (1 mm = 4 pixel).
Query	
Name	Defines the name of the **Query** node in the explorer of the **Report Assistant**.
Alfabet Query/ Query as Text/ Native Sql	Defines a query to find the objects that are displayed in the report. How the query must be defined depends on the location of the **Query** element in the report.
Cascading	**For reports based on one Query element per Item element only**: If the **Cascading** attribute is set to `True`, a query in a layer cannot only refer to an object of the directly superordinate layer, but can also refer to objects of all other superordinate layers. The parameters to refer to objects of the superordinate layers are then specified as `BASE0` to refer to the directly superordinate layer, `BASE1` to refer to the layer above the directly superordinate layer and so on. **Note**: It is not possible use the the parameter `BASE`<number> to refer to the object class that the report is assigned to in the property **Apply To Class** of the report. Only the query of the first layer in the report can refer to the base object that the report is applied to via the parameter `BASE`. In this case, the **Cascading** attribute must be set to "false" for that layer. If the **Cascading** attribute is set to False, a query in a layer can only refer to an object of the directly superordinate layer using the parameter `BASE`.
Default Attributes Item	
Class Name	Defines the object class specified in this **Default Attributes Item** element.: **NOTE**: For object classes allowing stereotype specification (For example, Project and Domain), the **Class Name** can specify an object of a specific stereotype. To define an **Item** element for a stereotype, the **Class Name** must be written with the following syntax: `ClassName:StereotypeName`

Elements (Bold) and Attributes	Description
	For example,: `Project:StatementOfWork`
Background Color	Defines the color of the boxes representing the objects in the report. If no value is specified, the value specified in the class settings of the object class defined in the **Class Name** attribute will be used. For more information about the default coloring for object classes, see Configuring Class Settings for Object Classes and Object Class Stereotypes. For more information about color selection, see Defining Color Rules.
Foreground Color	Defines the color of the text in the boxes representing the objects in the report. If no value is specified, the value specified in the class settings of the object class defined in the `Class Name` attribute will be used. For more information about the default coloring for object classes, see Configuring Class Settings for Object Classes and Object Class Stereotypes. For more information about color selection, see Defining Color Rules.
Border Color	Defines the border color of the boxes representing the objects in the report. If no value is specified, the value specified in the class settings of the object class defined defined in the **Class Name** attribute will be used. For more information about the default coloring for object classes, see Configuring Class Settings for Object Classes and Object Class Stereotypes. For more information about color selection, see Defining Color Rules.
Icon	Defines the icon displayed for the object class in the report. The icon must be an icon that has already been added to Alfabet Expand. For more information, see the section section Adding and Maintaining Icons for the Alfabet Interface. If no value is specified, the value specified in the class settings of the object class defined in the **Class Name** attribute will be used. For more information, see Configuring Class Settings for Object Classes and Object Class Stereotypes.
Item Size	Click the rectangle in front of the **Item Size** attribute to expand it and define the default width and height of the items (object boxes) of the object class in mm (1 mm = 4 pixel) by setting the sub-attributes **Width** and **Height**. If you define -1, the sub-attribute is undefined. For more information about the specification of object box sizes, see Defining the Size of Object Boxes in the Report.
Text Attributes	Click the rectangle in front if the **Text Attributes** attribute to define how text is displayed per default in the object boxes for the object class.

Elements (Bold) and Attributes	Description
	NOTE: To allow line breaks in the text of the object box, set the sub-attribute **Word Wrap** to `true`.

Defining the Size of Object Boxes in the Report

The size of the object boxes in a grid report is calculated differently for reports displaying trees or cluster maps.

For Trees:

All object boxes of all levels of the tree have the same size. The size can be specified with the sub-attributes **Width** and **Height** of the **ItemSize** attribute in the following elements:

- the **Default Attributes Item** element
- the root **Item** element that is child of the **Cell** element.

If the size is defined both in the **Default Attributes Item** element and in the root **Item** element the greater value is selected. Selection is evaluated per sub-attribute, which means that the resulting size can have the height specified in one element and the with specified in the other element.

If none of the elements includes a size specification, object boxes are displayed with the default value of 40 x 15 mm (1 mm = 4 pixel).

The object box size can be defined via the sub-attributes **Width** and **Height** of the **Item Size** attribute. If -1 is specified for a sub-attribute, the sub-attribute is undefined. If the size specification in the **Default Attributes Item** element contains either only a specification of **Width** or only a specification of **Height**, the missing width or height specification is evaluated from the size definition of the root **Item** element of each cell..

For Clusters:

The size of the object boxes is defined individually for each level in the report. The size of object boxes can even differ within a level of the report. The size depends on both the content of the object box and the size specification in the report configuration.

The size can be specified with the attribute **Item Size** or the attributes **Width** and **Height** in the following elements:

- the **Default Attributes Item** element
- the **Item** elements.

The size specification in the **Item** element overwrites the size specifications in the **Default Attribute Item** element.

The size specification in the elements have different effects on the display of the object boxes in the levels:

- The size specification in the **Item** element is an absolute size. If the **Item** element of a level has an **Item Size** attribute with both sub-attributes **Width** and **Height** defined, the object boxes have the defined size regardless of the size of the content. If the object boxes of the subordinate level that are displayed within a box of this level do not fit into the defined size, the content is overlaying the heading of the upper level box an partially displayed outside the boxes:

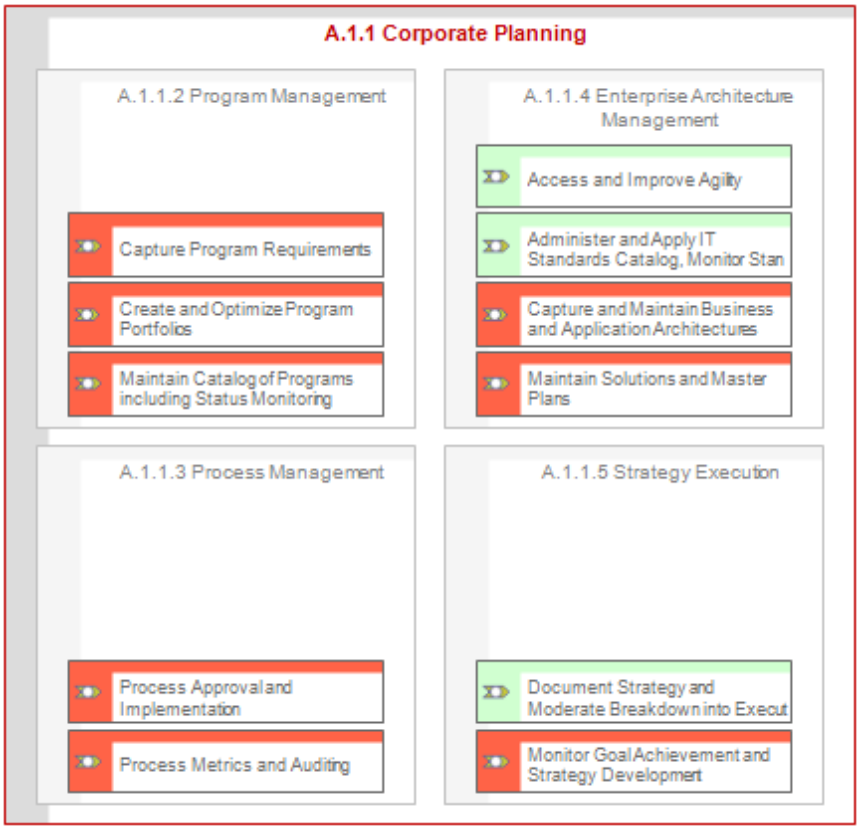
- Size specifications in the **Default Attributes Item** element are relative values that define a minimum size for elements without subordinate boxes for all levels in the report except the last one. Boxes of the last level of the report are displayed in the default size of 40,15 regardless of a size specification in the **Default Attributes Item** element if no size is specified in the **Item** element for the last level. Boxes of all other levels are displayed with the size defined in the **Default Attributes Item** element if the box content is smaller than the defined size. If the box content is bigger than the defined size, the box size is adapted to the content's size.

If none of the elements includes a size specification, object boxes that do not contain object boxes of a subordinate level are displayed with the default value of 40 x 15 mm (1 mm = 4 pixel) and all other box sizes are adapted dynamically to the content of the box.

If an element **Item** contains only a **Width** or only a **Height** specification, the size of the object boxes will adapt to the size of the content in the boxes, and the defined **Width** or **Height** will be used to overwrite the **Width** or **Height** specifications for the default size of boxes for the level.

If you want the boxes of a level to have the same size, but nevertheless the box size shall adapt to the size of the content of the box, you can set the attributes **Equal Width** and **Equal Height** in the **Item** element specification of the superordinate level or in the **Cell** element as superordinate level of the root `Item` element. These attributes are only valid if the **Item** element of the current level includes no size specification.

Equal Height is set in the root **Item** element. The **Item** element of the second level contains no size specification. Therefore, the second level elements are all displayed with the height of the box containing third-level sub-elements.



Defining Lane Reports

Lane reports are designed in the **Report Assistant**. For information about how to open the **Report Assistant**, see Creating a New Graphic Report. For more information about how to work with the **Report Assistant**, see Configuring the Report with the Report Assistant.

The content and layout of a lane report is defined by adding elements to the explorer of the **Report Assistant** and setting the attributes in the attribute pane of the **Report Assistant** window.

The content and layout of a lane report is defined in the root node element.

The following table lists the explorer node elements that can be configured to specify the content of the report as well as provides information about the purpose of each sub-element:

Explorer Node Element	Required to Configure:
Root Node of the report	Definition of the layout of the report.
Lane	Definition of a new lane added to the report. A lane consists of a row of objects and optionally a definition of a link to the next lane in the report. The next lane is the lane right of the current lane.
Node	Definition of the layout of the object row of the lane. The Node element is a child of the Lane element.
Link	Definition of the layout of the connections between this object row and the object row right of this object row. The Link element is a child of the Lane element.
Query	If defined as child of the Node element, the Query element defines the objects displayed in the object row of the lane. If defined as child of the Link element, the Query element defines the kind of connections displayed in the diagram between the object rows.
Color Rule	Definition of the colors used in the current cell of the grid report and the rules that define which objects are displayed in which color. For more information about the definition of color rules, see Defining Color Rules.
Indicator Rule	Definition of one or multiple icons displayed in the boxes representing the objects in the current cell of the lane report. The icons can either represent an indicator or any aspect defined via a query. For more information, see the section Defining Indicator Rules.

Defining the Content of a Lane Report

To define a lane report in the **Report Assistant**:

1) In the explorer, right-click the root node of the new report and select **Add New Lane**. A new **Lane** element is added to the report that has a **Node** and a **Link** child element.
2) Click the new **Lane** element and define the following attributes:

- **Name**: Define the name of the **Lane** element displayed in the explorer of the **Report Assistant**.
- **Caption**: Define the caption of the lane displayed above the object row of the lane in the report.
- **Has Link Lane**: Select `True` if the current lane is followed by another lane definition. Select `False` if the current lane is the last lane in the definition and Therefore, no links to objects in a following lane are required.

3) Expand the new **Lane** element, right-click the **Node** element and select **Add New Query**. A **Query** element is added to the **Node** element.
4) Click the **Node** element and define the layout of the object boxes in the lane. The attributes are described in the section Defining the Content of a Lane Report.
5) Click the **Query** element and define the following attributes:
   - **Name**: Define the name of the **Query** element displayed in the explorer of the **Report Assistant**.
   - **Alfabet Query/Native Sql/Query as Text**: Define a query to find the objects that are displayed in the object box column of the lane either in Alfabet query language or native Sql. All information that is given about the object in the dataset resulting from the query is displayed in the object box for the object in the lane.
6) Click the **Link** element and define the layout of the links in the lane. The attributes are described in the section Defining the Basic Layout of a Lane Report.
7) Right-click the **Link** element and select **Add New Query**. A **Query** element is added to the **Link** element.
8) Click the **Query** element and define the following attributes:
   - **Name**: Define the name of the **Query** element displayed in the explorer of the **Report Assistant**.
   - **Alfabet Query/Native Sql/Query as Text**: Define a query to find the objects that are displayed in the report either in Alfabet query language or native SQL. The query must result in a dataset with the following columns:
     - The REFSTR of the source object for the link. The object must be available in the object box column of the current lane to display the link.
     - The REFSTR of the target object for the link. The object must be available in the object box column of the next lane to display the link.

       By default a link is represented by an arrow from the current object box column to the object box column in the next lane. Therefore, the source object is the object in the current lane and the target object is the object in the next lane. you can change the direction of the link by setting the attribute **Reverse** of the **Link** element. When the direction is reversed, the source object is the object from the next lane and the target object is the object in the current lane.

     - If you want a label to be displayed in the link, at least one additional dataset column must be defined that returns the information to be displayed about the link in the label. The information of all datset columns that are not defined for technical reasons is displayed in the link label.

9) Click the **Link** element and define the following attributes:

- **From Column**: Enter the name of the database column of the dataset resulting from the query defined in the **Query** element that returns the REFSTR of the source object for the link. If the attribute **Reverse** is set to `False`, the source objects must be available in the object box column of the current lane. If the attribute **Reverse** is set to `True`, the source objects must be available in the object box column of the next lane.
- **To Column**: Enter the name of the database column of the dataset resulting from the query defined in the **Query** element that returns the REFSTR of the target object for the link. If the attribute **Reverse** is set to `False`, the target objects must be available in the object box column of the next lane. If the attribute **Reverse** is set to `True`, the target objects must be available in the object box column of the current lane.
- **Reverse**: Select `True` if you want the links to point from objects in the next lane to the objects in this lane. Select `False` if you want the links to point from obejcts in this lane to the objects in the next lane.

10) Repeat step 1 - 9 for each subsequent lane. For the last lane, repeat step 1 - 5 only.

Lanes are processed in the order given in the explorer. After having defined the lanes, you can reorder the lane definitions in the explorer, if applicable:

1) Click the root node of the report.
2) Click the **Browse** button in the attribute **Lanes** of the root node. A new window opens that lists all lane definitions of the report.
3) Click a lane definition in the list and use the **Up** and **Down** buttons on the upper right of the window to move the lane definition in the list.
4) Click **OK** to save your changes. The order of lane definitions in the explorer changes.
5) Click the **Lane** nodes in the explorer and check whether the setting of the **Has Link Lane** attributes is correct.
6) Adapt the link query definitions to the changes in the order of lanes. Links can only connect objects from one lane to the next lane in the definition.

Defining the Basic Layout of a Lane Report

The basic design of the lane report is configured via the attributes of the root node of the report.

For each lane, the design of the object boxes and links can be defined with the attributes of the Node and Link element of the lane definition.

The table lists all attributes that are available for configuring the layout of the report in the respective elements:

Attribute	Description
Root Node Element of	

Attribute	Description
the Report	
Show Legend	If set to `True`, a legend is shown for the color coding of the objects in the report and the indicator rules defined for the report.
Show Caption	If set to `True`, captions defined with the attribute **Caption** of the **Lane** elements of the report are displayed in the report.
Show Sub-Caption	If set to `True`, captions defined with the attribute **Caption** of the **Node** and **Link** elements are displayed in the report.
Lane Border Color	Defines the color of the borders displayed around object box rows and link rows in the report. By default, the border color is transparent and no border will be displayed.
Item Border Width	Defines the width of the border of the boxes in the report. The default value is 1 point. When using the border color as object property indicator via a color rule, it is recommended to set the border width to a higher value.
Caption Text Attributes	Click the rectangle in front if the **Text Attributes** attribute to define how the captions defined with the attribute **Caption** of the **Lane** elements of the report are displayed. **NOTE**: To allow line breaks in the text of the object box, set the sub-attribute **Word Wrap** to `true`.
Sub-Caption Text Attributes	Click the rectangle in front if the **Text Attributes** attribute to define how the captions defined with the attribute **Caption** of the **Node** and **Link** elements are displayed in the report. **NOTE**: To allow line breaks in the text of the object box, set the sub-attribute **Word Wrap** to `true`.
Node Element	
Caption	Defines a caption that is displayed as sub-caption beneath the Caption defined with the attribute **Caption** of the **Lane** element in top of the object box column defined by the **Node** element.
Width	Defines the width of the object box column.

Attribute	Description
Background Color	Defines the background color of the object box column.
Item Background Color	Defines the background color of the boxes representing the objects in the object box column. If the attribute is not defined, the value specified in the class settings of the object class represented by the object box will be used. For more information about the default coloring for object classes, see Configuring Class Settings for Object Classes and Object Class Stereotypes. For more information about color selection, see Defining Color Rules.
Item Foreground Color	Defines the text color of the boxes representing the objects in the object box column. If no value is specified, the value specified in the class settings of the object class represented by the object box will be used. For more information about the default coloring for object classes, see Configuring Class Settings for Object Classes and Object Class Stereotypes. For more information about color selection, see Defining Color Rules.
Item Border Color	Defines the border color of the boxes representing the objects in the object box column. If no value is specified, the value specified in the class settings of the object class represented by the object box will be used. For more information about the default coloring for object classes, see Configuring Class Settings for Object Classes and Object Class Stereotypes. For more information about color selection, see Defining Color Rules.
Icon	An icon from the icon gallery can be displayed in the object boxes of the lane. Select an icon from the drop-down list. If no icon is selected, the boxes are displayed without an icon. **NOTE**: Alternatively, the attribute **Show Class Icon** can be set to `True` to display the icon defined in the class settings of the object class in the object boxes. If an icon is selected with the attribute **Icon**, the setting of the attribute **Show Class Icon** is ignored.
Format	Defines a string to be displayed in the object boxes. By default, the object boxes display all information defined in the `Show` properties of the Alfabet query or `SELECT` statement of the native Sql query that is defined in the **Query** child element of the **Node** element. Alternatively, a static text can be configured that includes variables for data derived from the query. To display current query results in the string, add a variable in the format {dataset column name}. **NOTE**: The name and caption of a dataset column are not necessarily identical. Which value must be taken over depends on the way an Alfabet query or a native SQL query are

Attribute	Description
	defined. For more information about how to identify the correct technical name of a dataset column, see Defining Column Names and Captions in the chapter Defining Queries.
Text Attributes	Click the rectangle in front if the **Text Attributes** attribute to define how text is displayed per default in the object boxes for the object class. **NOTE**: To allow line breaks in the text of the object box, set the sub-attribute **Word Wrap** to `true`.
Alignment	This attribute alignes the object boxes in a column if other columns in the report are larger and this column is not completely filled with object boxes. Select `Top` to position the object boxes on top of the column. Select `Center` to position the object boxes at the center of the column. Select `Bottom` to position the object boxes on the bottom of the column.
Item Spacing	Defines the spacing between the object boxes in the object box column.
Item Padding	Defines the spacing between the column borders and the boxes in the column in number of pixels. Click the rectangle in front if the **Item Padding** attribute and define either one value for all spacings with the attribute **All** or single spacing values for the left, right, top and bottom border.
Item Height	Defines the height of the object boxes in the object box column in pixels.
Show Class Icon	Select `True` to display the class icon in the object boxes. the class icon is defined in the class settings of the object class. The **Show Class Icon** setting is ignored if an icon is defined with the attribute **Icon**.
Show Indicator	Select `True` to display an indicator icon in the upper right corner of the object box or multiple indicator icons at the bottom of the object box in a single row. Indicator icons are one displayed in the object box if an indicator rule is defined that specifies the dipslay of an indicator for the object. Indicator icons can represent an indicator value from the object evaluation or any other aspect that can be defined for the object via a query. Select `False` to exclude the display of the indicator icons for the object box column.
Show Multiple Indicators	Defines whether display of icons defined via indicator rules is limited to one icon per object box or whether multiple icons can be assigned to an object box. If **Show Multiple Indicators** is set to `False`, a single icon can be displayed on the right of the object box. If multiple icons are found by indicator rules, the first icon found is assigned and all other icons are ignored. If **Show Multiple Indicators** is set to `True`, one or multiple icons are displayed from left to right at the bottom of the object box. If the number of icons that are assigned to the object box via indicator rules exceeds the space available for display of icons in a single row,

Attribute	Description
	the first icons found are displayed and, if the object box space is exceeded, any other icons are ignored. The way icons are placed in the object box also depends on the attribute **Indicator Fill Policy** of the **Item** node. For more information about the placement of icons assigned via indicator rules, see the section Defining Indicator Rules.
Indicator Fill Policy	If **Show Multiple Indicators** is set to `True`, this attribute defines how icons assigned to an object box are placed in the row on the bottom of the object box: • `ByIndex`: This setting shall be used if multiple indicators are defined via multiple indicator rules, each returning a single icon. The position of the icon resulting from each indicator rule is defined by means of the attribute **Indicator Index** of the respective indicator rule that must be set to an unsigned integer starting with 0 for the left most position. If an **Indicator Index** attribute has been defined for each indicator rule and an indicator is not set for a specific object, the position of this indicator icon in the box will be left empty and the position of all other indicator icons will not be changed:  If the order of the **Indicator Index** attribute is not defined, the placement of indicators will be arbitrary. This method is designed for positioning only one icon per indicator rule. If an indicator rule returns multiple icons, only one of the icons is displayed. • `LeftAlign`: This setting shall be used if a single indicator rule is defined that returns multiple icons. It can also be applied when multiple indicator rules each return a single icon, but the position and order of icons is not important to understand the report. The Icons are displayed in the order of occurence within the indicator rule(s) from left to right. If a different number of indicator icons is returned, the remaining icons are moved to the left:

Attribute	Description
	 If the indicator icons are all found by a single indicator rule, the order of icons depends on the order of results in the result dataset of the query of the indicator rule and may be different for different objects if no sort order is defined in the query.
Link Element	
Caption	Defines a caption that is displayed as sub-caption beneath the Caption defined with the attribute **Caption** of the **Lane** element on top of the link column defined by the **Link** element.
Width	Defines the width of the link column.
Background Color	Defines the background color of the link column.
Item Background Color	Defines the color of the links in the report. If no value is specified, and the link is represented by an object that has class settings defined, the value specified in the class settings will be used. For example, a link can represent an information flow between two applications. For more information about the default coloring for object classes, see Configuring Class Settings for Object Classes and Object Class Stereotypes. If no value is specified, and the link is represented by an object that has no class settings defined, the link is invisible. If the link represents an object class, color rules can be defined to change coloring according to a given property value of the current object. For more information about color selection, see Defining Color Rules.
Item Foreground Color	Defines the text color of the boxes representing the objects in the object box column. If no value is specified, the value specified in the class settings of the object class represented by the link will be used. For more information about the default coloring for object classes, see Configuring Class Settings for Object Classes and Object Class Stereotypes.

Attribute	Description
	If the link represents an object class, color rules can be defined to change coloring according to a given property voalue of the current object. For more information about color selection, see Defining Color Rules. **NOTE**: This attribute is only relevant if the attribute **Show Label** is set to `True`.
Format	Defines a string to be displayed in the link label. By default, the link labels display all information defined in the `Show` properties of the Alfabet query or `SELECT` statement of the native Sql query that is defined in the **Query** child element of the **Link** element. Alternatively, a static text can be configured that includes variables for data derived from the query. To display current query results in the string, add a variable in the format {dataset column name}. **NOTE**: The name and caption of a dataset column are not necessarily identical. Which value must be taken over depends on the way an Alfabet query or a native SQL query are defined. For more information about how to identify the correct technical name of a dataset column, see Defining Column Names and Captions in the chapter Defining Queries. **NOTE**: This attribute is only relevant if the attribute **Show Label** is set to `True`.
Text Attributes	Click the rectangle in front if the **Text Attributes** attribute to define how text is displayed per default in the labels of the links. **NOTE**: To allow line breaks in the text of the link label, set the sub-attribute **Word Wrap** to `true`. **NOTE**: This attribute is only relevant if the attribute **Show Label** is set to True.
Show Label	If set to `True`, a label is displayed for each link in the report that provides information about the link. By default, the link labels display all information defined in the `Show` properties of the Alfabet query or `SELECT` statement of the native Sql query that is defined in the **Query** child element of the **Link** element. Alternatively, a static text can be configured that includes variables for data derived from the query. The attribute **Format** must be set to show static text in the labels.

Defining a Matrix Report

Matrix reports are designed in the **Report Assistant**. For information about how to open the **Report Assistant**, see Creating a New Graphic Report. For more information about how to work with the **Report Assistant**, see Configuring the Report with the Report Assistant.

The content and layout of a grid report is defined by adding elements to the explorer of the **Report Assistant** and setting the attributes in the attribute pane of the **Report Assistant** window.

The content and layout of a grid report is defined in the root node element.

The following table lists the explorer node elements that can be configured to specify the content of the report as well as provides information about the purpose of each sub-element:

Explorer Node Element	Required to Configure:
Root Node	General layout of the report.
Columns	Definition of the column header. The element is a container for one or multiple elements **Query** that define the objects displayed in the column header.
Rows	Definition of the row header. The element is a container for one or multiple elements **Query** that define the objects displayed in the row header.
Cells	Definition of the content of the cells in the report. The element is a container for one or multiple elements **Query** that define the objects displayed in the cells of the report.
Query	Definition of the content of the headers or cells of the report.
Color Rule	Definition of the colors used and the rules that define which objects are displayed in which color.
Indicator Rule	Definition of one or multiple icons displayed in the boxes representing the objects in the current cell of the lane report. The icons can either represent an indicator or any aspect defined via a query. For more information, see the section Defining Indicator Rules.

Defining the Basic Design of the Matrix Report

The basic design of the report depend on the sub-type of the matrix report. Two sub-types, `AffinityMatrix` and `Diagram` are available. For an overview of the differences between the two report types, see Matrix Reports in the section Types and Features of Configured Reports.

Customization of the basic report design is done via the attributes of the explorer root node. The report of the sub-type Diagram offers a greater flexibility for design changes than the report of the sub-type `AffinityMatrix`.

The design of the boxes representing objects in the report can be changed from the standard design with a white rectangle as background for text within the colored object box to fully colored object boxes. For more information see Defining the General Display of Object Boxes in Treemap, Diagram, Lane and Layered Diagram Reports.

Please note that the header cells for affinity matrices are displayed with text in white object boxes regardless of the setting for the general design.

The table below lists all attributes that specify the general layout of the report in the root node element and effect thereof.

The root node element also contains attributes for the definition of the cell content. These attributes are not listed in this section, but in the section Defining the Content of the Matrix Report.

Attribute	Description
Show Legend	Defines whether a legend is shown for the color coding of the objects in the report.
Render Type	Defines whether the matrix is displayed as an affinity matrix or a diagram. For an overview of the differences between the two report types, see Matrix Reports in the section Types and Features of Configured Reports.
Background Color	Defines the background color of the matrix. For more information about color selection, see Defining Color Attributes.
Grid Color	Defines the color of the borders between the cells of the matrix. For more information about color selection, see Defining Color Attributes.
Item Size	Defines the size of boxes that are displayed for all objects in the report in mm. (1 mm = 4 pixel). The size must be defined as length,height.
Item Border Width	Defines the width of the border of the boxes in the report. the default value is 1 point. When using the border color as object property indicator via a color rule, it is recommended to set the border width to a higher value.
Show Multiple Indicators	Defines whether display of icons defined via indicator rules is limited to one icon per object box or whether multiple icons can be assigned to an object box. If **Show Multiple Indicators** is set to `False`, a single icon can be displayed on the right of the object box. If multiple icons are found by indicator rules, the first icon found is assigned and all other icons are ignored. If **Show Multiple Indicators** is set to `True`, one or multiple icons are displayed from left to right at the bottom of the object box. If the number of icons that are assigned to the object box via indicator rules exceeds the space available for display of icons in a single row, the first icons found are displayed and, if the object box space is exceeded, any other icons are ignored. The way icons are placed in the object box also depends on the attribute **Indicator Fill Policy** of the **Item** node. For more information about the placement of icons assigned via indicator rules, see the section Defining Indicator Rules.
Indicator Fill Policy	If **Show Multiple Indicators** is set to `True`, this attribute defines how icons assigned to an object box are placed in the row on the bottom of the object box:

Attribute	Description
	• `ByIndex`: This setting shall be used if multiple indicators are defined via multiple indicator rules, each returning a single icon. The position of the icon resulting from each indicator rule is defined by means of the attribute **Indicator Index** of the respective indicator rule that must be set to an unsigned integer starting with 0 for the left most position. If an **Indicator Index** attribute has been defined for each indicator rule and an indicator is not set for a specific object, the position of this indicator icon in the box will be left empty and the position of all other indicator icons will not be changed:  If the order of the **Indicator Index** attribute is not defined, the placement of indicators will be arbitrary. This method is designed for positioning only one icon per indicator rule. If an indicator rule returns multiple icons, only one of the icons is displayed. • `LeftAlign`: This setting shall be used if a single indicator rule is defined that returns multiple icons. It can also be applied when multiple indicator rules each return a single icon, but the position and order of icons is not important to understand the report. The Icons are displayed in the order of occurence within the indicator rule(s) from left to right. If a different number of indicator icons is returned, the remaining icons are moved to the left:  If the indicator icons are all found by a single indicator rule, the order of icons depends on the order of results in the result dataset of the query of the indicator rule and may be different for different objects if no sort order is defined in the query.
Attributes for reports of the sub-type Diagram only	
Margin	Defines the space between the matrix and the border of the presentation object in number of pixels.

Attribute	Description
Border Color	Defines the color of the border between the matrix and the margin. For more information about color selection, see Defining Color Attributes.
Item Spacing	Defines the spacing between the boxes in a matrix cell in pixel.
Item Padding	Defines the spacing between the columns and between the boxes in the columns in number of pixels. The first number defines the vertical spacing between row borders and table content and the second number defines the horizontal spaces between column borders and cell content. The numbers must be specified comma-separated, that means vertical,horizontal.
Rounded Edges	Select `True` to display the diagram with rounded box edges, or `False` to display boxes with sharp edges.

Defining the Content of the Matrix Report

The explorer root node automatically contains the following child elements when opening the **Report Assistant**:

- one **Rows** element for the definition of the objects displayed in the row header cells on the left of the matrix.
- one **Columns** element for the definition of the objects displayed in the column header cells on top of the matrix.
- one **Cells** element for the definition of the objects displayed in the cells of the report.

The elements **Rows**, **Columns** and **Cells** must not have attributes. They are containers for one or multiple elements **Query**. The element **Query** defines the content of the header cells on basis of an Alfabet query or a native SQL query.

If you want to add objects from multiple classes to the row headers, column headers or cells, you must specify multiple elements **Query** within the respective container element, one for each object class.

Objects in a matrix cell are related to the objects in both the row and the column header. This relation must be defined in the query specifying the cell content. The query must be defined to deliver a tabular output that displays the `REFSTR` of both the object of the column header and the object in the row header in one of the table columns. That means that `REFSTR` of the object in the column header and the `REFSTR` of the object in the row header must be included in the Show properties of the Alfabet query or the `SELECT` clause of the native SQL query.

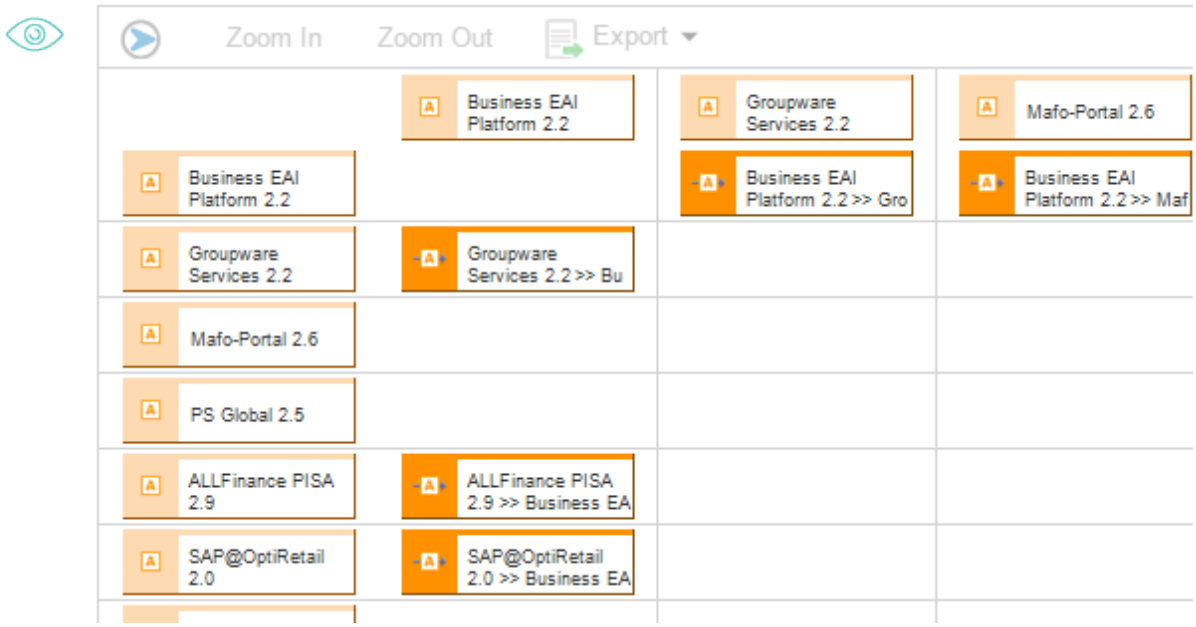
The position of this information within the Show property / the `SELECT` clause must be defined in the root node element with the attributes **Column Ref Index** and **Row Ref Index** . For example, if the `REFSTR` of the object in the column header is specified in the first column of the tabular output of the query, the **Column Ref Index** attribute must be set to 1.

In native SQL queries, the first column definition of the `SELECT` clause is not displayed in the resulting tabular output but exclusively used for technical processing of query results. Therefore, a **Column Ref Index** of 1 requires that the `REFSTR` of the object in the column header is the second column definition of the `SELECT` clause.

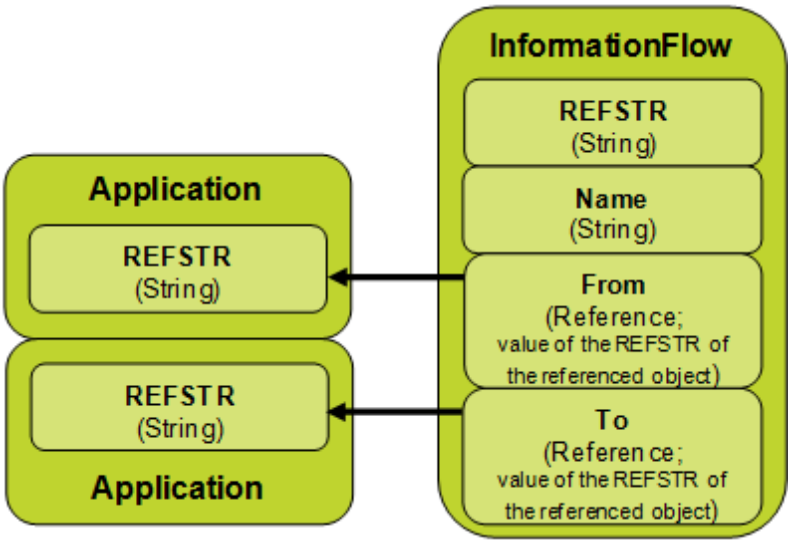
The columns of the tabular report output that are specified with **Column Ref Index** and **Row Ref Index** are not used for display of the object name in the matrix.

If multiple queries define cell content, the position of the `REFSTR`s of the column header and row header objects in the tabular output of the report must be identical for all queries.

A matrix of the sub-type AffinityMatrix shall display the information flows between applications. Applications are listed in both row and column headers. Each cell contains the information flows from the applications in the row headers to the applications in the column headers. The name of the business data that the information flow transfers is displayed in the boxes for the information flows:



The relation between the applications and the information flows are defined in the properties From and To of the information flow. The properties both reference a single application. The value of the properties is identical to the `REFSTR` property of the referenced application:



The report has a **Column Ref Index** of 2 and a **Row Ref Index** of 1.

The row headers list the applications the information flow is coming from and the **Row Ref Index** is 1. Therefore, when displaying the results from the query in a tabular report, the value of the property From of the information flow must be listed in the first column of the tabular query results.

The **Column Ref Index** is 2, which means that the property To of the the information flow must be listed in the second column of the tabular query output. All other columns define the information that shall be displayed in the object boxes in the cells of the report.

The queries resulting in the output in the image above are displayed below two times: with query definitions in Alfabet query language and with query definitions using native SQL. The query parts required for rendering of matrix cell content are marked in dark blue in the code.

When using Alfabet query language to define the report, the `FIND` class of each query must be the object class displayed in the part of the matrix defined by the Alfabet query. In the example, the find class for the cell content is `InformationFlow` although the information displayed in the boxes is exclusively about Business Data. The first and second Show properties of the Alfabet query defining the cell content define the position of the object in the matrix.

Column definition query:

```
ALFABET_QUERY_500
FIND Application
QUERY_XML
<QueryDef>
<ShowProperty Type="Property" ClassName="Application" Name="Name" />
<ShowProperty Type="Property" ClassName="Application" Name="Version"
/>
<SortProperty Type="Property" ClassName="Application" Name="Name" />
</QueryDef>
```

Row definition query:

```
ALFABET_QUERY_500
```

```
FIND Application
QUERY_XML
<QueryDef>
<ShowProperty Type="Property" ClassName="Application" Name="Name" />
<ShowProperty Type="Property" ClassName="Application" Name="Version"
/>
<SortProperty Type="Property" ClassName="Application" Name="Name" />
</QueryDef>
```

Cell definition query:

```
ALFABET_QUERY_500
FIND InformationFlow
QUERY_XML
<QueryDef>
<ShowProperty Type="Property" ClassName="InformationFlow"
Name="From" />
<ShowProperty Type="Property" ClassName="Application" Name="To" />
<ShowProperty Type="Property" ClassName="InformationFlow"
Name="Name" />
</QueryDef>
```

When using native SQL to define the report, the first column definition of the `SELECT` clause of all queries must define the `REFSTR` of the object to be displayed in the matrix. The second and third column of the `SELECT` clause of the native SQL query defining the cell content define the position of the object in the matrix.

Column definition query:

```
SELECTapp.REFSTR, app.NAME, app.VERSION
FROM APPLICATION app
```

Row definition query:

```
SELECTapp.REFSTR, app.NAME, app.VERSION
FROM APPLICATION app
```

Cell definition query:

```
SELECT inf.REFSTR,inf.A_FROM,inf.A_TO, inf.NAME
FROM INFORMATIONFLOW inf
```

The following table lists all attributes of the elements **Query** and **Root Node** that are required to define the content of matrix cells and headers.

Attribute	Description
Root Node	

Attribute	Description
ColumnRef Index	Specifies the column number in the tabular output of the query defined for cell content specification that contains the `REFSTR` of the object in the column header the cell content object is related to. The default is 1.
RowRefIndex	Specifies the column number in the tabular output of the query defined for cell content specification that contains the `REFSTR` of the object in the row header the cell content object is related to. The default is 2.
Cell Reference	Select `Implicit`. The value `Explicit` is displayed for reasons of backward compatibility and should not be used.
Query	
Name	Defines the name of the **Query** element in the explorer.
Alfabet Query / Native Sql / Query as Text	Defines the content, look and number of the column headers, row headers or cell content, depending on the container element for the **Query** element. A valid Alfabet query must be defined in either the **Alfabet Query** or **Query as Text** attribute or a native SQL query must be written in the **Native Sql** attribute. The query must find the relevant objects and defines which properties of the objects are displayed in the object boxes.
Cascading	Not relevant for matrix reports.

Defining Node Arc Reports or Node Arc Reports With Edge Bundling

Node arc reports are based on the design elements and layouts of standard Alfabet diagrams. The boxes displayed in the node arc report to represent objects are all based on customer defined diagram item templates. Instead of building the box design from scratch, the configured report references customer defined diagram item templates that are either used as defined or modified with the configurations done in the configured report.

Prior to creating a node arc report, you must Therefore, define diagram item templates for use in the configured report. For information about how to configured diagram item templates, see Configuring Custom Diagram Item Templates.

Please note the following about the configuration of diagram item templates for use in node arc reports:

- Standard diagram items cannot be used in configured reports. If you would like to use the standard design of a diagram item for a class in a node arc report, you must create a

custom diagram item template as copy of the standard diagram item template without changes in design.

- The information about the object displayed in the elements of the diagram item template can be modified via the configured report configuration. In that case, the information is taken over from a defined column in the result dataset of the query defined in the configured report. Matching of column data with the elements of the diagram item template is performed by name of the diagram item template element. If you define the configured report to display objects based on multiple different diagram item templates, make sure that the respective elements are all named identically for all configured diagram item templates.
- If you would like to display nodes within nodes, you must define an area for the display of the child nodes in the diagram item template to be used for the parent nodes. In addition, the **Layout Type** attribute must be set to `Scalable` for both the custom diagram item template used for rendering the outer and the inner nodes. Custom diagram item templates used for outer nodes must have an area for placement of the inner nodes defined. Please note that only one level of nesting is supported for nodes in node arc reports.

Node arc reports can be based on two different templates. For reports based on the template `NodeArcReport`, the user can select the diagram layout in runtime. The predefined filters will be the same as for standard Alfabet diagrams. Reports based on the template `NodeArcReportWithBundling` are always displayed in `Spring Layout`. The user can select at runtime, whether and how much connections are bundled to enhance visibility. The configuration options available are the same for both types of node arc reports.

Node arc reports are designed in the **Report Assistant**. For information about how to open the **Report Assistant**, see Creating a New Graphic Report. For more information about how to work with the **Report Assistant**, see Configuring the Report with the Report Assistant.

The content and layout of a node arc report is defined by adding elements to the explorer of the **Report Assistant** and setting the attributes in the attribute pane of the **Report Assistant** window.

The following table lists the explorer node elements that can be configured to specify the content of the report as well as provides information about the purpose of each sub-element:

Explorer Node Element	Required to Configure:
Root Node	Definition of the layout of the report.
Node Query	Definition of the dataset that defined which nodes are displayed with which information and design in the node arc report.
Arc Query	Definition of the dataset that defined which nodes are connected with each other and how the connections between the nodes are designed.

Explorer Node Element	Required to Configure:
Indicator Rule	Indicator rules can be defined to display icons within the nodes of the node arc report. Currently only indicator rules of the type `IconQuery` are supported. For more information about indicator rule definition, see .Defining Indicator Rules

The **Node Query** and **Arc Query** define the content and layout of the nodes and arcs, that means connections, in the node arc report. Which column in the result datasets of the **Node Query** and **Arc Query** provide which information required to build the node arc report with the correct content and layout is defined in the attributes of the root node of the node arc report. In the root node, it is also possible to define the general layout and a default layout for nodes and arcs that is used if nodes or arcs do not have a layout defined in the respective query result.

Defining the Nodes Displayed in the Node Arc Report

The nodes displayed in the node arc report are found by a query that has to be defined in the attribute **Alfabet Query** (or **Query as Text**) or **Native SQL** of the explorer node **Node Query**.

The query must return all information that is required to display the nodes of the configured report. The name of the column that contains the respective information must then be mapped with one of the attributes of the root node of the node arc report that are listed in the following table together with information about the required format of the information in the dataset and a description of the triggered functionality:

Attribute	Required value type in dataset	Description
Node Ref Column	REFSTR property value of an object	Returns the REFSTR of the object that is represented by the node. This definition is mandatory.
Node Shape Column	The name of an existing diagram item template.	Returns the diagram item template that the node should be based on. The diagram item template is defined by the name of the default diagram item template with the prefix `CustomItems:`, For example, `CustomItems:AppApplicationServer`.
Node Background Color Column	HTML color code	Returns the background color to be used for the diagram item that displays the current object. This value overwrites the background color defined for the diagram item template used to display the node.

Attribute	Required value type in dataset	Description
Node Navigation View Column	`View=ViewType:ViewName` The `ViewType` can be one of the following: • ***Report*** for a configured report • ***GraphicView*** for a standard Alfabet view • ***ObjectView*** for an object profile `ViewName` is the name of the view. If the link target is a configured report, optionally parameters can be specified for filling the filter fields of the report. For more information about defining navigation to a target view including definition of parameters, see Defining Navigation from the Report to Alfabet Views.	Defines the name of the column containing the definition of an alternative link target for the double click action on the object nodes. By default, the standard object profile of the object opens when a user double clicks on a node or clicks a node and then clicks the **Navigate** button. To enable navigation, both **Node Navigation View Column** and **Node Ref Column** must be defined. The `REFSTR` returned in the column defined with **Node Ref Column** is submitted as base object to the view that opens.
Node Icon Name Column	The name of an icon that is available in the icon gallery.	Returns the icon that shall be displayed on the node to represent the object. Icons must have been uploaded to the icon gallery to be used in the configured report. For more information about upload of icons see Adding and Maintaining Icons for the Alfabet Interface.
Node Tool Tip Column	String	Returns a text to be displayed as tooltip when the user points with the cursor to the node.
Node Legend Group Column	String	Returns a string that shall be displayed as heading for the legend entry defined with **Node Legend Text Column** in the same row of the dataset. All legend entries that have the same **Node Legend Group Column** value are grouped and displayed under the heading defined with **Node Legend Group Column**.
Node Legend Text Column	String	The text that shall be displayed for the kind of node in the legend. The legend shows an entry for each combination of coloring and icon in the node. The node icon is displayed in front, and the node legend text is displayed in a field with the background color identical to the one defined for the node.

Attribute	Required value type in dataset	Description
		Legend text is only displayed if a legend group for the text is also defined with **Node Legend Group Column**.
Node Labels and Areas	Any information about objects that can meaningfully be displayed on the nodes	With this attribute the information displayed about the object in the node is defined. Click into the attribute field and then click on the **Browse** button on the right of the attribute field to open an editor for the mapping of information from the result dataset of the query to elements defined to display information in the diagram item template that the node is based on. For each information to display: 1) Write the name of the dataset column containing the information into the field **Node Query Column**. 2) Write the name of the element in the diagram item template that shall be the container for the information into the field **Diagram Item Template Shape**. 3) Click the button **Add**. After having defined the mapping, click **OK** to close the editor and save your configuration. Please note that each dataset column can only be mapped once to an diagram item template element name. Therefore, if you want multiple diagram item templates to be used in your configured report, these shall all use the same names for elements displaying information.

Please note the following about the definition of the node query:

- **To display objects of multiple object classes as nodes in the node arc report**: As only one column name per functionality can be defined for the nodes in the attributes of the root node of the report, the query must return the values for all object classes that return the same type of information in columns of the same name. You can use For example, `UNION ALL` for a definition of multiple object classes in native SQL queries.
- **To display objects in a nested node infrastructure**: Nodes can be displayed within a two-level hierarchy nested into each other. To display child nodes within parent nodes, use the `GroupBy_Ex`

instruction to create a dataset with two levels with the parent node definition on the upper level. As only one column name per functionality can be defined for the nodes in the attributes of the root node of the report, the query must return the values for all object classes that return the same type of information in columns of the same name. Use `JoinColumn` instructions in both Alfabet queries or native SQL queries to join identical information from both levels into one column each.

For information about creating a grouped dataset with Alfabet instructions, see Grouping Query Results in Expandable Reports.

If nested nodes shall be defined, additional attributes must be defined in the root node of the report assistant. Most display options for nested nodes can either be defined statically by value definition in the attributes of the root node or dynamically in the query. If values are defined in the query, the values selectable for the static attributes must be returned in a column of the query and the attribute for dynamic value definition must be set to the column name of the column in the node query returning the value. Static values are then used as default values if values are not returned by the query:

Attribute for Static Definition	Attribute for Dynamic Definition	Description
Enable Box-in-Box		Set to `True` if you want to show two levels of nodes nested into each other. A section **In-Box Rendering** is added to the attributes of the root node of the report assistant if the attribute is set to `True`. Exand the **In-Box Rendering** in that section and define the attributes defined in this table in the following.
Node Resizing Model	Node Resizing Model Column Name	Defines how the availability of child nodes shall influence the size of nodes in the node arc report: • `KeepChildNodeSize`: Select if the size of inner nodes shall be maintained and the outer nodes shall be enlarged if this is required to fit in the inner nodes. • `KeepParentNodeSize`: Select if the size of the outer nodes shall be maintained and the size of the inner nodes shall be reduced to fit all inner nioes into the outer node. If text for the nodes • `KeepAllNodeSizes`: Select if all nodes shall have a fixed size and the display of inner nodes shall be limited to the number of inner nodes fitting into the available space in the placement area of the outer node.
Initial Child Item Size		Select the size of the inner nodes that shall apply if no node resizing is done. Please note that the size of the inner nodes must be smaller than the size of the outer nodes defined with the attribute **Item Size**. The values available in the drop-down list of the attribute **Initial Child Item Size** are configured in the XML object ***DiagramInformationFlowDef***. For more information, see the section Configuring the Sizes of Diagram Items in Automatically Generated Diagrams. Depending on the configuration, some sizes may be configured to hide the name, icon, and attributes. In this case, the user can point to the

Attribute for Static Definition	Attribute for Dynamic Definition	Description
		node to display a tooltip with the object's name or click-and-hold to open the preview of the object.
Minimal Child Node Size	Minimal Child Node Size Column Name	If the **Node Resizing Model** attribute was set to `KeepParentNodeSize`, you can optionally define a maximum required size of the inner nodes as an integer. If the inner nodes will not fit in to the outer node with the defined minimal node size, the number of displayed inner nodes will be restricted to the number of nodes fitting the available space and additional inner nodes returned by the node query for display in the outer node excluded from displayed.
Maximal Number Of Child Nodes	Maximal Number Of Child Nodes Column Name	Optionally define the maximum number of inner nodes that may be displayed per outer node as integer. This may be useful to restrict the size of the outer node if the **Node Resizing Model** attribute was set to `KeepChildNodeSize`.
Child Node Padding	Child Node Padding Column Name	Define the padding between inner nodes as integer.
Maximal Container Node Width	Maximal Container Node Width Column Name	If the **Node Resizing Model** attribute was set to `KeepChildNodeSize`, you can optionally define a maximum allowed width of the outer nodes as integer. If both the **Maximal Container Node Width** and **Maximal Container Node Height** attributes are defined, the number of displayed inner nodes will be restricted to the number of nodes fitting the available space and additional inner nodes returned by the node query for display in the outer node excluded from displayed.
Maximal Container Node Height	Maximal Container Node Height Column Name	If the **Node Resizing Model** attribute was set to `KeepChildNodeSize`, you can optionally define a maximum allowed width of the outer nodes as integer. If both the **Maximal Container Node Width** and **Maximal Container Node Height** attributes are defined, the number of displayed inner nodes will be restricted to the number of nodes fitting the available space and additional inner nodes returned by the node query for display in the outer node excluded from displayed.
Default Items Area Name	Container Area Name Column Name	Define a default name that will be used to identify the area in the custom diagram item template for the outer node if the definition in the query does not provide a valid area name.

Attribute for Static Definition	Attribute for Dynamic Definition	Description
Diagram Item To Container Area Map		Define the name of the area in the custom diagram item template for the outer node that shall contain the inner nodes. In the static definition, click the **Browse** button in the attribute. A new window opens. Click the **Add Diagram Items** button in the upper left corner, select a custom diagram item template that shall be used for display of outer nodes. the diagram item template is displayed in the window with custom diagram item template name on the left and a drop-down list of available areas in the custom diagram item template on the right. Select the relevant area from the drop-down list.

A default layout can be defined for the nodes in the configured report with the attributes listed in the following table. The default layout is used if a valid definition for the respective design is not provided in the query results. If the same design shall anyway be used for all nodes in the configured report, the default layout can be defined and the query does not have to return the design elements defined as default.

Attribute	Description
Default Node Shape Name	Specifies the name of the diagram item template that shall be used as default for all nodes that do not have a diagram item template defined in the node query. when you click into the attribute field and then click the **Browse** button on the right of the attribute field, a selector opens that lists all available diagram item templates sorted by object class in an expandable table. Click a row in the table and click **OK** to select the custom diagram item template. If you click a first level row with the object class name, the standard diagram item template for the object class is selected instead of a custom diagram item template. If neither the default nor a definition in the query is available, the standard diagram item template for applications will be used.
Default Node Label Area Name	Specifies a default for the area that information is displayed in for the case that in the Nodes And Areas Attribute a specification does only contain a column name but not a diagram item template area name.
Default Node Background Color	Specifies the default background color that will be used for all nodes for that no background color is defined via the node query. If neither the default nor a definition in the query is available, the standard diagram item template for applications will be used.

Defining the Arcs Connecting the Nodes in the Node Arc Report

The arcs displayed in the node arc report are found by a query that has to be defined in the attribute **Alfabet Query** (or **Query as Text**) or **Native SQL** of the explorer node **Arc Query**.

The query must at least return the RESTR of the start object and the end object for the arc. If the arc represents an object, the definition of the REFSTR of the object in the query has to be defined to enable navigation to hte object's object profile or any other view specified via an instruction. Styling of the arcs can also be defined individually via the query.

Attribute	Required value type in dataset	Description
Arc Start Node Ref Column	REFSTR property value of an object represented by a node	Returns the REFSTR value of the object the arc is starting at. This information is mandatory.
Arc End Node Ref Column	REFSTR property value of an object represented by a node	Returns the REFSTR value of the object the arc is pointing to. This information is mandatory.
Arc Label Column	String	Returns the text that shall be displayed as label on the arc. Labels are only displayed if this attribute is set and the attribute **Show Arc Labels** is set to `True`.
Arc Tooltip Column	String	Returns the text that shall be displayed as tooltip if the user moves the cursor over the arc line.

Arc Label Position Column	`Center`
	
	`Start`
	
	`End`
	
	`PureStart`
	
	`PureEnd`
	
	`PureCenter`
	
	`UserDefined`
		Returns the position of the label on the arc. While the label is positioned vertically on top of the line representing the arc when selecting `Start`, `Center` or `End`, the label is positioned vertically directly on the line when `PureStart`, `PureEnd` or `PureCenter` is used. `UserDefined` specifies that the value defined with **Default Label Position** is used.
		
		Labels are only displayed if the attribute **Arc Label Column** is set and the attribute **Show Arc Labels** is set to `True`.

Arc Reference Column	REFSTR property value of an object	Returns the REFSTR of the object represented by the arc. This attribute must be set to enable navigation from the arc in the node arc report.

Attribute	Required value type in dataset	Description
Arc Navigation View Column	`View=ViewType:ViewName` The `ViewType` can be one of the following: • ***Report*** for a configured report • ***GraphicView*** for a standard Alfabet view • ***ObjectView*** for an object profile `ViewName` is the name of the view. If the link target is a configured report, optionally parameters can be specified for filling the filter fields of the report. For more information about defining navigation to a target view including definition of parameters, see Defining Navigation from the Report to Alfabet Views.	Defines the name of the column containing the definition of a link target for the double click action on the arc arrows. By default, navigation is not provided for arcs. To enable navigation, both **Arc Navigation View Column** and **Arc Reference Column** must be defined. The `REFSTR` returned in the column defined with **Arc Reference Column** is submitted as base object to the view that opens.
Arc Color Column	HTML color code	Returns the color of the arc line in HTML compliant color coding.
Arc Label Back Color Column	HTML color code	Returns the color of the label background in HTML compliant color coding. Labels are only displayed if the attribute **Arc Label Column** is set and the attribute **Show Arc Labels** is set to `True`.
Arc Label Text Color Column	HTML color code	Returns the color of the text in the label in HTML compliant color coding. Labels are only displayed if the attribute **Arc Label Column** is set and the attribute **Show Arc Labels** is set to `True`.
Arc Label Border Color Column	HTML color code	Returns the color of the label border in HTML compliant color coding. Labels are only displayed if the attribute **Arc Label Column** is set and the attribute **Show Arc Labels** is set to `True`.

Attribute	Required value type in dataset	Description

Arc Line Style Column	`Solid`
	`Dash`
	`DashDot`
	`DashDotDot`
	`Dot`
		Returns the line style of the arc line. The line styles are limited to one of the preconfigured styles.

Arc Line Width Column	Integer	Returns the width of the arc line.
Arc Legend Text Column	String	Returns the text that shall be displayed next to the line color in the legend. The legend only destinguisches coloring. That means that independent from the styling selected for the line with and arrow style, lines are all displayed by a symbol with the same linestyle, but in the color returned in the column defined in the attribute **Arc Color Column** or, if no color is defined via the query, the color selected with the attribute **Default Arc Color**. the text returned in the column specified with the attribute Arc Legend Text Column is written next to the line symbol in the color and with the background color defined for the node labels. Legend text is only displayed if a legend group for the text is also defined with **Node Legend Group Column**.
Arc Legend Group Column	String	Returns a string that shall be displayed as heading for the legend entry defined with **Arc Legend Text Column** in the same row of the dataset. All legend entries that have the same **Arc Legend Group Column** value are grouped and displayed under the heading defined with **Arc Legend Group Column**.

Start Arc Arrow > Arrow Style Column	`None`
	`Angle`
	`ArrowedTriangle`
	`Circle`
	`LeftAngle`
		Returns the design of the arrow at the start of the line. The arrow styles are limited to one of the preconfigured styles.

Attribute	Required value type in dataset	Description

	`Rhomb`
	`RightAngle`
	`Triangle`	

Start Arc Arrow > Arrow Size Column	`Small`
	`Middle`
	`Large`
	`ExtraLarge`
		Returns the size of the arrow at the start of the arc as one of the allowed values between small and extra large.

End Arc Arrow > Arrow Style Column	`None`
	`Angle`
	`ArrowedTriangle`
	`Circle`
	`LeftAngle`
	`Rhomb`
	`RightAngle`
	`Triangle`
		Returns the design of the arrow at the end of the line. The arrow styles are limited to one of the preconfigured styles.

End Arc Arrow > Arrow Size Column	`Small`
	`Middle`
	`Large`
	`ExtraLarge`
		Returns the size of the arrow at the end of the arc as one of the allowed values between small and extra large.

A default layout can be defined for the arcs in the configured report with the attributes listed in the following table. The default layout is used if a valid definition for the respective design is not provided in the query results. If the same design shalll anyway be used for all arcs in the configured report, the default layout can be defined and the query does not have to return the design elements defined as default.

Attribute	Description
Default Arc Label Position	Select the default position position of the label of the arc if not returned via the query. While the label is positioned vertically on top of the line representing the arc when selecting `Start`, `Center` or `End`, the label is positioned vertically directly on the line when `PureStart`, `PureEnd` or `PureCenter` is used. `UserDefined` specifies that the value defined with **Default Label Position** is used.

Attribute	Description
	Labels are only displayed if the attribute **Arc Label Column** is set and the attribute **Show Arc Labels** is set to `True`.
Default Arc Color	Select a color that is used as default for the coloring of arc lines if a color is not defined via the column in the **Arc Node Query** defined with the attribute **Arc Color Column**.
Default Arc Label Back Color	Select a color that is used as default for the coloring of arc label backgrounds if a color is not defined via the column in the **Arc Node Query** defined with the attribute **Arc Label Back Color Column**. Labels are only displayed if the attribute **Arc Label Column** is set and the attribute **Show Arc Labels** is set to `True`.
Default Arc Label Text Color	Select a color that is used as default for the coloring of arc label text if a color is not defined via the column in the **Arc Node Query** defined with the attribute **Arc Label Text Color Column**. Labels are only displayed if the attribute **Arc Label Column** is set and the attribute **Show Arc Labels** is set to `True`.
Default Arc Label Border Color	Select a color that is used as default for the coloring of arc label borders if a color is not defined via the column in the **Arc Node Query** defined with the attribute **Arc Label Border Color Column**. Labels are only displayed if the attribute **Arc Label Column** is set and the attribute **Show Arc Labels** is set to `True`.
Default Arc Line Style	Select a line style that is used as default for the style of arc lines if a style is not defined via the column in the **Arc Node Query** defined with the attribute **Arc Line Style Column**.
Default Arc Line Width	Enter a line width in pixel that is used as default for the width of the arc lines if a width is not defined via the column in the **Arc Node Query** defined with the attribute **Arc Line Width Column**.
Start Arc Arrow > Default Arrow Style	Select an arrow style that is used as default for the arrows at the start of the arc if a style is not defined via the column in the **Arc Node Query** defined with the attribute **Start Arc Arrow** > **Arrow Style Column**.
Start Arc Arrow > Default Arrow Size	Select an arrow size that is used as default for the arrows at the start of the arc if a size is not defined via the column in the **Arc Node Query** defined with the attribute **Start Arc Arrow** > **Arrow Size Column**.

Attribute	Description
End Arc Arrow > Default Arrow Style	Select an arrow style that is used as default for the arrows at the end of the arc if a style is not defined via the column in the **Arc Node Query** defined with the attribute **End Arc Arrow** > **Arrow Style Column**.
End Arc Arrow > Default Arrow Size	Select an arrow size that is used as default for the arrows at the end of the arc if a size is not defined via the column in the **Arc Node Query** defined with the attribute **End Arc Arrow** > **Arrow Size Column**.

Defining the General Layout of the Node Arc Report

The general layout of the node arc report defines the default for the setting of diagram specific filters that are automatically added to the configured report view when the configured report view is created. When a user opens the node arc report, the layout defined by default is used to display the node arc report and the user can then change to a different layout using one of the following methods:

- Users can change the layout via the standard filters added to the report by default. If you do not want to the user to change the layout options defined as default, you can remove the corresponding filter fields from the filter panel. On demand, you can add custom filters to the filter panel. Definition of filters is described in the section Defining Filters for Configured Reports and Selectors
- Users with edit rights to the base object of the report can change the layout in the Alfabet Diagram Designer. The Alfabet Diagram designer opens when the user clicks the **Change Layout** button of the report. The layout of the report can be modified in the Alfabet Diagram Designer including changes to the size, alignment, coloring, and styling of the objects in the report. Additionally, the caption of the node arc report will be displayed in the Alfabet Diagram Designer. If objects are not found any longer via the query of the node arc reports, the objects and the connections of the objects to other objects will be removed from the rendering of the report. The changed layout will be saved for the current user and the node arc report will use the layout if the current user opens the report for the same base object. The user can re-open the diagram designer to change the layout or remove the layout at a later time.

Optionally, node arc reports can be configured to save a layout defined by one user for all users. The buttons **Change Layout** and **Delete Saved Layout** will be changed to **Change Saved Layout** and **Delete Shared Layout** if the layout is changed to inform the user that any change to the layout will also change the view for other users. Any changes performed by any authorized users will change the layout for all users.

In addition to the default settings for the standard filters, display of labels and legends are part of the standard layout definition.

The following attributes of the node arc report are part of the standard layout definition:

Attribute	Description
Layout	Dependent on the layout type, boxes and connections are differently arranged within the diagram. For example, Condensed displays all nodes in a circle with the connecting arcs between them. Which layout type is best for display of the report depends on the current content. For the same report, display of a high number of objects might require a different layout then the same report displaying only a few objects to give the best overview. Select a layout from the available layout types in the drop-down list. The layout will be used when the user first opens the diagram.
Item Size	Select the size of the nodes displayed in th the node arc report. The values available in the drop-down list of the attribute **Item Size** are configured in the XML object ***DiagramInformationFlowDef***. For more information, see the section Configuring the Sizes of Diagram Items in Automatically Generated Diagrams. Depending on the configuration, some sizes may be configured to hide the name, icon, and attributes. In this case, the user can point to the node to display a tooltip with the object's name or click-and-hold to open the preview of the object.
Format	Define the page format to use to display the diagram. The page format setting is not relevant if `Condensed` is selected as layout.
Landscape	Defines the orientation of the node arc report. If set to `True`, the node arc report is displayed in landscape orientation. If set to `False`, it is displayed in portrait orientation. The default value is `False`.
Show Arc Labels	Defines whether labels are displayed on the arcs of the node arc report. Labels are only displayed, if content and design is defined in the definition of the arcs and this attribute is set to `True`.
Show Legend	Defines whether a legend is shown for the node arc report. If set to `True`, legend texts and grouping should be defined as part of the node and arc definitions.
Indicator Fill Policy	If multiple indicator rules are defined for the node arc report, this attribute defines how icons assigned to a node are placed in a row on the bottom of the node: • `ByIndex`: This setting shall be used if multiple indicators are defined via multiple indicator rules, each returning a single icon. The position of the icon resulting from each indicator rule is defined by means of the attribute **Indicator Index** of the respective indicator rule that must be set to an unsigned integer starting with 0 for the left most position. If an **Indicator Index** attribute has been defined for each indicator rule and an indicator is not set for a specific object, the position of this indicator icon in the box will be left empty and the position of all other indicator icons will not be changed:

Attribute	Description
	 If the order of the **Indicator Index** attribute is not defined, the placement of indicators will be arbitrary. This method is designed for positioning only one icon per indicator rule. If an indicator rule returns multiple icons, only one of the icons is displayed. • `LeftAlign`: This setting shall be used if a single indicator rule is defined that returns multiple icons. It can also be applied when multiple indicator rules each return a single icon, but the position and order of icons is not important to understand the report. The icons are displayed in the order of occurence within the indicator rule(s) from left to right. If a different number of indicator icons is returned, the remaining icons are moved to the left:  If the indicator icons are all found by a single indicator rule, the order of icons depends on the order of results in the result dataset of the query of the indicator rule and may be different for different objects if no sort order is defined in the query.
Allow Others to View Saved Diagram	If set to `True`, users with edit permissions for the base object of the node arc report can define a diagram layout for the node arc report that will then be shared with all users. If another user opens the node arc report for the same base object, the shared layout will be displayed. Users with edit permissions to the base object of the node arc report can change or delete the shared layout.

Defining Portfolio Reports

Portfolio reports are designed in the **Report Assistant**. For information about how to open the **Report Assistant**, see Creating a New Graphic Report. For more information about how to work with the **Report Assistant**, see Configuring the Report with the Report Assistant.

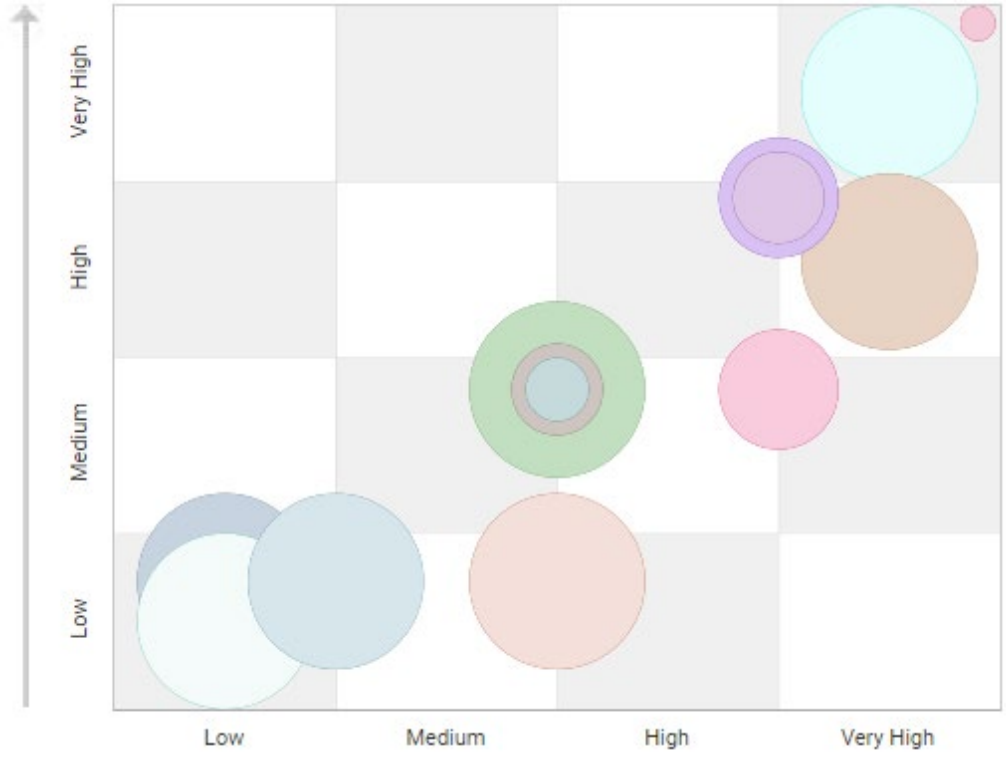
The content and layout of a portfolio report is defined by adding elements to the explorer of the **Report Assistant** and setting the attributes in the attribute pane of the **Report Assistant** window.

The following table lists the explorer node elements that can be configured to specify the content of the report as well as provides information about the purpose of each sub-element:

Explorer Node Element	Required to Configure:
Root Node	Definition of the layout of the report.
X-axis	Static definition of the X-axis of the portfolio.
Y-axis	Static definition of the Y-axis of the portfolio.
Power Axis	Static definition of the power axis of the portfolio. The power axis is the third dimension of evaluation displayed in a portfolio by variation of the size of the shapes representing the objects in the portfolio.
Query	Definition of the objects displayed in the portfolio and dynamic definition of portfolio layout and portfolio axes.
Connection	Definition of connections between objects in the portfolio.

The following sections guide you through the definition of various features of the portfolio.

The default layout displays objects represented by colored bubbles. If a power axis is defined, the bubbles will be sized according to the power axis value. The default portfolio displays an X-axis and Y-axis separated in four segments with the labels **Low**, **Medium**, **High** and **Very High**:



For the definition of a portfolio with default layout it is sufficient to define the base content as described in the sections Defining the Query the Portfolio is Based On and Defining the Objects and Evaluation Dimensions for the Portfolio Report. All other definitions are optional:

Defining the Query the Portfolio is Based On

The objects displayed in the portfolio, the indicators used for evaluation, and any variable design elements are defined in a query that can either be a native SQL query or Alfabet query.

It is recommended to use native SQL for creating portfolio reports. Alfabet query language does not provide the ability to include anything else than data from the tables in the Alfabet database into the search results, which excludes some of the features of the report.

The query must be defined in a ***Query*** node added to the **Report Assistant** explorer. To add the ***Query*** node:

Only one ***Query*** node can be defined for the portfolio definition.

1) Right-click the root node of the explorer in the **Report Assistant** and select **Add New Query** . A new ***Query*** element is added to the explorer node.
2) Click the ***Query*** node and define the attributes of the node. The following settings can be applied:

Attribute	Description
Name	Defines the name of the **Query** element displayed in the explorer of the **Report Assistant**.
Alfabet Query / **Query as Text** / **Native Sql**	Defines a query to find the objects that are displayed in the report, the indicator values that are used to calculate the location of the object shapes in the portfolio, and all optional dynamic design elements of the portfolio.

The query defined for the report must at least find the objects that shall be displayed in the report and the relevant values used for evaluation. In addition, configurations that are described in the following sections are based on optional data returned by the query.

Please note the following basic rules for the definition of the query:

- In native SQL queries, the first argument of the `SELECT` statement must return the `REFSTR` of the object to be displayed in the report in addition to defining the following information in the `SELECT` statement. The first argument is not part of the data set resulting from the query and cannot be mapped to attributes in the **Report Assistant**.
- In Alfabet queries, indicators cannot be added to the show properties using the show properties of the type `Indicator`.

The following information determines the objects defined in the query and the display of evaluation data for the X-axis, Y-axis and power axis:

Feature to be implemented	Mandatory/Optional	Column Content
Identification of the objects to be displayed in the portfolio report	Mandatory	The values of a unique property of the objects to be displayed in the report. This can either be the `REFSTR` of the object or any other unique property or combination of properties that ensures that the column in the report table can be mapped with objects in the database. If no tooltip is defined as described in the section Defining a Tooltip for Objects in the Portfolio Area, the information used to identify the object will be displayed as tooltip if the user moves the cursor around an object in the portfolio. A legend is available for the colors used for the objects in the portfolio. The information in the legend is identical to the value of the property that is used to identify the object. It is Therefore, recommended to Please note that the first argument of the `SELECT` statement in a native SQL query cannot be used for the report definitions. If the `REFSTR` returned in the first argument shall be used to identify the objects, it has to be added again as following argument.

Feature to be implemented	Mandatory/Optional	Column Content
The value determining the placement of the object bubble on the X-axis.	Mandatory	The values in the column must be numerical. Evaluation does not have to be based on indicator values, but any other aspect that can be expressed in numbers can be defined.
The value determining the placement of the object bubble on the Y-axis.	Mandatory	The values in the column must be numerical. Evaluation does not have to be based on indicator values, but any other aspect that can be expressed in numbers can be defined.
The value determining the size of the object bubble or geometric shape.	Optional	The values in the column must be numerical. Evaluation does not have to be based on indicator values, but any other aspect that can be expressed in numbers can be defined. The size is not variable for object representation via icons.

The following information can be returned by the query to define optional features for the portfolio report:

Feature to be implemented	For more information see:
Displaying a tooltip when the customer moves the cursor over the object bubble, shape or icon.	Defining a Tooltip for Objects in the Portfolio Area
Defining X-Axis and Y-Axis segment labels	Defining Axes for a Standard Layout Portfolio
Defining X-Axis and Y-Axis captions	Defining Axes for a Standard Layout Portfolio
Representing objects in the portfolio by different geometric shapes	Representing Objects as Geometric Shapes
Representing of objects in the portfolio by different icons	Representing Objects As Icons
Coloring of bubbles or geometric shapes in the portfolio	Defining the Coloring of Shapes in the Portfolio Report
Displaying a legend for the power axis of the portfolio report	Defining a Legend for the Power Axis of the Portfolio

Feature to be implemented	For more information see:
Defining connections between objects in the portfolio report	Defining Connections between Objects Displayed in the Portfolio
Defining a navigation target for navigation from objects in the portfolio	Defining Navigation from the Objects in the Portfolio to Alfabet Views
Defining a caption for the portfolio	Defining the Caption and Size of the Portfolio Report Area

Defining the Objects and Evaluation Dimensions for the Portfolio Report

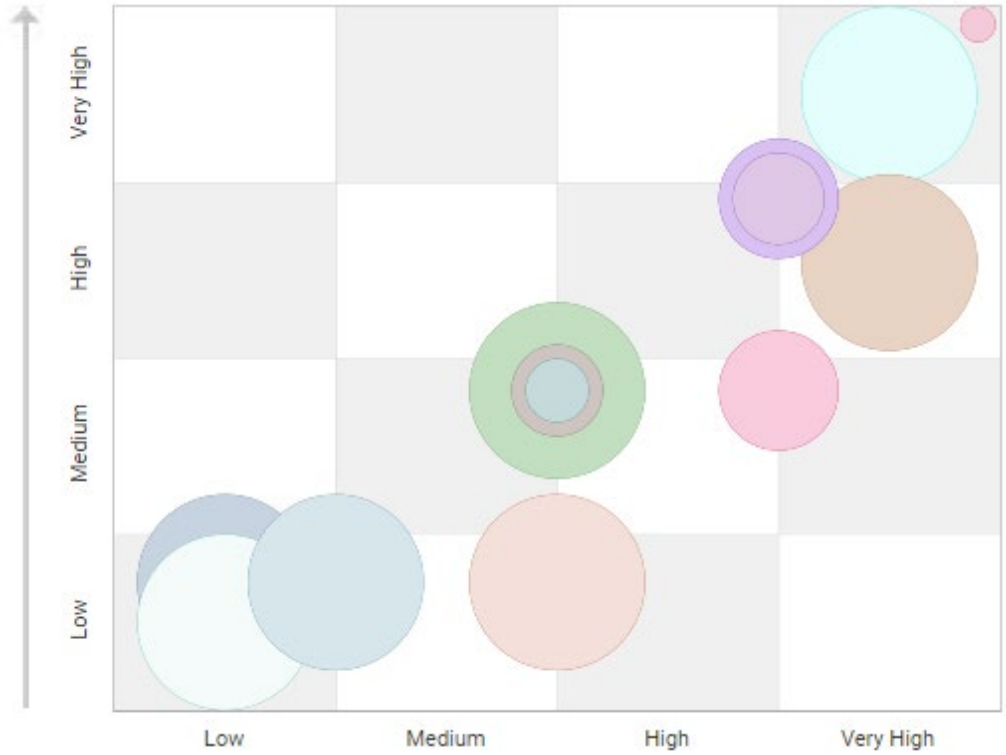
To define the basic content of the portfolio, the following attributes of the **Report Assistant** explorer's root node must be mapped to the column names in the dataset returned by the query defined in the ***Query*** element of the portfolio report described in the section Defining the Query the Portfolio is Based On:

Attribute	Description
X Value Column	Defines the name of the dataset column that contains the information about the placement of the object bubble on the X-axis.
Y Value Column	Defines the name of the dataset column that contains the information about the placement of the object bubble on the Y-axis.
Power Value Column	Defines the name of the dataset column that contains the values relevant for sizing of the object bubbles.
Image Column	Defines the name of the dataset column that contains the unique object c lass property used to identify the object.
Tooltip Column	Defines the name of the dataset column that contains the information to be displayed in a tooltip when the customer moves the cursor over the object bubble.

Defining the X-Axis And Y-Axis of the Portfolio Report

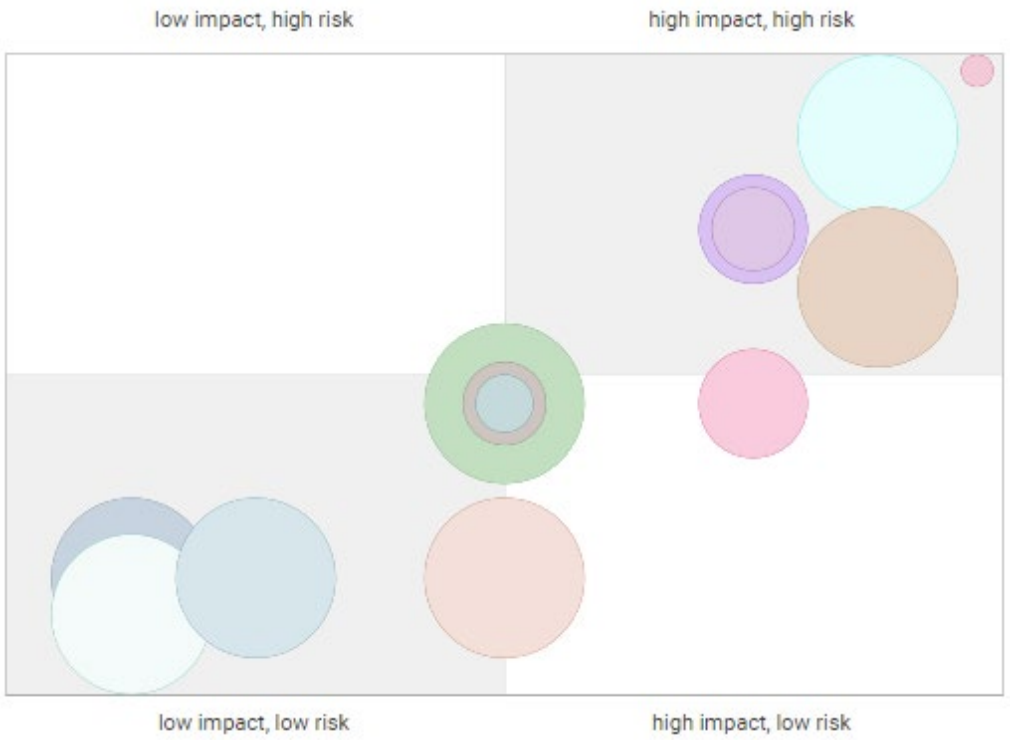
Portfolios can either have a quadrant design with a title for each quadrant or display an X-axis and Y-axis scale.

By default, the portfolio is displayed with an X-axis and Y-axis scale with four identically sized segments in each axis. The axis segments are by default labeled **Low**, **Medium**, **High** and **Very High**:



The following customization options are available for the axes of the portfolio:

- The number of segments on an axis and the titles displayed for the segments are configurable
- A caption can optionally be displayed for the axes.
- The minimum and maximum value can be defined for the axes. By default, the axes scope is defined by the minimum value and maximum value required to display the objects in the portfolio.
- The portfolio can alternatively be displayed in a quadrant layout with a title for each quadrant:



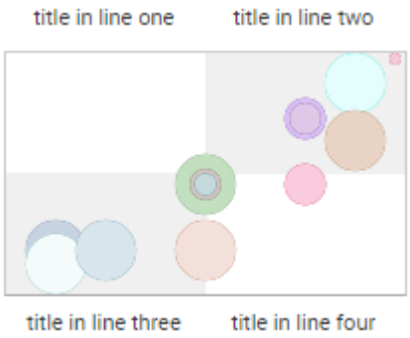
The configurations are described in the following sections:

- Defining a Quadrant Layout
- Defining Axes for a Standard Layout Portfolio
- Defining the Range of the Portfolio X-Axis and Y-Axis

Defining a Quadrant Layout

For the configuration of a quadrant layout, set the following attributes in the root node of the report assistant:

Attribute	Description
Quadrant Layout	Select `True`.
Quadrants	Click the **Browse** button in the attribute field and define each quadrant title in a separate line in the editor. The following graphic shows which quadrant title is defined by which line from top to bottom:

Attribute	Description
	


Defining Axes for a Standard Layout Portfolio

For the x-axis and y-axis layout of the portfolio, both the number of segments for an axis as well as the axis segment titles are configurable. In addition, a caption can be added for the axes.

Both axes captions and segmentations can be either defined statically for the report or dynamically via the query the report is based on. If both configurations are available, the dynamic design of the axes supersedes the static design.

Dynamic change of the X-axis and Y-axis design is For example, useful to define a flexible portfolio report with filters that allow the user to decide which evaluations to display. You can configured the caption and segment title of the axes in the portfolio to be adapted to the selected indicators.

To change the layout of the axes statically, set the following attributes of the Y-Axis and X-Axis elements in the **Report Assistant**:

Attribute	Description
X-Axis element	
Caption	Enter the caption to be displayed for the Y-axis.
Segment Names	Click the Browse button in the attribute field and define each segment title in a separate line in the editor. The number of segment titles defined equals the number of segments on the X-axis. Please note that there must not be a line break after the last specification. An empty row at the end of the definition will create an empty segment on the X-axis.

Attribute	Description
Y-Axis element	
Caption	Enter the caption to be displayed for the Y-axis.
Segment Names	Click the Browse button in the attribute field and define each segment title in a separate line in the editor. The number of segment titles defined equals the number of segments on the X-axis. Please note that there must not be a line break after the last specification. An empty row at the end of the definition will create an empty segment on the X-axis.

To change the layout of the axes dynamically, the data required to define the axes must be provided via the dataset returned by the query defined in the ***Query*** element of the portfolio report described in the section Defining the Query the Portfolio is Based On. The dataset column names must then be defined in the attributes of the root node of the Report Assistant. The following table lists the attributes that must be set and the required data to be returned in the query:

Attribute	Description
X-Caption Column	Enter the name of the dataset column returning the string to be displayed as X-axis caption. The first value in the defined dataset column that is not NULL will be displayed as X-axis caption.
Y-Caption Column	Enter the name of the dataset column returning the string to be displayed as X-axis caption. The first value in the defined dataset column that is not NULL will be displayed as X-axis caption.
X-Segment Names Column	Enter the name of the dataset column returning the segment title strings. The number of segment titles defined equals the number of segments on the X-axis. The segment titles must be separated with CHAR (10). For example, to define an axis with three segments having the titles **Small**, **Medium** and **Large**, the column can be defined as follows in a native SQL query: `'Small'+CHAR(10)+'Medium'+CHAR(10)+'Large' AS 'XSegments'`
Y-Segment Names Column	Enter the name of the dataset column returning the segment title strings. The number of segment titles defined equals the number of segments on the Y-axis. The segment titles must be separated with CHAR (10). For example, to define an axis with three segments having the titles **Small**, **Medium** and **Large**, the column can be defined as follows in a native SQL query: `'Small'+CHAR(10)+'Medium'+CHAR(10)+'Large' AS 'YSegments'`

Defining the Range of the Portfolio X-Axis and Y-Axis

For both quadrant and standard portfolio axis layout, the numerical range of the X-axis and the Y-axis can be defined.

By default, the range covered by the portfolio is defined by the highest and lowest value for an object in the portfolio. When the set of objects displayed is changed, the range covered by the axes also changes. The covered range is then segmented into equally sized segments. That means that very high can mark a range between For example, 4 and 5 but in another portfolio a range between 4.5 and 5.3. Defining a minimum and maximum value can be used For example, for the following reasons:

- With the flexible scaling of the portfolio axes, the objects with the minimum and maximum X-value and Y-value respectively will be displayed directly on the border of the portfolio diagram. The axes scope can be defined to allow spacing between all objects displayed in the portfolio and the portfolio border.
- With the flexible scaling of the portfolio axes, the positioning of object in the portfolio depends on the relative position with respect to other objects. For example, for an X-axis indicator that may have values from 1 to 5, an object that has an indicator setting of 3 will be displayed in the middle of the portfolio if the indicator settings for the other objects cover the complete range of 1 to 5, but will be displayed on the right border of the portfolio if compared to objects with indicator settings from 1 to 3. The axes scope can be defined to allow a better comparison of the display of objects in the portfolio for different filter settings.
- If the portfolio is displayed in standard layout with axes segments defined, the definition of the minimum and maximum value can be used to map the segment titles to defined numerical values.

If objects to be displayed in the portfolio have a value for an axis that lies outside of a defined range, the object is nevertheless displayed on the border of the diagram.

To define a range for the portfolio axis, set the following attributes in the X-Axis and Y-Axis elements in the **Report Assistant**:

Attribute	Description
X-Axis element	
Min Value	Enter a numerical value to start the X-axis with the defined value.
Max Value	Enter a numerical value to end the X-axis with the defined value.
Y-Axis element	
Min Value	Enter a numerical value to start the X-axis with the defined value.
Max Value	Enter a numerical value to end the X-axis with the defined value.

Defining the Graphic Representation of Objects in the Portfolio Area

While standard Alfabet portfolio report page views display the objects in the portfolio as differently colored bubbles only, configured portfolio reports offer a broader range of object representations.

Objects can be displayed in the configured portfolio report as a variety of geometric shapes or as icon. The shape or icon representing the objects can be identical for all objects or defined per object via the query defined in the ***Query*** element of the configured portfolio report.

If objects are represented by geometric shapes, the color of objects can also be defined via the query defined in the ***Query*** element of the configured portfolio report. The color can Therefore, represent an additional aspect of evaluation and a legend is available for the object shape and coloring.

By default, portfolio reports will display the objects in the report as bubbles in the same way as standard Alfabet portfolio report page views do.

The following configuration options are available:

- Representing Objects as Geometric Shapes
- Representing Objects As Icons
- Defining the Coloring of Shapes in the Portfolio Report

Representing Objects as Geometric Shapes

Configured portfolio reports can represent all objects with the same geometric shape or with different geometric shapes returned via the query of the portfolio report.

To configure use of the same geometric shape for all objects, expand the **Shape Source** attribute in the root node of the **Report Assistant** and set the following attributes in the order defined in the list:

Attribute	Description
Shape Type	Select `GeometricShape`.
Shape Source	Select `ReportDefinition`. This is the default value.
Fixed Shape	Select the shape that shall be used to display the objects in the portfolio. The following shapes are available: • `Rectangle` () • `Triangle` () • `Circle` ()

Attribute	Description
	• `Diamond` () • `FlippedTriangle` ()

To assign a shape to each object individually, the name of the geometric shapes must be provided via the dataset returned by the query defined in the ***Query*** element of the portfolio report described in the section Defining the Query the Portfolio is Based On. The use of the query result dataset for evaluation of object shapes must then be defined in the root node of the **Report Assistant**. Expand the **Shape Source** attribute and set the following attributes in the order defined in the table:

Attribute	Description
Shape Type	Select `GeometricShape`.
Shape Source	Select `Query`.
Shape Name Column	Enter the name of the column in the query dataset that returns the name of the shape for each object. The query can return any of the following shape names: • `Rectangle` () • `Triangle` () • `Circle` () • `Diamond` () • `FlippedTriangle` () If no or any other value is returned in the column, `Circle` is used as default.

Representing Objects As Icons

Configured portfolio reports can represent all objects as icons.

Representing objects as icons limits the availability of other features in the portfolio:

- Sizing of icons based on power axis values is not possible.
- Coloring cannot be defined for the object representations.

Icons can be represented by the icons defined for the object, or by any icon that has been uploaded to the 22x22 icon gallery. If objects defined for the object shall be used, the icon defined for the object in the standard object class property Icon is used to represent the object in the portfolio, or, if no icon is defined for the object, the icon defined for the object class or object class stereotype in the class settings is used.

For more information about uploading icons to the icon gallery, see Adding and Maintaining Icons for the Alfabet Interface.

For more information about assigning icons to an object class or object class stereotype via the class settings, see Specifying the Icons Implemented for Object Classes and Object Class Stereotypes.

To configure use of the object icon, expand the **Shape Source** attribute in the root node of the **Report Assistant** and set the following attributes in the order defined in the list:

Attribute	Description
Shape Type	Select `Icon`.
Shape Source	Select `Object`. This is the default value.

Please note that in the preview of the report that opens via the Review Report option in the context menu of the report the icons for the object class stereotype class settings are ignored and all objects are displayed either with the object icon or, if not defined, with the icon for the class settings for the object class without stereotype definition.

To use icons from the 22x22 icon gallery for display of objects in the portfolio, the name of the icon must be provided via the dataset returned by the query defined in the ***Query*** element of the portfolio report described in the section Defining the Query the Portfolio is Based On. The use of the query result dataset for evaluation of object shapes must then be defined in the root node of the **Report Assistant**. Expand the **Shape Source** attribute and set the following attributes in the order defined in the table:

Attribute	Description
Shape Type	Select `Icon`.
Icon Source	Select `Query`.
Icon Name Column	Enter the name of the column in the query dataset that returns the name of the icon for each object. If the icon name cannot be found in the icon gallery, there is no fallback and a missing icon symbol ( ) is displayed instead for the object in the portfolio.

Defining the Coloring of Shapes in the Portfolio Report

If objects in a portfolio are displayed as geometric shapes, object shapes are by default displayed in different colors. Icons cannot be colored.

The color used for an object is identical in all portfolios. The coloring of single objects can be changed via the following mechanisms:

- If a color is defined for an object via the private object class property **Color** of the object class, this color will be used to color the object in portfolio reports. The Color property is not part of standard custom editors. To set the coloring for objects of a defined class, a color selector must be defined in a custom editor for the respective object class. For information about defining custom editors, see .
- The color used for objects in the chart can be changed by the user viewing the portfolio if the **Colors**  button of the report is enabled or if a color selector is defined in a custom editor for the respective object class. The **Colors**  button is activated or deactivated in the server alias of the Alfabet Web Application. For information about the activation of the **Colors**  button, see *Allowing Users to Change the Color Assigned to Objects in Business Graphics* in the reference manual *System Administration*. Please note that the color defined for an object via the **Colors**  button changes the color assigned to the object via the private object class property **Color** and will Therefore, be applied to the object in all other reports that use object colors for all Alfabet users.

Instead of using the object colors, individual coloring of shapes can be defined for the portfolio report.

Please note that the legend for the portfolio displays one entry for each object returning the shape and color followed by the value of the object class property or object class properties used to identify the object. If you define an identical shape and color combination for different objects in the configured report, the legend will list these objects all with an identical shape and color in front.

To define the basic content of the portfolio, the following attributes of the **Report Assistant** explorer's root node must be mapped to the column names in the dataset returned by the query defined in the ***Query*** element of the portfolio report described in the section Defining the Query the Portfolio is Based On:

Attribute	Description
Color Column	Enter the name of the column that returns the HTML compliant color definition (For example, `#000000` for black).

Defining a Tooltip for Objects in the Portfolio Area

A tooltip is displayed if the user moves the mouse over an object in the portfolio report.

If no tooltip is defined via the settings in the **Report Assistant**, the information used to identify the object will be displayed as tooltip. If a power axis is defined, the numeric value of the power axis in parentheses will be added to the default tooltip after the object information.

Tooltip texts must be returned by the query defined in the ***Query*** element of the portfolio report described in the section Defining the Query the Portfolio is Based On. The texts are then mapped to attributes of the **Report Assistant** explorer's root node.

Tooltips can have the following elements:

- Any string defined in the query of the portfolio report
- Information about the value of the power axis. This can be either the numeric or semantic value of the indicator defined for the power axis.
- A caption for the power axis to inform the user about the meaning of the power axis value.

If all elements of the tooltip are defined, the syntax of the tooltip is:

tooltip text (power axis caption = power axis value)

To define the tooltips for the portfolio, the following attributes of the **Report Assistant** explorer's root node can optionally be set:

Attribute	Description
Tooltip Column	Defines the name of the dataset column that contains the information to be displayed in the tooltip. If not defined, the information returned in the dataset column mapped to the **Image Column** attribute is displayed as tooltip.
Add Power to Tooltip	If the **Power Value Column** attribute is defined and the **Add Power to Tooltip** attribute is set to `True`, the information about the power axis value for the current object will be added to the tooltip in parentheses. By default, this attribute is set to `True`.
Power Caption Column	Defines the name of the dataset column that returns the caption of the power axis. If the dataset column returns multiple different values, the first value that is not `NULL` returned in the dataset will be displayed. The caption for the power axis can alternatively be defined statically with the attribute **Caption** of the **Power Axis** element of the **Report Assistant**. If neither the **Power Caption Column** attribute nor the **Caption** attribute of the **Power Axis** element are defined, no caption will be displayed for the power axis value. If both attributes are defined, the setting of the **Power Caption Column** attribute supersedes the setting of the static **Caption** attribute of the **Power Axis** element. The power axis caption will only be added to the tooltip if the **Add Power to Tooltip** attribute is set to `True`. If a legend is defined for the power axis, the caption is also displayed as legend title to the left of the power axis value definitions. For more information about the definition of the power axis legend, see Defining a Legend for the Power Axis of the Portfolio.
Power Semantic	Defines the name of the dataset column that returns the semantic value of the indicator defined for the power axis.

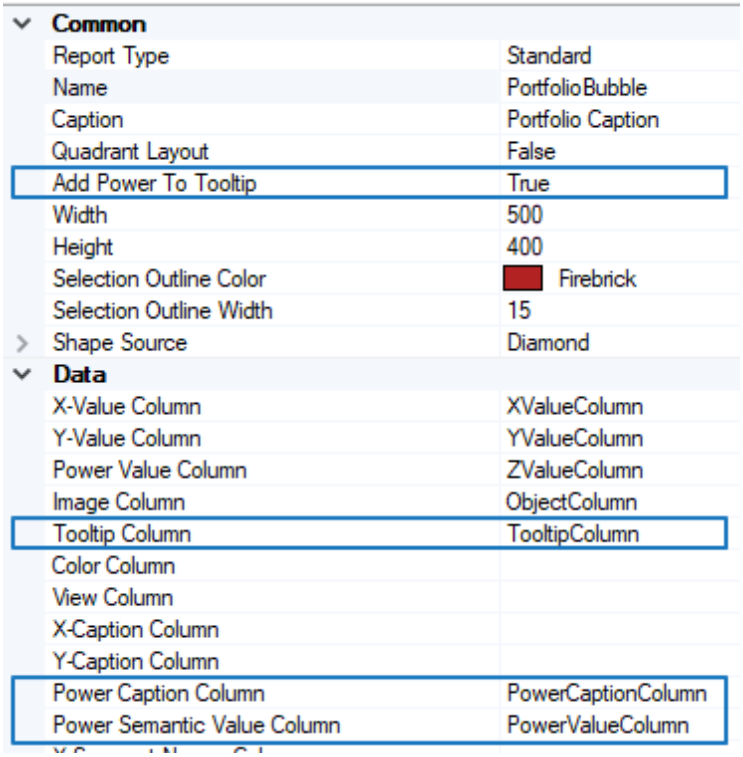
Attribute	Description
Value Column	If the **Power Semantic Value Column** attribute is not defined, and the **Add Power to Tooltip** attribute is set to `True`, the numeric value defined in the **Power Value Column** attribute will be displayed in the tooltip.
Power Axis element:	
Caption	Defines the caption of the power axis. The caption for the power axis can alternatively be defined dynamically with the attribute **Power Caption** of the root node of the **Report Assistant**. If neither the **Power Caption Column** attribute of the root node nor the **Caption** attribute of the **Power Axis** element are defined, no caption will be displayed for the power axis value. If both attributes are defined, the setting of the **Power Caption Column** attribute of the root node supersedes the setting of the static **Caption** attribute of the **Power Axis** element. The power axis caption will only be added to the tooltip if the **Add Power to Tooltip** attribute of the root node of the **Report Assistant** is set to `True`. If a legend is defined for the power axis, the caption is also displayed as legend title to the left of the power axis value definitions. For more information about the definition of the power axis legend, see Defining a Legend for the Power Axis of the Portfolio.

For example, the following query defines a portfolio report with a power axis definition for an application portfolio displaying applications in a selected application group. The tooltip shall display the name and version number of the object followed by the power axis value information that includes a string as title and the semantic value defined for the indicator. The tooltip information definition is highlighted with bold text:

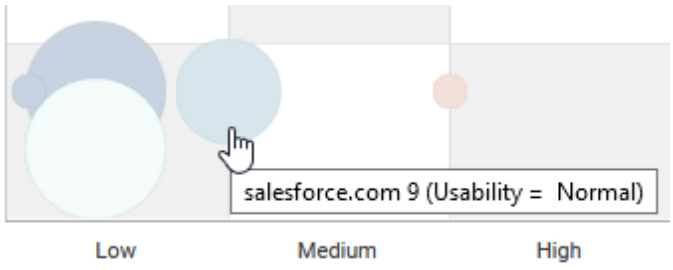
```
SELECT DISTINCT app.REFSTR, app.REFSTR AS 'ObjectColumn',
ind.VALUE AS 'ZValueColumn',
ind2.VALUE AS 'XValueColumn',
ind3.VALUE AS 'YValueColumn',
app.NAME + ' ' + app.VERSION AS 'TooltipColumn',
ind.SEMANTICVALUE AS 'PowerValueColumn',
'Usability' AS 'PowerCaptionColumn',
FROM APPLICATION app
INNER JOIN INDICATOR ind ON ind.OBJECT = app.REFSTR
INNER JOIN INDICATOR ind2 ON ind2.OBJECT = app.REFSTR
LEFT JOIN INDICATOR ind3 ON ind3.OBJECT = app.REFSTR
INNER JOIN RELATIONS rel ON rel.TOREF = app.REFSTR
INNER JOIN APPLICATIONGROUP appg ON appg.REFSTR = rel.FROMREF
WHERE rel.PROPERTY = 'Applications'
```

```
AND appg.REFSTR = @BASE
AND ind.NAME LIKE '%Usability'
AND ind2.NAME LIKE '%Customer Impact'
AND ind3.NAME LIKE '%Criticality (aggr.)'
```

In the report assistant, the values for the tooltip relevant parameters are defined to display all relevant information:

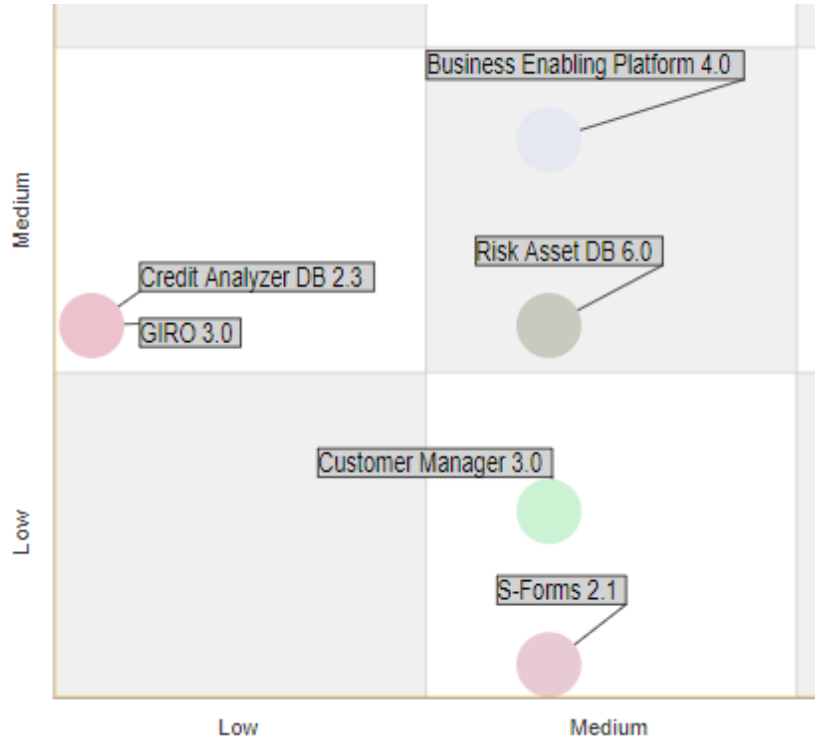


This configuration results in the following tooltip to be displayed:



Defining Labels for Objects in the Portfolio Area

Optionally, labels can be displayed in the portfolio.



Labels are only displayed if the label text is returned in the query of the portfolio report and the name of the column returning the text is mapped to the **Label Text** attribute in the expandable attribute **Label** in the root node of the report assistant.

Coloring and links from the label to the objects in the portfolio area can optionally be defined in the query and the child attributes of the expandable attribute **Label**:

Attribute	Description
Label Text	Defines the name of the dataset column that returns the label text. Labels are only displayed if this attribute is set.
Label Fore-color	Defines the name of the dataset column that returns the text color of the label in HTML compliant color code.
Label Background Color	Defines the name of the dataset column that returns the background color of the label in HTML compliant color code.
Label Border Color	Defines the name of the dataset column that returns the border color of the label in HTML compliant color code.
Label Connection Color	Defines the name of the dataset column that returns the color of the connecting line between the object and the label in HTML compliant color code. Connections will only be displayed if a connection color is defined.

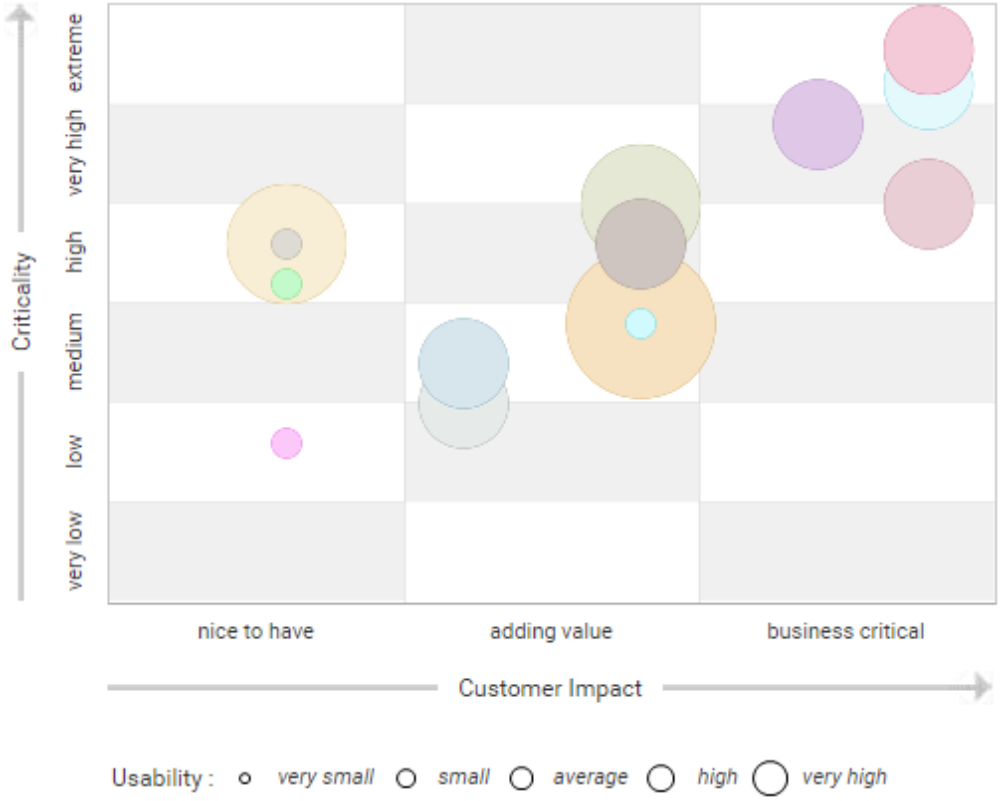
Attribute	Description
Label	Defines the relative height of the labels. the label height in pixel will be calculated for the available screen size and portfolio size and the relative height specification. Select one of the following from the drop-down list: • L = Large • M = Medium • S = Small

Defining a Legend for the Power Axis of the Portfolio

By default, a legend is available for the portfolio via the floating toolbar that lists all objects with the icon or shape and color combination used for the representation of the object. If background coloring is defined, the legend can also include the background coloring definition.

In addition to the legend that opens via the floating toolbar, a legend can optionally be added for the sizing defined by the power axis. The power axis legend will be displayed below the portfolio chart. It can distinguish between up to 5 different shape sizes. Shapes are displayed as bubbles only independent from the actual shapes used in the portfolio. The sizing is explained relative to each other and not in absolute sizes. The legend text displayed to explain the different sizing is configurable.

Optionally, a caption can be displayed in front of the size definitions.



The power axis caption and legend texts can be either defined statically for the report or dynamically via the query the report is based on. Dynamic definition may For example, be used to limit the number of entries to the number of different bubble sizes in the report. If both configurations are available, the dynamic design of the power axis legend supersedes the static design. It is possible to define the caption statically and the legend texts dynamically and vice versa.

To define a dynamic power axis legend, the data required to define the power axis must be provided via the dataset returned by the query defined in the ***Query*** element of the portfolio report described in the section Defining the Query the Portfolio is Based On. The dataset column names must then be defined in the attributes of the root node of the Report Assistant.

The power axis is defined with the following attributes of the root node and the **Power Axis** element in the **Report Assistant**:

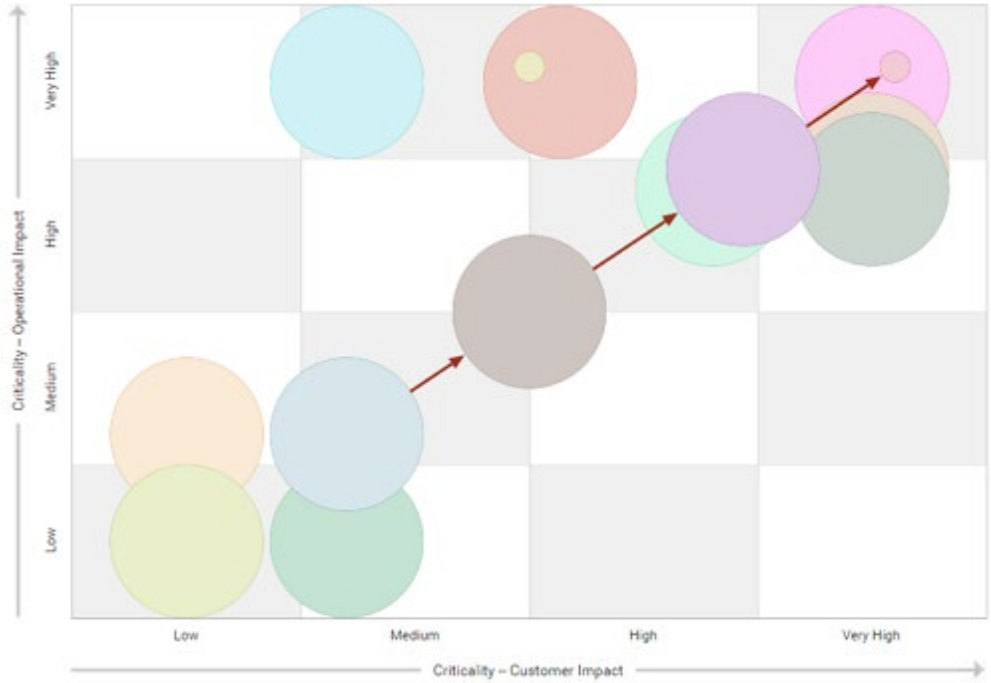
Attribute	Description
Root node	
Power Caption Column	Defines the name of the dataset column that returns the caption of the power axis displayed in front of the legend items. If the dataset column returns multiple different values, the first value that is not `NULL` returned in the dataset will be displayed. The caption for the power axis can alternatively be defined statically with the attribute **Caption** of the **Power Axis** element of the **Report Assistant**. If neither the **Power Caption Column** attribute nor the **Caption** attribute of the **Power Axis** element are defined, no caption will be displayed in front of the power axis legend. If both attributes are defined, the setting of the **Power Caption Column** attribute supersedes the setting of the static **Caption** attribute of the **Power Axis** element. If the attribute **Add Power to Tooltip** is set to `True` in the root node of the `Report Assistant`, the caption is also displayed in the tooltip that is visible if the user moves the cursor over an object in the portfolio report. For more information about the definition of the tooltip content, see Defining a Tooltip for Objects in the Portfolio Area.
Bubble Size Legend Column	Enter the name of the dataset column returning the power axis legend texts. The first result returned in the column that is not NULL will be used as legend text definition. The legend texts must be separated with CHAR(10). For example, to define an legend for three bubble sizes having the legend texts **Small**, **Medium** and **Large**, the column can be defined as follows in a native SQL query: `'Small'+CHAR(10)+'Medium'+CHAR(10)+'Large' AS 'PowerLegendTexts'` The legend text definition must start with the text for the smallest size and end with the text for the largest size. The legend definition is restricted to five different sizes. If more than five texts are defined, the legend will nevertheless display 5 different bubble sizes and will use texts from the beginning and the end of the definition as titles in the legend.

Attribute	Description
	If neither the **Bubble Size Legend** attribute nor the **Segment Names** attribute in the **Power Axis** element is defined, the power axis legend will not be displayed.
Power Axis element	
Caption	Optionally define the caption of the power axis legend. If defined, the caption will be displayed in front of the legend. The caption for the power axis can alternatively be defined dynamically with the attribute **Power Caption** of the root node of the **Report Assistant**. If neither the **Power Caption Column** attribute of the root node nor the **Caption** attribute of the **Power Axis** element are defined, no caption will be displayed for the power axis legend. If both attributes are defined, the setting of the **Power Caption Column** attribute of the root node supersedes the setting of the static **Caption** attribute of the **Power Axis** element. If the attribute **Add Power to Tooltip** is set to `True` in the root node of the `Report Assistant`, the caption is also displayed in the tooltip that is visible if the user moves the cursor over an object in the portfolio report. For more information about the definition of the tooltip content, see Defining a Tooltip for Objects in the Portfolio Area.
Segment Names	Click the Browse button in the attribute field and define up to five legend texts, each in a separate line in the editor. The text order from top to bottom is identical to the size order from small to big. If more than five texts are defined, the legend will nevertheless display 5 different bubble sizes and will use texts from the beginning and the end of the definition as titles in the legend. Please note that there must not be a line break after the last specification. An empty row at the end of the definition will create a bubble size specification without a text. Definition of the **Bubble Size Legend** attribute in the root node of the **Report Assistant** supersedes the definition in the **Segment Names** attribute. If neither the **Segment Names** attribute nor the **Bubble Size Legend** attribute in the root node of the **Report Assistant** is defined, the power axis legend will not be displayed.

Defining Connections between Objects Displayed in the Portfolio

Objects in a portfolio report can optionally be connected with lines indicating a configurable relationship.

In the following example, a portfolio report displays evaluation of applications in an application group. If a migration is defined to migrate from one application to the other, the migration is displayed as a red arrow:



To display connections between objects in the report, all relevant data for rendering the connections must be provided via th optional **Connections Query**. The **Connections Query** must at least return the `REFSTR` of the object the connection is coming from and the `REFSTR` of the object the connection is ending at. Both objects must be displayed in the portfolio.

The columns in the result dataset of the **Connections Query** must then be mapped to attributes in the root node of the report assistant that are available when expanding the attribute **Connection Query Columns** in the section **Data**.

In addition to the mandatory definition of the start object and end object of the connection, the query can return styling parameters, legend texts and a link target to activate navigation from the connection to an Alfabet view. The columns must be mapped to the following sub-attributes of the attribute **Connection Query Columns**:

Attribute	Column must return:	Mandatory
Start Ref Column	The `REFSTR` of the object the connection is starting at.	Yes
End Ref Column	The `REFSTR` of the object represented with by the item the connection is ending at.	Yes
Line Style Column	The style of the connecting line. Allowed values are `Solid`, `Dash`, `DashDot`, `DashDotDot` and `Dot`.	No, by default connections are displayed as solid lines (`Solid`).

Attribute	Column must return:	Mandatory
Line Weight Column	The width of the connecting line as integer.	No, the default value is 1.
Line color Column	The color of the connecting line as HTML compliant color code.	No, by default connections are displayed as black lines.
Start Arrow Style Column	The style of the start point of the connection. Allowed values are `None`, `Angle`, `Triangle`, `Square`, `Circle` and `Rhomb`. If you would like to activate navigation or the display of a tooltip and the line drawn for the connection is very thin, definition of a start arrow style will make it easier for the user to point to the connection.	No, by default connections are displayed with no extra decoration at the start point (`None`).
End Arrow Style Column	The style of the end point of the connection. Allowed values are `None`, `Angle`, `Triangle`, `Square`, `Circle` and `Rhomb`. If you would like to activate navigation or the display of a tooltip and the line drawn for the connection is very thin, definition of an end arrow style will make it easier for the user to point to the connection.	No, by default connections are displayed with no extra decoration at the end point (`None`).
Tooltip Column	A string that is displayed as tooltip when the user moves the cursor over the start or end point of the connection.	No, by default no tooltips are displayed.
Link Ref Column	The `REFSTR` of an object. If this column is specified, navigation from the connection is activated. When the user clicks and holds the connection, a preview of the object with the `REFSTR` returned in the **Link Ref Column** opens. The user can navigate to the object profile or object cockpit of the object by clicking the **Show Details** button in the preview. If **View Column** is defined, the defined navigation target opens instead of the object profile or object cockpit of the object.	No, if not set, navigation is deactivated.
View Column	Definition of a link target that shall open if a user double-clicks on a connection or clicks and holds the connection. The format is `View=`*`ViewType`*`:`*`ViewName`* The `ViewType` can be one of the following: • ***Report*** for a configured report • ***GraphicView*** for a standard Alfabet view	No, if not set, but **Link Ref Column** is set, navigation is opening the object profile or object cockpit of the object defined with **Link Ref Column**.

Attribute	Column must return:	Mandatory
	• ***ObjectView*** for an object profile `ViewName` is the name of the view. For detailed information about the required configuration to activate navigation, see Defining Navigation from the Report to Alfabet Views.	
Legend Group Column	A string that shall be displayed as heading for the legend entry defined with **Legend Text Column** in the same row of the dataset. All legend entries that have the same **Legend Group Column** are grouped and displayed under the heading defined with **Legend Group Column**. A legend is only displayed for connections if both **Legend Group Column** and **Legend Text Column** are defined.	No, if the attribute is not defined, the legend does not display entries for connection styles.
Legend Text Column	A string that shall be displayed next to the style of the connection in the legend of the report. A legend is only displayed for connections if both **Legend Group Column** and **Legend Text Column** are defined.	No, if the attribute is not defined, the legend does not display entries for connection styles.

Defining Background Coloring for the Portfolio

By default, the background of a portfolio report is divided into black and light grey areas in a checkered pattern. Optionally, the background of the portfolio can be colored in three different design types.

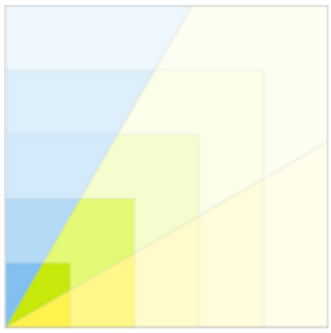
This feature is not available for portfolio reports displaying a quadrant layout. For portfolio reports with an X-axis and Y-axis definition, the portfolio background can be colored with user-defined colors. Color zones are applied diagonally applying to the portfolio background either from left to right or from right to left. The following design types are available:

- ***Wave***: The colors are displayed in circles of different diameters with the neutral position of the axes of the portfolio as the center of the circle with the portfolio displaying a quarter of each colored circle. The circles can have segments of different color. The center of the design can start on the lower left or upper right corner of the portfolio chart area.

Left to Right

Right to Left

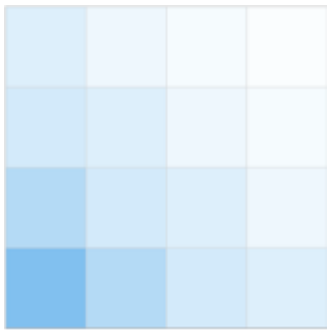
- ***NestedSquare***: The portfolio background displays nested squares. The solution designer can specify the number of squares and their relative size. The center of the design can start on the lower left or upper right corner of the portfolio chart area.



Left to Right

Right to Left

- ***CheckerBoard***: The portfolio background is a raster of squares with squares in a diagonal line colored in the same color. The solution designer can specify the number of colors to be used and the relative proportion of their sizes.



If a background design is defined, a legend is available explaining the meaning of the coloring in the configured report. The legend explains the coloring for each series in a `NestedSquare` and `Wave` design separately.

In the root node of the Report Assistant, the following attributes must be set to defined the background layout of the portfolio chart area:

Attribute	Description
Report Type	Select `DesignedBackground` from the drop-down list.
Background Design	Select the design type from the drop-down list. The design type can be `Wave`, `Nested-Square`, or `CheckerBoard`. The different design types are explained above in this section.
Default Background Color	Select the color that shall be displayed in all areas of the portfolio chart that are not colored by the background design definition.
Background Orientation	This attribute is set to `Left2Right` by default and the center of the design is the lower left of the portfolio chart. For `NestedSquare` and `Wave` design, you can optionally set this attribute to `Right2Left`. The center of the design will then be in the upper right corner of the portfolio chart.
Background Info	Click the **Browse** button in the attribute field to open the editor for the definition of the cell coloring. The way colors are defined is explained below.

The **Background Info** attribute displays a table for the definition of the cell coloring. Definition requires the following steps:

1. Defining of the colors to be used for the background

Color are defined in the **Series 1** - **Series 5** columns of the editor. Colors can be defined by entering the HTML color code into the field or by picking a color with the color picker on the right of the series column.

The orders of colors in the portfolio chart from left to right is identical to the order of colors within a series definition from top to bottom. This is independent from the setting of the **Background Orientation** attribute.

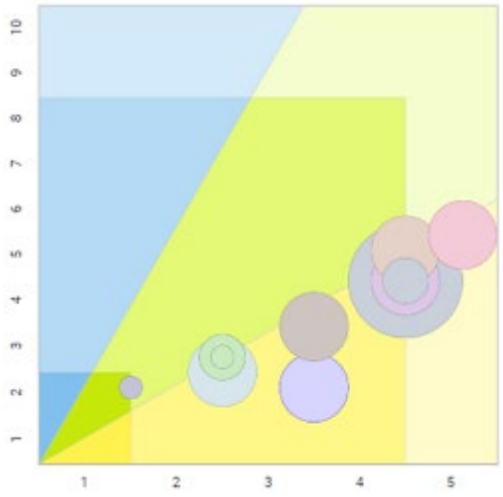
For a `CheckerBoard` design, colors are defined in the `Series 1` column only. For `Wave` and `NestedSquare` design, up to five color series can be defined. The number of color series defines the number of diagonal segments with different coloring. The order of colors is identical to the order of series. For `Left2Right` orientation, the series are displayed from left to right, while for `Right2Left` orientation, they are displayed from right to left.

It is recommended to read the part of about sizing of colored segments prior to defining the individual colors to ensure that enough colors are defined in the correct order for the intended design.

2. Defining the size of colored segments

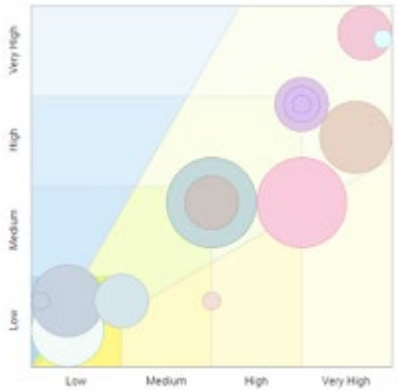
The size of colored segments is defined in the **Value** column based on the values of the X-axis of the portfolio report. The color distribution along the X-axis is repeated along the Y-axis with the same distribution pattern irrespective of the underlying values on the Y-axis.

The following portfolio has an x-axis with a range from 0 to 5 and a y-axis range from 0 to 10. Coloring is identical for both axes of the report. While the coloring is change on the x-axis at the end of segment 1 and 4, this corresponds on the y-axis to a color change at the end of segment 2 and 8:

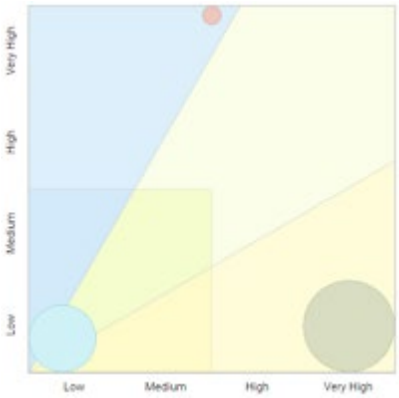


Coloring is based on the numerical values of the indicator of the X-axis definition. It is recommended to define minimum and maximum value for the X-axis as described in the section Defining the Range of the Portfolio X-Axis and Y-Axis. If no minimum and maximum value is defined for the X-axis, the scope of the x-axis depends on the lowest and highest X-axis indicator value returned for an object displayed in the portfolio. This might lead to different distribution of coloring dependent on the current scope of the X-axis.

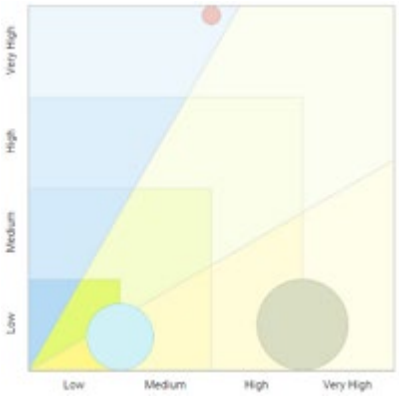
For example, the following configured report is defined for the evaluation of applications in an application group. The indicator on the X-axis can have values from 1 to 5. No minimum and maximum value are defined for the X-axis. A `NestedSquare` design is selected for the background of the portfolio chart. The background color is defined to change at the positions 1, 2, 3, 4 and 5 . If the indicator values for the applications in the group covers all available values, the X-axis will display the range of 1-5 and the portfolio will show all colors:



If the application group only contains applications with an X-indicator set to 2 and 4, the x-axis will display the range of 2 - 4 and only part of the colors are visible:



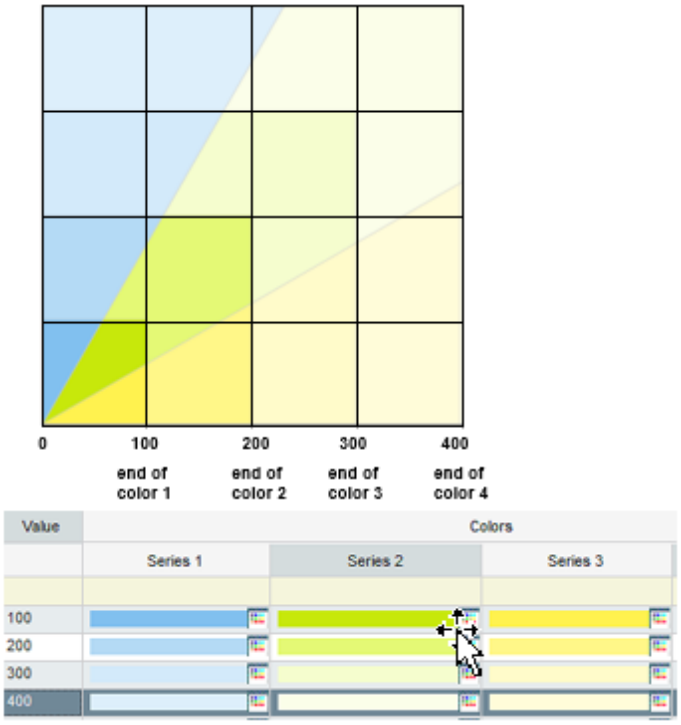
This is not necessarily wrong and might be the designed behavior. Setting of a minimum and maximum value for the x-axis will change the portfolio design to show the complete range of colors independent from the location of elements in the portfolio:



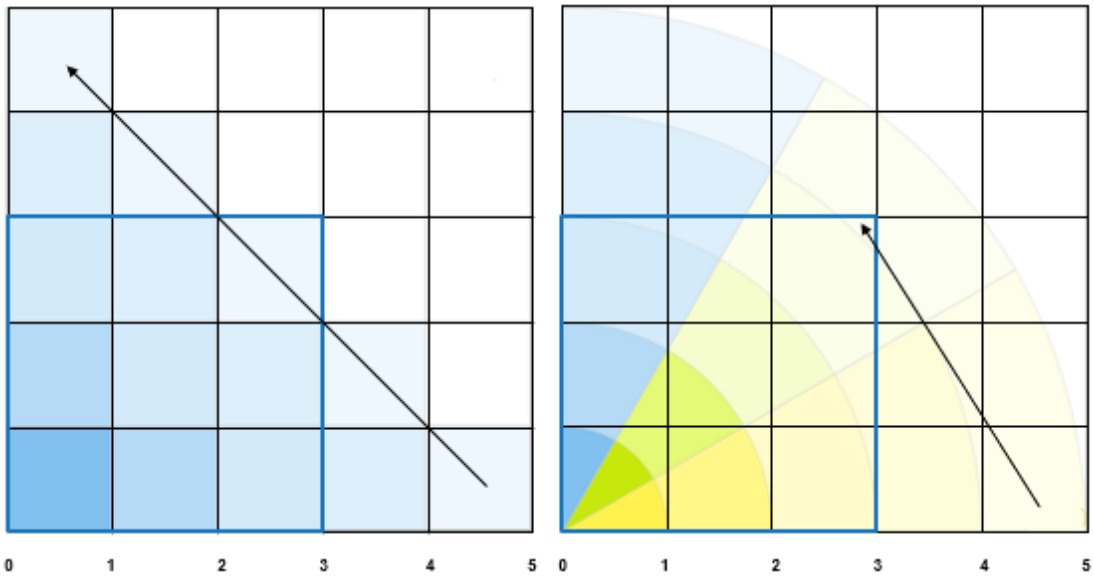
To define the size of a colored area, enter the X-axis end value for the colored block. The way the blocks are defined depends on the definition of the **Background Orientation** attribute of the portfolio chart:

- **Defining color positions for a Left2Right design**

Left centered design starts at the lower left corner of the portfolio chart with the first row for each series. The define the size of the color block, enter the value on the x-axis column where the coloring should end in the **Value** column for the respective color row in the editor. For example, to define a coloring for an X-axis with a range from 0 - 400 with each of the four default axis segments colored differently, the Value elements of the first four colors in a series must be 100, 200, 300 and 400, starting from top to bottom:

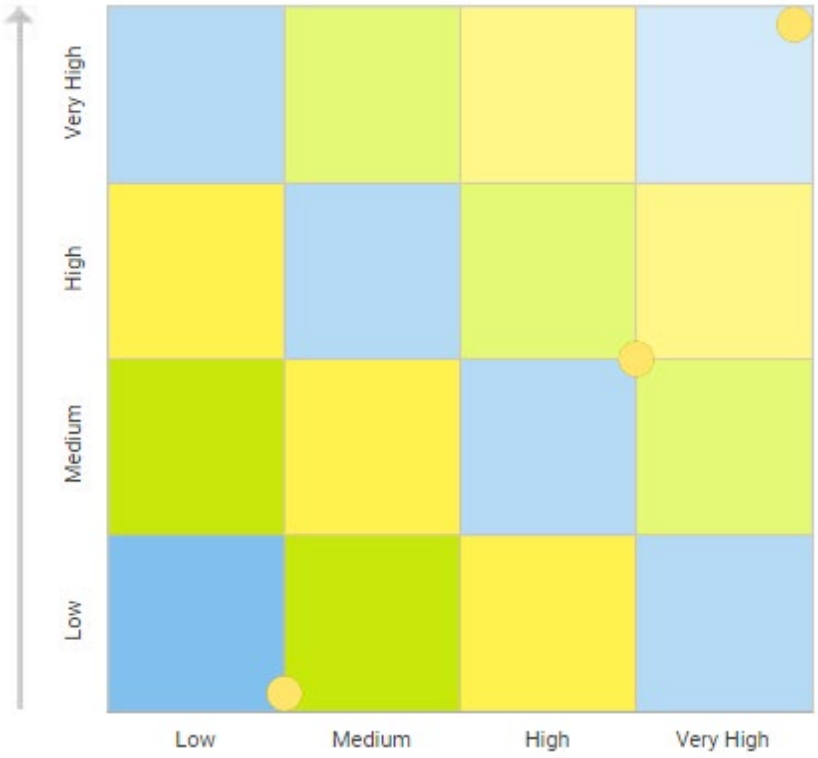


Please note that for coloring of the complete area of a `CheckerBoard` and `Wave` design, you must define additional colors for segments that are starting after the maximum of the x-axis. This can be best demonstrated by displaying the design of the actual portfolio chart as a part of a wider screen filled with the designed colors. The following graphics show a portfolio chart that has an X-axis range from 0 - 3 in a screen with a range from 0 - 5. As you can see from the graphic below, the colors defined for the segments ending with the virtual end position 4 and 5 are still part of the design of a `CheckerBoard` or `Wave` design:



The width of the elements with a virtual end point is irrelevant for the design, because the size of the areas in the portfolio is only defined by the colors with visible end point definitions. The **Value** defined for virtual end points of color definitions must be higher than the maximum value of the x-axis.

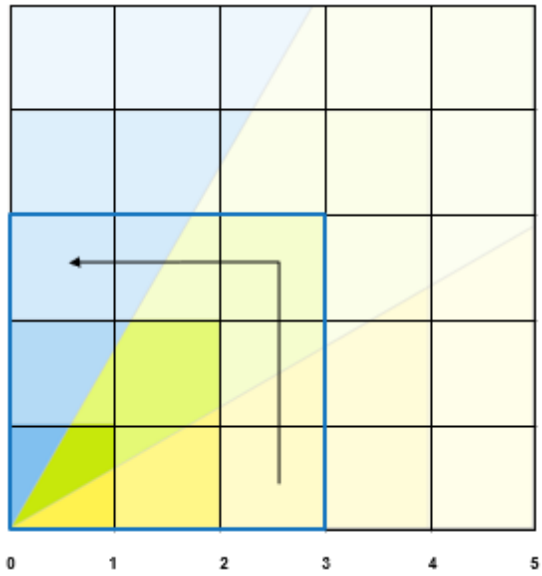
For example, the following report is displaying a `CheckerBoard` background design:



The x axis of the report has a range from zero to 5. 6 different colors are displayed in the report design. The color definition must Therefore, include 7 colors. The definition of where the coloring ends on the x-axis covers the range from 1 as end of the first color to 7 as end of the last color directly on the x-axis. The values from 5 to 7 are on the in-visible prolongation of the x-axis:

		Series 1
Series Caption		
First color defined (top of series)	1	
Second color defined	2	
Third color defined	3	
Fourth color defined	4	
Fifth color defined	5	
sixth color defined	6	
Seventh color defined	7	

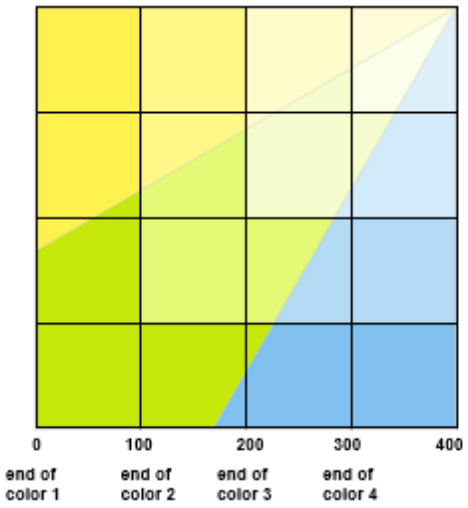
For `NestedSquare` design, it is not required to defined coloring for virtual segments. The last color displayed on the visible x-axis is the last color that is used in the report:



- **Defining color positions in a Right2Left design**

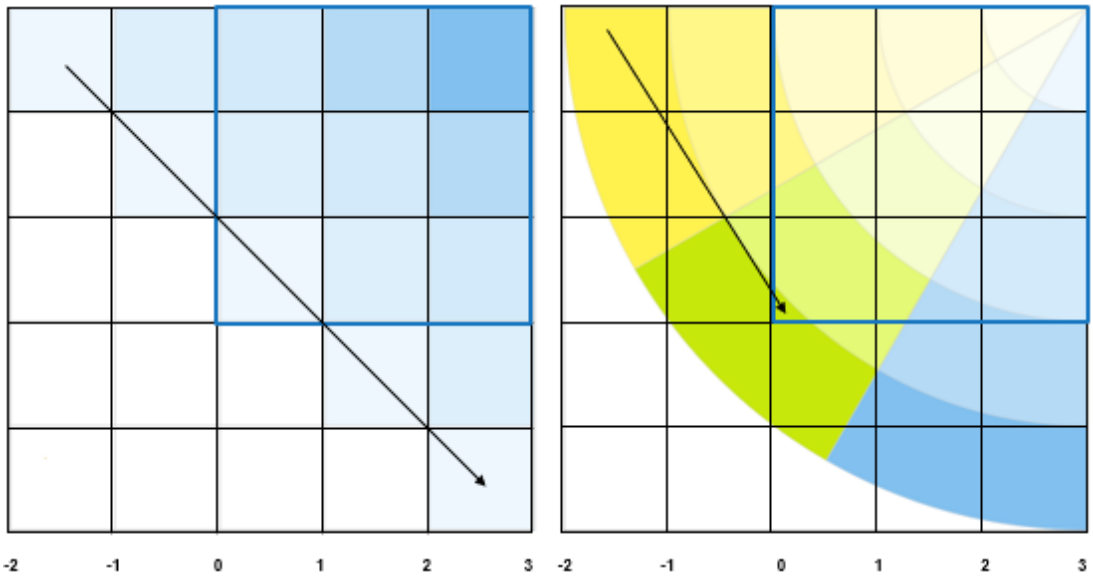
Right centered design starts at the upper right corner of the portfolio chart with the last row for each series. The define the size of the color block, enter the value on the x-axis column where the coloring should end, beginning at the start point of the design, in the **Value** column for the respective color row in the editor. For example, to define a coloring for an X-axis with a range from 0 - 400 with each of the four default

axis segments colored differently, the **Value** settings of the first four colors in a series must be 0, 100, 200 and 300, starting from top to bottom:



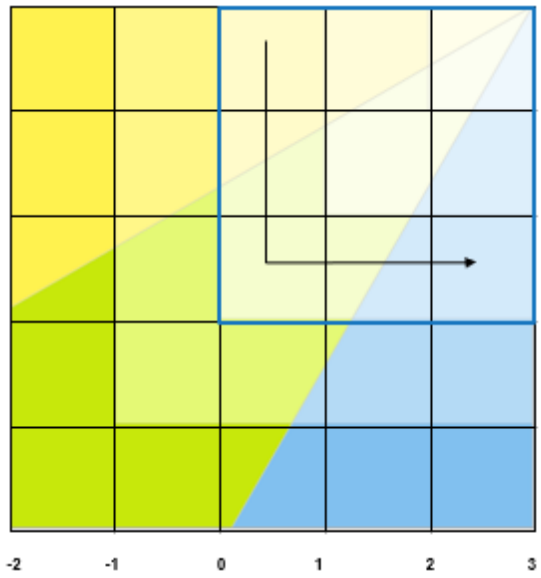
Value	Colors		
	Series 1	Series 2	Series 3
0			
100			
200			
300			
400			

Please note that for coloring of the complete area of a `CheckerBoard` and `Wave` design, you must define additional colors for segments that are having an end position before the minimum of the x-axis. This can be best demonstrated by displaying the design of the actual portfolio chart as a part of a wider screen filled with the designed colors. The following graphics show a portfolio chart that has an X-axis range from 0 - 3 in a screen with a range from -2 to 3. As you can see from the graphic below, the colors defined for the segments ending with the virtual end position -1 and -2 are still part of the design of a `CheckerBoard` or `Wave` design:



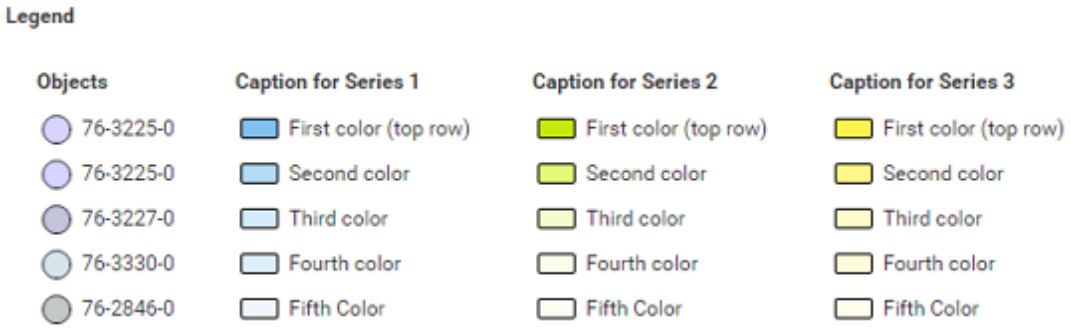
The width of the elements with a virtual end point is irrelevant for the design, because the size of the areas in the portfolio is only defined by the colors with visible end point definitions. The **Value** defined for virtual end points of color definitions must be lower than the minimum value of the x-axis.

For `NestedSquare` design, it is not required to defined coloring for virtual segments. The last color displayed on the visible x-axis is the last color that is used in the report:



3. Definition of the legend for the coloring

Colors defined for the background of the portfolio are automatically added to the legend of the report. The legend displays all colors grouped by series definition.



The text displayed for each color within the series is defined in the **Caption** column of the editor.

The title displayed for the legend of each series is defined in the **Series Caption** row of the editor in the columns for the definition of the series on top of the color definitions. The example legend displayed above is based on the following definition:

Caption	Value	Colors		
		Series 1	Series 2	Series 3
Series Caption		Caption for Series 1	Caption for Series 2	Caption for Series 3
First color (top row)	1			
Second color	4			
Third color	5			
Fourth color	6			
Fifth Color	7			

Defining Navigation from the Objects in the Portfolio to Alfabet Views

By default, a user can click and hold a shape in the configured portfolio report to open a preview of the object. Navigation to the object profile or object cockpit of the object is also available by default via the Show Details button in the preview or via double click on the object. The default behavior can be changed to open any other standard or configured view for the object.

To change the default navigation of the portfolio, the following attribute of the **Report Assistant** explorer's root node must be mapped to the column name in the dataset returned by the query defined in the ***Query*** element of the portfolio report described in the section Defining the Query the Portfolio is Based On:

Attribute	Description
View Column Name	The name of the database column in the query that returns the definition of an alternative link target for navigation from objects in the portfolio. By default, the standard object profile of the object opens when a user double clicks on a node or clicks a node and then clicks the **Navigate** button. The column must return a string with the following structure: `View=ViewType:ViewName` The `ViewType` can be one of the following: • ***Report*** for a configured report • ***GraphicView*** for a standard Alfabet view • ***ObjectView*** for an object profile `ViewName` is the name of the view. For more information about defining navigation to a target view including handing over of parameters, see Defining Navigation from the Report to Alfabet Views.

Defining the Caption and Size of the Portfolio Report Area

Optionally the size reserved for display of the graphic can be changed and a caption can be displayed on top of the portfolio.

The graphic is displayed in the defined size independent from the size of the client device's screen. If the screen size is not sufficient to display the whole graphic, scroll bars are added to the graphic. In order to

ensure that business graphics can be adequately viewed on a variety of devices, it is recommended that graphic reports and object cockpits are designed for a low screen resolution (such as 1280 x 800 or 1280 x 1024).

To define the caption of the portfolio, the string to be displayed as caption must be provided via the dataset returned by the query defined in the ***Query*** element of the portfolio report described in the section Defining the Query the Portfolio is Based On. The dataset column names must then be defined in the attributes of the root node of the Report Assistant.

To define the layout of the report area, you can optionally set the following attributes in the root node of the **Report Assistant**:

Attribute	Description
Portfolio Caption Column	Defines the name of the dataset column that returns the caption of the portfolio displayed on top of the portfolio chart area. If the dataset column returns multiple different values, the first value that is not `NULL` returned in the dataset will be displayed.
Width	Defines the width of the graphic in pixel. Allowed values are between 1 and 1000. The default value is 800.
Height	Defines the height of the graphic in pixel. Allowed values are between 1 and 1000. The default value is 600.

Defining Portfolio Diagnostics Reports

Portfolio diagnostics reports are designed in the **Report Assistant**. For information about how to open the **Report Assistant**, see Creating a New Graphic Report. For more information about how to work with the **Report Assistant**, see Configuring the Report with the Report Assistant.

The report assistant for portfolio diagnostics reports provides configuration options to specify the scope of analyzed objects and to fine-tune the analysis:

1) In the **Data Source Definition** tab of the **Report Assistant**, define one of the following:

   - A native SQL query selecting all properties of a single object class. To define the query, click the **Browse** button in either the **Alfabet Query** attribute to open the **Alfabet Query Builder** or in the **Query as Text** attribute to open a text editor.
   - An Alfabet query without **Show Properties**. To define the query, click the **Browse** button in either the **Native SQL Query** attribute to open the native SQL editor in Alfabet that provides a button for the definition of Alfabet query language instructions or in the **Query as Text** attribute to open a text editor.

   The definition of `WHERE` conditions and `JOIN`s (`FROM` clauses in Alfabet queries) is only allowed for the definition of filters for the report or to reduce the report's dataset to a subset of objects of the

selected object class. Objects of joint object classes are not included in the analysis. The configured report exclusively handles one object class.

To build a configured report for analysis of objects of the class **Component**, a native SQL query without `WHERE` conditions will read:

```
SELECT * FROM COMPONENT
```

2) Open the **Default Layout** tab. A table is displayed containing all object class properties of the selected object class that have the **Property Type** attribute set to `Boolean`, `Integer`, `Real`, `Reference`, or `String` and all indicators and role types that are available for the object class. The following information is displayed about each object class property/indicator:

- **Feature**: The name of the object class property, role type or indicator.
- **Type**: The property type of the object class property. For indicators, the type is `Indicator` if the indicator is manually defined, or `Indicator Computed` if the indicator is automatically calculated. For role types, the type is `RoleType`.
- **Caption**: The caption of the object class property, role type or indicator.

If new object class properties, role types, or indicators are available for an object class, these are not automatically added to the list in an already existing portfolio diagnostics report. To add new object class properties, role types, or indicators to the list, click the **Refresh Available Features** button.

3) In the **Exclude** column, set a checkmark for all object class properties, role types or indicators that you would like to exclude from the analysis via the augmented AI mechanism calculating the portfolios.

To remove all checkmarks from the column, click the **Include All** button in the toolbar. To set a checkmark in all cells of the column, click the **Exclude All** button in the toolbar.

4) Define the number of results that shall be displayed for the levels of the portfolio analysis by means of the parameters in the right pane of the table:

- **Factor Charts**: In the drop-down list, select the number of bar charts that shall be displayed for each of the drill-down levels created via factor analysis. Please note that the number must be selected via the drop-down list. It is not possible to change the number via text edit.
- **Variance Charts**: In the drop-down list, select the number of bar charts that shall be displayed on the root level of the analysis when a user opens the report. Please note that the number must be selected via the drop-down list. It is not possible to change the number via text edit.

5) When the user opens the portfolio diagnostics report, a dataset is generated based on the calculation. The dataset includes all objects found via the query defined in the **Data Source Definition** tab and all properties listed in the table of the **Default Layout** tab. Prior to starting the analysis, the software will check whether a configurable amount of data is available in each row or column of the dataset. If the percentage of allowed undefined values is higher than the allowed value, the row or column will be removed from the dataset. The resulting dataset is used for all subsequent analysis steps without further changes. Define the limits for availability of undefined data with the following parameters on the right of the table:

- **Feature Elimination %**: Define the percentage of undefined values that shall result in the indicator being excluded from the analysis.

- **Object Elimination %**: Define the percentage of undefined indicators that shall result in the object being excluded from the analysis.

6) Define the following default values in the right pane of the table. If a property of the respective value type is not set for an object, the specified value will be used in the analysis for the object. The value does not change the actual setting of the object class property for the object but is exclusively used in the analysis. It is entered in the dataset created for analysis after the removal of columns and rows with an exceedingly high number of undefined values.

- **Default Integer/Real**: Enter an integer value to be used as the default for numeric values.
- **Default Boolean**: Select 1 if the Boolean value should be `True` or select 0 if the Boolean value should be `False`.
- **Default Indicator**: Select a numeric default for the indicator.
- **Default String/Reference**: Enter a default string that is displayed for undefined indicators specified to have a semantic value, undefined object class properties of the type `String` or `Reference`, or role types that have no roles assigned.

7) If more than 20 values are available for a chart, the values are combines in buckets and the overall number of objects with one of the values in the bucket is shown as Y-Value for the bucket. The X-Value is then a range of values. The overall number of buckets to be formed from the values is configurable. Set the attribute **Bucket Number** to a number between 1 and twenty to specify how many buckets shall be available.

For example, analyzed applications have 40 different values for an indicator that returns the number of support requests per year. If the number of buckets is ten, each bucket will include 4 values. If the number of buckets is 5, each bucket will combine 8 values.

8) Open the **Additional Report Properties** tab and define the following attributes:

- **Portfolio Diagnostics Report Details View Caption**: Enter the caption that shall be displayed on all factor analysis views of the portfolio analytics report.
- **Portfolio Diagnostics Report Details View Description**: Enter the description that shall be displayed in the header of all factor analysis views of the portfolio analytics report.
- **Portfolio Diagnostics Report Object View Caption**: Enter the caption that shall be displayed on the object list views of the portfolio analytics report.
- **Portfolio Diagnostics Report Object View Description**: Enter the description that shall be displayed in the header of the object list views of the portfolio analytics report.
- **Chart Height**: Enter the height of the charts displayed in the report views as number of pixel. the default is 300.
- **Chart Width**: Enter the width of the charts displayed in the report views as number of pixel. the default is 400.

9) Click **OK** to save your settings and to close the report assistant.

10) In the toolbar, click the **Save**  button to save your changes.

Defining a Treemap Report

Treemap reports are designed in the **Report Assistant**. For information about how to open the **Report Assistant**, see Creating a New Graphic Report. For more information about how to work with the **Report Assistant**, see Configuring the Report with the Report Assistant.

The content and layout of a treemap report is defined by adding elements to the explorer of the **Report Assistant** and setting the attributes in the attribute pane of the **Report Assistant** window.

The following table lists the types of explorer node elements that can be added to the report configuration to specify the content of the report and provides information about the purpose of each explorer node element:

Explorer Node Element	Required to Configure:
Root Node	General layout of the report
Root Queries	Container for **Query** elements that define the column headers for the report.
Query	Definition of the column headers for the report when specified as a sub-element of the **Root Queries** node. Defines the choice of elements displayed in the columns when specified as a sub-element of the **Class Entry** node.
Class Entry	Definition of the object classes included in the report.
Color Rule	Definition of the colors used in the treemap report and the rules that define which objects are displayed with which color.
Size Rule	Definition of three different heights for the boxes representing the objects in the treemap report and the rules that define which objects are displayed with which height.
Indicator Rule	Definition of one or multiple icons displayed in the boxes representing the objects in the current cell of the lane report. The icons can either represent an indicator or any aspect defined via a query. For more information, see the section Defining Indicator Rules.

Defining the Basic Design of the Treemap Report

The basic design of the report is designed directly in the attributes of the root node element of the **Report Assistant** explorer.

Attribute	Description
Area Background Color	Defines the background color of the columns and color of the column header fields.
Layout	Defines whether this is a layered diagram, a rectangualr treemap or a treemap report. Set this attribute to `TreeMap` to define a treemap report.
Use Mandates	Defines whether the implementation of the mandate capability must be taken into consideration to view objects in the report. If set to `True`, a user can only view objects that have a mandate specification identical to the user's mandate.
Show Legend	Defines whether a legend is shown for the color coding, indicators, and size of the objects in the report.
Margin	Defines the space between the treemap and the border of the presentation object in pixel.
Space	Defines the spacing between the columns and between the boxes in the columns in pixel.
Item Width	Defines the width of the boxes in the report in pixel.
Medium Height	Defines the height of the boxes that are displayed for all objects when no size rules are specified in pixel. **Note**: If size rules are specified, additional box heights must be defined. The definition of these attributes is described in the section Displaying Evaluation Criteria By Size or Color Variation or Addition of Indicator Icons.
Item Border Width	Defines the width of the border of the boxes in the report. The default value is 1 point. when using the border color as object property indicator via a color rule, it is recommended to set the border width to a higher value.
Show Indicator	Select `True` to display an indicator icon in the upper right corner of the object boxes or multiple indicator icons at the bottom of the object boxes. Indicator icons are one displayed in the object boxes if an indicator rule is defined that specifies the dipslay of an indicator for the object. Indicator icons can represent an indicator value from the object evaluation or any other aspect that can be defined for the object via a query. Select `False` to exclude the display of the indicator icons for the object box column. For more information about the definition of indicator rules to assign icons to object boxes, see Defining Indicator Rules.

Attribute	Description
Show Multiple Indicators	Defines whether display of icons defined via indicator rules is limited to one icon per object box or whether multiple icons can be assigned to an object box. If **Show Multiple Indicators** is set to `False`, a single icon can be displayed on the right of the object box. If multiple icons are found by indicator rules, the first icon found is assigned and all other icons are ignored. If **Show Multiple Indicators** is set to `True`, one or multiple icons are displayed from left to right at the bottom of the object box. If the number of icons that are assigned to the object box via indicator rules exceeds the space available for display of icons in a single row, the first icons found are displayed and, if the object box space is exceeded, any other icons are ignored. The way icons are placed in the object box also depends on the attribute **Indicator Fill Policy** of the **Item** node. For more information about the placement of icons assigned via indicator rules, see the section Defining Indicator Rules.
Indicator Fill Policy	If **Show Multiple Indicators** is set to `True`, this attribute defines how icons assigned to an object box are placed in the row on the bottom of the object box: • `ByIndex`: This setting shall be used if multiple indicators are defined via multiple indicator rules, each returning a single icon. The position of the icon resulting from each indicator rule is defined by means of the attribute **Indicator Index** of the respective indicator rule that must be set to an unsigned integer starting with 0 for the left most position. If an **Indicator Index** attribute has been defined for each indicator rule and an indicator is not set for a specific object, the position of this indicator icon in the box will be left empty and the position of all other indicator icons will not be changed:  If the order of the **Indicator Index** attribute is not defined, the placement of indicators will be arbitrary. This method is designed for positioning only one icon per indicator rule. If an indicator rule returns multiple icons, only one of the icons is displayed. • `LeftAlign`: This setting shall be used if a single indicator rule is defined that returns multiple icons. It can also be applied when multiple indicator rules each return a single icon, but the position and order of icons is not important to understand the report. The Icons are displayed in the order of occurence within the indicator rule(s)

Attribute	Description
	from left to right. If a different number of indicator icons is returned, the remaining icons are moved to the left:  If the indicator icons are all found by a single indicator rule, the order of icons depends on the order of results in the result dataset of the query of the indicator rule and may be different for different objects if no sort order is defined in the query.

The design of the boxes representing objects in the configured report can be changed from the standard design with a white rectangle as background for text within the colored object box to fully colored object boxes. For more information see Defining the General Display of Object Boxes in Treemap, Diagram, Lane and Layered Diagram Reports.

Defining the Objects to Display in the Report

The objects displayed in the column headers and the columns of the report are found via queries defined for the elements of the report. The queries can either be native SQL queries or Alfabet queries.

If you are not familiar with Alfabet queries, see the chapter Defining Queries.

For special rules that apply to the definition of native SQL queries in the context of configurations for Alfabet, see the section Defining Native SQL Queries.

The information displayed in the object boxes of the report is identical to the column headers that result from a tabular output of the defined query.

Report columns that are defined for technical reasons are not displayed in the object boxes in the report. This includes:

- The first column of the output of a native SQL query. This column must specify the `REFSTR` of the object for technical reasons and is ignored in the visible output..

There are two methods to define a treemap report:

- The complete content of the report is defined in one query resulting in a grouped dataset.

- A separate query is added to the report configuration to find the objects in the column header and the objects beneath the column header.

  When separate queries are defined, a high number of queries must be executed by the database to display the report. This can lead to performance issues. Therefore, it is recommended to base the report on a grouped dataset defined in a single query.

Defining a Treemap Report With a Single Query

The columns in the treemap report including column headers and column content are specified via an Alfabet query or a native SQL query defined in an element node **Query** as sub-node of the **Root Queries** node. The query finds the objects that are displayed in the column header. It also determines the information that is displayed about the objects in the header cells and the sorting of the column headers in the first grouping level. The second grouping level defines the content of the columns.

One **Class Entry** child element must be added to the explorer root node for each object class that is included in the report. The attribute **Class Name** defines the name of the specified object class and is mandatory for the configuration. The result is as follows:

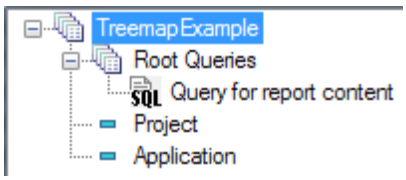
- One **Class Entry** element for the object class displayed in the column headers.
- One **Class Entry** element for each object class displayed in the columns. You can display objects of multiple classes in the report.

The **Class Entry** elements may not contain a sub-element **Query**.

The following example displays the position and structure of the elements **Class Entry** and the **Query** elements defining the column header and the objects in the report for an example report that displays projects in the column headers and the applications assigned to the project architecture in the columns.

The root element must contain two **Class Entry** elements. One for the object class Project displayed in the column headers and one for the applications displayed in the columns of the treemap.

A **Query** element is added to the **Root Queries** node to find the projects that are displayed in the column headers and the applications displayed in the columns in a grouped dataset.



The query defined for the **Query** element must define a grouped dataset with one grouping level:

```
ALFABET_QUERY_500
FIND Project
   InnerJoin ProjectArch ON Project.REFSTR = ProjectArch.Project
   InnerJoin Application ON ProjectArch.Object = Application.REFSTR
Instructions
```

```
    GroupBy_Ex("Project.REFSTR","Application.REFSTR","Project",0);
    RemoveColumns("Application.REFSTR");
EndOfInstructions
QUERY_XML
<QueryDef>
    <ShowProperty Type="Property" ClassName="Project" Name="REFSTR"
    />
    <ShowProperty Type="Property" ClassName="Project" Name="Name" />
    <ShowProperty Type="Property" ClassName="Application"
    Name="REFSTR" />
    <ShowProperty Type="Property" ClassName="Application" Name="Name"
    />
    <ShowProperty Type="Property" ClassName="Application"
    Name="Version" />
    <SortProperty Type="Property" ClassName="Project" Name="REFSTR"
    />
    <SortProperty Type="Property" ClassName="Application"
    Name="REFSTR" />
</QueryDef>
```

Optionally, an icon can be selected in the attributes of the **Class Entry** element. The icon is then displayed in the object boxes of the defined object class in the report.

Defining a Treemap Report With One Query Per Object Class

The columns in the treemap report are defined via an Alfabet query or a native SQL query defined in an element node **Query** defined as sub-node of the **Root Queries** node. The query finds the objects that are displayed in the column header and determines the information that is displayed about the objects in the header cells and the sorting of the column headers.

One **Class Entry** child element must be added to the explorer root node for each object class that is included in the report with the mandatory attribute **Class Name** that defines the name of the specified object class. The result is as follows:

- One **Class Entry** element for the object class displayed in the column headers
- One **Class Entry** element for each object class displayed in the columns. You can display objects of multiple classes in the report.

The object class defined for the column headers of the report is the base class for the objects displayed in the report. The Alfabet queries that define which objects are to be displayed in the report are specified as the child elements **Query** of the **Class Entry** element of the object class defined for the column header.

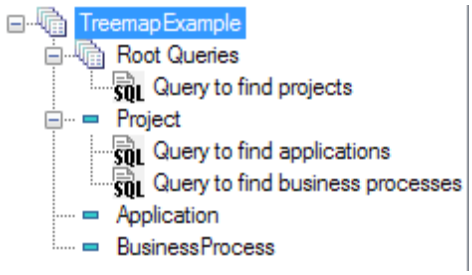
All other **Class Entry** elements may not contain a sub-element `Query`.

The Alfabet query defining an object class displayed in the columns must contain the parameter:`BASE` in a `WHERE` clause to map the objects to a column. `BASE` is identical to the `REFSTR` of the object in the column header.

The following example displays the position and structure of the elements **Class Entry** and the **Query** elements defining the column header and the objects in the report for an example report that displays projects in the column headers and the applications and business processes assigned to the project architecture in the columns.

The root element must contain three **Class Entry** elements. One for the object class Project displayed in the column headers and one for each object class displayed in the columns of the treemap.

A **Query** element is added to the RootQueries node to find the projects that are displayed in the column headers. The Alfabet queries that define which applications and business are displayed in which column must be specified as child elements of the **Class Entry** element for Project.



The queries defined for the **Query** element of the **Class Entry** for Project must contain a `WHERE` clause mapping applications and business processes to the project in the column header with the parameter `BASE`. For example,:

```
ALFABET_QUERY_500
FIND Application
   InnerJoin ProjectArch ON ProjectArch.Object = Application.REFSTR
   InnerJoin Project ON Project.REFSTR = ProjectArch.Project
WHERE
   Project.REFSTR CONTAINS:BASE
QUERY_XML
<QueryDef>
   <ShowProperty Type="Property" ClassName="Application" Name="Name"
   />
   <ShowProperty Type="Property" ClassName="Application"
   Name="Version" />
</QueryDef>
```

Optionally, an icon can be selected in the attributes of the `ClassEntry` element. The icon is then displayed in the object boxes of the defined object class in the report.

The table below lists all available attributes in the **Query** element.

Attribute	Description
Name	Defines the name of the **Query** element displayed in the explorer of the **Report Assistant**.

Attribute	Description
Alfabet Query/ Query as Text/ Native Sql	Defines a query to find the objects that are displayed in the report. The way the query must be defined depends on the location of the **Query** element in the report.
Cascading	Not relevant for treemap reports.

The table below lists all available attributes in the **Class Entry** element.

Attrib-ute	Description
Class Name	Defines the object class specified in this **Class Entry** element. For the object classes that allow stereotype specifications (For example, `Project` and `Domain`), the XML attribute `ClassName` can specify an object of a specific stereotype. To define an XML element ***Query*** for a stereotype, the XML attribute `ClassName` must be *`ClassName:StereotypeName`* For example,: *`Project:StatementOfWork`*
Icon	Defines the icon to be displayed for the object in the object boxes. An icon can be selected from a drop-down list.
Param Name	Not relevant for treemap reports.

Displaying Evaluation Criteria By Size or Color Variation or Addition of Indicator Icons

Evaluation criteria can be added to the report:

- Rules can be defined that assign colors on the basis of property values of the current object. For example, coloring can be different for boxes of objects that are planned, active, or retired. For more information about the definition of color rules, see Defining Color Rules.
- Rules can be defined that trigger the display of an indicator icon in the object boxes of selected objects. For more information, see Defining Indicator Rules.
- Rules can be defined that lead to objects with defined property values to be displayed in smaller or larger object boxes. Size rules are described below.

The boxes in the report can be displayed with three different heights. You can specify a size rule for each box height that allows you to display objects with different attribute values with different box sizes. For example, you can display application groups in a report in a different size determined by the number of applications assigned to the application group. If the number is lower than 5, a small box is displayed. If the number is higher than 20, a big box is displayed. Other application groups are displayed with a medium box height.

To define the size of the boxes in the report, you have to specify the following:

- The height in pixel for the small, medium, and large box size. These are defined by means of the attributes of the root node element.
- The size rules that define which objects are displayed with which box size. Size rules are defined in the element `Size Rule`, which is a child element of the root node element.

You can define two different types of size rules:

- `ObjectQuery`: The query defined for the size rule returns the `REFSTR` of the object that the box height shall be applied to. The size that shall be applied to the object boxes is defined separately via attributes of the size rule.

  When defining an Alfabet query, no Show property definition is required. The `REFSTR` of the `FIND` object class is returned.

  When defining a native SQL query, the `SELECT` statement of the query must have the `REFSTR` of the relevant object class defined as the first argument. No further arguments are required in the `SELECT` statement.

- `SizeQuery`: The query defined for the size rule not only returns the `REFSTR` of the objects that the size shall be applied to but also the size specification that shall be applied.

  SizeQuery rules require the specification of a native SQL query.

  The `SELECT` statement of the SQL query must return the following in the given order:

  - the `REFSTR` of the current object
  - a string that is used as the caption for the size assignment in the legend of the report
  - the size specification as string. Allowed values are `Small`, `Large` and `Medium`.

  For example,:

  ```
  SELECT DOMAIN.REFSTR, "Legend text", "Large"
  ```

  - The definition of a size query in a size rule has the following advantages as compared to an object query: The number of overall size rules required for a report can be reduced. For example, if you want to apply a different box size to applications in a different object state, you can define the size for all object states in one query while a separate size rule for each object state would be required when using object queries.
  - Dynamic size assignment can be applied to a report. You can, For example, define a query that sizes object boxes according to the indicator values assigned to the objects. In the report, you can define a filter that allows the user viewing the

report to choose an indicator type. The size of object boxes is then reassigned according to the values for the selected indicator.

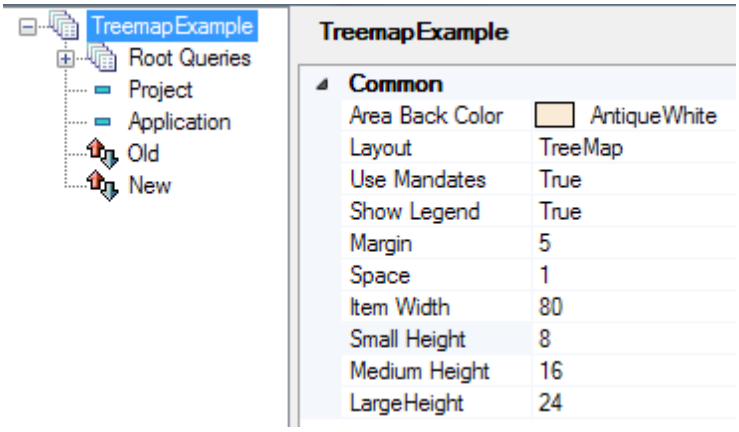
The specification of box sizes and size rules is optional. If no box sizes are defined, all boxes will be displayed in a default height of 12 for all size rules. If no size rules are specified, all objects will be displayed with the defined medium box size.

When you define the queries for the size rules of the report, make sure that all objects can be assigned explicitly to one size rule. If this is not the case, the following applies:

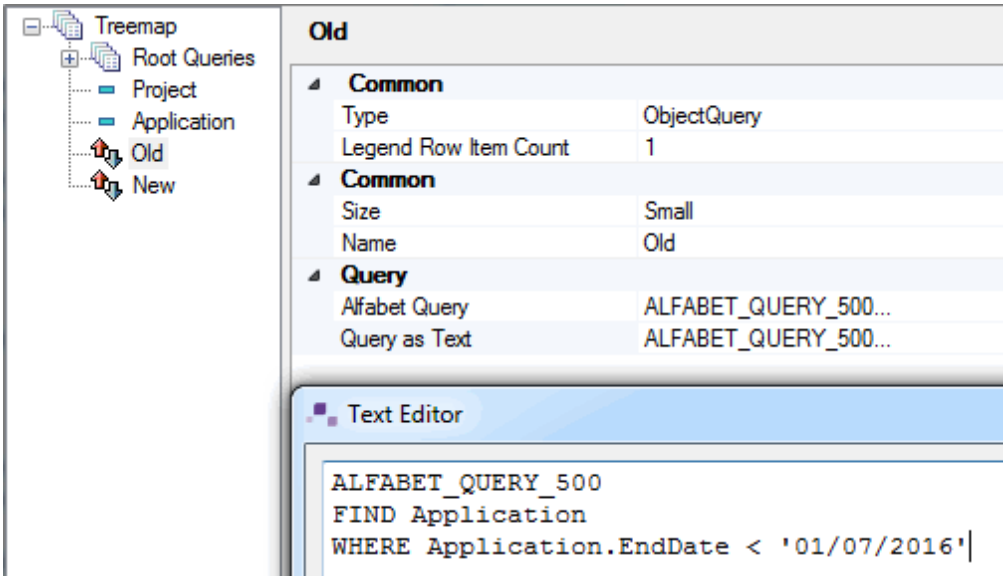
- Objects that correspond to more than one size rule are displayed in the size of the first rule written in the XML object that applies.
- Objects that do not correspond to any of the defined size rules are displayed in medium size. You cannot distinguish between these objects and objects corresponding to the medium size rule in the treemap report.

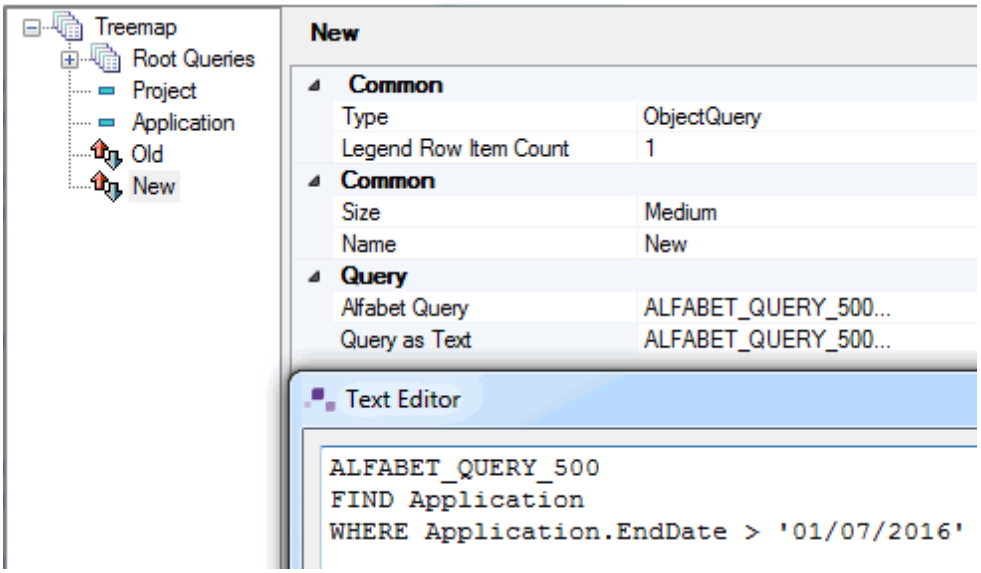
The following example displays a report where applications are displayed in different box height dependent on the start date definition. Old applications are displayed in a smaller height as new applications.

In the root node attributes, three different of object box sizes are defined:



Two size rules are defined, each specifying the box size with the attribute Size and the objects to that the size rule applies with an Alfabet query.





The table below lists all attributes for the specification of box sizes in treemap reports.

Attribute	Description
In the root node element	
Small Height	Defines the height of the boxes that are displayed for objects corresponding to the size rule with **Size** = `"Small"`.
Medium Height	Defines the height of the boxes that are displayed • for objects corresponding to the size rule with **Size** = `"Medium"`. • for all objects when no size rules are specified.
Large Height	Defines the height of the boxes that are displayed for objects corresponding to the size rule with **Size** =`"Large"`.
In the Size Rule element	
Name	Defines the title displayed for the size in the legend. For size rules of the **Type** `ObjectQuery`, also defines the the caption displayed for the size rule in the explorer of the **Report Assistant**. **NOTE**: The attribute **Show Legend** of the **Root** element must be set to true to display the legend. If this element is set to `false`, you do not need to specify a name for the size rule.
Type	Select `ObjectQuery` to define the objects that the size rules apply to with a query and the size specification with the attributes of the size rule. Select `SizeQuery` to define both the size specification and the objects that the size rule applies to with a query.
Size	Defines the size of the boxes of objects corresponding to this size rule if the Type of the size rule is ObjectQuery. The pixel size of the boxes is specified with the `Small Height, Medium Height` and `Large Height`attributes of the root node element.
Alfabet Query/ Native Sql/ Query as Text	If the **Type** of the size rule is `SizeQuery`, define a native SQL query in the **Native Sql** attribute or an Alfabet query in the **AlfabetQuery** or **Query as Text** attribute. The query must return the `REFSTR` of the objects that the size rule shall apply to. If the **Type** of the size rule is `SizeQuery`, define a native SQL query in the **Native Sql** attribute that returns: • the `REFSTR` of the current object

Attribute	Description
	• a string that is used as caption for the size assignment in the legend of the report • a string that defines which box size applies. Valid values are `Medium`, `Small` and `Large`.
Legend Row Item Count	Defines the number of sizes displayed in one row of the legend of the report. For size rules of the type `ObjectQuery`, only the value defined in the first size rule of the type `ObjectQuery` of the report is applied to the group. By default, 4 items are displayed in a row of the legend.

Defining a Rectangular Treemap Report

Rectangular treemap reports are designed in the **Report Assistant**. For information about how to open the **Report Assistant**, see Creating a New Graphic Report. For more information about how to work with the **Report Assistant**, see Configuring the Report with the Report Assistant.

The content and layout of a layered diagram report is defined by adding elements to the explorer of the **Report Assistant** and setting the attributes in the attribute pane of the **Report Assistant** window.

Rectangular Treemap reports can only be defined using native SQL. Alfabet query language does not provide the ability to include text into search results, that is required to define the report.

The following table lists the types of explorer node elements that can be added to the report configuration to specify the content of the report. Information is provided in the table about the purpose of each explorer node element:

Explorer Node Element	Required to Configure:
Root Node	General layout of the report.
Root Queries	Container for the **Query** element that defines the content of the report.
Query	Definition of the content and design of the report.
Indicator Rule	Definition of one or multiple icons displayed in the boxes representing the objects in the current cell of the lane report. The icons can either represent an indicator or any aspect defined via a query. For more information, see the section Defining Indicator Rules.

Defining the Basic Design of the Rectangular Treemap Report

The basic design of the report is designed directly in the attributes of the root node element of the **Report Assistant** explorer. Only a subset of the available attributes for treemaps are relevant for rectangular treemap reports. The following table lists only attributes relevant for the overall design of a rectangular treemap report:

Attribute	Description
Layout	Defines whether this is a layered diagram, a rectangular treemap report or a treemap report. Set this attribute to `RectangularTreeMap` to define a rectangular treemap report.
Use Mandates	Defines whether the implementation of the mandate capability must be taken into consideration to view objects in the report. If set to `True`, a user can only view objects that have a mandate specification identical to the user's mandate.
Show Legend	Defines whether a legend is shown for the color coding and indicators in the report.
Margin	Defines the space between the object boxes of the rectangular treemap and the border of the presentation object in pixel.
Space	Defines the spacing between the boxes in pixel. The spacing is applied to boxes of both levels of the report hierarchy.
Report Height	Defines the overall height of the resulting report. The size of the object boxes is adjusted accordingly.
Report Width	Defines the overall width of the resulting report. The size of the object boxes is adjusted accordingly.
Item Border Width	Defines the width of the border of the boxes in the report. The default value is 1 point. When using the border color as object property indicator via a **Border Color Column** specification, it is recommended to set the border width to a higher value. For more information about defining colors in the report dependent on an object property or simply deviating from the default colors for the object, see Displaying Evaluation Criteria By Color Variation.
Show Class Icon	Select `True` to display the class icon in the object boxes. the class icon is defined in the class settings of the object class.
Show Indicator	Select `True` to display an indicator icon in the upper right corner of the object boxes or multiple indicator icons at the bottom of the object boxes. Indicator icons are one displayed in the object boxes if an indicator rule is defined that specifies the dipslay of an indicator

Attribute	Description
	for the object. Indicator icons can represent an indicator value from the object evaluation or any other aspect that can be defined for the object via a query. Select `False` to exclude the display of the indicator icons for the object box column. For more information about the definition of indicator rules to assign icons to object boxes, see Defining Indicator Rules.
Show Multiple Indicators	Defines whether display of icons defined via indicator rules is limited to one icon per object box or whether multiple icons can be assigned to an object box. If **Show Multiple Indicators** is set to `False`, a single icon can be displayed on the right of the object box. If multiple icons are found by indicator rules, the first icon found is assigned and all other icons are ignored. If **Show Multiple Indicators** is set to `True`, one or multiple icons are displayed from left to right at the bottom of the object box. If the number of icons that are assigned to the object box via indicator rules exceeds the space available for display of icons in a single row, the first icons found are displayed and, if the object box space is exceeded, any other icons are ignored. The way icons are placed in the object box also depends on the attribute **Indicator Fill Policy** of the **Item** node. For more information about the placement of icons assigned via indicator rules, see the section Defining Indicator Rules.
Indicator Fill Policy	If **Show Multiple Indicators** is set to `True`, this attribute defines how icons assigned to an object box are placed in the row on the bottom of the object box: • `ByIndex`: This setting shall be used if multiple indicators are defined via multiple indicator rules, each returning a single icon. The position of the icon resulting from each indicator rule is defined by means of the attribute **Indicator Index** of the respective indicator rule that must be set to an unsigned integer starting with 0 for the left most position. If an **Indicator Index** attribute has been defined for each indicator rule and an indicator is not set for a specific object, the position of this indicator icon in the box will be left empty and the position of all other indicator icons will not be changed:  If the order of the **Indicator Index** attribute is not defined, the placement of indicators will be arbitrary. This method is designed for positioning only one icon per indicator rule. If an indicator rule returns multiple icons, only one of the icons is displayed.

Attribute	Description
	• `LeftAlign`: This setting shall be used if a single indicator rule is defined that returns multiple icons. It can also be applied when multiple indicator rules each return a single icon, but the position and order of icons is not important to understand the report. The Icons are displayed in the order of occurence within the indicator rule(s) from left to right. If a different number of indicator icons is returned, the remaining icons are moved to the left:  If the indicator icons are all found by a single indicator rule, the order of icons depends on the order of results in the result dataset of the query of the indicator rule and may be different for different objects if no sort order is defined in the query.

Defining the Objects to Display in the Report

The object boxes in the first and second level in the rectangular treemap report, including the text displayed in the boxes, are specified via a native SQL query defined in an element node **Query** as sub-node of the `RootQueries` node. The query must define a grouped dataset via definition of Alfabet query language instructions. The grouped dataset finds the objects that are displayed in the column header. It also determines the information that is displayed about the objects in the cells of the report. The first grouping level defines the information about the object boxes of the superordinate level and the second grouping level defines the content of the object boxes of the subordinate level.

For information about how to define a grouped dataset using Alfabet query language instructions see the section Grouping Query Results in Expandable Reports in the chapter Defining Queries.

The native SQL query defined for a rectangle treemap report can be very complex. To make sure that your query corresponds to the above-mentioned requirements without taking the configuration of the report into account, you can first define a configured report of the **Type** `NativeSQL` and control that the output is a grouped table with the column joined in the correct way. When the output is as expected, paste the query into the rectangular treemap report and set the required attributes in the report assistant.

The native SQL query can return the following information about an object:

- The text to display in the object boxes.
- A link to a view that shall open when the user clicks the text in the object boxes.
- A size definition for the object boxes in the report. This definition must be an integer that is then used to calculate the relative size of the object boxes in relation to other boxes of the report.

- A color definition for the background of the object boxes.
- A color definition for the text of the object boxes.
- A color definition for the border of the object boxes.

After having defined the native SQL query, the name of the column containing the respective information must be defined in the attributes of the root node of the report assistant:

Attribute	Description
Image Column	Defines the name of the column containing the text to be displayed in the boxes.
Value Column	Defines the name of the column containing integer values that shall be used to calculate the sizing of the boxes in the report.
Aggregated Value	If set to `True`, the upper level of boxes is sized according to the aggregated sizing values defined for the subordinate level of boxes in the **Value Column**. Sizing values defined for objects on the superordinate objects within the dataset resulting from the query are ignored. If set to `False`, the upper level of boxes is sized according to the size specification for the objects in the superordinate level in the **Value Column**. If no values are defined for the superordinate level of boxes and **Aggregated Value** is set to `False`, the report cannot be executed. For more information about sizing of object boxes, see Displaying Evaluation Criteria By Size Variation.
Tooltip Column	Defines the content of the tooltip that is displayed when the user moves the mouse over the text in the boxes. If **Tooltip Column** is not set, the tooltip is identical with the text displayed in the boxes.
Background Color Column	Defines the name of the column containing a HTML compliant color definition for coloring of the background of the boxes.
Foreground Color Column	Defines the name of the column containing a HTML compliant color definition for coloring of the text in the boxes.
Border Color Column	Defines the name of the column containing a HTML compliant color definition for coloring of the border of the boxes.
Color Legend Column	Defines the name of the column containing a text to display in the legend for the coloring of the boxes.

Attribute	Description
View Column	Defines the name of the column containing the definition of an alternative link target for the double click action on the object boxes.

In the attributes of the root node of the report assistant, only one column can be defined for a type of information. For example, only one column can be defined to display the text of the object boxes. Therefore, the native SQL query must be defined to display information about both levels in the grouped dataset in the same column. This can be achived with `JoinColumn` instructions of the Alfabet query language.

In the following, the building of the report query is described stepwise on basis of an example. Each column definition is handled in a separate section. This section describes the basic definition of object boxes containing a name via an example. For the other aspects of the report, the following sections are providing information about the query definition:Displaying Evaluation Criteria By Size Variation

- Displaying Evaluation Criteria By Size Variation
- Displaying Evaluation Criteria By Color Variation
- Defining Indicator Rules
- Defining Navigation from the Report to Alfabet Views

To define the native SQL query for the report:

1) In the report assistant, right-click the node **Root Queries** and select **Add New Root Query**.
2) Click on the new **Query** node under the **Root Queries** node. The attributes for the **Query** are displayed on the right.
3) Define the native SQL query either in the attribute **Sql Query** or **Query As Text**.
4) Optionally, define a name for the query element that is displayed in the explorer of the report assistant with the attribute **Name**. All other attributes of the **Query** element are not relevant for rectangular treemaps.
5) Click on the root node of the report assistant.
6) Enter the name of the columns in the dataset defined by your query into the relevant attributes of the section **Data** of the attributes of the root node.

The example report shall display projects as superordinate objects and applications that are part of the project architecture as subordinate objects. In the select statement of the native SQL query of the report four columns are defined. Two columns define the RESTR of the projects and the applications respectively to identify the objects in the report. Two columns are added to return the name of the projects and the name and version of the applications. These names shall be displayed in the object boxes of the report.

```
SELECT proj.REFSTR AS 'proj.REFSTR', proj.NAME AS 'proj.NAME',
app.REFSTR AS 'app.REFSTR', app.NAME + app.VERSION AS 'Application'

FROM PROJECT proj

INNER JOIN PROJECT_ARCH pa ON pa.PROJECT=proj.REFSTR

INNER JOIN APPLICATION app ON app.REFSTR = pa.OBJECT

ORDER BY proj.NAME,app.NAME
```

Please note that the first argument of the `SELECT` statement must include an explicit definition of a column name to be used in the `GroupBy_Ex` instruction that is used to group the dataset. Otherwise the column name would be ignored. The Alfabet query language instructions defined for the native SQL query consist of one `GroupBy_Ex` instruction for grouping of the dataset and one `JoinColumns` instruction to join the columns `proj.NAME` and `Application` into one column named `proj.Name`:

```
GroupBy_Ex("proj.REFSTR","app.REFSTR","proj",0);

JoinColumns("proj.NAME,Application","proj.NAME", "");
```

In the attributes of the root node of the report assistant, the attribute **Image Column** of the report is set to the name of the column containing the object names:
