
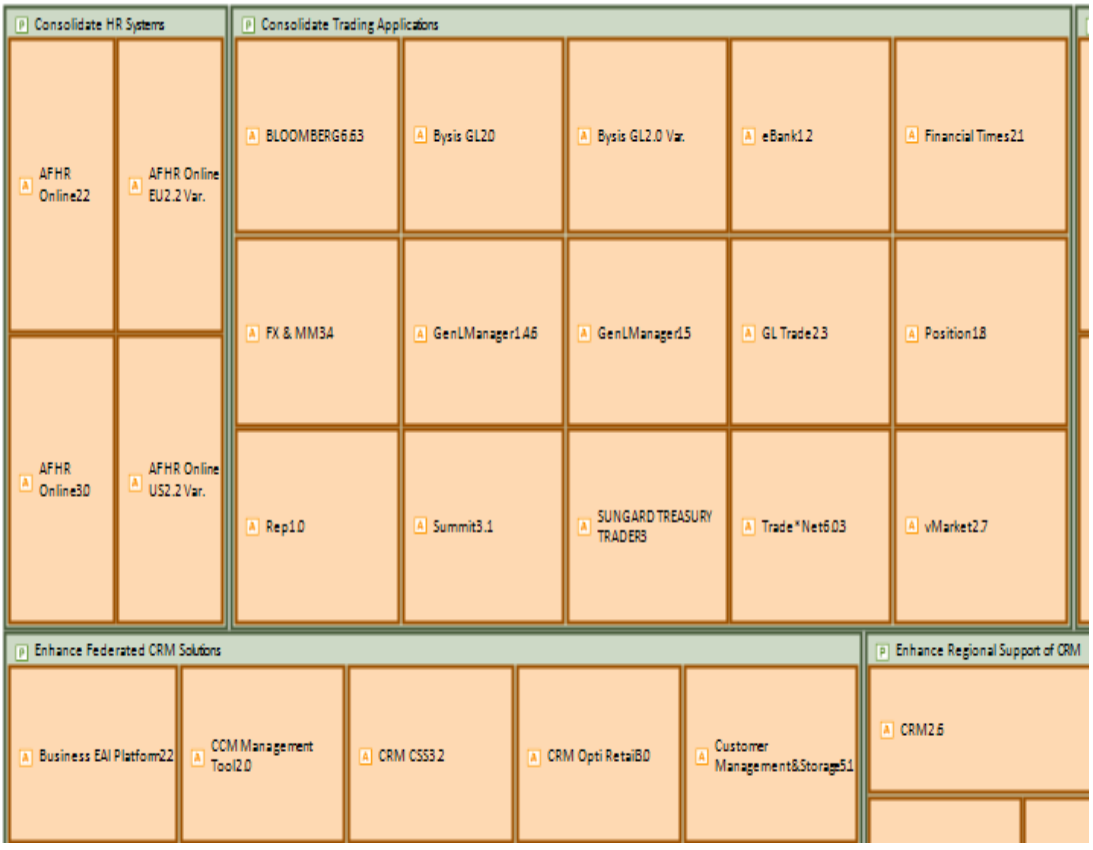
The resulting report shows reports as boxes with application as small boxes within with the name of the object displayed in each box. When the user double clicks a box, the object profile of the object represented by the box opens.

The colors of the boxes are the default colors defined for the objects in the class settings of the object class. The boxes for applications in the subordinate level all have the same size, because no size specification is included in the report. The size of the superordinate box reflects the number of applications that are part of the project's affected architecture:



In the following sections, evaluation criteria and navigation to objects is added to the report.

Displaying Evaluation Criteria By Size Variation

The object boxes can be sized relative to an integer value, For example, the number of subordinate objects or the value of an indicator cast as an integer.

Sizing of boxes can be performed for both levels of object boxes or for one level only. The value for the size specification of the object boxes is read from a column of the output of the native SQL query that the report is based on. This column must return an integer.

The column of the native SQL query that contains the integer values as basis for the relative sizing of the object boxes can contain values for both levels of object boxes. You can use a `Join Column` instruction to combine the values for the superordinate and subordinate level of boxes in one column.

In the attributes of the root node of the report, you must define the name of the column in the dataset containing the sizing values with the attribute **Value Column**.

In addition, you should define the attribute **Aggregated Value** to define how the sizing on the superordinate level of object boxes is performed. If **Aggregated Value** is set to `True`, the sizing of the object boxes in the superordinate level is exclusively performed by aggregating all sizing values of the subordinate objects of the respective box and using the aggregated value as sizing value. Sizing values for the superordinate level defined in the native SQL query are ignored.

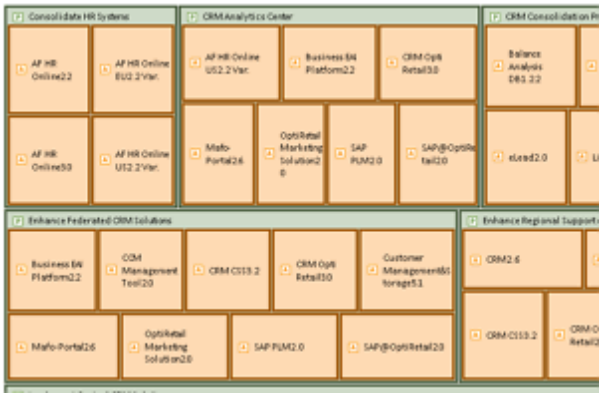
If **Aggregated Value** is set to `False`, the sizing of both levels of object boxes is done according to the sizing values in the column defined with the attribute **Value Column**. If the **Value Column** does not contain values for the superordinate boxes, the report cannot be executed.

If **Value Column** is set, the configured report can only be executed if values are defined for the subordinate level of object boxes. If you want a report to show box sizing exclusively dependent on values from the superordinate level, you can define a fixed integer as value for the subordinate level.

The following examples show the same report defined with all kind of settings for the **Value Column** and **Aggregated Value** attributes:

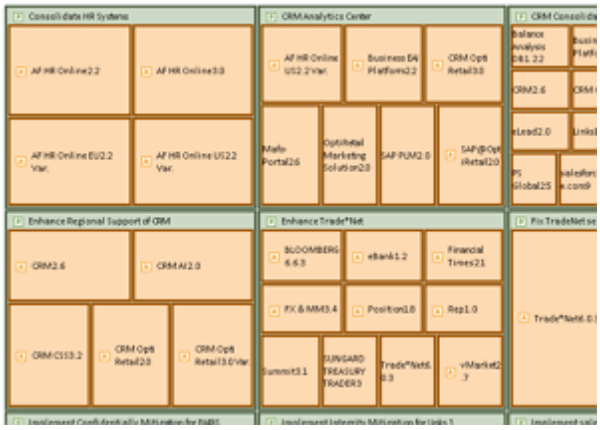
- **Value Column is not set and Aggregated Value is set to True**

All object boxes on the subordinate level have the same size. The size of the superordinate object boxes depend on the number of subordinate object boxes displayed in the superordinate box.



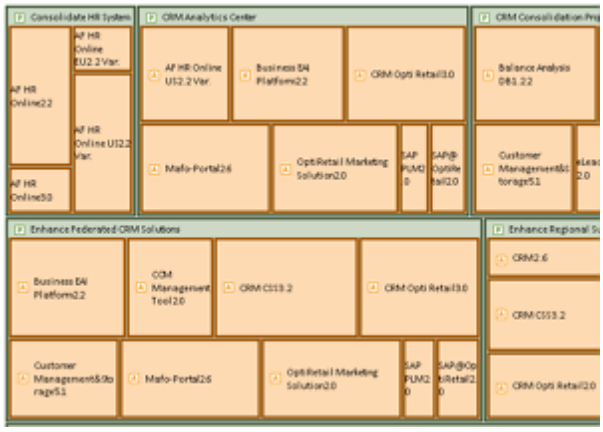
- **Value Column is not set and Aggregated Value is set to False**

All object boxes on the superordinate level have the same size. The size within the superordinate box is equally shared by all subordinate object boxes. That means that subordinate boxes are bigger if less object boxes are in the superordinate object box.



- **Value Column is set and contains only values for subordinate object boxes and Aggregated Value is set to True**

The size of the object boxes on the subordinate level depend on the sizing value defined in the **Value Column**. The size of the superordinate object boxes is calculated from the aggregated values of the subordinate object boxes. This means that the superordinate box size depends on the size of the object boxes displayed within the box. This setting allows to compare all objects on the subordinate level, even if they are displayed within different superordinate object boxes.

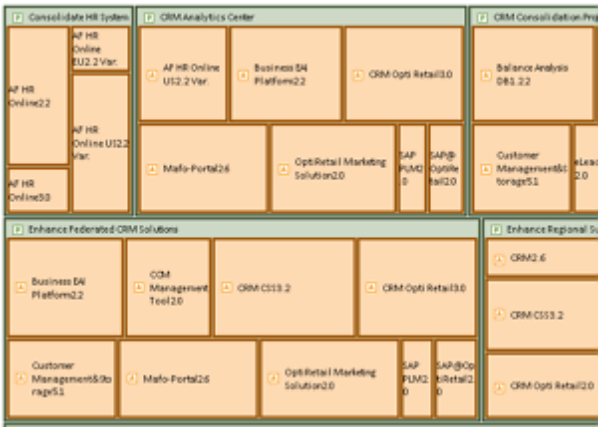


- **Value Column is set and contains only values for subordinate object boxes and Aggregated Value is set to False**

The report cannot be executed.

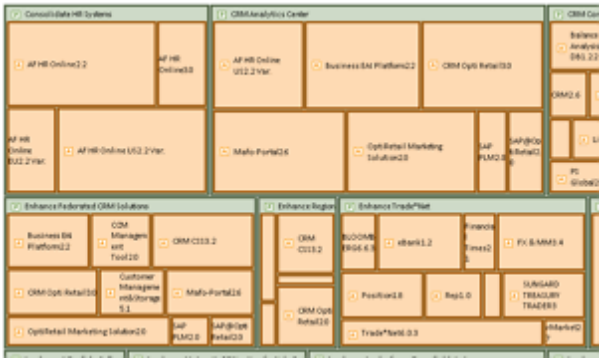
- **Value Column is set and contains values for both levels of object boxes and Aggregated Value is set to True**

The size of the object boxes on the subordinate level depend on the sizing value defined in the **Value Column**. The size of the superordinate object boxes is calculated from the aggregated values of the subordinate object boxes. This means that the superordinate box size depends on the size of the object boxes displayed within the box. This setting allows to compare all objects on the subordinate level, even if they are displayed within different superordinate object boxes.



- **Value Column is set and contains values for both levels of object boxes and Aggregated Value is set to False**

The size of the object boxes on the superordinate level depends on the sizing value defined in the **Value Column**. Within one superordinate box, the sizing of the subordinate boxes depend on the sizing values defined in the **Value Column**. The absolute sizing of the subordinate boxes in the different superordinate object boxes depends on the size of the superordinate box. The size of two subordinate boxes with the same sizing value, but in different superordinate boxes can be different.



The example report displaying projects and applications that are part of the project architecture shall show applications sized according to the setting of an indicator that informs about the criticality of the application for the customer. At the same time, the size of the boxes representing projects shall depend on an indicator that reflects the strategic importance of the project in the enterprise. Both indicators are added to the query results. Indicator vlaues are stored as real values in the Alfabet. Therefore, a `CAST` expression is required in the `SELECT` statement of the native SQL query to convert the value to an integer. The column name for the size speicification of the superordinate project object boxes must follow the naming convention for the superordinate level and start with `proj.`.

```
SELECT proj.REFSTR AS 'proj.REFSTR', proj.NAME AS 'proj.NAME',
app.REFSTR AS 'app.REFSTR', app.NAME + app.VERSION AS
'Application',CAST(indproj.VALUE AS Integer) AS 'proj.BoxSize',
CAST(ind.VALUE AS Integer) AS 'BoxSize'

FROM PROJECT proj

INNER JOIN PROJECT_ARCH pa ON pa.PROJECT=proj.REFSTR

INNER JOIN APPLICATION app ON app.REFSTR = pa.OBJECT

INNER JOIN INDICATOR ind ON ind.OBJECT=app.REFSTR
```

```
INNER JOIN INDICATORTYPE indtype ON ind.INDICATORTYPE =
indtype.REFSTR

INNER JOIN EVALUATIONTYPE evtype ON ind.EVALUATIONTYPE =
evtype.REFSTR

INNER JOIN INDICATOR indproj ON indproj.OBJECT=proj.REFSTR

INNER JOIN INDICATORTYPE indprojtype ON indproj.INDICATORTYPE =
indprojtype.REFSTR

INNER JOIN EVALUATIONTYPE evprojtype ON indproj.EVALUATIONTYPE =
evprojtype.REFSTR

WHERE evprojtype.NAME = 'Business Value'

   AND indprojtype.NAME = 'Strategic Value'

   AND evtype.NAME = 'Criticality'

   AND indtype.NAME = 'Criticality -- Customer Impact'

ORDER BY proj.NAME,app.NAME
```

An additional `JoinColumns` instruction must be added to the Alfabet query language instructions defined for the native SQL query to join the columns `proj.BoxSize` and `BoxSize`, which contain the indicator values, into one column named `BoxSize`:

```
GroupBy_Ex("proj.REFSTR","app.REFSTR","proj",0);

JoinColumns("proj.NAME,Application","proj.NAME", "");

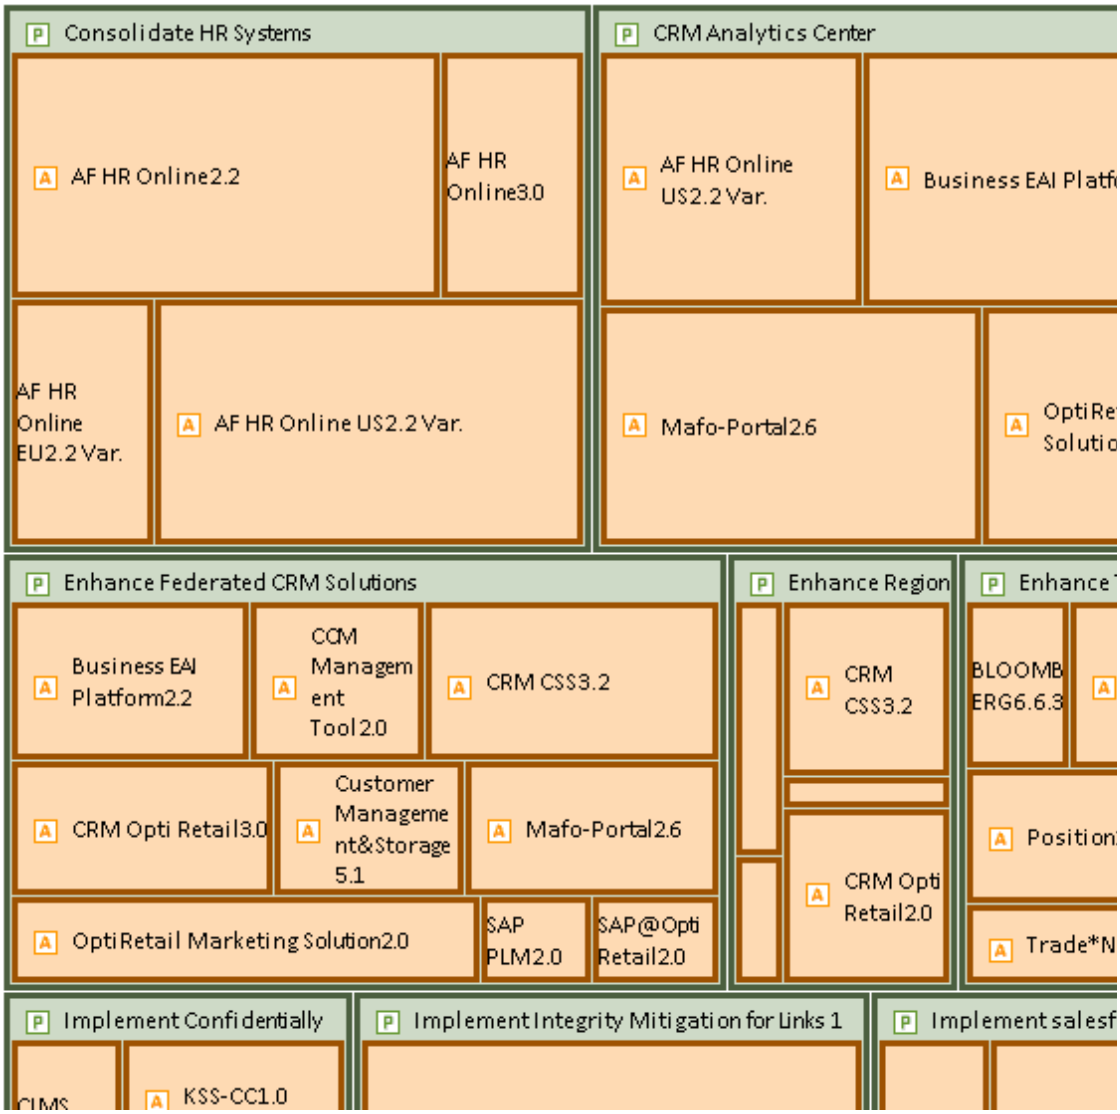
JoinColumns("proj.BoxSize,BoxSize","BoxSize","");
```

In the attributes of the root node of the report assistant, the attribute **Value Column** of the report is set to the name of the column containing the object names and the attribute Aggregated Value is set to False to size both level of boxes according to the individual indicator defined for the respective level:

Aggregated Value	False
Show Class Icon	True
Show Indicator	True
Data	
Image Column	proj.NAME
Value Column	BoxSize

The resulting report shows reports as boxes with application as small boxes within with the name of the object displayed in each box. When the user double clicks a box, the object profile of the object represented by the box opens.

The colors of the boxes are the default colors defined for the objects in the class settings of the object class. The boxes for applications in the subordinate level all have the same size, because no size specification is included in the report. The size of the superordinate box reflects the number of applications that are part of the project's affected architecture:



Displaying Evaluation Criteria By Color Variation

By default the object boxes in rectangular treemap reports are colored according to the colors defined for the displayed objects in the object's class settings. The colors of the report can be customized to either display other static colors or to display objects in different colors dependent on defined criteria. The color of the background, the border and the text of the object boxes can be changed. Coloring can be changed for a single level or both level of boxes in the report. It is also possible to define For example, only the background color without changing border or text color.

If the color definition depend on defined criteria, a legend text can be defined and displayed in the legend that is available for graphic reports via the floating toolbar. The legend can contain a string for each combination of background, border and text color.

The following configuration is required to define coloring of the report:

1) In the native SQL defined as root query of the rectangular treemap report, define a column in the output of the query for each color that you want to change. The column must contain HTML compliant color specifications (HTML color name or HEX code).

   The background color, the text color and the border color must each be defined in a separate, single column. If you want to define coloring for both level of object boxes, The columns containing the coloring information for one type of coloring for the superordinate and for the subordinate level must be combined by a `JoinColumns` instruction.

2) If your color definitions give information about the object, because the color depends on an attribute of the object, add an additional column to the query that returns an explanatory text for the color definition in the respective row.

3) in the root node of the rectangular treemap report, enter the name of the columns containing the color definition in the following attributes:

   - **Background Color Column**: Enter the name of the column defining the background color of the object boxes.
   - **Foreground Color Column**: Enter the name of the column defining the text color of the object boxes.
   - **Border Color Column**: Enter the name of the column defining the border color of the object boxes.
   - **Color Legend Column**: Enter the name of the column containing the text that explains the meaning of the combination of colors for the object.

The example report displaying projects and applications that are part of the project architecture shall show applications colored according to their object state. A legend shall be displayed that explains which state is represented by each color. In the select statement of the native SQL query, the color definitions are added with a condition that relates the coloring with the object state. Background color, text color and border color are all changed for the subordinate level of object boxes in the example. The column that is used for the legend text returns the object state of the current object.

The color of the object boxes of the superordinate level is not changed.

```
SELECT proj.REFSTR AS 'proj.REFSTR', proj.NAME AS 'proj.NAME',
app.REFSTR AS 'app.REFSTR', app.NAME + app.VERSION AS 'Application',
CAST(indproj.VALUE AS Integer) AS 'proj.BoxSize', CAST(ind.VALUE AS
Integer) AS 'BoxSize',

app.OBJECTSTATE As 'Legend',

CASE app.OBJECTSTATE WHEN 'Plan' THEN '#9DE2F7' WHEN 'Retired' THEN
'#FFFFFF' ELSE '#0E89AD' END As 'BackColor',

CASE app.OBJECTSTATE WHEN 'Plan' THEN '#11A6D0' WHEN 'Retired' THEN
'#919191' ELSE '#07475A' END As 'BorderColor',

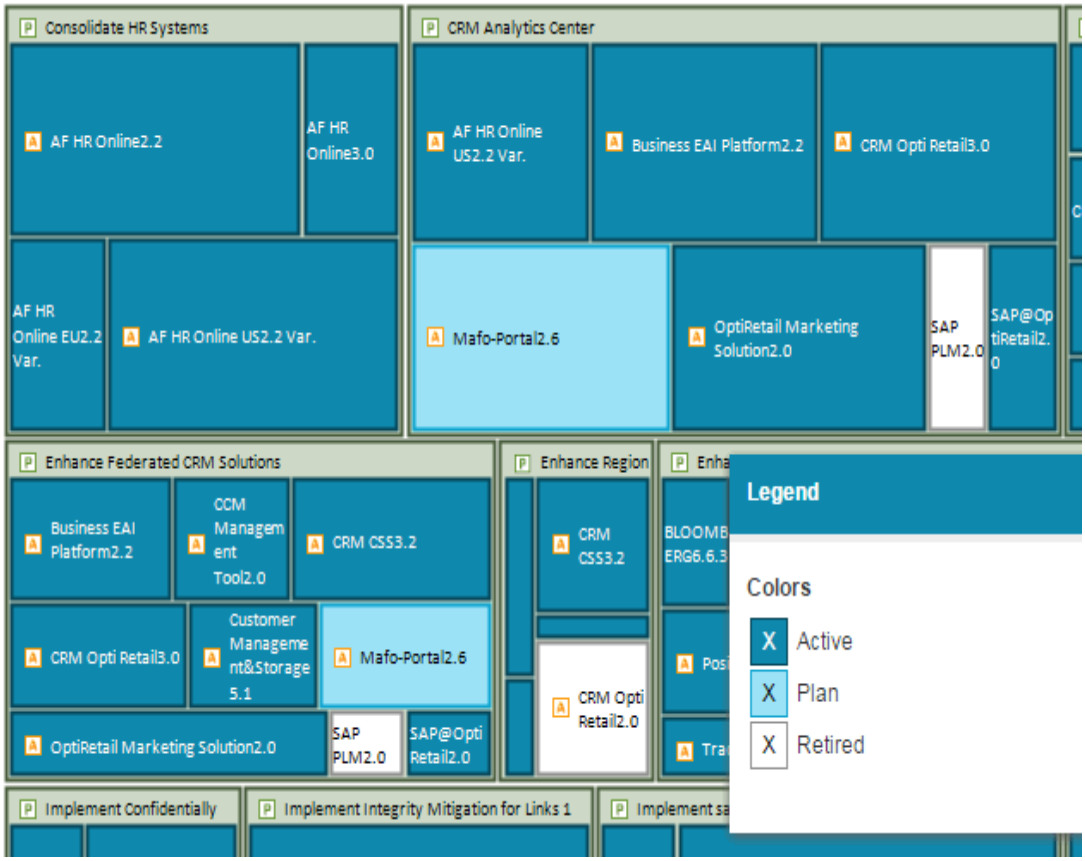
CASE app.OBJECTSTATE WHEN 'Active' THEN '#FFFFFF' ELSE '#000000' END
As 'ForeColor'

FROM ....
```

In the attributes of the root node of the report assistant, the attributes **Background Color Column**, **Foreground Color Column**, **Border Color Column**, and **Color Legend Column** of the report are set to the names of the columns containing the respective information:

Data	
Image Column	proj.NAME
Value Column	BoxSize
Back Color Column	BackColor
Fore Color Column	ForeColor
Border Color Column	BorderColor
Color Legend Column	Legend

In the resulting report, the object boxes for applications are displayed in different colors according to their object state and the color coding is explained in the legend:



Defining Navigation from the Report to Alfabet Views

By default, the object profile of the object represented by the box opens when the user double-clicks a box in the report or uses the Navigate button in the toolbar of the report. Alternatively, the rectangular treemap report can be configured to open another configured report, an object profile or a standard Alfabet view with the object represented by the box as base object. You can define an alternative navigation target for both or only for a single level of the object boxes. If no navigation target is defined for one level, the default is used and the object profile of the object opens.

Navigation to a defined configured report from the configured chart report requires the following configurations:

1) In the native SQL query defined as root query of the report, a column must be added for the definition of the navigation target. If you want to define the navigation target for both levels of

object boxes in the report, you must specify two columns, one with the navigation target definition of the superordinate level and one with the navigation target definition if the subordinate level and then combine the two columns into one with a `JoinColumns` instruction.

The syntax required for definition of the view is the following:

`View=`*`ViewType`*`:`*`ViewName`*

The `ViewType` can be one of the following:

- ***Report*** for a configured report
- ***GraphicView*** for a standard Alfabet view
- ***ObjectView*** for an object profile

`ViewName` is the name of the view.

If the navigation target is a configured report, parameters values can be handed over to the view that opens.

The query of the report must contain each parameter definition as a variable defined as

`@`*`ParameterName`*

Please note that the old syntax of the Alfabet query language defining parameters as:`ParameterName` is not supported.

The parameters can be used in `WHERE` clauses of the query without defining a filter for the report, because the parameter values are already defined in the navigation link.

Optionally, filters can be defined for the report to allow the user opening the report to alter the parameter values. In this case the parameter values in the navigation link are used as default values for the filter when opening the report. The filter settings are also stored in the user context settings for the report. That means, when the user first opens the report via drilldown from a chart report and then afterwards opens the report in any other context, For example, via the **Reports** functionality, the report will open with the last filter settings derived from the drill-down.

For each parameter the following string must be added to the navigation target definition:

`&`*`ParameterName=ParameterValue`*

The setting of three parameters would result in the following navigation link:

`View=`*`ViewType`*`:`*`ViewName`*`&`*`ParameterName1=ParameterValue1`*`&`*`ParameterName2=ParameterValue2`*`&`*`ParameterName1=ParameterValue2`*

2) In the attributes of the root node of the report assistant, enter the name of the column containing the navigation target specification into the attribute **View Column**.

In the example report, navigation from a box representing an application shall open the **Evaluations** page view instead of the application's object profile. The **Evaluations** page view is a standard Alfabet view with the name `ObjectEvaluation`. A new column for the definition of the target is added to the `SELECT` statement of the native SQL query defined as root query:

```
SELECT proj.REFSTR AS 'proj.REFSTR', proj.NAME AS 'proj.NAME',
app.REFSTR AS 'app.REFSTR', app.NAME + app.VERSION AS 'Application',
CAST(indproj.VALUE AS Integer) AS 'proj.BoxSize', CAST(ind.VALUE AS
Integer) AS 'BoxSize', app.OBJECTSTATE As 'Legend', CASE
```

```
app.OBJECTSTATE WHEN 'Plan' THEN '#9DE2F7' WHEN 'Retired' THEN
'#FFFFFF' ELSE '#0E89AD' END As 'BackColor', CASE app.OBJECTSTATE
WHEN 'Plan' THEN '#11A6D0' WHEN 'Retired' THEN '#919191' ELSE
'#07475A' END As 'BorderColor', CASE app.OBJECTSTATE WHEN 'Active'
THEN '#FFFFFF' ELSE '#000000' END As
'ForeColor','View=GraphicView:ObjectEvaluation' As 'ViewDefinition'

FROM ....
```

In the attributes of the root node of the report assistant, the attribute **View Column** of the report is set to the name of the column containing the navigation target definition:

Defining a Layered Diagram Report

Layered diagram reports are designed in the **Report Assistant**. For information about how to open the **Report Assistant**, see Creating a New Graphic Report. For more information about how to work with the **Report Assistant**, see Configuring the Report with the Report Assistant.

The content and layout of a layered diagram report is defined by adding elements to the explorer of the **Report Assistant** and setting the attributes in the attribute pane of the **Report Assistant** window.

The following table lists the types of explorer node elements that can be added to the report configuration to specify the content of the report. Information is provided in the table about the purpose of each explorer node element:

Explorer Node Element	Required to Configure:
Root Node	General layout of the report
Root Queries	Container for **Query** elements that define the first layer or the overall content of the report depending on the type of query definition selected for the report. For more information about the query definitions, see Defining the Objects to Display in the Report.
Query	Definition of the content of the first layer or the overall content of the report when specified as a sub-element of the **Root Queries** node. Defines the choice of elements displayed in the layer below the current layer when specified as a sub-element of the **Class Entry** node.
Class Entry	Definition of the object classes included in the report.

Explorer Node Element	Required to Configure:
Color Rule	Definition of the colors used in the layered diagram report and the rules that define which objects are displayed with which color.
Size Rule	Definition of three different heights for the boxes representing the objects in the layered diagram report and the rules that define which objects are displayed with which height.
Indicator Rule	Definition of one or multiple icons displayed in the boxes representing the objects in the current cell of the lane report. The icons can either represent an indicator or any aspect defined via a query. For more information, see the section Defining Indicator Rules.

Defining the Basic Design of the Layered Diagram Report

The basic design of the report is configured directly in the attributes of the root node element. The table below lists all attributes that specify the general layout of the report in the root node element.

Attribute	Description
Layout	Defines whether this is a layered diagram or a treemap report. Set this attribute to `LayerDiagram` to define a layered diagram report.
Show Legend	Defines whether a legend is shown for the color coding, indicators, and the size of the objects in the report.
Use Mandates	Defines whether the implementation of the mandate capability must be taken into consideration to view objects in the report. If set to `True`, a user can only view objects that have a mandate specification identical to the the user's mandate.
Margin	Defines the space between the layered diagram and the border of the presentation object and between the layers of the diagram in number of pixels.
Area Background Color	Defines the background color of the layers in the report. For more information about defining colors, see Defining Color Attributes.
Space	Defines the spacing between the boxes representing the objects in a layer in number of pixels.

Attribute	Description
Medium Height	Defines the height of the boxes that are displayed for all objects in number of pixels.
Item Border Width	Defines the width of the border of the boxes in the report. The default value is 1 point. When using the border color as object property indicator via a color rule, it is recommended to set the border width to a higher value.
Show Indicator	Select `True` to display an indicator icon in the upper right corner of the object boxes or multiple indicator icons at the bottom of the object boxes. Indicator icons are one displayed in the object boxes if an indicator rule is defined that specifies the dipslay of an indicator for the object. Indicator icons can represent an indicator value from the object evaluation or any other aspect that can be defined for the object via a query. Select `False` to exclude the display of the indicator icons for the object box column. For more information about the definition of indicator rules to assign icons to object boxes, see Defining Indicator Rules.
Show Multiple Indicators	Defines whether display of icons defined via indicator rules is limited to one icon per object box or whether multiple icons can be assigned to an object box. If **Show Multiple Indicators** is set to `False`, a single icon can be displayed on the right of the object box. If multiple icons are found by indicator rules, the first icon found is assigned and all other icons are ignored. If **Show Multiple Indicators** is set to `True`, one or multiple icons are displayed from left to right at the bottom of the object box. If the number of icons that are assigned to the object box via indicator rules exceeds the space available for display of icons in a single row, the first icons found are displayed and, if the object box space is exceeded, any other icons are ignored. The way icons are placed in the object box also depends on the attribute **Indicator Fill Policy** of the **Item** node. For more information about the placement of icons assigned via indicator rules, see the section Defining Indicator Rules.
Indicator Fill Policy	If **Show Multiple Indicators** is set to `True`, this attribute defines how icons assigned to an object box are placed in the row on the bottom of the object box: • `ByIndex`: This setting shall be used if multiple indicators are defined via multiple indicator rules, each returning a single icon. The position of the icon resulting from each indicator rule is defined by means of the attribute **Indicator Index** of the respective indicator rule that must be set to an unsigned integer starting with 0 for the left most position. If an **Indicator Index** attribute has been defined for each indicator rule and an indicator is not set for a specific object, the position of this indicator icon in the box will be left empty and the position of all other indicator icons will not be changed:

Attribute	Description
	 If the order of the **Indicator Index** attribute is not defined, the placement of indicators will be arbitrary. This method is designed for positioning only one icon per indicator rule. If an indicator rule returns multiple icons, only one of the icons is displayed. • `LeftAlign`: This setting shall be used if a single indicator rule is defined that returns multiple icons. It can also be applied when multiple indicator rules each return a single icon, but the position and order of icons is not important to understand the report. The Icons are displayed in the order of occurence within the indicator rule(s) from left to right. If a different number of indicator icons is returned, the remaining icons are moved to the left:  If the indicator icons are all found by a single indicator rule, the order of icons depends on the order of results in the result dataset of the query of the indicator rule and may be different for different objects if no sort order is defined in the query.

The design of the boxes representing objects in the configured report can be changed from the standard design with a white rectangle as background for text within the colored object box to fully colored object boxes. For more information see Defining the General Display of Object Boxes in Treemap, Diagram, Lane and Layered Diagram Reports.

Defining the Objects to Display in the Report

Each layer in the layered diagram report displays objects of an object class that is related to the object class of the layer displayed above the current layer.

The objects displayed in the layers of the report are found on the basis of queries defined for the elements of the report. The queries can either be native SQL queries or Alfabet queries.

If you are not familiar with Alfabet queries, see the chapter Defining Queries.

For special rules that apply to the definition of native SQL queries in the context of configurations for Alfabet, see the section Defining Native SQL Queries.

The information displayed in the object boxes of the report is identical to the column headers that result from a tabular output of the defined query.

Report columns that are defined for technical reasons are not displayed in the object boxes in the report. This includes:

- The first column of the output of a native SQL query. This column must specify the `REFSTR` of the object for technical reasons and is ignored in the visible output.

There are two methods to define a layered diagram report:

- The complete content of the report is defined in one query resulting in a grouped dataset.
- A separate query is added to the report configuration to find the objects in each layer of the report.

  When separate queries are defined, a high number of queries must be executed by the database to display the report. This can lead to performance issues. Therefore, it is recommended to built the report on a grouped dataset defined in a single query.

Defining a Layered Diagram Report With a Single Query

The content of all layers in the layered diagram is defined in one query in a **Query** element that is defined as sub-node of the `RootQueries` node. The query finds the objects that are displayed in the first layer and all subordinate layers in a grouped dataset with each layer corresponding to a grouping level in the query.

The `FIND` class of the Alfabet query or the first column of the output of the native SQL query must find objects of the class displayed in the first layer of the report.

One **Class Entry** child element must be added to the explorer root node for each object class that is included in the report with the mandatory attribute **Class Name** that defines the name of the specified object class.

The **Class Entry** elements may not contain a sub-element **Query**.

Optionally, an icon can be selected in the attributes of the **Class Entry** element. The icon is then displayed in the object boxes of the defined object class in the report.

Defining a Layered Diagram Report With One Query Per Object Class

For each layer, the objects in the layer must be specified by the following:

- An element **Class Entry** that specifies the object class in the layer and the default display of object boxes.
- An element **Query** that is child element of the **Class Entry** element for the objects in the layer above. In the element **Query**, an Alfabet query or a native SQL query specifies which objects are displayed in the next layer below the layer defined by the **Class Entry** element.

For the first and last layer, the following must be taken into account:

- To define which objects are displayed in the top layer of the diagram, an element **Query** is specified directly as child element of the `Root Queries` element.
- The **Class Entry** element for the bottom layer of the diagram does not contain a child element **Query**, because no objects for a next layer must be specified. Nevertheless, the **Class Entry** element must be specified for the bottom layer.

The object class defined for a layer of the report is the same as the base class for the objects displayed in the next layer. The Alfabet query or native SQL query defining the object class displayed in the next layer must contain the parameter `BASE` in a `WHERE` clause to map the objects to the objects of the current layer. `BASE` is identical to the `REFSTR` of the objects in the current layer.

This specification is not mandatory for the top layer objects. The attribute `BASE` can only be used in the Alfabet query or native SQL query defining the top layer objects if the report is assigned to an object class with the attribute **Apply To Class**.

The use of the parameter `BASE` depends on the setting of the attribute **Cascading** in the element **Query**:

- If **Cascading** is set to `True`, a query in a layer cannot only refer to an object of the directly superordinate layer, but also to objects of all other superordinate layers. The parameters to refer to objects of the superordinate layers are then `BASE0` to refer to the directly superordinate layer, `BASE1` to refer to the layer above the directly superordinate layer and so on.
- If **Cascading** is set to `False`, a query in a layer can only refer to an object of the directly superordinate layer using the parameter `BASE`.

To refer to objects of any superordinate layer, you can either set **Cascading** to `True` and user the `BASE`<number> parameters or you can define the attribute **Param Name** of the **Class Entry** elements and refer to the objects defined by a class entry element with the Param Name string as parameter. For example, if a Class Entry element for applications has a Param Name attribute set to APP, you can define, For example, the following `WHERE` clause in an Alfabet query of a sub-ordinate layer to refer to the `REFSTR` of the current application:

```
WHERE Application.Name =:BASE
```

or in native SQL queries:

```
WHERE APPLICATION.NAME = @BASE
```

The table below lists all available attributes in the **Query** element.

Attribute	Description
Name	Defines the name of the **Query** element displayed in the explorer of the **Report Assistant**.
Alfabet Query/ Query as Text/ Native Sql	Defines a query to find the objects that are displayed in the report. The way the query must be defined depends on the location of the **Query** element in the report.
Cascading	Only relevant for layered diagram reports defined with one query per layer: If **Cascading** is set to `True`, a query in a layer cannot only refer to an object of the directly superordinate layer, but also to objects of all other superordinate layers. The parameters to refer to objects of the superordinate layers are then `BASE0` to refer to the directly superordinate layer, `BASE1` to refer to the layer above the directly superordinate layer, and so on. **Note**: It is not possible to refer to the object class that the report is assigned to with the property **Apply To Class** of the report with the parameter `BASE`<number>. Only the query of the first layer in the report can refer to the base object the report is applied to with the parameter `BASE`. **Cascading** must be set to `"false"` for that layer. If **Cascading** is set to `false`, a query in a layer can only refer to an object of the directly superordinate layer using the parameter `BASE`.

The table below lists all available attributes in the **ClassEntry** element.

Attribute	Description
Class Name	Defines the object class specified in this ***ClassEntry*** element. For the object classes that allow stereotype specifications (For example, `Project` and `Domain`), the XML attribute `ClassName` can specify an object of a specific stereotype. To define an XML element ***Query*** for a stereotype, the XML attribute `ClassName` must be *`ClassName:StereotypeName`* For example,: *`Project:StatementOfWork`*
Icon	Defines the icon to be displayed for the object in the object boxes. An icon can be selected from a drop-down list.
Param Name	Defines the string that can be used as parameter in queries of subordinate layers to return the `REFSTR` of the current object of this layer.

Displaying Evaluation Criteria By Size or Color Variation or Addition of Indicator Icons

Evaluation criteria can be added to the report:

- Rules can be defined that assign colors on the basis of property values of the current object. For example, coloring can be different for boxes of objects that are planned, active, or retired. For more information about the definition of color rules, see Defining Color Rules.
- Rules can be defined that trigger the display of an indicator icon in the object boxes of selected objects. For more information, see Defining Indicator Rules.
- Rules can be defined that lead to objects with defined property values to be displayed in smaller or larger object boxes. Size rules are described in the following.

The boxes in the report can be displayed with three different heights. You can specify a size rule for each box height that allows you to display objects with different attribute values with different box sizes. For example, you can display application groups in a report in a different size determined by the number of applications assigned to the application group. If the number is lower than 5, a small box is displayed. If the number is higher than 20, a big box is displayed. Other application groups are displayed with a medium box height.

To define the size of the boxes in the report, you have to specify the following:

- The height in pixel for the small, medium, and large box size. These are defined by means of the attributes of the root node element.
- The size rules that define which objects are displayed with which box size. Size rules are defined in the element **Size Rule**, which is a child element of the root node element.

You can define two different types of size rules:

- `ObjectQuery`: The query defined for the size rule returns the `REFSTR` of the object to that the box height shall be applied. The size that shall be applied to the object boxes is defined separately via attributes of the size rule.

  When defining an Alfabet query, no Show property definition is required. The `REFSTR` of the `FIND` object class is returned.

  When defining a native SQL query, the `SELECT` statement of the query must have the `REFSTR` of the relevant object class defined as the first argument. No further arguments are required in the `SELECT` statement.

- `SizeQuery`: The query defined for the size rule not only returns the `REFSTR` of the objects that the size shall be applied to but also the size specification that shall be applied.

  `SizeQuery` rules require the specification of a native SQL query.

  The `SELECT` statement of the SQL query must return the following in the given order:

  - the `REFSTR` of the current object
  - a string that is used as caption for the size assignment in the legend of the report
  - the size specification as string. Allowed values are `Small`, `Large` and `Medium`.

  For example,:

```
SELECT DOMAIN.REFSTR, "Legend text", "Large"
```

- The definition of a size query in a size rule has the following advantages as compared to an object query: The number of overall size rules required for a report can be reduced. For example, if you want to apply a different box size to applications in a different object state, you can define the size for all object states in one query while a separate size rule for each object state would be required when using object queries.
- Dynamic size assignment can be applied to a report. You can for, example, define a query that sizes object boxes according to the indicator values assigned to the objects. In the report, you can define a filter that allows the user viewing the report to choose an indicator type. The size of object boxes is then reassigned according to the values for the selected indicator.

The specification of box sizes and size rules is optional. If no box sizes are defined, all boxes will be displayed in a default height of 12 for all size rules. If no size rules are specified, all objects will be displayed with the defined medium box size.

When you define the queries for the size rules of the report, make sure that all objects can be assigned explicitly to one size rule. If this is not the case, the following applies:

- Objects that correspond to more than one size rule are displayed in the size of the first rule written in the XML object that applies.
- Objects that do not correspond to any of the defined size rules are displayed in medium size. You cannot distinguish between these objects and objects corresponding to the medium size rule in the treemap report.

The table below lists all attributes for the specification of box sizes in layered diagram reports.

Attribute	Description
In the root node element	
Small Height	Defines the height of the boxes that are displayed for objects corresponding to the size rule with **Size** ="Small".
Medium Height	Defines the height of the boxes that are displayed • for objects corresponding to the size rule with **Size** ="Medium". • for all objects when no size rules are specified.
Large Height	Defines the height of the boxes that are displayed for objects corresponding to the size rule with **Size** ="Large".

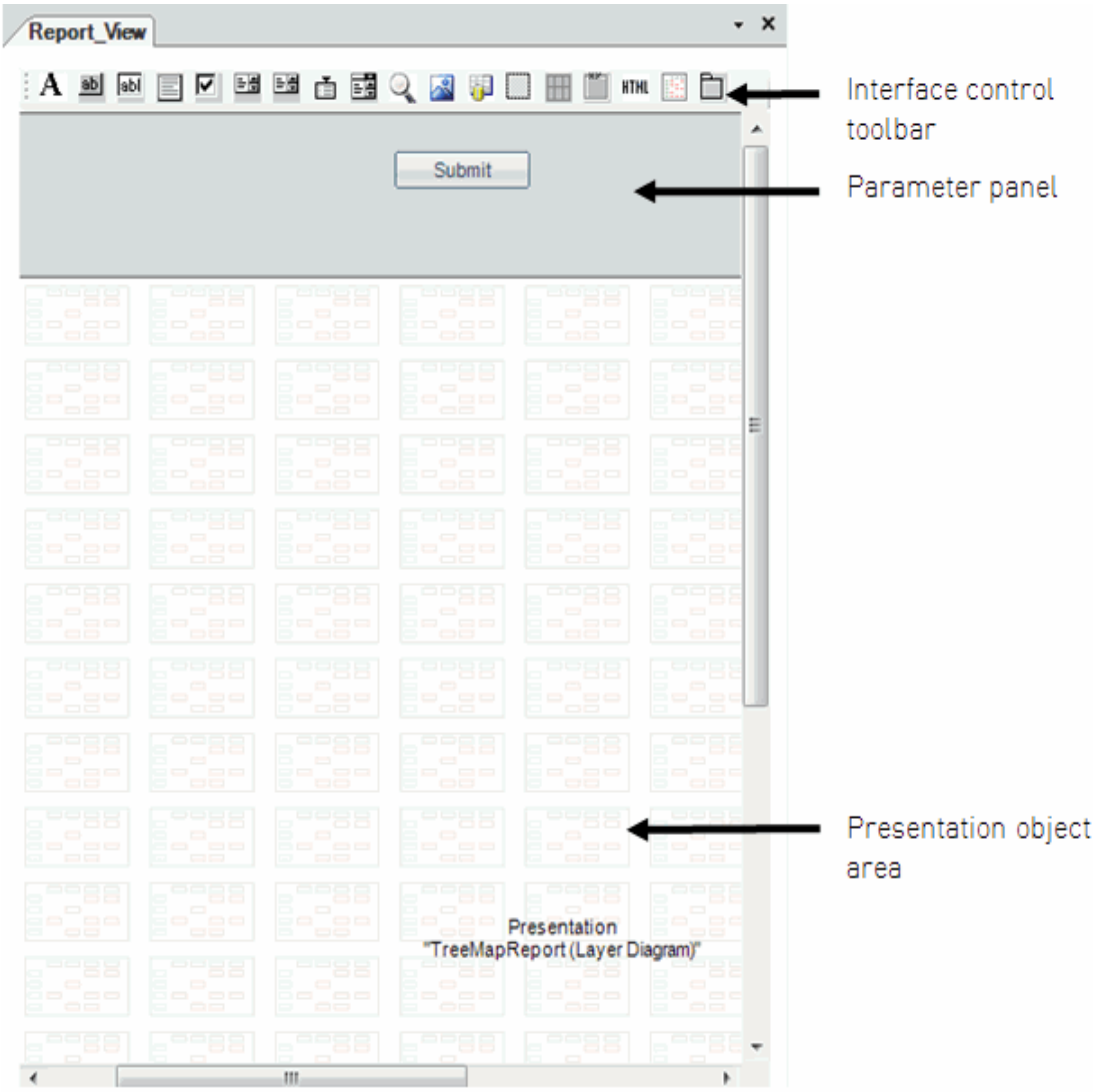
Attribute	Description
In the Size Rule element	
Name	Defines the title displayed for the size in the legend and for size rules of the `TypeObjectQuery` the caption displayed for the size rule in the explorer of the **Report Assistant**. **NOTE**: The attribute **ShowLegend** of the Root node element must be set to `true` to display the legend. If this element is set to `false`, you do not need to specify a name for the size rule.
Type	Select `ObjectQuery` to define the objects that the size rules apply to with a query and the size specification with the attributes of the size rule. Select `SizeQuery` to define both the size specification and the objects to that the size rule applies with a query.
Size	Defines the size of the boxes of objects corresponding to this size rule if the `Type` of the size rule is `ObjectQuery`. The pixel size of the boxes is specified with the **Small Height**, **Medium Height** and **Large Height** attributes of the root node element.
Alfabet Query/ Native Sql/ Query as Text	If the `Type` of the size rule is `SizeQuery`, define a native SQL query in the Native Sql attribute or Alfabet query in the AlfabetQuery or Query as Text attribute. The query must return the `REFSTR` of the objects that the size rule shall apply to. If the `Type` if the size rule is `SizeQuery`, define a native SQL query in the Native Sql attribute that returns: • the `REFSTR` of the current object • a string that is used as caption for the size assignment in the legend of the report • a string that defines which box size applies. Valid values are `Medium`, `Small` and `Large`.

Defining HTML Reports

The **Report Assistant** is not available for HTML reports. To define or edit the HTML report, you must define an XML object in the attribute window of the presentation object of the report.

To edit the presentation object in the report view of the report:

1) In the explorer, double-click the custom report view of the report. The view editor opens.



2) In the editor, click the **Presentation** area. You will see the attributes of the presentation object in the attribute window.

3) In the **SubType** field of the attribute window, select `HTMLView`.

4) In the **Source** field select `Object_Indicators_Html_Report`.

5) In the **Parameters** field, paste the following code:

```
<!DOCTYPE HTML>
<html>
<head>
    <meta content="text/html; charset=utf-8" http-equiv="Content-Type" />
    <style type="text/css">
    table#HTML_REPORT_TABLE
    {
    border: Solid 1px #cecfce;
    border-collapse: collapse;
    border-spacing: 0px;
```

```
    font-family: Verdana;
    color: Black;
    font-size: 7pt;
    }
    td#HTML_REPORT_TD
    {
    border: Solid 1px #cecfce;
    }
    </style>
</head>
<body>
    <div id="IndicatorReport" style="overflow-x:auto;overflow-y:visible">
    <table id='HTML_REPORT_TABLE' cellpadding="4" cellspacing="0"
    style="width: 100%;">
    <col width='50%' />
    <col width='30%' />
    <col width='30%' />
    <!--INDICATOR ROW-->
    <tr height="20px">
    <td id="HTML_REPORT_TD" align="left" style="background-
    color:#d6dfde;color:#161530;">
    <b><!--INDICATOR NAME--></b>
    </td>
    <td id="HTML_REPORT_TD" style="border-right:0px;">
    <!--INDICATOR PICTURE-->
    </td>
    <td id="HTML_REPORT_TD" align="right" style="border-left:0px;">
    <!--INDICATOR VALUE-->
    </td>
    </tr>
    <!--INDICATOR ROW END-->
    </table>
    </div>
</body>
</html>
```

6) In the attribute window, click the **Browse** button in the **XML Def** field. An editor opens.

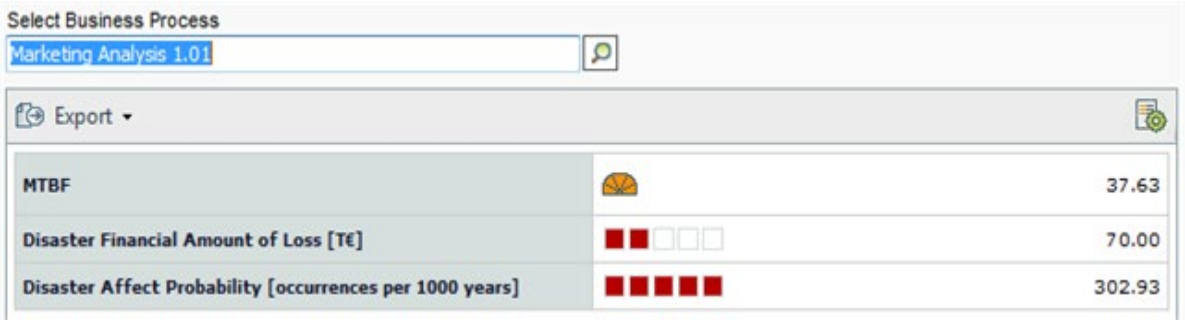
7) Define the content and layout of the report in the editor as described below.

Please note the following when configuring the XML definition of an HTML report:

- It is not possible to specify XML elements or attributes other than the ones described in the section below.
- XML is case-sensitive.
- Some definitions may be left out if they are not required in the configured report. For example, it is possible to specify configured reports that do not display an indicator in the object boxes.

The content and layout of an HTML report is defined in the XML element ***ReportDef***. The general design of the grid is defined via the attributes of the ***ReportDef*** element. The ***ReportDef*** element can contain one or multiple ***Indicator*** elements. For each ***Indicator*** element, a new row is added to the HTML table that is generated for the report. Each row of the report displays a caption for the indicator, a symbol that allows a quick overview over the criticality and the numerical value of the indicator. The ***Indicator*** element defines which indicator is displayed in a row and which caption and symbol are used for display.

The following example displays an example for an HTML report that displays indicators for a selected business process.



The filter for the selection of the business process displayed in the report is generated automatically because the report is applied to the class Business Process with the attribute **Apply To Class** in the attribute window of the report.

The indicators listed in the report and the caption and image used for each indicator is configured in the XML object of the presentation object for the report. The root element `ReportDef` of the XML object contains one child ***Indicator*** element for each indicator displayed in the report.

```
<ReportDef
   GaugeBackColor="#b50000"
   GaugeBorderColor="#d6dfde"
   GaugeWidth="10"
   GaugeHeight="10"
   GaugeSpace="2"
   GaugeCount="5">
      <Indicator
         Type="Indicator"
         Name="MTBF/Max. Mean Time Between Failures"
         Caption="MTBF"
         ReportType="Icon" />
      <Indicator
```

```
            Type="Indicator"
            Name="Risk Management (Business Process)/Disaster
            Financial Amount of Loss [T€]"
            Caption="Disaster Financial Amount of Loss [T€]"
            ReportType="Gauge"
            MaxValue="200"/>
        <Indicator
            Type="Indicator"
            Name="Risk Management (Business Process)/Derived Disaster
            Affect Probability [occurrences per 1000 years]"
            Caption="Disaster Affect Probability [occurrences per 1000
            years]"
            ReportType="Gauge"
            MaxValue="200"/>
</ReportDef>
```

Please note the following when configuring the images representing the indicators in the report:

- An icon can only be displayed in the report if the indicator type has been configured to display icons rather than numerical values. Indicator types are specified in the **Evaluations and Portfolios** functionality of Alfabet. For information about the configuration of indicator types and the icon gallery used to visualize their values, see the section *Configuring Indicator Types for an Evaluation Type* in the reference manual *Configuring Evaluation and Reference Data in Alfabet*.
- All gauge graphics in the report have the same coloring and graduation. The look of the gauge element is directly defined in the ***ReportDef*** root element of the XML object. The maximum value of the gauge is defined separately for each indicator in the respective Indicator element.
- The report can display up to 5 indicators. If you want a higher number of indicators to be displayed directly in an object view, you must display indicators in any of the other types of configured reports, assign the report to the object view, and define it to be expanded in the object profile.

The table below lists all XML elements (bold) and their attributes for the specification of indicators in HTML reports and effect thereof.

Element/ Attribute	Allowed Values or Data Types	Default Values / Mandatory	Description
ReportDef			
`GaugeBack-Color`	HTML valid color codes (e.g.	`grey`	Defines the color of the boxes representing shares of the maximum value of the gauge reached by the indicator value displayed in the gauge. The boxes representing shares of the maximum value of the gauge not reached by the indicator are white.

Element/ Attribute	Allowed Values or Data Types	Default Values / Mandatory	Description
	hexadecimal)		
`GaugeBorderColor`	HTML valid color codes (e.g. hexadecimal)	`black`	The border colors of the boxes representing shares of the maximum value of the gauge.
`GaugeWidth`	width in mm	12	Specifies the width of each gauge field in mm (1 mm = 4 pixel)
`GaugeHeight`	height in mm	12	Specifies the height of each gauge field in mm (1 mm = 4 pixel)
`GaugeSpace`	distance in mm	2	Specifies the distance between two gauge fields in mm (1 mm = 4 pixel)
`GaugeCount`	number of fields	5	Specifies the number of fields of a gauge. Each field represents a share of the maximum value of the gauge that is specified with the attribute **MaxValue** of the **Indicator** element. For example, if GaugeCount is 6, each box represents 1/6 of the maximum value. For a maximum value of 600, the first field represents the numerical values between 1 and 100, the second field represents the values between 101 and 200 and so on. A field is colored if the indicator value is within or higher as the range of values represented by the box.
Indicator			
`Type`	`"Indicator"`	`Indicator`	The indicator type must be set to `"Indicator"`.
`Name`	Name of indicator	**MANDATORY**	The name of the indicator. **Note**: The name of the indicator is the value of the property Name of the class `Indicator`. It is identical to the name of the evaluation type and the name of the indicator type of the indicator separated with a slash:

Element/ Attribute	Allowed Values or Data Types	Default Values / Mandatory	Description
			EvaluationTypeName/IndicatorTypeName
Caption	String	**MANDATORY**	The caption displayed for the indicator in the table.
ReportType	"Icon" "Gauge"	Icon for indicators configured to use an icon gallery. No graphic display for indicators without icon gallery specification.	Defines the graphic display of the indicator value in the report: Select Icon to use the icon gallery of the indicator or select Gauge to display the fulfilled share of a configured maximum value for the indicator. **Note**: If you select Icon, the indicator must be configured to use an icon gallery to display its value in evaluations. This is done in the **Evaluations and Portfolios** functionality in Alfabet. For more information, see the section *Configuring Indicator Types for an Evaluation Type* in the reference manual *Configuring Evaluation and Reference Data in Alfabet*. **Note**: If you select Gauge, you must also specify the ***MaxValue*** attribute of the Indicator element. Optionally, you can specify the coloring and size of the gauge with the attributes of the ***ReportDef*** element.
MaxValue	Integer	MANDATORY for reports of the ReportTypeGauge	For reports of the ReportTypeGauge only: The maximum numeric value displayed in the gauge. The gauge displays fields that represent equal shares of the maximum numeric value. Shares that are covered by the indicator value are colored in the gauge.

Defining Widget Reports

For widget reports, the definition of design and content is partly decoupled. Widget reports are based on a layout that is defined in a separate configuration object widget . The widget configuration object contains placeholders for images and text. The widget configuration object must be defined prior to defining the widget report. It is then referenced by the widget reports and the placeholders are filled with data via the widget report.

A widget configuration object can be referenced by multiple widget reports, each defining a different content for the same layout.

Do the following to define a widget report:

- Defining a Widget

Defining a Widget

Widgets are configured in the **Presentation** tab of Alfabet Expand:

1) In the **Presentation** tab of Alfabet Expand, right-click the **Widgets** node and select **New Widget** from the context menu.
2) In the attribute window of the new widget that opens on the right, define the following attributes according to demand:
   - **Name**: Change the default name to a unique, meaningful name. The name is used to identify the widget in technical processes and shall not contain whitespaces or special characters. It is also displayed in the widget selector of the widget report assistant.
   - **Description**: Enter a description that explains the purpose of the widget for other solution designers. The description is displayed in the widget selector of the widget report assistant next to the widget's name to ease widget selection.

Widgets are technically views and have multiple standards view attributes that are also available for configured reports and standard Alfabet views. Most of the available attributes are of no relevance for widgets and can be ignored. The respective settings are done on the level of the configured report.

3) Right-click the new widget in the explorer and select **Edit Widget** from the context menu. The widget opens in the middle pane of Alfabet Expand. Design elements are displayed in the toolbar of the widget.

4) Click into the widget area. The attribute window opens.

5) In the attribute window, define the overall size of the widget with the attributes **Height** and **Width**. The height and width are defined as an integer defining the number of pixels.

Please note that there are three different places where a size can be defined for a widget report:

- The widget can be resized.
- The configured widget report referencing the widget has a defined height and width.
- If the configured report is included in an object cockpit, guide page or guide view, the area reserved for displaying the report is configurable in size.

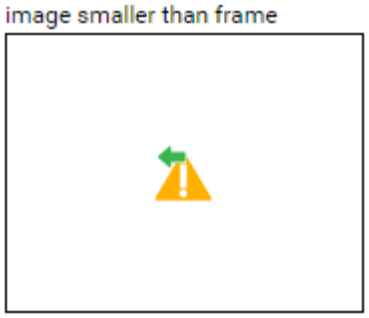
All height and width definitions should be identically to ensure that the widget is fully displayed.

- 6) Design the widget as described in the following sections: General Instruction for Adding and Positioning Elements on the Widget
  - Changing the Size of a Single Widget Element
  - Changing the Location of a Single Widget Element
  - Aligning the Size and Position of Multiple Widget Elements
  - romefnsfmDocking A Widget Element to the Borders of the Widget Area
- Adding Background Color and Borders to the Widget
  - Defining a Default Background Color on the Widget Definition
  - Defining a Panel Element for the Widget
- Using a Flow Panel or Table to Structure the Design Elements in the Widget
- Adding a Widget Picture Field to the Widget
- Adding a Widget Text Field to the Widget
- Changing a Widget Definition Already Used In Configured Widget Reports

Note the following about designing the widget:

- If you want to add a **Panel**, **Flow Panel** or **Table Layout Panel** as background element to the Widget, you must do this before placing images or text elements. The elements added to the widget cannot be moved to back or front. Elements added first are hidden under by overlapping elements added later.
- The widget designer does not display the widget elements exactly as displayed on the user interface.

  The font size is larger and the positioning of text and images within the elements is not always matching the position on the user interface. For example, if you add an image smaller than the **Widget Picture** element, the image is displayed in the upper left of the field, while in the report, the image is displayed centered.



- The design that you add to the widget is a default that may be overwritten with design specifications in the configured report using the widget.
- Not all attributes that are visible for elements added to the widget or for the widget itself have a visible effect on the widget design. For example, a background color defined for the widget itself will be ignored. Background colors are only taken over if defined on elements added to the widget. The documentation describes the valid settings. Attributes not described below may not have any effect on the widget layout.

7) In the toolbar, click **Save**  to save your changes.

The first of the following sections is giving information about how to generate and position elements. The subsequent section inform about the styling options available via the elements:

- General Instruction for Adding and Positioning Elements on the Widget
  - Changing the Size of a Single Widget Element
  - Changing the Location of a Single Widget Element
  - Aligning the Size and Position of Multiple Widget Elements
  - romefnsfmDocking A Widget Element to the Borders of the Widget Area
- Adding Background Color and Borders to the Widget
  - Defining a Default Background Color on the Widget Definition
  - Defining a Panel Element for the Widget
- Using a Flow Panel or Table to Structure the Design Elements in the Widget

- Adding a Widget Picture Field to the Widget
- Adding a Widget Text Field to the Widget
- Changing a Widget Definition Already Used In Configured Widget Reports

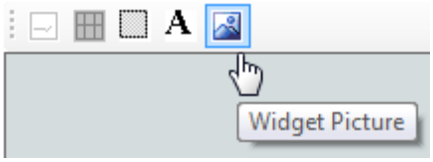
General Instruction for Adding and Positioning Elements on the Widget

The toolbar in the design area of the widget displays all elements that can be added to the widget:

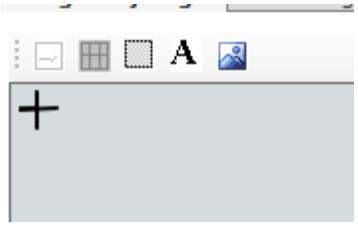
- **Panel** : The **Panel** element adds a background element to the widget to define background coloring and borders. For information about the layout configuration options available via **Panel** elements, see Adding Background Color and Borders to the Widget.
- **Flow Panel** : The **Flow Panel** elements can be used to define a layout that adapts element sizes to the size of the element content. For information about the layout configuration options available via **Flow Panel** elements, see Using a Flow Panel or Table to Structure the Design Elements in the Widget.
- **Table Layout Panel** : The **Table Layout Panel** elements can be used to structure elements on the widget in a tabular layout. For information about the layout configuration options available via **Table Layout Panel** elements, see Using a Flow Panel or Table to Structure the Design Elements in the Widget.
- **Widget Picture** : The **Widget Picture** element adds a placeholder for images and optionally a default image to the widget. The actual image displayed to the user on the Alfabet user interface is added via the configured widget report. For information about the layout configuration options available via **Widget Picture** elements, see Adding a Widget Picture Field to the Widget.
- **Widget Text** : The **Widget Text** element adds a placeholder for text to the widget. The actual text displayed to the user on the Alfabet user interface is added via the configured widget report. For information about the layout configuration options available via **Widget Text** elements, see Adding a Widget Text Field to the Widget.

To add any of the elements to the widget:

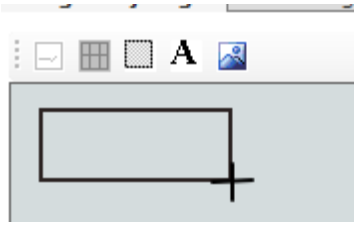
1) Click the element's icon in the toolbar of the design view:



2) In the widget area, click and hold the position where you want to place one corner of the element.



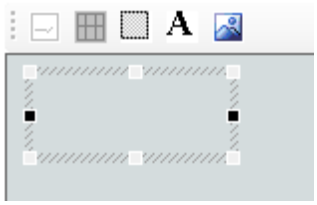
3) Hold the mouse key while you move the mouse pointer to the opposite corner position.



4) After having placed the element box, the attributes of the element are displayed in the attribute window and the design can be changed for the element by setting the attributes.

5) In the toolbar, click the **Save** button to save your changes.

After releasing the mouse click when placing the widget element, the field is displayed highlighted in the widget area:



Clicking anywhere into the widget area will move the focus away from the element. For **Panel**, **Flow Panel** and **Table Layout Panels** dotted lines will be displayed on non focused elements. For **Widget Text** and **Widget Picture** elements, the field itself is not visible, but a caption is displayed by default that allows you to locate the field. Please note that the caption of the **Widget Text** element is displayed in the text field and the caption of the **Widget Picture** element is displayed above the image field. You must click on the caption of a **Widget Text** element to activate the text field and on the empty area below the caption of a **Widget Picture** element to activate the image field.

The position and size of placed widget elements can be changed anytime with one of the following mechanisms:

- Changing the Size of a Single Widget Element
- Changing the Location of a Single Widget Element
- Aligning the Size and Position of Multiple Widget Elements
- romefnsfmDocking A Widget Element to the Borders of the Widget Area

Changing the Size of a Single Widget Element

There are two methods to change the size of a widget element in the widget area:

- Click the element and pull the handles to resize it.

Please note that the frames are not displayed while you pull the handles.

- Click the element in the panel to open the attribute window and change the following attributes in the section **Coordinates**:
  - **Height**: Define the height of the element as an integer.
  - **Width**: Define the width of the element as an integer.

  Please note that borders are drawn outside the element. If you define a width of 10 for an element with a left and right border with a width of 2, the overall width of the element is 14.

After changing the size, click the **Save** button in the toolbar to save your changes.

You can combine both methods for easy and correct sizing of elements in the widget area. After having resized the elements using the handles to define the basic layout of the widget, correct the size of the elements in relation to each other using the attributes in the section **Coordinates**. For example, you can define an equal **Width** for elements that are placed below each other or an equal **Height** for elements displayed in the same row.

Changing the Location of a Single Widget Element

There are two methods to change the location of a widget element in the widget area:

- Drag and drop the widget element to the correct location and click the **Save** button in the toolbar to save your changes.
- Click the element in the widget area to open the attribute window and change the following attributes in the section **Coordinates**:
  - **Left**: Define the distance from the left of the widget area.
  - **Top**: Define the distance from the top of the widget area.

  If the element is placed on one of the panel elements, the values for **Left** and **Top** are marking the distance to the border of the panel element instead to the border of the widget area.

After changing the field location, click the **Save** button in the toolbar to save your changes.

You can combine both methods for easy and correct placement of widget element in the widget area. After having used drag and drop to define the basic layout of the widget, correct the location of the widget element in relation to each other using the attributes in the section **Coordinates**. Widget elements that are

placed below each other should have the same value for the attribute **Left**. Widget element that are placed next to each other in the same row should have the same value for the attribute **Top**.

Aligning the Size and Position of Multiple Widget Elements

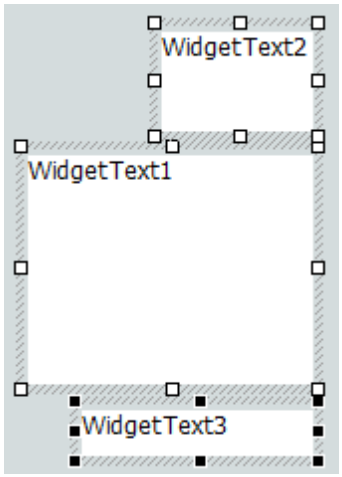
When you click a widget element on a widget area, you can see a menu **Format** in the menu bar of Alfabet Expand. Via the options in the **Format** menu the design of multiple widget in the widget area can be aligned to each other with regard to the position of the widget elements in the widget area and the widget size:

Aligning the Position of Multiple Widget Element

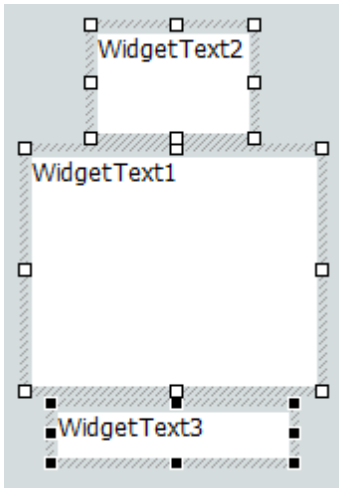
You can align multiple widget elements with one another to have an equal position for one of the borders of the widget area. For example, if you select multiple widget elements that are located next to each other in the same row, you can align the position of the top border to ensure that all widget elements are on the same horizontal axis.

1) In the widget area, place one of the widget element in the correct position.
2) Select all widget element that you want to align with each other holding CTR + SHIFT while clicking on the widget element. The last widget element that you select is the widget element that determines the position.
3) In the toolbar, select:
   - **Format** > **Align Left** to align the position of the left border of all selected widget elements with the position of the last selected widget element.

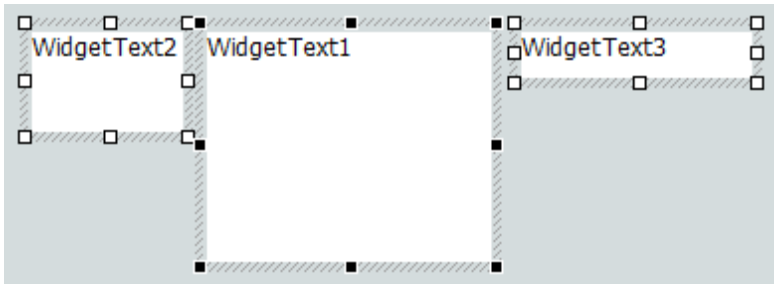
   - **Format** > **Align Right** to align the position of the right border of all selected widget elements with the position of the last selected widget element.



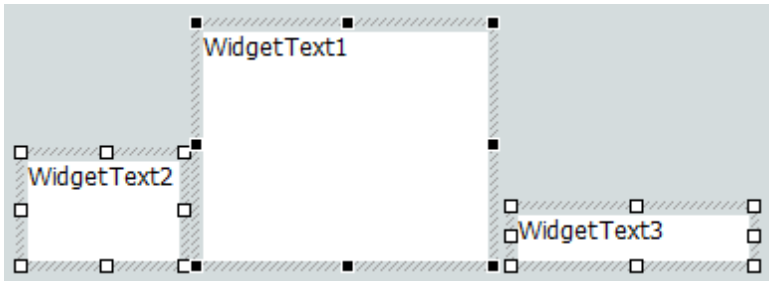
- **Format** > **Align Center** to align the horizontal middle position of all selected widget elements with the horizontal middle position of the last selected widget element.



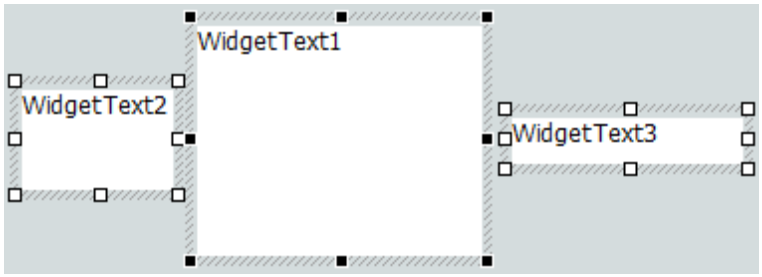
- **Format** > **Align Top** to align the position of the top border of all selected widget element with the position of the last selected widget element.



- **Format** > **Align Bottom** to align the position of the bottom border of all selected widget elements with the position of the last selected widget element.



- **Format** > **Align Middle** to align the vertical middle position of all selected widget elements with the vertical middle position of the last selected widget element.



4) In the toolbar, click the **Save** button to save your changes.

Aligning the Size of Multiple Widget Elements

The width or height or one or multiple selected widget elements can be aligned to the width or height of a selected widget element.

1) In the widget area, select all widget elements that you want to resize holding CTR + SHIFT while clicking on the widget elements. The last widget element that you select is the widget element that determines the resulting width or height of all widget elements.
2) In the toolbar, select:
   - **Format** > **Make Widths Equal** to adapt the widths of all selected widget elements to the width of the last selected widget element.
   - **Format** > **Make Heights Equal** to adapt the heights of all selected fields to the height of the last selected widget element.
3) In the toolbar, click the **Save** button to save your changes.

Aligning Spacing between Widget Elements

If multiple widget elements are placed in a horizontal row or a vertical column you can define an equal spacing between all fields in a single row or in a single column. The position of the first and the last widget element in the row or column is maintained and the fields in between are distributed equally in between.

1) In the widget area, select all filter fields that you want to distribute equally along a vertical or horizontal axis. Please note that only fields that are located next to each other on an axis shall be selected.
2) In the toolbar, select:

- **Format** > **Make Vertical Spacing Equal** to distribute the widget elements equally along the vertical axis.
- **Format** > **Make Horizontal Spacing Equal** to distribute the widget elements equally along the horizontal axis.

3) In the toolbar, click the **Save** button to save your changes.

Aligning the Widget Elements Along a Grid

The widget elements can be aligned along a grid that is invisibly drawn on the widget area. This method allows to align the position to the widget elements horizontally and vertically.

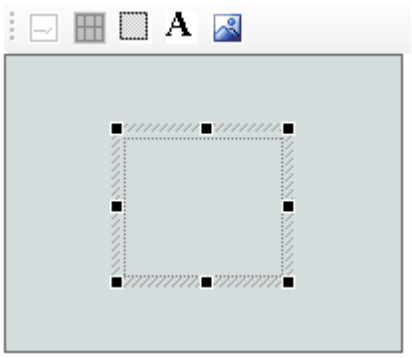
The top left corners of the widget elements are aligned with the respective crossing point of the grid lines left and above the respective widget element.

1) Select the widget elements that you want to align with along the grid by holding CTR + SHIFT while clicking the widget elements.
2) In the toolbar, select **Format** > **Snap to Grid**. The selected widget elements are positioned with the upper left corner matching the nearest crossing point of grid lines.
3) If the results are not as expected, you can alter the spacing between grid lines by selecting **Format** > **Grid Size...** in the toolbar and setting the spacing between grid lines in the window that opens. The default value is 2. It is recommended to select a number between 2 and 10 for a start and check the resulting effect on the widget first before moving on to higher numbers. If the spacing between grid lines is too high, the widget elements might be placed outside the widget area.
4) In the toolbar, click the **Save** button to save your changes.

romefnsfmDocking A Widget Element to the Borders of the Widget Area

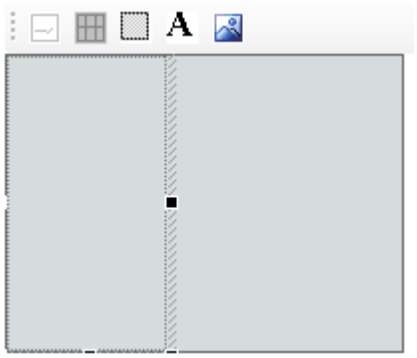
Widget elements can be configured to be docked to one or all borders of the widget area. If a widget element is docked to a border, the size changes to stretch along the whole border and the position of the widget element is fixed for directly starting with the attached border.

For example, a **Panel** element is placed in the middle of the widget area:

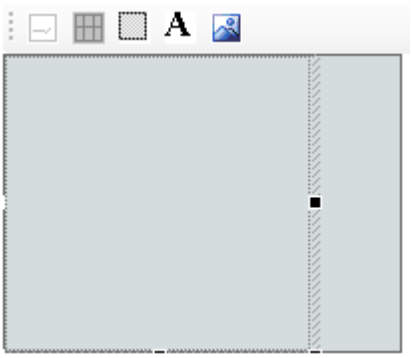


Configuring the widget element to be docked to the left border will change the size and position. The height is changed. The widget element is now stretching along the whole left border. The

position is changed. The widget element is now starting directly at the left border of the widget. The width of the widget element is kept.



After having docked the panel to the left border, the panel cannot be moved to a position further to the right any longer and the height cannot be changed. Only the width of the panel element is resizable:



This method for placement is especially useful for placement of **Panel**, **Tabular Layout Panel** and **Flow Panel** elements.

To dock a widget element to a single or all borders of the widget area:

1) Click the widget element in the widget area. The attribute window of the widget element opens.
2) In the attribute **Dock** a docking option from the dropdown list:
   - **Right**, **Top**, **Bottom**, **Left** will dock the widget element to the right, top, bottom or left border of the widget respectively.
   - **Fill** will dock the widget element to all borders. The element will cover the whole widget area and all resizing and re-positioning options will be deactivated.
   - **None** shall be selected if you do not want the element to be docked at all.
3) In the toolbar, click the **Save** button to save your changes.

If you set the **Dock** attribute, the attributes in the section **Coordinates** are altered according to your settings. The width and height of the element are not exactly matching the size defined for the widget area but are reduced by two. For example, if the widget area has a height of 400, a widget element with **Dock** set to **Left**, **Right** or **Fill** will have a height of 398.

This allows for a frame to be defined for the elements. Lines defined for the widget element borders are drawn outside of the element. The actual size of the widget element is then the widget size plus the width defined for the borders. The reduction of size during docking allows a border with a width 1 to be displayed around the widget element.

If you would like to define border lines with a higher width, you must reset **Dock** to **None** and reduce the defined widget element height and width accordingly. For example, if the widget area width is 400 and your element has a left and right border line with a width of 3, the size must be defined as: widget area width minus sum of line width, which is 400 - (3 + 3) = 394 in the example.

Adding Background Color and Borders to the Widget

By default, a widget has a transparent background and no borders. The following options are available to define a border and background color for the widget:

- A background color can be defined for the widget area. This is then used as default if no background color is defined in the configured widget report. Borders cannot be defined in the widget, but border lines can be defined in the configured widget report for the report area.
- A background color and border can be defined for the complete widget or part of the widget by adding an element **Panel** to the widget. Background color and borders defined with panel elements are fixed for all configured widget reports based on the widget. They cannot be changed via the report definition. Multiple panel elements can be defined for the widget to structure the background, For example, by defining a heading area with one color and a content area with a different color.

Defining a Default Background Color on the Widget Definition

To define a background color for the complete widget:

1) Click into the background of the widget area. The attribute window of the widget area opens.
2) Click into the field for the attribute **Background Color**, click the arrow that is displayed on the right of the field and select a color from the color picker.

   Please note that the background color is not visible in the design area. Nevertheless it will be visible in any configured widget report based on this widget and not including any background color definition in the cponfigured report.

3) In the toolbar, click the **Save** button to save your changes.

Defining a Panel Element for the Widget

Please note the following about the relation between the **Panel** element and other elements placed on the widget:

- **Panel** elements must be defined first. The visibility of elements depends on the order of definition. If you have defined For example, **Widget Picture** and **Widget Text** elements in a widget and then add a Panel element covering the whole widget area to define a background color for the widget, the

already placed **Widget Picture** and **Widget Text** elements are hidden behind the **Panel** element. There is no functionality to move elements to front or back.

- Elements placed on a **Panel** become part of the **Panel**. If you delete the **Panel**, all elements placed on the **Panel** are also deleted.

To add a **Panel** element to the widget area:

1) In the toolbar, click the **Panel** icon and add the **Panel** element to the widget area with the size and location matching your demands.

   For detailed information about placing elements on the widget area and sizing them, see the section General Instruction for Adding and Positioning Elements on the Widget.

2) Click the **Panel** element that you have added to the widget area to open the attribute window.
3) In the attribute window, expand the **Style** attribute and set the following subordinate attributes according to demand:

   - **Background Color**: Select a color from the color picker to add a background color to the panel. By default, **Panel** elements are transparent.
   - **Border Bottom**, **Border Left**, **Border Right** and **Border Top**: To define a line to be displayed on the top, left, right or bottom of the panel, expand the respective attribute and set the following attributes:
     - **Border**: Define the line width for the border as a positive integer. If the line width is zero, the line will not be displayed.
     - **Color**: Select the color for the line from the color picker.

     Border lines are drawn outside of the **Panel** element. The size required for display of the **Panel** element is the size defined for the borders plus the width of the border lines. This is of special importance if the panel shall fill the whole widget area. For example, if the widget area width is 400 and your element has a left and right border line with a width of 3, the size of the panel must be reduced to: widget area width minus sum of line widths, which is 400 - (3 + 3) = 394 in the example.

     The top and left position defined for a panel element include border lines. Lines are drawn right of the defined left position and under the defined top position. If the **Panel** shall fill the complete widget area, the **Top** and **Left** attributes must be defined as zero.

4) In the toolbar, click the **Save** button to save your changes.

Using a Flow Panel or Table to Structure the Design Elements in the Widget

Flow Panel and **Table Layout Panel** elements that are the basic for designing object cockpits are also available to structure the content of a widget. This design is only relevant for specific use cases, For example, if you are not sure whether the dynamically generated widget content will match the sizing of the widget and would like to make sure that scrollbars will be available if the content exceeds the widget size. But usually widgets are small windows containing only a limited number of text and image elements and it is recommended to define them without using a table or a flow panel.

The visibility of elements depends on the order of definition. If you have defined For example, **Widget Picture** and **Widget Text** elements in a widget and then add a Table Layout Panel element covering the whole widget area, the already placed **Widget Picture** and **Widget Text** elements are hidden behind the **Panel** element. There is no functionality to move elements to front or back.

Using a **Table Layout Panel** will have the following effect on design:

- A table grid layout will be created. **Widget Text** and **Widget Picture** elements can be added to the cells in the table grid and will always span the whole table cell. Resizing of **Widget Text** and **Widget Picture** elements themselves is no longer available, but the **Widget Text** or **Widget Picture** elements can be configured to span multiple rows or columns with the attributes **Column Span** and **Row Span**, that are only visible on the **Widget Text** or **Widget Picture** elements if added to a **Table Layout Panel**.
- The table grid is created with equal column width. If an image is wider than the column width, only the left part of the image fitting the column width is displayed. If a text does not fit into one row in the column width, line breaks are used.
- The row height depends on the row content. If the content of all rows requires a size that is larger than the widget area size, a scroll bar is displayed. The row height depends on the biggest image or text element in the row. Images are always fully displayed in height.
- Captions defined for **Widget Picture** elements are ignored and not displayed in the configured widget report.
- Text defined in **Widget Text** elements is always displayed in all upper case letters.
- **Border Radius** definitions for **Widget Picture** elements are ignored.
- Border lines defined for **Widget Text** elements are displayed doubled:

  - One border is displayed around the field and one is displayed around the text. If the text is For example, centered and small, the distance between the two borders will be large.
  - The availability of lines depends on the definition of the borders in the **Widget Text** element. Border color and border width are used for both border lines.
  - **Border Radius** definitions are only used for the inner border.
  - If two text fields are located next to each other, the border between the elements is displayed in the design of the thicker border line.

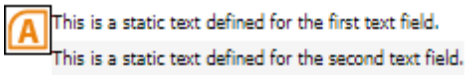
Using a **Flow Panel** will have the following effect on design:

- The size and location specifications of the elements in your widget will be ignored.
- The size of the elements matches the size of content of the element. Text is displayed without line breaks.

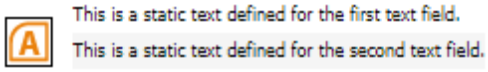
- The elements are all located one after the other without a spacing. If you would like to add a spacing between elements, you can set the attribute **Margin** of the **Widget Text** and **Widget Image** elements to define the spacing between the element and the next elements beside it or the border of the Flow Panel element. The attribute is expandable and allows to define the margin for each side of the element separately. If two elements are located next to each other and both have a margin defined, the distance between the elements is the sum of the **Margin** settings.

For example, one **Widget Picture** element and two **Widget Text** elements are added with a spacing and in a row on the **Flow Panel** added to the widget area:

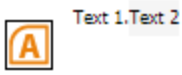
In the final configured report, the design will look like this without margin definition:



Defining a margin for the image will change the design to:



If the configured report adds shorter texts to the Widget Text elements, the two text elements are displayed side by side in the same row instead of below each other:



To add a **Flow Panel** or **Table Layout Panel** element to the widget area:

1) In the toolbar, click the **Flow Panel** icon or the **Table Layout Panel** icon and add the element to the widget area with the size and location matching your demands.

   For detailed information about placing elements on the widget area and sizing them, see the section General Instruction for Adding and Positioning Elements on the Widget.

2) If you have added a **Table Layout Panel** element, define the attribute **Table Layout** attribute of the element as <number of rows>x<number of columns>. For example, a definition of 2x4 will create a table grid with two rows and four columns.

3) In the toolbar, click the **Save** button to save your changes.

Adding a Widget Picture Field to the Widget

A **Widget Picture** element is a placeholder for any image that can be defined in the configured widget report referencing the widget. Only images uploaded to the icon gallery via Alfabet Expand can be displayed in the **Widget Picture** element.

For information about how to upload images to the icon gallery, see Adding and Maintaining Icons for the Alfabet Interface.

Optionally, you can add an image to the **Widget Picture** element that will then be displayed as default if no image is provided via the configured report. The **Widget Picture** element can be designed via its attributes to have a caption, borders or a background color.

In the configured report, only the image to be displayed in the **Widget Picture** element is specified. Borders, background color and caption as well as the size of the **Widget Picture** element cannot be changed within the configured widget report.

Please note the following about the display of images within the **Widget Picture** element:

- Images are not resized in the final configured widget report rendered on the Alfabet user interface.
- Images that are smaller than the **Widget Picture** element will be displayed centered in the **Widget Picture** element.
- If the image is bigger than the **Widget Picture** element, only the upper left corner of the image is displayed.
- If you add a default image to the **Widget Picture** element, the default image is displayed if the configured report does not provide any image definition for the **Widget Picture** element. If the configured report provide image definitions via a query and the query does not return a valid image definition, the icon for missing images is displayed in the configured widget report rendered on the Alfabet user interface.
- If you add a default image to the **Widget Picture** element, the default image is not displayed in the position and size it is displayed in the configured widget report rendered on the Alfabet user interface. In the widget area in Alfabet Expand, images that are smaller than the **Widget Picture** element are displayed in the upper left corner of the **Widget Picture** element and images that are bigger than the **Widget Picture** element are resized to match the element size.

If you would like to design or structure the background of the widget via a **Panel**, **Flow Panel** or **Table Layout Panel**, you must add these elements prior to adding **Widget Picture** elements. The elements cannot be moved to back or front and a panel added to a widget hides all already defined **Widget Picture** elements that it covers.

To define a **Widget Picture** element:

1) In the toolbar, click the **Widget Picture**  icon and add the **Widget Picture** element to the widget area with the size and location matching your demands.

   For detailed information about placing elements on the widget area and sizing them, see the section General Instruction for Adding and Positioning Elements on the Widget.

2) In the **Name** attribute, change the default name to a short, meaningful name. The name is displayed in the explorer of the report assistant for configured widget reports referencing the

widget. The name must be unique within the widget specification and shall not contain special characters.

If you are changing the name of a **Widget Picture** element after having used the widget in a configured report, the **Widget Picture** element is regarded as a new element and the element with the prior name is regarded as removed. The existing definition in the configured report is removed and substituted with an unspecified element.

3) In the **Caption** attribute, either delete the default caption to display the **Widget Picture** element without a caption, or define a caption to be displayed in the widget on top of the **Widget Picture** element.

Please note the following about the caption of the **Widget Picture** element:

- The caption cannot be overwritten or removed by a specification of the configured widget report.
- The font style and size and the location of the caption, that is displayed on the top left of the Widget Picture element cannot be altered neither in the **Widget Picture** element definition nor in the configured widget report. The caption is displayed in the same design as filter and editor fields.

4) If you want to add a default image that shall be displayed if no image definition is provided in the configured report, expand the **Picture Source Definition** attribute and define the following attributes in the order given below:

- **Icon Type**: Select the icon gallery that the image is available in.
- **Icon Name**: Select the image from the dropdown list displaying all images in the icon gallery selected with the attribute **Icon Type**.

5) In the attribute window, expand the **Style** attribute and set the following subordinate attributes according to demand. The style definitions are fixed for the **Widget Picture** element and cannot be altered via the configured widget report:

- **Background Color**: Select a color from the color picker to add a background color to the **Widget Picture** element. By default, **Widget Picture** elements are transparent.
- **Border Bottom**, **Border Left**, **Border Right** and **Border Top**: To define a line to be displayed on the top, left, right or bottom of the **Widget Picture** box, expand the respective attribute and set the following attributes:
  - **Border**: Define the line width for the border as a positive integer. If the line width is zero, the line will not be displayed.
  - **Color**: Select the color for the line from the color picker.

  Border lines are drawn outside of the **Widget Picture** element. The size required for display of the **Widget Picture** element is the size defined for the borders plus the width of the border lines.

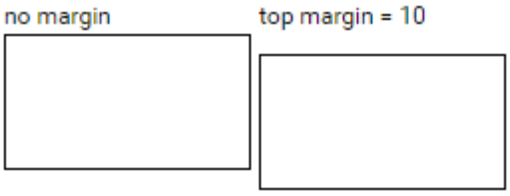
  The top and left position defined for a **Widget Picture** element is the position outside the lines.

- **Border Radius**: Define the positive integer to cause border edges to be rounded. The higher the integer, the more intense is the rounding of the border. Zero means that a straight corner

is displayed as edge. The rounding of borders is also visible if no border lines, but only a background is defined.

The **Border Radius** setting is not visible in the design area for the widget, but only in the configured report.

- **Margin**: Setting a margin will define a spacing between the **Widget Picture** element and all other elements. The **Margin** will also be applied to the spacing between the defined caption and the box itself:



To define a margin, expand the **Margin** attribute and define the margin as a positive integer either separately for each side of the box in the attributes **Bottom**, **Left**, **Right**, **Top**, or for all sides equally in the attribute **All**.

Setting a **Margin** is only useful if the **Widget Picture** element is located in a **Flow Panel**. For **Widget Picture** elements on a **Panel** or directly added to the widget area, the **Margin** will alter the position of the **Widget Picture** element in a way that is hard to control. If you do not need more spacing to be added between caption and box, it is recommended to use the positioning options described in the section General Instruction for Adding and Positioning Elements on the Widget to define spacing between elements.

The **Margin** setting is not visible in the design area for the widget, but only in the configured report.

6) In the toolbar, click the **Save** button to save your changes

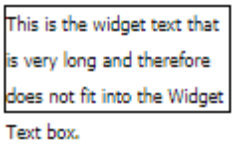
Adding a Widget Text Field to the Widget

A **Widget Text** element is a placeholder for text defined in the configured widget report referencing the widget. In the widget itself no text can be defined as default. Widget Text elements are empty elements that are exclusively filled via the configured widget report.

The layout of the **Widget Text** element, like For example, background color, borders and font style and size are both configurable in the widget and in the configured widget report referencing the widget. The configuration provided via the widget definition is used as default if no styling is provided in the configured widget report.

Please note the following about the sizing of **Widget Text** elements:

- The size and position of the **Widget Text** element that you define in the widget is fixed. It cannot be changed via the configured report.
- If text is smaller that the text box, you can define the location of the text in the box via the attributes of the **Widget Text** element as default. The default can be overwritten by a definition in the configured widget report.
- Line breaks are added automatically to keep the text within the left and right borders of the **Widget Text** element. If the text added via the configured report is longer than the place in the text box allows to display, the text is nevertheless completely displayed, with part of the text being displayed outside the box:



Text box.

If you would like to design or structure the background of the widget via a **Panel**, **Flow Panel** or **Table Layout Panel**, you must add these elements prior to adding **Widget Text** elements. The elements cannot be moved to back or front and a panel added to a widget hides all already defined **Widget Text** elements that it covers.

To define a **Widget Text** element:

1) In the toolbar, click the **Widget Text** icon and add the **Widget Text** element to the widget area with the size and location matching your demands.

   For detailed information about placing elements on the widget area and sizing them, see the section General Instruction for Adding and Positioning Elements on the Widget.

2) In the **Name** attribute, change the default name to a short, meaningful name. The name is displayed in the explorer of the report assistant for configured widget reports referencing the widget. The name must be unique within the widget specification and shall not contain special characters.
3) In the **Caption** attribute, either delete the default caption, or define a caption to be displayed in the **Widget Text** element in the widget design area as a placeholder text. The caption is not displayed in the configured widget report, even if no text is provided for the text box in the configured widget report definition. It may be useful to define a caption with a typical text to be added via the configured widget report prior to defining the standard layout of the text box to see the effect of your design on the text in the final report. Font style, size and color that you define for text in the text box will also be applied to the caption text.
4) In the attribute window, expand the **Style** attribute and set the following subordinate attributes according to demand. Style definitions for the **Widget Text** element are default values that can be altered via the configured widget report:
   - **Background Color**: Select a color from the color picker to add a background color to the **Widget Text** element. By default, **Widget Text** elements are transparent.
   - **Border Bottom**, **Border Left**, **Border Right** and **Border Top**: To define a line to be displayed on the top, left, right or bottom of the **Widget Text** box, expand the respective attribute and set the following attributes:

- **Border**: Define the line width for the border as a positive integer. If the line width is zero, the line will not be displayed.
- **Color**: Select the color for the line from the color picker.

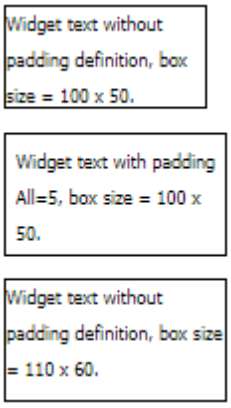
Border lines are drawn outside of the **Widget Text** element. The size required for display of the **Widget Text** element is the size defined for the borders plus the width of the border lines.

The top and left position defined for a **Widget Text** element is the position outside the lines.

- **Border Radius**: Define the positive integer to cause border edges to be rounded. The higher the integer, the more intense is the rounding of the border. Zero means that a straight corner is displayed as edge. The rounding of borders is also visible if no border lines, but only a background is defined.

The **Border Radius** setting is not visible in the design area for the widget, but only in the configured report.

- **Padding**: Define the spacing between the border of the text box and the text. Please note that the definition of a padding resizes the text box. The resulting size is the box size plus the defined padding. For example, if you have a text box with a width of 100 and a height of 50, and you define padding for all sides as 5, the actual width of the box will be 100 + 5 + 5 = 110, because the left and right padding must be added, and the resulting height will be 50 + 5 + 5 = 60, because the top and bottom padding must be added.



To define a padding, expand the **Padding** attribute and define the padding as a positive integer either separately for each side of the box in the attributes **Bottom**, **Left**, **Right**, **Top**, or for all sides equally in the attribute **All**.

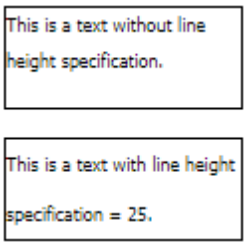
- **Margin**: Setting a margin will define a spacing between the **Widget Text** element and all other elements. To define a margin, expand the **Margin** attribute and define the margin as a positive

integer either separately for each side of the box in the attributes **Bottom**, **Left**, **Right**, **Top**, or for all sides equally in the attribute **All**.

Setting a **Margin** is only useful if the **Widget Picture** element is located in a **Flow Panel**. For **Widget Picture** elements on a **Panel** or directly added to the widget area, the **Margin** will alter the position of the **Widget Picture** element in a way that is hard to control. If you do not need more spacing to be added between caption and box, it is recommended to use the positioning options described in the section General Instruction for Adding and Positioning Elements on the Widget to define spacing between elements.

The **Margin** setting is not visible in the design area for the widget, but only in the configured report.

- **Line Height**: If a text spans multiple lines, the **Line Height** defines the space reserved for each text line. Make sure to define a number higher than the one defined for the font size. Otherwise the text will overlap. If you define `-1`, the line height is automatically adapted to the text size. The line height can be used to define additional spacing between lines of text:



- **Font**: Expand the attribute and define the style of the text font according to your demands with the following subordinate attributes:
  - **(Name)**: Select the font type from the drop-down list.
  - **Bold**: Set to `True` if you want the text to be displayed bold.
  - **Color**: Select a text color from the color picker.
  - **Horizontal Alignment**: Select the horizontal alignment of text either to the right (`Right`), to the left (`Left`) or to the center (`Center`) of the text field. If you select `Unknown`, the horizontal text alignment is `Right`, which is the default.
  - **Italic**: Set to `True` if you want the text to be displayed italic.
  - **Size**: Define the font size as a positive integer.
  - **Underline**: Set to `True` if you want the text to be underlined.
  - **Vertical Alignment**: Select the horizontal alignment of text either to the top (`Top`), to the bottom (`Bottom`) or to the center (`Center`) of the text field. If you select `Unknown`, the vertical text alignment is `Top`, which is the default.

5) In the toolbar, click the **Save** button to save your changes.

Changing a Widget Definition Already Used In Configured Widget Reports

You can also edit an existing widget or delete it even if it has been used in one or multiple configured reports. The following applies for changes to a widget that is already in use:

- If you delete a widget that is used in configured widget reports, the widget report definition is completely removed from the configured widget reports even if they are having the **Report Status** set to **Active**. When you try to delete the widget, a warning will pop up informing you that the widget is used in configured reports.
- If you change the name of a widget, the widget name is automatically updated in all configured reports using the widget. The existing configuration is maintained.
- If you change the name of a widget element within the widget, the definition of this widget element is removed from all configured reports using the widget and a new, undefined element with the new name is added to the configured widget report definition. Renaming of widget elements Therefore, require a re-definition of the renamed widget element in all configured reports referencing the widget. Definitions of all other widget elements in the configured widget report are not affected.
- If you change the default layout defined for a widget element, the change is immediately applied to all configured reports that reference the widget. If the default layout has been changed via the configured report definition, the configuration in the configured report definition will be maintained and you will not see any changes in the configured widget report rendered on the user interface.

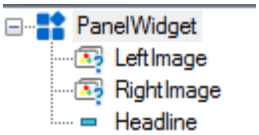
Prior to changing or deleting a widget, you should right-click the widget and select **Show Usage** from the context menu to see a list of configured reports the widget is assigned to.

Defining the Configured Widget Report

Widget reports are designed in the **Report Assistant**. For information about how to open the **Report Assistant**, see Creating a New Graphic Report. For more information about how to work with the **Report Assistant**, see Configuring the Report with the Report Assistant.

Widget reports are based on widgets. A widget must be created and defined prior to creating the configured widget report. Definition of the widget is described in detail in the section Defining a Widget.

In the report assistant, you must first select a widget in the attribute **Widget Source** of the root node of the report assistant. After you have selected the **Widget Source**, the **Widget Picture** and **Widget Text** elements in the widget are added as sub-nodes to the explorer tree: The elements are displayed with an icon followed by the string defined in the **Name** attribute of the **Widget Text** or **Widget Picture** element:



You can see from the icon which kind of widget elements and report definitions are used:

- : A **Widget Text** element that is filled with a static text. This is the default that is displayed for all **Widget Text** elements if no further specification is provided via the configured widget report.
- : A **Widget Text** element that is filled via a query.
- : A **Widget Picture** element.

To create the widget report, you must fist define the basic design in the root node of the widget report assistant by setting the following attributes:

Attribute	Description
Widget Source	Click the **Browse** button on the right of the attribute field to open the **Select Widget Source** window. Select the widget the configured widget report shall be based on in the table and click **OK**. **This attribute is mandatory and must be set first.**
Value Column Name	If your widget includes **Widget Text** elements and you would like to define the content of one or multiple **Widget Text** elements via a query, enter the name of the column in the result dataset of the query that returns the text. The column name must be identical in all queries defined for **Widget Text** elements in the configured widget report. For more information about the definition of text via a query, see Defining Dynamic Content for a Widget Text Element.
Picture Name Column Name	If your widget includes **Widget Picture** elements and you would like to define the content of one or multiple **Widget Picture** elements via a query, enter the name of the column in the result dataset of the query that returns the image name. The column name must be identical in all queries defined for **Widget Picture** elements in the configured widget report. For more information about the definition of images via a query, see Defining the Content of a Widget Picture Element.
Font Size Column Name	If your widget includes **Widget Text** elements and you would like to define the content and the font size of one or multiple **Widget Text** elements via a query, enter the name of the column in the result dataset of the query that returns the font size. The column name must be identical in all queries defined for **Widget Text** elements in the configured widget report. For more information about the definition of text via a query, see Defining Dynamic Content for a Widget Text Element.
Font Color Column Name	If your widget includes **Widget Text** elements and you would like to define the content and the font color of one or multiple **Widget Text** elements via a query, enter the name of the column in the result dataset of the query that returns the font color. The column name must be identical in all queries defined for **Widget Text** elements in the configured widget report. For more information about the definition of text via a query, see Defining Dynamic Content for a Widget Text Element.
Object Reference Column Name	If you would like to enable navigation from an image or text in the configured widget report to the object view or object cockpit of an object represented by the graphic or text, the image or text must be defined via a query. The `REFSTR` of the object must be returned in a column of the result dataset and the name of the column must be entered into this attribute.

Attribute	Description
	If you would like to navigate to any other view instead of the object view or object cockpit of the object, the **Object View Column Name** must also be defined. For more information about the definition of text or images via a query, see Defining Dynamic Content for a Widget Text Element or Defining the Content of a Widget Picture Element. For detailed information about activating navigation from a configured report, see Defining Navigation from the Report to Alfabet Views.
Object View Column Name	If you have enabled navigation from the widget report as described for the **Object Reference Column Name** attribute, you can define a view that shall be opened instead of the object view or object cockpit of the reference object. The view is opened with the `REFSTR` of the reference object handed over as parameter `BASE`. `View= ViewType: ViewName` The view must be defined in a column of the result dataset of the query and the column name must be defined in this attribute. The column name must be identical in all queries defined for widget elements in the configured widget report. In the result dataset, the view must be defined as: The view type can be `Report`, `GraphicView` or `ObjectView`. For more information about the definition of text or images via a query, see Defining Dynamic Content for a Widget Text Element or Defining the Content of a Widget Picture Element. For detailed information about activating navigation from a configured report, see Defining Navigation from the Report to Alfabet Views.
Tooltip Column Name	A tooltip can be displayed in the configured widget report if the user moves the mouse over an image or text defined via a query. The tooltip must be returned in a column of the result dataset and the name of the column must be entered into this attribute. The column name must be identical in all queries defined for widget elements in the configured widget report. For more information about the definition of text or images via a query, see Defining Dynamic Content for a Widget Text Element or Defining the Content of a Widget Picture Element.
Width	The width of the configured widget report is automatically set to the width of the widget when a **Widget Source** is selected. It can be changed if required, but usually should be left unchanged to ensure complete visibility of the widget design on the interface.
Height	The height of the configured widget report is automatically set to the width of the widget when a **Widget Source** is selected. It can be changed if required, but usually should be left unchanged to ensure complete visibility of the widget design on the interface.

Attribute	Description
Style > **Background Color**	Select a color from the color picker to change the background color of the widget background. This setting will overwrite a default background color setting of the widget. If the widet background is filled with a panel element defined to have a background color, this setting will not have any effect, because it is overlaid by the panel element.
Style > **Border Bottom**, **Border Left**, **Border Right** and **Border Top**	To define whether and how a line will be displayed on the top, left, right or bottom of the configured widget report, expand the respective attribute and set the following attributes: • **Border**: Define the line width for the border as a positive integer. If the line width is zero, the line will not be displayed. • **Color**: Select the color for the line from the color picker. Border lines are drawn outside of the configured widget report area defined with the attributes **Width** and **Height**. This alters the size required for display of the configured widget report.
Style > **Border Radius**	Define the positive integer to cause border edges to be rounded. The higher the integer, the more intense is the rounding of the border. Zero means that a straight corner is displayed as edge. The rounding of borders is also visible if no border lines, but only a background is defined. 

After having created the basic design, you can add text and images to the **Widget Picture** and **Widget Text** elements and change the styling of text fields:

- Defining the Content of a Widget Picture Element
- Defining The Content and Design for a Widget Text Element
  - Defining Static Content for a Widget Text Element
  - Defining Dynamic Content for a Widget Text Element
  - Defining the Layout of the Widget Text Element in the Subordinate Attributes of the Style Attribute
  - Revert all Layout to the Default Layout of the Underlying Widget

Defining the Content of a Widget Picture Element

The content of a **Widget Picture** element is dynamically defined via a query.

Please note the following about the display of images within the **Widget Picture** element:

- Images are not resized in the configured widget report rendered on the Alfabet user interface.
- Images that are smaller than the **Widget Picture** element will be displayed centered in the **Widget Picture** element.
- If the image is bigger than the **Widget Picture** element, only the upper left corner of the image is displayed.
- If a default image is defined in the **Widget Picture** element in the widget, the default image will be displayed if the configured report does not provide any image definition for the **Widget Picture** element. If the configured report provide image definitions via a query and the query does not return a valid image definition, the icon for missing images is displayed in the configured widget report rendered on the Alfabet user interface.
- Background color and borders as well as a caption defined for the **Widget Picture** element cannot be changed via the configured report.

Only images that are uploaded to the icon gallery can be displayed in configured widget reports. For information about uploading images to the icon gallery, see Adding and Maintaining Icons for the Alfabet Interface.

If you define the content of the **Widget Picture** in the configured widget report, you must define a query that returns at least the image source from the icon gallery. Optionally, a tooltip and navigation from the image to an Alfabet view can be defined.

To define dynamic content for a **Widget Picture** element, click the **Widget Picture** node in the explorer and define a native SQL query in either the attribute **Native SQL** or **Query as Text**, or define an Alfabet query in either the attribute **Alfabet Query** or **Query as Text**.

The query must return a result dataset with a single row and the columns required to define the content. The column names in the dataset must match the column names defined in attributes in the root node of the report assistant. The following table lists all content that can be defined in the query together with the attribute in the root node that must contain the column name:

Definition of	Required return value	Column name to be defined in attribute
Image to be displayed.	The image source must be defined as `ImageSource:ImageName` *ImageSource* defines the icon gallery the image is located in. Allowed values are: • `SmallIcon` for images from the 22x22 icon gallery and images assigned to object classes via the class settings.	**Picture Name Column Name**

Definition of	Required return value	Column name to be defined in attribute
	• `LargeIcon` for images from the Large Icons (30x30) icon gallery. • `FreeIcon` for images from the Free Icons gallery. *ImageName* is the name of the icon in the icon gallery. `SmallIcon:Application`	
Tooltip to be displayed if the user moves the mouse over the image.	The data to be displayed, For example, a string, text, date, integer or real number.	**Tooltip Column Name**
Activation of navigation and specification of the navigation target object.	The `REFSTR` of an object that shall be the target of the navigation. Please note that this specification is required even if the view that opens does not require a base object specification. If the column is not defined or not returning a valid `REFSTR`, navigation is disabled.	**Object Reference Column Name**
Definition of the navigation target view.	If no navigation target view is defined, the object view or object cockpit that is the standard for the object in the current user profile opens. To alter the navigation target, the target view must be defined as: `View=`*`ViewType`*`:`*`ViewName`* The `ViewType` can be one of the following: • ***Report*** for a configured report • ***GraphicView*** for a standard Alfabet view • ***ObjectView*** for an object profile `ViewName` is the name of the view. For more information about defining navigation to a target view, see Defining Navigation from the Report to Alfabet Views.	**Object View Column Name**

Defining The Content and Design for a Widget Text Element

The text to be displayed in a **Widget Text** element is exclusively defined via the configured widget report. The caption that is specified in the Widget Text element in the widget is a placeholder that is only displayed in the widget design area and never displayed in the configured reports based on the widget.

In the configured widget report, either static text or dynamic text evaluated via a query can be defined for a **Widget Text** element. If you do not define any text, the **Widget Text** element is displayed empty if it has a border and/or background color defined. Otherwise it is not displayed at all. There is not default provided via the widget configuration.

The styling of the underlying **Widget Text** elements can also be changed.

The **Widget Text** element in the report assistant has an attribute **Style** containing all styling option as default. The default values for all styles are identical to the values configured in the **Widget Text** element in the referenced widget. The styling can then be changed according to demand.

If the text is defined via a query, the font size and font color can be defined in the query instead of the attribute. Apart from that, the **Style** attributes are the same for **Widget Text** elements defining a static text or a text via a query.

The following sections provide an overview of the required settings for dynamic and static text definition:

- Defining Static Content for a Widget Text Element
- Defining Dynamic Content for a Widget Text Element
- Defining the Layout of the Widget Text Element in the Subordinate Attributes of the Style Attribute
- Revert all Layout to the Default Layout of the Underlying Widget

Defining Static Content for a Widget Text Element

A static text can be defined within a **Widget Text** element.

To define a static text for a **Widget Text** element, click the **Widget Picture** node in the explorer and define the following attributes:

Attribute	Description
Content Type	Select `StaticText` from the dropdown list. **This attribute must be set first.**
Caption	Enter the text to be displayed.
Style	If applicable, change the default layout of the **Widget Text** field and the text font in the subordinates attributes of the attribute **Style**. Details are given in the section Defining the Layout of the Widget Text Element in the Subordinate Attributes of the Style Attribute.

Defining Dynamic Content for a Widget Text Element

The content of a **Widget Text** element can be dynamically defined via a query.

If you define the content of the **Widget Text** in the configured widget report, you must define a query that returns at least the text to be displayed. Strings, text and numeric values can be displayed as text. For numeric values, the number of decimal values displayed in the widget can be specified as well as the display of a currency symbol or a percentage sign next to the number.

Optionally, text color and font size, a tooltip and navigation from the text to an Alfabet view can be dynamically defined via the query.

To define dynamic content for a **Widget Text** element, click the **Widget Text** node in the explorer and define the following attributes:

Attribute	Description
Content Type	Select `QueryResult` from the dropdown list. **This attribute must be set first.**
Style	If applicable, change the default layout of the **Widget Text** field and the text font in the subordinates attributes of the attribute **Style**. Details are given in the section Defining the Layout of the Widget Text Element in the Subordinate Attributes of the Style Attribute.
Numeric Format	If the query returns a numeric value, this attribute specifies how the numeric value is displayed. Select one of the following: • `None`: The number is displayed in the shortest possible format without any number grouping symbols. • `Generic`: The number is displayed with number grouping symbols. The number of decimal digits can then be specified with the attribute **Decimals**. • `Percentage`: The % sign is displayed behind the number. The number of decimal digits can then be specified with the attribute **Decimals**. • `Currency`: The symbol of the currency defined as the standard currency in the Alfabet database is displayed in front of the number. The number of decimal digits can then be specified with the attribute **Decimals**. The standard currency is defined in the **Reference Data** functionality. For more information, see *Configuring Currencies and Currency Exchange Rates for Cost Management Capabilities* in the reference manual *Configuring Evaluation and Reference Data in Alfabet*.
Decimals	If the query returns a numeric value and the **Numeric Format** attribute is set to `Generic`, `Percentage` or `Currency`, this attribute specifies how many decimals are

Attribute	Description
	displayed. By default, no decimals are displayed and values with decimals are rounded.
Native SQL / **Query as Text** / **Alfabet Query**	Define a native SQL query in either the attribute **Native SQL** or **Query as Text**, or define an Alfabet query in either the attribute **Alfabet Query** or **Query as Text**. Details about the required output of the query are given below.

The query must return a result dataset with a single row and the columns required to define the content. The column names in the dataset must match the column names defined in attributes in the root node of the report assistant. The following table lists all content that can be defined in the query together with the attribute in the root node that must contain the column name:

Definition of	Required return value	Column name to be defined in attribute
Text or number to be displayed.	The data to be displayed, For example, a string, text, date, integer or real number. Please note that a display value is required and if no column name is defined in the **Value Column Name** attribute, the value in the last column returned by the query is displayed as fallback value.	**Value Column Name**
Tooltip to be displayed if the user moves the mouse over the image.	The data to be displayed, For example, a string, text, date, integer or real number.	**Tooltip Column Name**

The font size of the text.	The text size returned as integer.
	
	Please note that a number returned as string will not be evaluated.
	
	  For example, in the SELECT statement of a native SQL query, the font size must be defined as:
	`20 AS 'FontSize'`
	and not as
	`'20' AS 'FontSize'`
		Font Size Column Name

The text color.	An HTML compliant color code.	**Font Color Column Name**

Definition of	Required return value	Column name to be defined in attribute
Activation of navigation and specification of the navigation target object.	The `REFSTR` of an object that shall be the target of the navigation. Please note that this specification is required even if the view that opens does not require a base object specification. If the column is not defined or not returning a valid `REFSTR`, navigation is disabled.	**Object Reference Column Name**
Definition of the navigation target view.	If no navigation target view is defined, the object view or object cockpit that is the standard for the object in the current user profile opens. To alter the navigation target, the target view must be defined as: `View=`*`ViewType`*`:`*`ViewName`* The `ViewType` can be one of the following: • ***Report*** for a configured report • ***GraphicView*** for a standard Alfabet view • ***ObjectView*** for an object profile `ViewName` is the name of the view. For more information about defining navigation to a target view, see Defining Navigation from the Report to Alfabet Views.	**Object View Column Name**

Defining the Layout of the Widget Text Element in the Subordinate Attributes of the Style Attribute

To change the layout of the **Widget Text** element defined in the widget to any other styling, expand the **Style** attribute of the **Widget Text** element in the report assistant and change the style with the following attributes:

Attributes that are not described in the following table currently do not have any effect on the layout.

Attribute	Description
Background Color	Select a color from the color picker to change the background color of the **Widget Text** element.
Border Bottom, **Border Left**, **Border**	To define whether and how a line will be displayed on the top, left, right or bottom of the **Widget Text** box, expand the respective attribute and set the following attributes:

Attribute	Description
Right and **Border Top**	• **Border**: Define the line width for the border as a positive integer. If the line width is zero, the line will not be displayed. • **Color**: Select the color for the line from the color picker. Border lines are drawn outside of the **Widget Text** element. This alters the size required for display of the **Widget Text** element. The top and left position defined for a **Widget Text** element is the position outside the lines and are not changed by changing the border width.
Border Radius	Define the positive integer to cause border edges to be rounded. The higher the integer, the more intense is the rounding of the border. Zero means that a straight corner is displayed as edge. The rounding of borders is also visible if no border lines, but only a background is defined. 
Padding	Define the spacing between the border of the text box and the text. Please note that the definition of a padding resizes the text box. The resulting size is the box size plus the defined padding. For example, if you have a text box with a width of 100 and a height of 50, and you define padding for all sides as 5, the actual width of the box will be 100 + 5 + 5 = 110, because the left and right padding must be added, and the resulting height will be 50 + 5 + 5 = 60, because the top and bottom padding must be added.  To define a padding, expand the **Padding** attribute and define the padding as a positive integer either separately for each side of the box in the attributes **Bottom**, **Left**, **Right**, **Top**, or for all sides equally in the attribute **All**.
Margin	Define a spacing between the text box and other elements. Setting a **Margin** is only useful if the **Widget Text** element is located in a **Flow Panel**. For **Widget Text** elements on a **Panel** or directly added to the widget area, the definition of a margin changes the

Attribute	Description
	location of the text box in a way that is not easy to predict. It is recommended to change the location of text boxes via the underlying widget. To define a margin, expand the **Margin** attribute and define the margin as a positive integer either separately for each side of the box in the attributes **Bottom**, **Left**, **Right**, **Top**, or for all sides equally in the attribute **All**.
Line Height	If a text spans multiple lines, the **Line Height** defines the space reserved for each text line. Make sure to define a number higher than the one defined for the font size. Otherwise the text will overlap. If you define `-1`, the line height is automatically adapted to the text size. The line height can be used to define additional spacing between lines of text:  Font	Expand the attribute and define the style of the text font according to your demands with the following subordinate attributes: • **(Name)**: Select the font type from the drop-down list. • **Bold**: Set to `True` if you want the text to be displayed bold. • **Color**: Select a text color from the color picker. Please note that this setting will be ignored if a font color is defined via a query in a **Widget Text** element with the **Content Type** set to `QueryResult`. • **Horizontal Alignment**: Select the horizontal alignment of text either to the right (`Right`), to the left (`Left`) or to the center (`Center`) of the text field. If you select `Unknown`, the horizontal text alignment is `Right`, which is the default. • **Italic**: Set to `True` if you want the text to be displayed italic. • **Size**: Define the font size as a positive integer. Please note that this setting will be ignored if a font color is defined via a query in a **Widget Text** element with the **Content Type** set to `QueryResult`. • **Underline**: Set to `True` if you want the text to be underlined.

Attribute	Description
	• **Vertical Alignment**: Select the horizontal alignment of text either to the top (`Top`), to the bottom (`Bottom`) or to the center (`Center`) of the text field. If you select `Unknown`, the vertical text alignment is `Top`, which is the default.

Revert all Layout to the Default Layout of the Underlying Widget

The layout of the **Widget Text** elements defined in the subordinate attributes of the attribute **Style** can be removed from the widget report to fall back to the default layout defined in the widget.

This does not include the text definitions itself. They will still be available after removal of the layout. Styling options defined via a query are also still available.

To revert to the layout defined in the widget:

1) In the report assistant, click the button **Remove Field Styles**.

Defining a Words Cloud Report

Words cloud reports are designed in the **Report Assistant**. For information about how to open the **Report Assistant**, see Creating a New Graphic Report. For more information about how to work with the **Report Assistant**, see Configuring the Report with the Report Assistant.

The report assistant has a single node in the explorer with the attributes displayed in the area on the right.

The content of the words cloud report is defined via a query that returns the data in the required formats. The names of the columns in the dataset resulting from the query must then be mapped to the attributes in the **Report Assistant** to define which information required to build the report is returned in which column of the query.

It is recommended to use native SQL for creating words cloud reports. Alfabet query language does not provide the ability to include anything else than data from the tables in the Alfabet database into the search results, and the data is usually not corresponding to meaningful text size or text orientation values for the words cloud report.

The following table lists the attributes available to define the query and the mapping of data from the query to the respective functionality. The description informs about the data type to return in the column mapped to the respective attribute:

Attribute	Description
Native SQL / **Query as Text** /	Define a native SQL query in either the attribute **Native SQL** or **Query as Text**, or define an Alfabet query in either the attribute **Alfabet Query** or **Query as Text**. Details about the required output of the query are given below with the description of the column mapping attributes.

Attribute	Description
Alfabet Query	
Text Column Name	The name of the database column in the query that returns the text to be displayed. This attribute is mandatory.
Font Size Column Name	The name of the database column in the query that returns the font size for the text in pixel. This attribute is mandatory.
Rotation Column Name	The name of the database column in the query that returns the text orientation. Allowed values are 0 - 180. 0 will display the text in normal horizontal orientation, while 180 will display the text upside down. The text is turned clockwise. This attribute is mandatory.
Tooltip Column Name	The name of the database column in the query that returns a string to be displayed as tooltip on mouse over on the text. This attribute is optional. By default, no tooltip is displayed.
Text Color Column Name	The name of the database column in the query that returns the color of the text in HTML compatible format. This attribute is optional. The default text color is black (#000000).
Legend Group Column Name	A legend for cell coloring can be defined for the configured report if the coloring is defined via the **Text Color Column Name** attribute. A legend will only be displayed if the **Show Legend** attribute is set to `True` and both the **Legend Caption Column Name** attribute and the **Legend Group Column Name** attribute are defined. Optionally, the legend can be grouped in sections. This can be useful For example, in case coloring has a different impact for different font sizes. The legend will be grouped in sections if the **Legend Group Column Name** attribute is set to the name of the database column in the query that returns the caption of the legend group that the text color returned in the same row shall be displayed in. If **Legend Group Column Name** is not set, all coloring will be listed under the heading **Legend** without grouping.
Legend Caption Column Name	A legend for cell coloring can be defined for the configured report if the coloring is defined via the **Text Color Column Name** attribute. A legend will only be displayed if the **Show Legend** attribute is set to `True` and both the **Legend Caption Column Name** attribute and the **Legend Group Column Name** attribute are defined. To display the legend, the **Legend Caption Column Name** attribute must be set to the name of the database column in the query that returns an explanatory string for the text color returned in the same row. Please note that the legend will contain one entry for each different text. If the color is equal for different texts, colors will be listed twice. This can be used For example, in

Attribute	Description
	combination with different text returned in the column defined with the **Legend Group Column Name** attribute to create different legend groups per text size and list each color in each group with a different text. If the same legend caption text and legend group text is returned for multiple colors, only the color of the first result returned for the legend caption text will be displayed in the legend.
View Column Name	The name of the database column in the query that returns the definition of an alternative link target for navigation from words. By default, the standard object profile of the object opens when a user double clicks on a node or clicks a node and then clicks the **Navigate** button. The column must return a string with the following structure: `View=`*`ViewType`*`:`*`ViewName`* The `ViewType` can be one of the following: • ***Report*** for a configured report • ***GraphicView*** for a standard Alfabet view • ***ObjectView*** for an object profile `ViewName` is the name of the view. For more information about defining navigation to a target view including handing over of parameters, see Defining Navigation from the Report to Alfabet Views.
Reference Column Name	The name of the database column in the query that returns the `REFSTR` of the objects represented by the words. If a user clicks and holds on a word, the preview will open for the corresponding object and navigation will be enabled for the object. By default, this is the object defined via the `REFSTR` returned in the first `SELECT` statement of the native SQL query or the object of the `FIND` class of the Alfabet query. If the first `SELECT` statement of the native SQL query does not return a `REFSTR` or if any other object shall be used as navigation and preview target, an additional column returning a `REFSTR` value can be added to the query and mapped to the **View Column Name** attribute.

In addition to the dynamic content, static formatting can be applied to the report with the following attributes. All these attributes are optional.

Attribute	Description
Width	Defines the width of the area that can be filled with text in pixel. The default value is 800 pixel.
Height	Defines the height of the area that can be filled with text in pixel. The default value is 600 pixel.

Attribute	Description
Background Color	Defines the background color of the area reserved for the report. By default, the background is white. The color can be changed via the color picker. For more information about working with the color picker, see Defining Color Attributes.
Border Color	Defines the color of the border drawn around the report area. By default, the border color is white. As the default for the background color is also white, no border will be visible per default for the report. The color can be changed via the color picker. For more information about working with the color picker, see Defining Color Attributes.
Border Thickness	Defines the thickness of the border drawn around the report area. The default value is 1 pixel. Please note that the border is drawn within the area filled with text by the report algorithm. Therefore, if the report shows a very high number of results, the text may overlap the border.
Padding	Defines the space between texts in the report. The default is 2 pixel.
Show Legend	A legend for cell coloring can be defined for the configured report if the coloring is defined via the **Text Color Column Name** attribute. A legend will only be displayed if the **Show Legend** attribute is set to `True` and both the **Legend Caption Column Name** attribute and the **Legend Group Column Name** attribute are defined.

Creating Geo Map Reports

The geo map reports are based on the interactive FusionMaps® provided by FusionMaps. These maps are not part of the Alfabet database by default. Therefore, configuration of geo map reports require import of FusionMaps® data prior to configuring the configured report.

Do the following to configure geo map reports:

- Importing FusionMaps® Data
  - Importing Marker Positions Not Included In Standard Marker Import
- Configuring the Relevant Object Classes in the Alfabet database for Use in Geo Map Reports
- Creating a New Geo Map Report
- Configuring the Content of the Geo Map Report
  - Defining the Basic Design of the Geo Map Report
  - Defining Coloring of Map Regions Dependent on Data in the Alfabet database

Importing FusionMaps® Data

Import of data for FusionMaps and markers to be set on the map is imported from a Microsoft® Excel® file delivered by Software AG via predefined ADIF schemes. ADIF schemes and the import file are available on request only. Please contact Software AG Support if the files and schemes are not included in your product delivery.

Two ADIF schemes are available for data import:

Name of the ADIF scheme	Name of the import file	Description	Import required for
`FUSIONMAPINFO_IMPORT`	`fc_150302.xslx`	This import adds information about the FusionMaps and the different regions that a map is divided into to the Alfabet database.	Activation of the functionality. The execution of this ADIF scheme is mandatory as basis for any geo map report configuration.
`FusionMaps-Markers`	`FusionMaps-Markers.xlsx`	This import adds information about main cities and their location on different map. For each combination of map and location, the x-axis and Y-axis position of the location is given.	Definition of geo map reports containing markers on locations. If only geo map reports displaying coloring of regions are configured, this import is not required.

For information about how to execute an ADIF import, see *Configuring ADIF Schemes*.

As a result of the import, data is added to the database tables of the object classes ALFA_FUSIONMAPINFO and ALFA_FUSIONMAPMARKER in the Alfabet database.

For each available FusionMap, information about the map elements is stored in the database table ALFA_FUSIONMAPINFO. A map element can be either a country or a region or a city. It is an area on the map that can be colored independent from the rest of the map. The following properties of the object class ALFA_FUSIONMAPINFO are relevant for the configuration of the geo maps:

Property Name	Property Caption	Description
MAPNAME	Geographic Map Name	The name of the FusionMap this map element is part of.
ID	ID	The identifier of the map element on the map. The ID explicitly identifies the map element as a combination of map and region information. For example, France has different IDs on a world map or on a map of Europe.
LABEL	Label	The label assigned to the map element on the map. Usually this is the name of a continent, a country, a region or a city.
SHORTLABEL	Short Label	A short label used for display of map element labels in the geo map report if the geo map report is configured to display a label and no label is defined in the map element query of the geo map report.

For each available FusionMap, information about the markers on the map is stored in the database table ALFA_FUSIONMAPMARKER. Markers are defined locations on the map identified by there x-axis and Y-axis position on the map that can be colored and configured separately independent from the map element that they are located in. Markers can be connected via lines that represent an interconnection between the two locations the markers are defined for.

Property Name	Property Caption	Description
MAPNAME	Geographic Map Name	The name of the FusionMap this marker is part of.
ID	ID	The identifier of the marker on the map. The ID explicitly identifies the marker as a combination of map and position information.
XPOS	X Position	The horizontal position of the marker on the map.

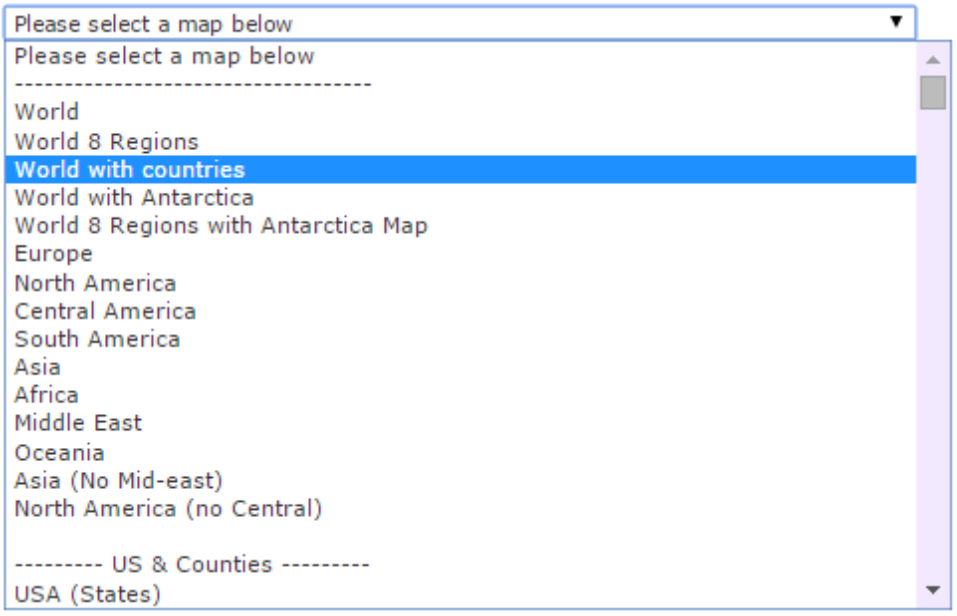
Property Name	Property Caption	Description
YPOS	Y Position	The vertical position of the marker on the map.
LABEL	Label	The label assigned to the marker on the map. Usually this is the name of a city.
TOOLTIP	Marker Tooltip	The tooltip displayed when a user moves with the mouse over the marker position on the map.

Importing Marker Positions Not Included In Standard Marker Import

Each position on the map can potentially be defined as a marker. The import file delivered by Software AG imports markers for prominent locations that are most likely to be used as markers. Markers can be added to the import file any time and imported via the ADIF scheme `FusionMapsMarkers`.

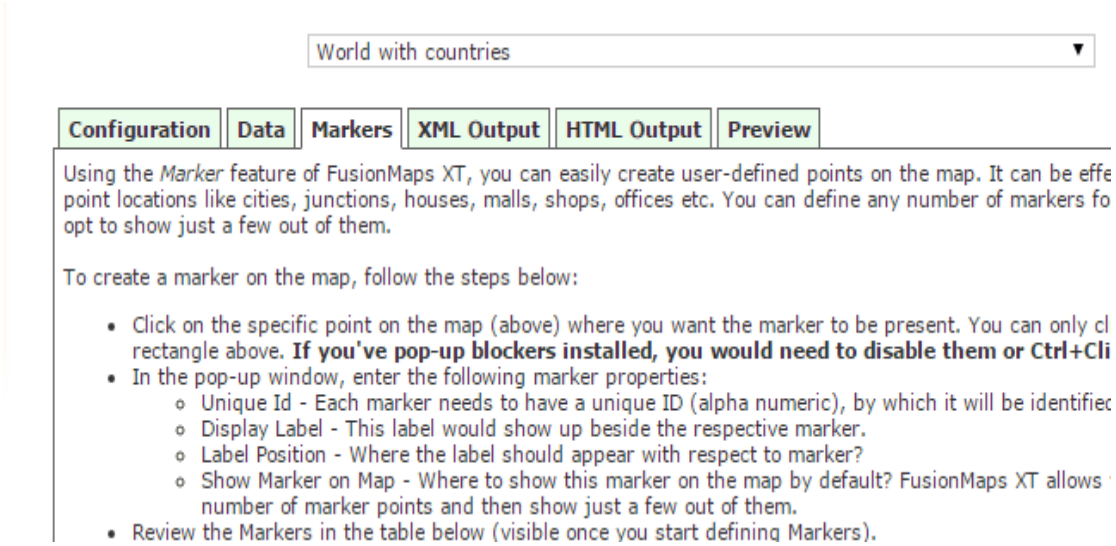
To add locations, that are not included in the standard markers, to the marker information in the Application architecture:

1) In your browser, open the URL http://docs.fusioncharts.com/maps/Tools/GUI/FusionMapsGUI.html.
2) Select the map for that you want to define markers in the drop-down list at the bottom of the page:



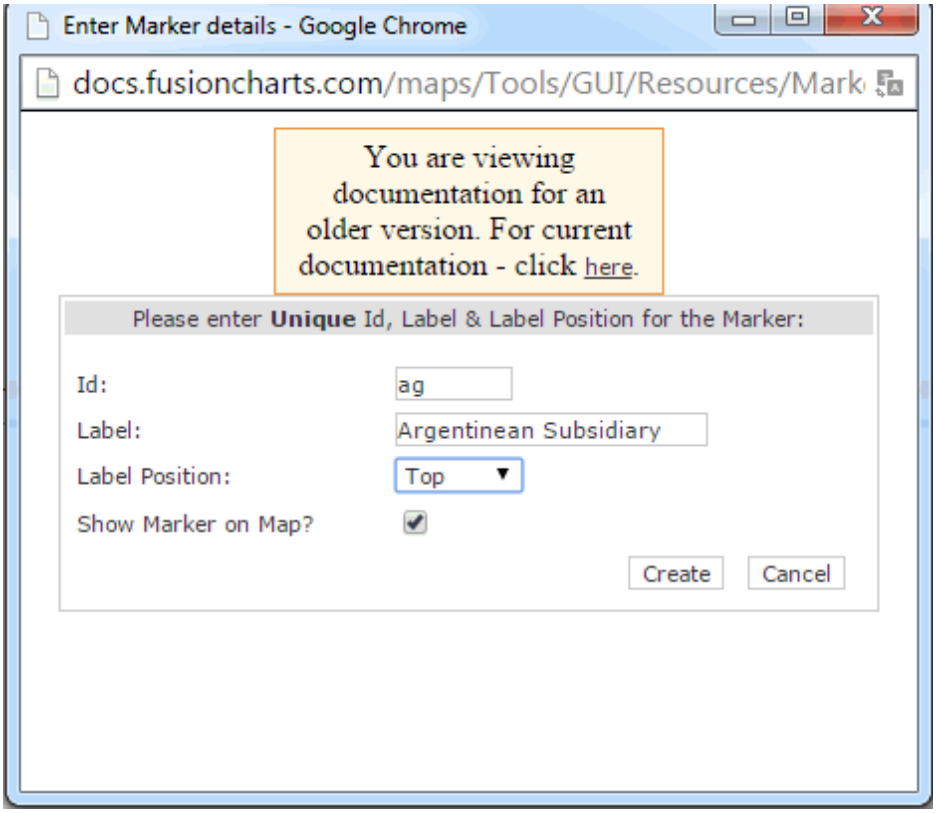
The map opens.

3) Below the map, a number of tabs for map content is displayed. Click the `Markers` tab to open it:



4) Click the location for that you want to define a marker in the map:

A new window opens with an editor for the definition of the marker:



5) Define the following attributes of the marker:

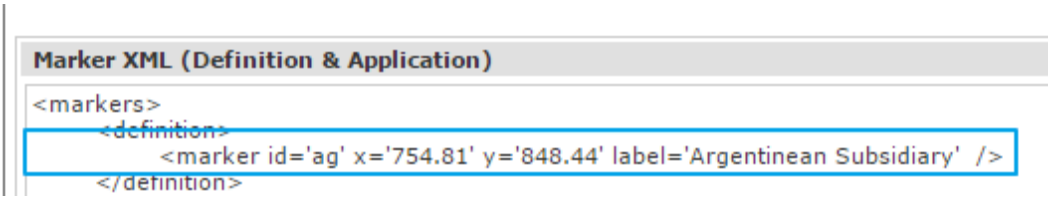
- `Id`: Define a short unique id for the marker.
- `Label`: Define a name for the marker.

> If you set markers for the same location, For example, a subsidiary, on different maps, you should define the same label for the location markers on all maps. This will ease the configuration of geo map reports because the assignment of objects to a location is independent form the map currently displayed.

The settings for `Label Position` and `Show Marker on Map` are irrelevant because they are not used in Alfabet geo map reports.

6) Click `Create` to create the marker. The new marker is displayed in the markers tab.

7) Click the `XML Output` tab to open it and scroll down to the section `Marker XML (Definitions & Application)`. The data for your marker including x-axis and Y-axis position is displayed:



8) Open the Alfabet marker import file `FusionMapsMarkers.xlsx`.

9) Add a new row to the Microsoft® Excel® sheet containing the marker definitions and copy the information about the marker into the respective fields in the columns for the definition of the marker properties:

	A	B	C	D	E	F
1	MapName	Label	XPosition	YPosition	ID	ToolTip
2	WorldwithCountries	Argentinean Subsidiary	754,81	848,44	ag	Argentinean Subsidiary
3	USA	Montgomery	485,40	284,19	AL	Montgomery

Please note that the `XPosition` and `YPosition` must be included with a comma instead of a dot as decimal separator.

10) Save your changes and import the markers via ADIF using the `FusionMapsMarkers` import scheme.

Configuring the Relevant Object Classes in the Alfabet database for Use in Geo Map Reports

In order to display data from the Alfabet database in the FusionMaps, a connection between IT related objects and the marker and map element information in the Alfabet database must be defined. There is no standard property on an object class for the definition of such a relation, because the way that data shall be represented in a map is customer specific.

If you want to display information in a map, you must first determine the object classes that shall be used to bound the information to a location on a map and configure custom properties for them that enable mapping between the objects of the class and the map elements or markers on the FusionMaps.

In FusionMaps, the same region, country or city normally has the same label name in all maps. The example below displays a part of the import file for map elements that displays the data for the country Iran in different maps. The Entity Label, that is store in the property `LABEL` of the object class `ALFA_FUSIONMAPINFO` is identical for all maps:

A	B	C	D	
Map Name	Entity Original	Entity ID	Entity Short Lab	Entity Label
bahia	2914307	2914307	IM	Iramaia
asia	016	016	IR	Iran
middleeast	03	03	IN	Iran
southernasia	106	106	IA	Iran
worldwithcountries	106	106	IA	Iran
amazonas	1301852	1301852	IR	Iranduba
santacatarina	4207809	4207809	IN	Irani

Therefore, it is recommended to define custom properties of the Type `String` that are identical to For example, a label of a map element rather than defining a custom property that contains a reference to an object of the object class `ALFA_FUSIONMAPINFO`. The reference would combine one object with a region on one single map while a string that is identical to a label name can be used in queries to combine the object with a region on all maps that display that region.

The following table lists objects of the Alfabet object class Location with three custom properties `SC_CONTINENT`, `SC_COUNTRY` and `SC_REGION` defined to couple the locations with the map elements on FusionMaps. The Name property of the location is also displayed:

	NAME	SC_CONTINENT	SC_COUNTRY	SC_REGION
1	Albany	North America	United States	New York
2	Argentina	South America	Argentina	NULL
3	Atlanta	North America	United States	Georgia
4	Berlin	Europe	Germany	Berlin
5	Bordeaux	Europe	France	Aquitaine
6	Boston, MA	North America	United States	Massachusetts
7	Brazil	South America	Brazil	Acre

Creating a New Geo Map Report

To create a new geo map report, create a configured report of the type `Custom` in Alfabet Expand:

1) In the **Reports** tab, right-click the **Reports** folder or a sub-folder thereof and select **Create New Report**. You will see the new configured report listed below the selected report folder.

As an alternative to defining all attributes for a new configured report, you can copy and paste an existing configured report and make modifications, as needed. To do so, right-click the existing configured report that you want to copy and select **Copy**. Right-click the new configured report and select **Paste**. Modify the necessary attributes described below.

2) In the attribute window, select `Custom` in the **Type** field.

3) In the attribute window, define the following attributes for the geo map report.

- **Name**: Optionally, change the technical name of the configured report. The technical name of the configured report must be unique.

The technical name is used for identification of the configured report in the context of technical processes such as merging the report configuration with a report configuration saved as an XML file. Therefore, the following is required when defining the name of a configured report:

- The name must be unique. The name must be unique regardless of the report folder it is structured in.
- The name may not be changed once a configured report has been created.
- A validation mechanism checks for correct syntax when defining a technical name. Please note that names may not begin with an empty space nor include special characters. For a list of the special characters that are not allowed, see the section Defining Attributes for Configuration Objects in the chapter Getting Started with Alfabet Expand.

- If the technical name of the configured report is changed, the name will be correctly updated in other configuration objects referencing the changed report during design time.

  Please note that the name of a changed configuration object will not be updated in guide pages or guide views. If you plan to change the name of a configuration object, the reference in the navigation page should be changed prior to changing the configuration object name. You can use the **Show Usage** functionality in the context menu of the configured report to evaluate whether the configured report has been added to a guide view or guide page.

- **Caption**: Enter a caption for the configured report. The caption you define here will be displayed in the **Reports Administration** functionality in the **Administration** module and the **Configured Reports** views of the Alfabet interface. If the configured report is assigned to an object view as a page view, the text will be displayed as the page view caption in the object view. The caption of the configured report may exceed the conventional 64 character limit.
- **Description**: Provide a short information about the configured report that is useful to Alfabet users. This comment will be displayed on the Alfabet user interface in the header of the configured report in a single line under the report caption and the **Description** field for the configured report in the table of all views listing configured reports, like the **Configured Reports** views of the **Search** functionalities. If the configured report is assigned to an object view as a page view, the text will be displayed under the page view caption as short description in the object view.

  In the configured report, the description will be truncated if it is longer than one line on the screen. Therefore, the description should be short to ensure complete display in the configured report header.

- **Usage Guideline**: Provide information that helps users to execute and interpret the configured report. This information will not be displayed directly on the user interface. The user can access the information using the following mechanisms:
  - If the user moves the cursor over the description provided for the configured report with the attribute **Description**, a tooltip opens that includes both the description and the usage guideline.
  - The **Options**  button will be displayed on the upper right with an option **Help On Filter Fields** to open a new window displaying the usage guideline in addition to any filter field hints, if configured.

    For views that have filters defined, the **Options**  button will only be displayed if the filter panel either allows batch clearing of filter fields or collapsing and expanding of the filter panel. For more information about the configuration of these functionalities, see Configuring the Complete Filter Area to be Collapsible and Allowing the User to Clear the Filter Area.

- **Technical Comment**: Provide information that is useful for solution designers working with Alfabet Expand in order to better understand the configured report from a technical perspective. The **Technical Comment** will not be displayed in the user interface. Nevertheless, you can configure the interface to display the information in, For example, the attribute section of the configured report's object profile in the **Reports Administration** functionality.

- **Template**: Select `MapChartReport`.
- **Report State**: The **Report State** attribute is view only and is set to `Plan` for new configured reports. The configured report can only be edited when the **Report State** attribute is set to `Plan`. After finishing all configuration steps described in the following, the **Report State** attribute must be set to `Active` as described in the section General Guidelines for Creating Configured Reports. The configured report is then visible to users in the Alfabet user interface.
- **Help Index**: Specify the location of the external Help file using the following syntax:(For example,:). The external help file will be displayed when the user clicks the context-sensitive Help link in the standardHelp menu.

  Server variables can be used in the Help links. Server variables allow you to define all or part of the URL definition in the server alias configuration of the Alfabet Server instead of directly defining it in the configuration in Alfabet Expand. Use of server variables is useful, For example, in order to change a Web server name defined in multiple URL definitions in Alfabet Expand. Instead of changing all URL definitions, only the variable value in the server alias configuration must be updated. The use of server variables is described in the section Using Server Variables in Web Link and Database Server-Related Specifications in the chapter Configuring Reports.

- **Apply to Class**: When the configured report is applied to a class, a base object can be selected for the configured report. A filter for selection of a base object will automatically be set on top of the configured report. When configuring queries for the configured report, you can use the parameter `BASE` to refer to the object selected in the filter and define search conditions dependent on the base object. To apply the configured report to a base object class or object class stereotype, click the **Browse** button to open a dialog box and select the object class or object class stereotype to which you want to apply the configured report and click **OK**.

  Note the following:

  - If the configured report is assigned to the object view for the relevant object class, the configured report will automatically open with the current object selected as the base object even if the **Apply to Class** attribute is not set.
  - If the configured report is applied to an object class stereotype, the filter field for selection of the base object will use the caption of the object class stereotype as caption of the filter field and the selector defined in the class settings for the object class stereotype for selection of the base object.
  - Alternatively, the base object of a configured report can be set with the **Base Query** attribute. Whereas the **Apply to Class** attribute enables the user to determine the current base object by setting a filter, the **Base Query** attribute evaluates the base object by executing a query when the configured report is opened. A filter field is not available and the user cannot change the base object.
  - The **Apply to Class** attribute also influences the availability of the configured report in the Alfabet interface. Select a class to make the configured report available in the **Configured Reports** page view in the object view for the selected object class. If you do not set the attribute, the configured report will only be available in the **Configured Reports** functionality. The configured

report can be assigned to object views and wizards independent of the attribute.

- **Base Object Query**: If a base object query is defined for the configured report, a base object will be evaluated for the configured report at runtime. When configuring the other queries for the configured report, you can use the parameter `BASE` to refer to the object returned by the base object query and define search conditions dependent on the base object. To apply the configured report to a base class, click the **Browse** button to open a text editor, define either a native SQL query or an Alfabet query that returns a single object, and click **OK**.

  Note the following:

  - Alternatively, the base object of a configured report can be set by means of the **Apply To Class** attribute. Whereas the setting of the **Base Object Query** attribute triggers the evaluation of the base object by executing a query when the configured report t is opened, the **Apply to Class** attribute enables the user to determine the current base object by setting of an automatically-generated filter.
  - The query defined for the base object query is executed when the user opens the configured report to evaluate the base object at runtime. Parameters referring to the current working environment can be used in the query to find a base object dependent on the user opening the configured report or the user profile used for login, For example,. A base object query may also find, For example, the ICT object that a specific application is currently assigned to.
  - If the **Base Object Query** attribute is set and the configured report is assigned as a view to an object profile, the Alfabet parameter `BASE` referring to the `REFSTR` of the object that the user is working with when the configured report is opened can be used in the base object query.

- **Selector Behavior**: The attribute can be used to exclude configured reports that are defined for special purposes, like For example, triggering of data export via the RESTful API, from being selectable in the **Configured Reports** table. By default, the attribute is set to `Visible` and the configured report is visible in the selector for adding configured reports to the **Configured Reports** table if all other conditions for access to the configured report apply. If the attribute is set to `NotVisible`, the configured report is excluded from the selector for adding configured reports to the **Configured Reports** functionality. Please note however, that this setting is not excluding the configured report from any standard views or customer configured views and selectors, but exclusively from the standard selector for configured reports implemented in Alfabet.

The attribute cannot be edited in the attribute window directly. To change the setting, right-click the configured report and select **Set Report Selector Behavior to 'Not Visible'** or **Set Report Selector Behavior to 'Visible'** respectively.

- **Applicable for AlfaBot**: Specify whether the configured report is accessible via the AlfaBot. By default, the attribute will be set to `True` for new reports. Set the attribute to `False` if the configured report should not be opened outside of a specific context. For example, this may be relevant for reports that are specifically designed to be embedded in an object cockpit.

This attribute is only relevant if the AlfaBot is implemented. For information about the implementation of the AlfaBot, see Implementing the AlfaBot for Navigation via a Full-Text Command.

- **Business Problem Statement**: Optionally enter a description that will help users to search for the configured report in the AlfaBot. The text is not displayed in the user interface, but it is of special relevance for the search mechanisms implemented for the AlfaBot. If the report caption entered by the user in the AlfaBot for a request to open a configured report does not match the caption of one of the available configured reports, the AlfaBot will split the caption entered by the user into keywords and will perform a keyword search on the **Caption**, **Description** and the **Business Problem Statement** attributes of the configured reports that are accessible via the AlfaBot. In addition to a keyword search, a synonym search is performed on the text provided in the **Business Problem Statement** attribute.

  This attribute is only relevant if the AlfaBot is implemented. For information about the implementation of the AlfaBot, see Implementing the AlfaBot for Navigation via a Full-Text Command.

- **Base Classes**: Define the object classes that must be available to run the configured report. If this attribute is set, the Alfabet Server checks whether the object classes specified as base classes are excluded from the view scheme used to access the configured report. If the user does not have access permissions to one of the base classes, the configured report will be disabled. To set the attribute, click the **Browse**  button to select the object classes that are required to run the configured report and click **OK**.

- **Can Create Express View**: Select `True` if an express view may be created for the report. Select `False` if an express view may not be created for the report. Please note that for reports that have a custom report view, the setting must be consistent with the setting of the attribute **Can Create Express View** of the custom report view.

  An express view is a link to a specific Alfabet view displaying data that allows individuals inside or outside of the user community to view information in Alfabet. When the express view is created, an email notification is automatically mailed to a specified recipient. The recipient receives a URL that allows him/her to access the current page view in Alfabet. For more information, see the section *Sending and Receiving Express Views* in the reference manual *Getting Started with Alfabet*.

4) In the explorer, right-click the configured report and select **Create Custom Report View**. The view editor opens. In the explorer, the custom report view is displayed as a subordinate object of the configured report. The attributes for the custom report view are displayed in the attribute window. You can optionally edit the following attributes:

   - **Name**: Optionally you can change the name for the custom report view. The **Name** must be unique for custom report views.

   - **Can Create Bookmark**: Select `True` if a bookmark may be created for the configured report. Select `False` if a bookmark may not be created for the configured report.

   - **Can Create Express View**: Select `True` if an express view may be created for the configured report. Select `False` if an express view may not be created for the configured report. Please note that the setting must be consistent with the setting of the attribute **Can Create Express View** of the configured report.

An express view is a link to a specific Alfabet view displaying data that allows individuals inside or outside of the user community to view Alfabet information. When the express view is created, an e-mail notification is automatically mailed to the specified recipient who receives a URL that allows him/her to access the current page view in Alfabet. For more information, see *Sending and Receiving Express Views* in the reference manual *Getting Started with Alfabet*.

The custom report view initiates the **Report Assistant**. A custom report view shall never be deleted from the configured report after the **Report Assistant** was already used to configure the report. When you delete the custom report view of an existing template-based configured report and create a new one, the **Report Assistant** is reset to the example specified by default and your configuration is lost.

5) In the explorer, right-click the configured report and select **Start Alfabet Report Assistant**. The **Report Assistant** opens.
6) Define the geo map report as described below in the section Configuring the Content of the Geo Map Report. For general information about working with the **Report Assistant**, see Configuring the Report with the Report Assistant.
7) Delete or edit the parameter panel for the geo map report. For more information, see Configuring Filter Layout and Defining Filters for Configured Reports and Selectors.
8) Click **OK** to save the configuration.
9) In the toolbar, click the **Save** button to save your changes.
10) In the explorer, right-click the configured report and select **Review Report**. The configured report opens in a web browser. If the results are not as expected, you can edit the configured report until the output of the configured report meets your expectations.

Configuring the Content of the Geo Map Report

Geo map reports are designed in the **Report Assistant**. For information about how to open the **Report Assistant**, see Creating a New Geo Map Report. For more information about how to work with the **Report Assistant**, see Configuring the Report with the Report Assistant.

The content and layout of a geo map report is defined by setting the attributes of the explorer element in the attribute pane of the **Report Assistant** window.

Geo map reports can in general be defined using Alfabet query language or native SQL. But drill down to other configured reports from a geo map element, For example, opening continent maps from a world map, requires a native SQL query.

The following table lists the types of explorer node elements that can be added to the report configuration to specify the content of the geo map report. Information is provided in the table about the purpose of each explorer node element:

Explorer Node Element	Required to Configure:
Root Node	General layout of the geo map report and mapping of the information provided by the queries of the geo map report to the relevant graphic display in the geo map report.
Map Element Query	Definition of a query that defines the display of map elements depending on data in the Alfabet database.
Marker Query	Definition of a query that defines the display of markers depending on data in the Alfabet database.
Marker Connection Query	Definition of a query that defines the display of connections between markers depending on data in the Alfabet database.

Defining the Basic Design of the Geo Map Report

The basic design of the geo map report is designed directly in the attributes of the root node element of the **Report Assistant** explorer. The following table lists only the attributes related to basic settings. Attributes that are relevant for the configuration of map elements, markers or marker connections are not included.

The basic design includes the specification of the map to be displayed and the general display of colors, labels and tooltips on the map:

Section/Attribute	Description
Hover Color	Defines the color that shall be used to color a region on mouse-over.
Title	Defines the title that is displayed on top of the map. This attribute is optional. If it is not set, the graphic is displayed without a title.
Map Name	Defines the FusionMap that shall be displayed in the geo map report. Enter the name of the map as defined in the property `MAPNAME` of the object classes `ALFA_FUSIONMAPMARKER`Sand `ALFA_FUSIONMAPINFO`.
Number Suffix	This feature is not yet documented.
Show Labels	Defines whether labels are shown on colored regions of the map.

Section/Attribute	Description
Show Tooltips	Defines whether a tooltip is displayed on colored regions of the map.
Include Values in Labels	This feature is not yet documented.
Width	Defines the overall width of the map graphic.
Height	Defines the overall width of the map graphic.

A geo map report with only the basic design settings cannot be displayed using For example, the **Review Report** functionality in the context menu of the custom report view. The geo map report must contain either marker or map element definitions to be displayed.

Defining Coloring of Map Regions Dependent on Data in the Alfabet database

Regions of the maps can be colored depending on a numeric value derived from data in the Alfabet database.

The colored regions can display a label, that means a text in the colored map element, and a tooltip that is displayed when a user moves the mouse over the colored region. The label text is either derived from the data in the map element query or the short name of the map element stored in the object class property `SHORTLABEL` of the `ALFA_FUSIONMAPINFO` object class storing the map element data is displayed either with or without information about the value the coloring is based on.

To color the map elements of a geo map report, the following configuration steps are required:

- A query must be defined that returns the data that shall be displayed.
- The columns in the query containing the relevant information must be mapped to attributes in the root node of the geo map report assistant to enable the graphic display of the data returned by the query.
- Optionally the range of colors for coloring of the regions according to data in the query and the display of labels can be defined in the attributes of the root node of the report assistant.

To color the map elements, a map element query has to be defined in the explorer node **Map Element Query**. To define an Alfabet query, use the attribute **Alfabet Query** to open the **Alfabet Query Builder** or the attribute **Query as Text** to define the Alfabet query in a text editor. To define a native SQL query, use the attribute ***Native Sql*** to define the query.

The query must return a tabular dataset providing the data required for display of the map. The information which column contains which information must then be added to the attributes of the root nodes of the report assistant. The relevant attributes are available in the section **Data**. For each relevant attribute, a column name of the map element query must be defined.

For information about the column names in Alfabet queries and native SQL queries see Defining Column Names and Captions in the chapter Defining Queries.

The following table lists the attributes of the root node and informs about the kind of data that must be returned in the defined column of the query:

Attribute of the root node of the report assistant returning the column name	Required data to be returned for the defined column in the query	Specification is
Id Column	The identifier of the map element on the map. The column must contain the values of the ID property of existing objects of the object class `ALFA_FUSIONMAPINFO`.	Mandatory
Label Column	A string to be displayed as label on the map element. For more information about the definition of labels see Defining the Display of Labels and Tooltips in the Geo Map Report.	Optional. If no column is defined in the Label Column attribute, the `SHORTLABEL` object class property of the current map element is displayed as label.
Tooltip Column	A string to be displayed as tooltip when the user moves the cursor over the map element in the geo map report. For more information about the definition of tooltips see Defining the Display of Labels and Tooltips in the Geo Map Report.	Optional. If no column is defined in the Tooltip Column attribute, the `LABEL` object class property of the current map element and the value defined in the value column is displayed as tooltip.
Color Column	A HTML compliant color specification for coloring of the map element.	Optional. If no column is defined in the **Color Column** atttibute, the coloring of the map element must be defined by defining a color range in the **Color Range** attribute of the root node. Please note that a legend is only available for definition of colors as color range.
Value Column	An integer or real value that the coloring of the map elements depends on.	Mandatory.

Attribute of the root node of the report assistant returning the column name	Required data to be returned for the defined column in the query	Specification is
View Column	The definition of a link to another configured report that opens when the user clicks on the label in the map element. The required syntax for the link is: `View=Report:`*`ReportName`* For detailed information about the definition of the link including parameter values handed over to the configured report that opens see the section Defining Navigation from the Geo Map Report to Alfabet Views.	Optional.

The color displayed for each map element depending on the numeric value in the dataset column defined with the **Value Column** attribute can be set in three ways:

- The color can be read from the respective row of the query in the column defined with the attribute **Color Column** of the root node of the report assistant.
- In the **Color Range** attribute of the root node of the report assistant, a color can be defined for different ranges of values that might be returned in the dataset column defined as **Value Column**.
- In the **Color Range** attribute of the root node of the report assistant, a color gradient can be defined with a fixed color setting for the lowest and the highest possible value that might be returned in the dataset column defined as **Value Column**. The colors for the map elements then correspond to the gradient color matching their position in the range of values.

A legend for the coloring is only available for the definitions via the **Color Range** attribute.

Defining the Display of Color in the Map Element Query

To define the coloring of map elements in the query defined as **Map Element Query**:

1) In the query defined as **Map Element Query**, add a column to the tabular output of the query that returns an HTML compliant color code (For example, #336699 for dark blue).
2) In the attributes of the root node of the report assistant, set the following attributes in the section **Data**:
   - **Color Column**: Enter the name of the column in the dataset containing the label text.

Defining the Display of Colors via Color Definitions in the Root Node of the Report Assistant

To define the colors for regions by defining fixed colors for ranges of values:

1) In the root node of the report assistant, expand the attribute **Color Range**.
2) Set the attribute **Type** to `Simple`.
3) Define the following attributes of the **Color Range**:
4) Click into the value field of the attribute **Colors** and click on the button that is displayed on the right of the field. The **Edit Object Collection** window opens.
5) To define coloring for a range of values, click the button **Add** and define the following in the **Properties** window:
   - **Caption**: Enter a caption that is displayed for the color in the legend.
   - **Min Value**: Enter the lowest numeric value for the range.
   - **Max Value**: Enter the highest numeric value for the range.

     Max Value must be higher than **Min Value**. If you want to define a range with only one value, you must define the value as **Min Value** of this range and for **Max Value** of this range, you must enter the same numeric value as for the **Min Value** of the next range. The **Min Value** setting of the next range supersedes the **Max Value** of the current range.

   - **Color**: Select a color from the color selector.
6) Repeat the previous steps for all ranges that you want to define.
7) Click **OK** to save your changes.

Defining the Display of Colors via a Color Range Definition in the Root Node of the Report Assistant

To define the colors for regions by defining a range of colors:

1) In the root node of the report assistant, expand the attribute **Color Range**.
2) Define the following attributes of the **Color Range**:
   - **Type**: Set to Gradient.
   - **Min Value**: Enter the lowest numerical value defined for a result.
   - **Start Label**: Enter the label to be displayed on the lowest end of the gradient in the legend.
   - **End Label**: Enter the label to be displayed on the highest end of the gradient in the legend.
   - **Start Color**: Enter the color that shall be used for the lowest value of the range of values used for coloring.
3) Click into the value field of the attribute **Colors** and click on the button that is displayed on the right of the field. The **Edit Object Collection** window opens.
4) Click the button **Add** and define the following in the **Properties** window:
   - **Min Value**: Enter the highest numeric value for the range of values used for coloring.
   - **Max Value**: Enter the highest numeric value for the range of values used for coloring.

Max Value must be identical to **Min Value** to define a color gradient.

- **Color**: Select a color from the color selector.

5) Click **OK** to save your changes.

Defining Markers to be Displayed in the Map

A marker is a spot on the map that can either be marked with a circle, a polygon or an icon. Markers can only be set for locations that are stored in the database table `ALFA_FUSIONMAPMARKERS`.

The shape of the markers as well as the colors of polygons and circles can be defined in the geo map report depending on a numeric value derived from data in the Alfabet database.

The markers can display a label, that means a text in the colored map element, and a tooltip that is displayed when a user moves the mouse over the colored region. The label text is derived from the data in the marker query.

To define the markers of a geo map report, three configuration steps are required:

- A query must be defined that returns the data that shall be displayed.
- The columns in the query containing the relevant information must be mapped to attributes in the root node of the geo map report assistant to enable the graphic display of the data returned by the query.
- Optionally the shapes of markers can be defined in the attributes of the root node of the report assistant.

To define markers, a marker query has to be defined in the explorer node **Marker Query**. To define an Alfabet query, use the attribute **Alfabet Query** to open the **Alfabet Query Builder** or the attribute **Query as Text** to define the Alfabet query in a text editor. To define a native SQL query, use the attribute **Native Sql** to define the query.

The query must return a tabular dataset providing the data required for display of the marker. The information which column contains which information must then be added to the attributes of the root nodes of the report assistant. The relevant attributes are available in the sections **Data** and **Special Marker Data**. For each relevant attribute, a column name of the marker query must be defined.

For information about the column names in Alfabet queries and native SQL queries see Defining Column Names and Captions in the chapter Defining Queries.

The following table lists the attributes of the root node and informs about the kind of data that must be returned in the defined column of the query:

Attribute of the root node of the report assistant returning the column name	Required data to be returned for the defined column in the query	Specification is
Data		
Id Column	The identifier of the marker on the map. The column must contain the values of the ID property of existing objects of the object class `ALFA_FUSIONMAPMARKER`.	Mandatory
Label Column	A string to be displayed as label on the marker. For more information about the definition of labels see Defining the Display of Labels and Tooltips in the Geo Map Report.	Optional. If no column is defined in the **Label Column** attribute, the marker is displayed without a label.
Tooltip Column	A string to be displayed as tooltip when the user moves the cursor over the marker in the geo map report. For more information about the definition of tooltips see Defining the Display of Labels and Tooltips in the Geo Map Report.	Optional. If no column is defined in the **Tooltip Column** attribute, no tooltips are displayed.
View Column	The definition of a link to another configured report that opens when the user clicks on the label in the map element. The required syntax for the link is: `View=Report:`*`ReportName`* For detailed information about the definition of the link including parameter values handed over to the configured report that opens see the section Defining Navigation from the Geo Map Report to Alfabet Views.	Optional.
Special Marker Data		
X Pos Column	The column must contain the values of the `XPOS` object class property of the current object of the object class `ALFA_FUSIONMAPMARKER`.	Mandatory
Y Pos Column	The column must contain the value of the `YPOS` object class property of the current object of the object class `ALFA_FUSIONMAPMARKER`.	Mandatory

Attribute of the root node of the report assistant returning the column name	Required data to be returned for the defined column in the query	Specification is
Shape Column	The column must return a string that is identical to the value of the `Name` attribute of one of the defined shapes of the geo map report.	Optional. If no shape column is defined, all markers will be displayed as circles in a light color.

Defining the Display of Marker Shapes Depending on Results Returned by the Marker Query

To define the shaping of markers:

1) In the root node of the report assistant, click into the value field of the attribute **Colors** and click on the button that is displayed on the right of the field. The **Edit Object Collection** window opens.
2) Click the button **Add** and define the following in the **Properties** window:
   - **Type**: Select the type of marker that you want to define from the drop down list. A marker can either be displayed as circle, polygon or image.
   - **Name**: Enter a unique name for the marker shape. This value is used to identify the marker in the marker query.
   - **Radius**: Enter the radius of the marker. For images this attribute is not relevant.
   - **Sides Count**: Enter the number of sides for a polygon. For images and circles this attributes is not relevant..
   - **Background Color**: Select the background color of the marker. For images this attribute is not relevant.
   - **Border Color**: Select the border color of the marker. For images this attribute is not relevant.
   - **Legend Text**: Select the text that shall be displayed for the shape in the legend.
   - **Icon Type**: If the **Type** attribute is set to **Image**, select an icon gallery from the drop-down list.
   - **Icon**: If the **Type** attribute is set to **Image**, select an icon from the icon gallery selected with the **Icon Type** attribute.
3) Repeat the previous step for all shapes that you want to define.
4) Click **OK** to save your changes.
5) In the query defined as **Marker Query**, add a column to the tabular output of the query that returns the value of the Name attribute of one of the defined shapes.
6) In the attributes of the root node of the report assistant, set the following attributes in the section **Special Marker Data**:

- **Shape Column**: Enter the name of the column in the dataset containing the name of the shape.

Defining Connections Between Markers in the Map

Markers in the map can be connected by lines. The color and the thickness of the marker connections can be configured in the query defining each connection.

To define connections between the markers of a geo map report, two configuration steps are required:

- A query must be defined that returns the data that shall be displayed.
- The columns in the query containing the relevant information must be mapped to attributes in the root node of the geo map report assistant to enable the graphic display of the data returned by the query.

To define marker connections, a marker connection query has to be defined in the explorer node **Marker Connection Query**. To define an Alfabet query, use the attribute **Alfabet Query** to open the **Alfabet Query Builder** or the attribute **Query as Text** to define the Alfabet query in a text editor. To define a native SQL query, use the attribute **Native Sql** to define the query.

The query must return a tabular dataset providing the data required for display of the marker connection. The information which column contains which information must then be added to the attributes of the root nodes of the report assistant. The relevant attributes are available in the sections **Data** and **Special Marker Connection Data**. For each relevant attribute, a column name of the marker query must be defined.

For information about the column names in Alfabet queries and native SQL queries see Defining Column Names and Captions in the chapter Defining Queries.

The following table lists the attributes of the root node and informs about the kind of data that must be returned in the defined column of the query:

Attribute of the root node of the report assistant returning the column name	Required data to be returned for the defined column in the query	Specification is
Data		
Color Column	A HTML compliant color specification for coloring of the map element.	Optional. If no column is defined in the **Color Column**, black connections are displayed.

Attribute of the root node of the report assistant returning the column name	Required data to be returned for the defined column in the query	Specification is
View Column	The definition of a link to another configured report that opens when the user clicks on the label in the map element. The required syntax for the link is: `View=Report:`*`ReportName`* For detailed information about the definition of the link including parameter values handed over to the configured report that opens see the section Defining Navigation from the Geo Map Report to Alfabet Views.	Optional.
Special Marker Data		
From Column	The column must contain the value of the ID object class property of the object of the object class **ALFA_FUSIONMAP-MARKER** in the map where the connection starts.	Mandatory
To Column	The column must contain the value of the ID object class property of the object of the object class **ALFA_FUSIONMAP-MARKER** in the map where the connection ends.	Mandatory
Thickness Column	The column must return a number that is used to define the thickness of the connection.	Optional. If no thickness column is defined, all connections have the same thickness.

Defining the Display of Labels and Tooltips in the Geo Map Report

For each region that is colored in the map, that means a map element, and for each marker, a label and a tooltip can be displayed. The content of the labels and tooltips can either be configured in the query defined as **Map Element Query** or **Marker Query**.

The display of labels and tooltips for map elements only can alternatively be configured via the attributes of the root node of the report assistant. A definition in the query overwrites settings in the attributes of the root node. You can also define the labels via the root nodes and the tooltips via the query or vice versa.

Defining the Display of Labels and Tooltips in the Query

To define the text displayed in the labels and tooltips in a query:

1) In the query defined as **Map Element Query** or **Marker Query**, add the following to the output of the query:
   - To define a label text, add a column to the tabular output of the query that returns a string to be displayed as label text.
   - To define a tooltip text, add a column to the tabular output of the query that returns a string to be displayed as label text.

   Please note the following:
   - If you want to define the same text as tooltip and label, it is sufficient to define the text once and map it to both the label and tooltip in step 2.
   - If you want to define the label or tooltip in **Map Element Query** and **Marker Query** the column names in the tabular output of both queries must be identical.

2) In the attributes of the root node of the report assistant, set the following attributes in the section **Data**:
   - **Label Column**: Enter the name of the column in the dataset containing the label text.
   - **Tooltip Column**: Enter the name of the column in the dataset containing the tooltip text.

Defining the Display of Labels and Tooltips of Map Elements in the Root Node of the Report Assistant

If the attribute **Label Column** for the root node of the geo map report assistant is not set and the attribute **Show Labels** is set to `True`, the short label of the map element is displayed as label on colored regions in the map. For markers, no label is displayed.

If the attribute **Tooltip Column** for the root node of the geo map report assistant is not set and the attribute **Show Tooltips** is set to `True`, the label of the map element is displayed as tooltip on colored regions in the map.

Optionally, the numeric value that the coloring is based on can be displayed. The following attributes of the root node of the geo map report assistant must be set to define display of values in labels and tooltips:

Section/Attribute	Description
Common	
Number Suffix	Optionally a suffix can be defined that is displayed after the value to explain the meaning of the value. For example, if the numeric value refers to the number of market products that are available in a region, the suffix " products" may be defined. Please note that the

Section/Attribute	Description
	suffix is displayed directly after the number. If you want a whitespace to be displayed between numeric value and suffix, you must add the whitespace to the suffix specification.
Include Values in Labels	Numeric values are displayed in the labels and tooltips if this attribute is set to `True`. Please note that this attribute is only applied for tooltips and labels not based on a value in the query.

Deactivating the Display of Labels and Tooltips

By default labels as well as tooltips are displayed for the map elements and markers of the geo map report. You can hide labels and/or tooltips by setting the following attributes of the root node of the report assistant to `False`:

Section/Attribute	Description
Common	
Show Labels	Defines whether labels are shown on colored regions of the map.
Show Tooltips	Defines whether a tooltip is displayed on colored regions of the map.

Defining Navigation from the Geo Map Report to Alfabet Views

The geo map report can be configured to open another configured report.

Navigation to a defined configured report from the geo map report requires the following configurations:

1) The labels of the map elements or markers that shall provide the link must be defined in the query.
2) In the native SQL query defined as **Map Element Query** or **Marker Query** of the geo map report, a column must be added for the definition of the navigation target.

   The syntax required for definition of the view is the following:

   `View=Report:`*`ReportName`*

   `ReportName` is the name of the configured report.

   Optionally, values can be handed over to the configured report that opens.

The query of the configured report that opens must contain each parameter definition as an Alfabet parameter defined as

`@ParameterName`

Please note that the old syntax of the Alfabet query language defining Alfabet parameters as:`ParameterName` is not supported.

The Alfabet parameters can be used in `WHERE` clauses of the query without defining a filter for the configured report, because the Alfabet parameter values are already defined in the navigation link.

Optionally, filters can be defined for the configured report to allow the user opening the configured report to alter the Alfabet parameter values. In this case the Alfabet parameter values in the navigation link are used as default values for the filter when opening the configured report. The filter settings are also stored in the user context settings for the configured report. That means, when the user first opens the configured report via drill-down from a chart report and then afterwards opens the configured report in any other context, For example, via the **Configured Reports** functionality, the configured report will open with the last filter settings derived from the drill-down.

For each Alfabet parameter the following string must be added to the navigation target definition:

`&ParameterName=ParameterValue`

The setting of three Alfabet parameters would result in the following navigation link:

`View=Report:ViewName&ParameterName1=ParameterValue1&ParameterName2=ParameterValue2&ParameterName1=ParameterValue2`

3) In the attributes of the root node of the report assistant, enter the name of the column containing the navigation target specification into the attribute **View Column**.

- Coloring of countries/regions
- Setting markers
- Configuring connections between markers

Creating Configured Reports With Editing Capabilities

Software AG offers a number of configured reports that allow object editing:

- A tabular report for multi-editing of object class properties including indicator values and role assignments.
- A Kanban report to maintain and change object relations or enumeration based properties in a tabular or matrix based interface.
- A matrix for multi-editing of business supports.
- A matrix for multi-editing of object relations that provides editability via an editor.
- A matrix for multi-editing of object relations that provides editability directy in the matrix without opening an editor.
- A tabular report for multi-editing of indicators.

- A tabular report for multi-editing of questionaire questions.
- A tabular report providing the functionality available in the standard data capture environments.
- A tabular report providing the functionality of the user administration functionality.

Configured reports with editing capabilities are based on a template.

Configured reports providing a standard data capture environment or access to user administration functionality are of the type Query or NativeSQL and are described in the context of the definition of these types of reports. For more information, see and

- Defining a Data Capture Environment for a Configured Report of the Type Query for the definition of a data capture environment based on an Alfabet query.
- Defining a Data Capture Environment for a Configured Report of the type NativeSQL for the definition of a data capture environment based on a native SQL query.
- Defining a User Management Functionality via a Configured Report of the Type Query for the definition of a user administration functionality based on an Alfabet query.
- Defining a User Management Functionality via a Configured Report of the Type NativeSQL for the definition of a user administration functionality based on a native SQL query.

All other types of configured reports with editing capability are of the type Custom. For these configured reports, a **Report Assistant** is available that allows easy definition of configured report visualization by setting predefined attributes and defining queries. The definition of these configured reports is described in this section.

To generate a configured report with editing capabilities:

- In the **Reports** tab in Alfabet Expand, create a new configured report and define the general attributes for the configured report and the attributes specific for template-based configured reports. For more information about creating a configured report and defining the configured report's attributes, see Creating a New Report for Multi-Editing of Objects below.
- Define a custom report view for the configured report. For more information, see Creating a New Report for Multi-Editing of Objects below.
- Open the **Report Assistant** and configure the configured report.
  - For more information about defining a tabular report for multi-editing of object class properties in an editor, see Defining Tabular Configured Reports for Multi-Editing of Object Class Properties.
  - For more information about defining a Kanban report to maintain and change object relations or enumeration based properties in a tabular or matrix based interface, see Configuring Kanban Reports for Maintenance of Relationships between Objects.
  - For more information about defining a matrix for multi-editing of business supports or object relations, see Configuring Matrices for Multi-Editing of Object Relations or Business Supports.

        - For more information about defining an editable matrix for the specification of the affected architecture for object classes like projects, IT policies, or value nodes, or for the specification of business data usage, see XXX.
        - For more information about defining an editable tabular report for the definition of aspect indicators, see XXX.
        - For more information about defining a tabular report for multi-editing of indicators, see Configuring a Report for Multi-Editing of Indicators.
        - For more information about defining a tabular report providing the functionality available via the **Job Schedule** functionality, see XXX.
    - If the configured report has filters defined, filter fields must be added manually to the custom report view. For more information, see Defining Filters for Configured Reports and Selectors in the chapter Defining Queries.
    - Define access rights for the configured report in the **Reports Administration** functionality of Alfabet. By default, access is possible for all users. For more information, see the chapter *Defining and Managing User Access to Configured Reports* in the reference manual *User and Solution Administration*.
    - Set the state of the configured report to `Active`. For information on how to change theattribute of the configured report, see.

The following information is available:

- Creating a New Report for Multi-Editing of Objects
- Defining Tabular Configured Reports for Multi-Editing of Object Class Properties
    - Configuring a Report to Restrict Drop-Down List Content Via a Query
    - Configuring a Report to Restrict Drop-Down List Content Depending on A Master Control
    - Considering Access Permissions in Configured Reports for Multi-Editing of Object Class Properties
        - Edit Permissions for Objects
        - Edit Permissions for Object Class Properties
- Configuring Kanban Reports for Maintenance of Relationships between Objects
    - Defining the Content and Structure of the Kanban Report
    - Defining the Toolbar Buttons Available for the Kanban Report
    - Defining the Layout of the Kanban Report
    - Defining Tooltips for the Kanban Report
    - Displaying Evaluation Aspects in Kanban Reports
    - Defining Connections between Objects in the Cells of a Kanban Report
    - Defining Navigation from the Kanban to Other Views
- Configuring Matrices for Multi-Editing of Object Relations or Business Supports

Creating a New Report for Multi-Editing of Objects

To create a new configured report with editing capabilities in Alfabet Expand:

1) In the **Reports** tab, right-click the **Reports** folder or a sub-folder thereof and select **Create New Report**. You will see the new configured report listed below the selected folder.

   As an alternative to defining all attributes for a new configured report, you can copy and paste an existing configured report and make modifications, as needed. To do so, right-click the existing configured report that you want to copy and select **Copy**. Right-click the new configured report and select **Paste**. Modify the necessary attributes described below.

2) In the attribute window select `Custom` in the **Type** attribute.
3) In the **Template** attribute, select the template the report shall be based on:
   - `EditableClassViewReport` to create a tabular report for multi-editing of object class properties including indicator values and role assignments.
   - `KanbanReport` to maintain and changing object relations or enumeration based properties in a tabular or matrix based interface.
   - `ITMAP_TableReport` to create a matrix for multi-editing of business supports.
   - `Relationships_TableReport` to create a matrix for multi-editing of object relations that provides editability via an editor.

- `Relationships_EditableTableReport` to create a matrix for multi-editing of object relations that provides editability directy in the matrix without opening an editor.
- `EvaluationReport` to create a tabular report for multi-editing of indicators.

4) In the attribute window, you can define the following attributes according to demand:

- **Name**: Optionally, change the technical name of the configured report. The technical name of the configured report must be unique.

  The technical name is used for identification of the configured report in the context of technical processes such as merging the report configuration with a report configuration saved as an XML file. Therefore, the following is required when defining the name of a configured report:

  - The name must be unique. The name must be unique regardless of the report folder it is structured in.
  - The name may not be changed once a configured report has been created.
  - A validation mechanism checks for correct syntax when defining a technical name. Please note that names may not begin with an empty space nor include special characters. For a list of the special characters that are not allowed, see the section Defining Attributes for Configuration Objects in the chapter Getting Started with Alfabet Expand.
  - If the technical name of the configured report is changed, the name will be correctly updated in other configuration objects referencing the changed report during design time.

  Please note that the name of a changed configuration object will not be updated in guide pages or guide views. If you plan to change the name of a configuration object, the reference in the navigation page should be changed prior to changing the configuration object name. You can use the **Show Usage** functionality in the context menu of the configured report to evaluate whether the configured report has been added to a guide view or guide page.

- **Caption**: Enter a caption for the configured report. The caption you define here will be displayed in the **Reports Administration** functionality in the **Administration** module and the **Configured Reports** views of the Alfabet interface. If the configured report is assigned to an object view as a page view, the text will be displayed as the page view caption in the object view. The caption of the configured report may exceed the conventional 64 character limit.
- **Description**: Provide a short information about the configured report that is useful to Alfabet users. This comment will be displayed on the Alfabet user interface in the header of the configured report in a single line under the report caption and the **Description** field for the configured report in the table of all views listing configured reports, like the **Configured Reports** views of the **Search** functionalities. If the configured report is assigned to an object view as a page view, the text will be displayed under the page view caption as short description in the object view.

  In the configured report, the description will be truncated if it is longer than one line on the screen. Therefore, the description should be short to ensure complete display in the configured report header.

- **Usage Guideline**: Provide information that helps users to execute and interpret the configured report. This information will not be displayed directly on the user interface. The user can access the information using the following mechanisms:
  - If the user moves the cursor over the description provided for the configured report with the attribute **Description**, a tooltip opens that includes both the description and the usage guideline.
  - The **Options** button will be displayed on the upper right with an option **Help On Filter Fields** to open a new window displaying the usage guideline in addition to any filter field hints, if configured.

    For views that have filters defined, the **Options** button will only be displayed if the filter panel either allows batch clearing of filter fields or collapsing and expanding of the filter panel. For more information about the configuration of these functionalities, see Configuring the Complete Filter Area to be Collapsible and Allowing the User to Clear the Filter Area.

- **Technical Comment**: Provide information that is useful for solution designers working with Alfabet Expand in order to better understand the configured report from a technical perspective. The **Technical Comment** will not be displayed in the user interface. Nevertheless, you can configure the interface to display the information in, For example, the attribute section of the configured report's object profile in the **Reports Administration** functionality.
- **Report State**: The **Report State** attribute is view only and is set to `Plan` for new configured reports. The configured report can only be edited when the **Report State** attribute is set to `Plan`. After finishing all configuration steps described in the following, the **Report State** attribute must be set to `Active` as described in the section General Guidelines for Creating Configured Reports. The configured report is then visible to users in the Alfabet user interface.
- **Help Index**: Specify the location of the external Help file using the following syntax:(For example,:). The external help file will be displayed when the user clicks the context-sensitive Help link in the standardHelp menu.

  Server variables can be used in the Help links. Server variables allow you to define all or part of the URL definition in the server alias configuration of the Alfabet Server instead of directly defining it in the configuration in Alfabet Expand. Use of server variables is useful, For example, in order to change a Web server name defined in multiple URL definitions in Alfabet Expand. Instead of changing all URL definitions, only the variable value in the server alias configuration must be updated. The use of server variables is described in the section Using Server Variables in Web Link and Database Server-Related Specifications in the chapter Configuring Reports.

  For matrix based report for data maintenance, Software AG provides a standard help file that can be linked to configured reports to provide help for the user. To specify a link to a page in the standard help in Alfabet, the syntax specified above is not required. The help will be available when the name of the HTML file is entered without any prefix. The following file names can be specified in the **Help Index** for help on reports for multi-editing of objects:

- `Understand_RelationshipsMatrixReport.html` (for `Relationships_TableReport`)
- `Understand_BSMatrixReport.html` (for `ITMPAP_TableReport`)

- **Apply to Class**: When the configured report is applied to a class, a base object can be selected for the configured report. A filter for selection of a base object will automatically be set on top of the configured report. When configuring queries for the configured report, you can use the Alfabet parameter `BASE` to refer to the object selected in the filter and define search conditions dependent on the base object. To apply the configured report to a base object class or object class stereotype, click the **Browse** button to open a dialog box and select the object class or object class stereotype to which you want to apply the configured report and click **OK**.

  Note the following:

  - This parameter is mandatory for configured reports displaying an HTML report about indicators. It is optional for all other configured reports of the type `Custom`.
  - If the configured report is applied to an object class stereotype, the filter field for selection of the base object will use the caption of the object class stereotype as caption of the filter field and the selector defined in the class settings for the object class stereotype for selection of the base object.
  - If the configured report is assigned to the object view of an object of the object class it is applied to, the configured report will automatically open with the current object selected as base object, even if **Apply to Class** is not set.
  - Alternatively, the base object of a configured report can be set with the attribute **Base Query**. While the attribute **Apply to Class** enables the user to determine the current base object by setting a filter, the **Base Query** evaluates the base object by execution of a query when opening the configured report. A filter field is not available and the user cannot change the base object.
  - The attribute **Apply to Class** also influences the availability of the configured report on the Alfabet interface. Select a class to make the configured report available in the **Configured Reports** page view on the object view of objects of the selected object class. If you do not set the attribute, the configured report is only available in the **Configured Reports** functionality. The configured report can be assigned to object views and wizards independent from the parameter.

- **Base Object Query**: When a base object query is defined for the configured report, a base object is evaluated for the configured report at runtime. When configuring the other queries for the configured report, you can use the Alfabet parameter `BASE` to refer to the object returned by the base object query and define search conditions dependent on the base object. To apply the configured report to a base class, click the **Browse** button to open a text editor, define either a native SQL query or an Alfabet query that returns a single object, and click **OK**.

Note the following:

- Alternatively, the base object of a configured report can be set with the attribute **Apply To Class**. While the setting of **Base Object Query** triggers the evaluation of the base object by execution of a query when opening the configured report, the attribute **Apply to Class** enables the user to determine the current base object by setting of an automatically generated filter.
- The query defined for base object query is executed when the user opens the configured report to evaluate the base object at runtime. Alfabet parameters referring to the current working environment can be used in the query to find a base object dependent For example, on the user opening the configured report or the user profile used for login. A base object query may also find For example, the ICT object that a specific application is currently assigned to.
- If **Base Object Query** is set and the configured report is assigned as a view to an object profile, the Alfabet parameter `BASE` referring to the `REFSTR` of the object the user is working with when opening the configured report can be used in the base object query.

- **Selector Behavior**: The attribute can be used to exclude configured reports that are defined for special purposes, like For example, triggering of data export via the RESTful API, from being selectable in the **Configured Reports** table. By default, the attribute is set to `Visible` and the configured report is visible in the selector for adding configured reports to the **Configured Reports** table if all other conditions for access to the configured report apply. If the attribute is set to `NotVisible`, the configured report is excluded from the selector for adding configured reports to the **Configured Reports** functionality. Please note however, that this setting is not excluding the configured report from any standard views or customer configured views and selectors, but exclusively from the standard selector for configured reports implemented in Alfabet.

The attribute cannot be edited in the attribute window directly. To change the setting, right-click the configured report and select **Set Report Selector Behavior to 'Not Visible'** or **Set Report Selector Behavior to 'Visible'** respectively.

- **Applicable for AlfaBot**: Specify whether the configured report is accessible via the AlfaBot. By default, the attribute will be set to `True` for new reports. Set the attribute to `False` if the configured report should not be opened outside of a specific context. For example, this may be relevant for reports that are specifically designed to be embedded in an object cockpit.

  This attribute is only relevant if the AlfaBot is implemented. For information about the implementation of the AlfaBot, see Implementing the AlfaBot for Navigation via a Full-Text Command.

- **Business Problem Statement**: Optionally enter a description that will help users to search for the configured report in the AlfaBot. The text is not displayed in the user interface, but it is of special relevance for the search mechanisms implemented for the AlfaBot. If the report caption entered by the user in the AlfaBot for a request to open a configured report does not match the caption of one of the available configured reports, the AlfaBot will split the caption entered by the user into keywords and will perform a keyword search on the **Caption**, **Description** and the **Business Problem Statement** attributes of the configured reports that are accessible via the AlfaBot. In addition to a keyword search, a synonym search is performed on the text provided in the **Business Problem Statement** attribute.

This attribute is only relevant if the AlfaBot is implemented. For information about the implementation of the AlfaBot, see Implementing the AlfaBot for Navigation via a Full-Text Command.

- **Base Classes**: Define the object classes that must be available to run the configured report. If this attribute is set, the Alfabet Server checks whether the object classes specified as base classes are excluded from the view scheme used to access the configured report. If the user does not have access permissions to one of the base classes, the configured report will be disabled. To set the attribute, click the **Browse** button to select the object classes that are required to run the configured report and click **OK**.
- **Can Create Express View**: Select `True` if an express view may be created for the report. Select `False` if an express view may not be created for the report. Please note that for reports that have a custom report view, the setting must be consistent with the setting of the attribute **Can Create Express View** of the custom report view.

  An express view is a link to a specific Alfabet view displaying data that allows individuals inside or outside of the user community to view information in Alfabet. When the express view is created, an email notification is automatically mailed to a specified recipient. The recipient receives a URL that allows him/her to access the current page view in Alfabet. For more information, see the section *Sending and Receiving Express Views* in the reference manual *Getting Started with Alfabet*.

5) In the explorer, right-click the configured report and select **Create Custom Report View**. The view editor opens. In the explorer, the custom report view is displayed as a subordinate object of the configured report. The attributes for the custom report view are displayed in the attribute window. You can optionally edit the following attributes:
   - **Name**: Optionally you can change the name for the custom report view. The **Name** must be unique for custom report views.
   - **Can Create Bookmark**: Select `True` if a bookmark may be created for the configured report. Select `False` if a bookmark may not be created for the configured report.
   - **Can Create Express View**: Select `True` if an express view may be created for the configured report. Select `False` if an express view may not be created for the configured report. Please note that the setting must be consistent with the setting of the attribute **Can Create Express View** of the configured report.

     An express view is a link to a specific Alfabet view displaying data that allows individuals inside or outside of the user community to view Alfabet information. When the express view is created, an e-mail notification is automatically mailed to the specified recipient who receives a URL that allows him/her to access the current page view in Alfabet. For more information, see *Sending and Receiving Express Views* in the reference manual *Getting Started with Alfabet*.

   The custom report view initiates the **Report Assistant**. A custom report view shall never be deleted from the configured report after the **Report Assistant** was already used to configure the report. When you delete the custom report view of an existing template-based configured report and create a new one, the **Report Assistant** is reset to the example specified by default and your configuration is lost.

6) In the explorer, right-click the configured report and select **Start Alfabet Report Assistant**. The **Report Assistant** opens.

7) Define the configured report as described below in the sections for the configuration of the different configured report types:

   - Defining Tabular Configured Reports for Multi-Editing of Object Class Properties (for configured reports based on the template `EditableClassViewReport`)
   - XXX (for configured reoprts based on the template `KanbanReport`)
   - Configuring Matrices for Multi-Editing of Object Relations or Business Supports (for configured reports based on the templates `Relationships_TableReport` and `Relationships_EditableTableReport`)
   - Configuring a Report for Multi-Editing of Indicators (for configured reports based on the template `ITMAP_TableReport`)

8) Edit the parameter panel for the configured report according to demand. For more information, see Defining Filters for Configured Reports and Selectors.

   Please note that the **Submit** button must not be deleted for configured reports based on the templates `ITMPAP_TableReport` or `Relationships_EditableTableReport` if these reports are not included into a wizard but opened as separate view on the Alfabet user interface. The **Submit** button is required to submit changes made in the dataset.

9) Click **OK** to save the configuration.

10) In the toolbar, click the **Save** button to save your changes.

11) In the explorer, right-click the configured report and select **Review Report**. The configured report opens in a web browser. If the results are not as expected, you can edit the configured report until the output of the configured report meets your expectations.

    Please note the following:

    - In the **Review Report** functionality the ability to edit objects is disabled.
    - The **Configure Report** functionality allows the visibility of toolbar buttons of the configured report to be defined for different view schemes. For more information, see Refining Visibility Issues in the View Scheme.

Defining Tabular Configured Reports for Multi-Editing of Object Class Properties

The report is configured in the report assistant opening for configured reports based on the template `EditableClassView`. For information about creating the report and opening the report assistant, see Creating a New Report for Multi-Editing of Objects.

The **Report Assistant** allows you to define both the content of the tabular dataset and the editor of the report:

1) In the **Data Source Definition** tab of the **Report Assistant**, define one of the following:

   - A native SQL query selecting all properties of a single object class. To define the query, click the **Browse** button in either the **Alfabet Query** attribute to open the **Alfabet Query Builder** or in the **Query as Text** attribute to open a text editor.

- An Alfabet query without **Show Properties**.

  To open the **Alfabet Query Builder**, click the **AQL Builder** button. To define the query, click the **Browse** button in either the **Native SQL Query** attribute to open the Alfabet specific native SQL editor with enhanced usability for the definition of Alfabet query language instructions or in the **Query as Text** attribute to open a text editor.

The definition of `WHERE` conditions and `JOIN`s (`FROM` clauses in Alfabet queries) is only allowed for the definition of filters for the report or for reducing the dataset in the report to a subset of objects of the selected object class. Object class properties of joint object classes are not included into the column definitions of the configured report. The configured report is exclusively handling one object class.

It is recommended to define the query to return only objects editable for the current user, taken the implemented access permission concepts into account.

To build a configured report view for editing of the object class properties of the class **Information Flow**, a native SQL query without filter definitions will read:

```
SELECT * FROM INFORMATIONFLOW
```

2) Go to the **Default Layout** tab. The table displays all object class properties of the selected object class as well as indicators and role types assigned to the selected object class. The property caption is displayed in the column **Property** and the property type is displayed in the column **Type**. Clicking a column header sorts the table rows according to the values in the column.

Please note:

- Aspect indicators and project indicators are not editable via the configured report and not included into the dataset.
- Computed indicators are configured to be non-editable for users. They are included into the dataset with a checkmark in the column **Computed** to mark them as computed. For these editors, the definition as **View Only** cannot be changed.

3) Define the visibility and editability of each property in the following columns by clicking into a table cell to set a checkmark or remove a set checkmark:

- **Exclude**: Set a checkmark to exclude the property from both the table in the view and the editor.

  If you want to exclude most properties, you can use the button **Exclude all** in the toolbar above the table to first set a checkmark in all columns and then only remove the checkmark in the columns you want to view. The button **Include all** removes all checkmarks in the **Exclude** column.

- **Show in Editor**: Remove the checkmark if the property shall not be included into the editor.

- **View Only**: Set a checkmark if the property shall be displayed non editable in the editor, For example, to provide additional information required for editing to the user. The setting is only taken into account if **Show in Editor** is also checked for the property.

If you would like to set identical values in the columns for all properties of a defined data type, you can use the **Group Settings** button on top of the table to perform the changes. The **Group Settings** button opens an editor. Specify the following and then click **OK** to change the visibility and editability settings according to your specification:

- **Attribute Types**: Select the checkbox of all property types the changes shall be applied to.
- **Role in Editable View**: Select the checkbox of all columns in the table the changes shall be applied to.
- **Include All** / **Exclude All**: Select whether you would like to exclude or include all of the selected attribute types in the selected columns of the table.

4) In the table, change the order of rows in the dataset to define the column order in the table of the resulting configured report and editor. The row order from top to bottom in the **Report Assistant** corresponds to the order of columns in the report from left to right, or from right to left when rendering the interface in Arabic language.

   To change the position of one or multiple rows, select the rows in the table and use the following buttons in the toolbar to change the position of the selected rows:

- **Move down**  : Click to move the selected row(s) one position down.
- **Move up**  : Click to move the selected row(s) one position up.
- **Move to top**  : Click to move the selected row(s) directly to the top of the dataset.

If you click one of the header cells of the dataset, the columns are resorted according to the values in the column that you clicked and you will loose your defined sort order. It is recommended to click the **OK** button close the **Report Assistant** after having defined the sort order of columns for presentation in the configured report and editor. Reopen the **Report Assistant** again. If you then change the sort order by chance, you can click **Cancel** to revert to the version stored before last opening of the **Report Assistant**.

5) If you want the first columns in the editor and in the result dataset to stay visible during horizontal scrolling, you can select the number of columns that shall be frozen during scrolling in the field **Number of Frozen Columns** above the table. If the first columns in the dataset include columns that are excluded from display in the editor, the number of frozen columns in the editor will be reduced by the number of excluded columns. This ensures that the same information remains visible on scrolling in the result dataset and in the editor.

The value defined here can be overwritten per user profile with the **Configure**  button available to the users working with the configured report and to solution designers opening the Alfabet user interface via the **Configure User Profile** option in the context menu of a user profile in the **Admin** tab. For more information, see Configuring User Profiles for the User Community. For more information about the handling of columns in views in the Alfabet user interface, see the section *Working with Data in Tabular Datasets* in the reference manual *Getting Started with Alfabet*.

Please note that the option to change the sort order of columns usually available via the **Configure** button is not available for this type of configured report.

6) If you want the rows displayed in the configured report to be sorted by the values in a column of the configured report, select the row in the dataset that represents the column in the configured report and click the **Add to Sort By** button in the toolbar above the dataset. The column is added to the field **Sort by** below the dataset. You can add multiple rows to the **Sort by** field either one by one or by selecting multiple rows in the datset prior to clicking the the **Add to Sort By** button.

   Sorting is performed in the order of the sort options in the **Sort by** field. The values in the column in the configured report that corresponds to the first row in the **Sort by** field is sorted alphanumerically in ascending order. The values of the column in the configured report that corresponds to the next row in the **Sort by** filed is then only sorted within the identical results for values of the already sorted column. You can change the sort order of the rows in the Sort by field with the buttons **Move down** and **Move up** in the toolbar above the **Sort by** field.

   You can remove a sort option by selecting it in the **Sort by** field and click the **Delete** button in the toolbar above the **Sort by** field.

   The user can change the sorting at runtime by clicking in the header of the column he/she want to sort by.

7) Go to the **Options** tab. An explorer is displayed with an attribute window on the right that lists the attributes of the node selected in the explorer. The explorer displays all relevant properties and role types available for the object class to be edited. Object class properties are excluded from display if they are marked as **Exclude** or **View Only** in the **Default Layout** tab. Only object class properties of the data type `String` or `Reference` are displayed. Object class properties of other data types and indicator types are not available in the explorer, because no attributes can be set for them.

8) In the attribute window of the root node, define the following for the processing of changes to the meta-model and to the reference data configuration:

   - **Add New Class Properties**: If set to `True`, a new object class property created for the object class in Alfabet Expand is automatically added to the bottom of the dataset in the tab **Default Layout** of the configured report. If set to `False`, the new role type must be added explicitly to the dataset in the configured report by clicking the button **Refresh Available Properties** in the **Default Layout** tab. For both methods, the object class property added to the dataset will be configured to be both visible and editable in the configured report. The default is `False`.
   - **Automatically Add New Indicator Types**: If set to `True`, and a new evaluation type is assigned to the object class in the **Class Configuration** functionality, the indicator(s) of the evaluation type are automatically added to the bottom of the dataset in the tab **Default Layout** of the configured report. If set to `False`, the new indicator(s) must be added explicitly to the dataset in the configured report by clicking the button **Refresh Available Properties** in the **Default Layout** tab. For both methods, the indicator added to the dataset will be configured to be both visible and editable in the configured report. The default is `True`.
   - **Automatically Add New Role Types**: If set to `True`, a new role type is assigned to the object class in the **Class Configuration** functionality is automatically added to the bottom of the dataset in the tab **Default Layout** of the configured report. If set to `False`, the new role type

must be added explicitly to the dataset in the configured report by clicking the button **Refresh Available Properties** in the **Default Layout** tab. For both methods, the role type added to the dataset will be configured to be both visible and editable in the configured report. The default is `True`.

9) In the attribute window of the root node, define the following for the behaviour of the edit capabilities in the configured report:

- **Validate Edit Permissions**: If set to `True`, access permissions of the user are evaluated when the user opens the editor. If objects selected by the user are not editable for the user because of any of the implemented access permission concepts, the objects are not displayed in the editor. If none of the objects is editable, an empty editor might open. Therefore, it is recommended to define the query of the configured report to take access permission concepts of the user into account and display only editable objects in the dataset. If **Validate edit permissions** is set to `False`, the user can edit any object in the editor even if the access permission concepts implemented would not allow him/her to edit the object. The default is `True`.

- **Enforce Property Editability Rules**: If set to `True`, the editability of the properties in the editor will depend on the editability of the property in the editor or wizard for the base object class used in the class settings for the object profile:

  - If the **Read-Only** attribute of the editor interface control is set ot `True`, the property will not be editable for all objects, even if explicitly defined as editable in the configured report.

  - If a condition defined in the **Read-Only Condition** attribute of the editor inhibits editing for a specific object, the property will not be editable for the specific object. The default is `False`.

  - If a validator is defined with the attribute Validator of an object class property, the validation is also performed in the editor of the configured report.

  - If the editor for the base object class checks whether start dates are set to a date prior to end dates, the validation of start and end dates is also performed in the editor of the configured report.

  Please note the following:

  - Evaluation of conditions requires a lot of computing capacity. Therefore, the number of objects that are simultaneously editable should be set to a small number with the attribute **Max Number of Records** if **Enforce Property Editability Rules** is set to `True`.

  - The restrictions based on editability in editors and wizards are not applied to editing in the **Set All** functionality.

  - Wizard Step conditions are not evaluated for the editor in the configured report.

- **Max Number of Records**: Defines the maximum number of objects that can be edited simultaniously in the editor. If the user selects more objects for editing, some of the selected objects are not displayed for editing and the user will be informed about that via a message on top of the editor.

- **Restrict Properties to Editor/Wizard Definition**: If set to `True`, properties not ediable to the user via an editor or wizard will also be automatically set to view only in the editor of the configured report. This is independent of the editability setting in the **Default Layout** tab.
- **Enable 'Set All' for Class Properties**: If set to `True`, the user can select multiple objects in the table of the configured report, select **Properties** from the drop-down list of the button **Set all** and open an editor to set identical values for properties of all selected objects. The user first selects the properties to be reset. Then he/she assignes one value to each selected property and these values are then set for all selected objects when the user closes the editor. If set to `False`, the option **Properties** is not visible in the dropdown list of the **Set all** button.
- **Enable 'Set All' for Indicators**: If set to `True`, the user can select multiple objects in the table of the configured report, select **Indicators** from the drop-down list of the button **Set all** and open an editor to set identical values for indicators of all selected objects. The user first selects the indicators to be reset. Then he/she assignes one value to each selected indicator and these values are then set for all selected objects when the user closes the editor. If set to `False`, the option **Indicators** is not visible in the dropdown list of the **Set all** button.
- **Enable 'Set All' for Role Types**: If set to `True`, the user can select multiple objects in the table of the configured report, select **Role types** from the drop-down list of the button **Set all** and open an editor to set identical values for roles of all selected objects. The user first selects the role types to be reset. Then he/she assignes one value to each selected role type and these values are then set for all selected objects when the user closes the editor. If set to `False`, the option **Role types** is not visible in the dropdown list of the **Set all** button.

10) If your data includes properties that are returning a color, click the object class property returning the color in the explorer and set the attribute **Is Color** to `True`. The table of the configured report will then show the colors defined with the attributes as background color of the respective cells for the property and a color picker will be available in the editor to change the color. If the attribute is set to `False`, the hexadecimal color code is displayed in the table of the configured report and the user must enter the hexadecimal color code for the color into a text field in the editor.

11) Optionally define how the selection of objects for properties of the type `Reference` or the selection of objects of the class `Person` for role types shall be handled in the editor. Click on the node of the object class property or role type in the explorer and configure the attributes according to the descriptions below.

    By default, the editor in the configured report will display a drop-down list with all available objects of the object class the property allows to add. For example, the dropdown list for the property Application Group of the object class Application will list all application groups in the database. For performance reasons, the number of objects displayed in the combo box is limited to 300. This might cause objects in your database to be unavailable for selection.

    There are three methods to change the content of the dropdown list to a limited number of available objects:

    - The field can be configured to display a text box with a autocomplete functionality and, optionally, a selector button. If the user starts typing into the field, a dropdown list with objects is displayed with the name starting with the already typed in text. The user can stop typing after the dropdown list is conveniently small and select the object from the remaining values in the dropdown list. Set the following attributes:
        - **Property enumeration type**: Select `LookAhead` from the drop-down list.

- **Selector Name**: Optionally, select a custom selector from the drop-down list. Selection of a custom selector provides the following functionality:
  - The user can open the selector via a button displayed at the end of the field and select the object from the selector.
  - The autocomplete functionality searches for matches only within the subset of objects that match the query defined in the **Lookahead** attribute of the selector.

  A custom selector must be available for the object class to attach a selector to the autocomplete field. Standard selectors are not considered. For information about creating a custom selector, including the definition of the query for the auto-fill function in selectors, see the section Configuring a Custom Selector for Search Functionalities.

- The field can be configuring to display a dropdown list filled only with objects found by a configured report that defines a subset of the object that are available in the database. For example, the users displayed in a dropdown list for defining a role can be limited to the users that are in the same user group than the authorized user of the currently edited object. The configured report can reference the objects currently selected by the user for editing or which filters have been set for the configured report for multi-editing of objects when opening the editor. After having defined the configured report for the dropdown list content as described below in the section Configuring a Report to Restrict Drop-Down List Content Via a Query, set the following attributes:
  - **Property enumeration type**: Select `Simple` from the dropdown-list.
  - **Enumeration provider name**: Select the name of the configured report providing information about the objects to be found.
  - **Parameters mapping**: f your secondary configured report contains filters, click the Browse button of the **Parameters mapping** attribute to open an editor that allows mapping of the parameters in the secondary report with the filter fields or selected objects of the configured report for multi-editing of objects.

The column **Query Parameter Name** lists all parameters defined in the query of the secondary report.

In the column **Control Name**, select the filter field defined for the configured report for multi-editing of properties that the parameter refers to. Please note that filter fields are only listed here if they are already defined in the report's filter panel and not only as parameter in the query of the configured report for multi-editing of properties. If you select:`SELECTION`, the value of the `REFSTR` of the objects that are currently displayed for editing in the editor of the report are returned to fill the parameter.

- The field can be configured to display a dropdown list filled with values that depend on the setting of another property of the type `Reference` of the object class edited in the configured report for multi-editing of objects. The information about which objects are permissable to select in the dropdown list for which setting of the master property is read from a linked, secondary report of the type `Query` or `NativeSQL`. After having defined the configured report for the dropdown list content as described below in the section Configuring a Report to Restrict Drop-Down List Content Depending on A Master Control, set the following attributes:
  - **Property enumeration type**: Select `Dependent` from the dropdown-list.

- **Enumeration provider name**: Select the name of the configured report providing information about the objects to be found.
- **Master Field**: Select the master property from the dropdown list of the attribute. The list also includes properties that are excluded from display and editability of the configured report for multi-editing of properties. The dependency is also evaluated for non-visible properties.
- **Parameters mapping**: f your secondary configured report contains filters, click the Browse button of the **Parameters mapping** attribute to open an editor that allows mapping of the parameters in the secondary report with the filter fields or selected objects of the configured report for multi-editing of objects.

The column **Query Parameter Name** lists all parameters defined in the query of the secondary report.

In the column **Control Name**, select the filter field defined for the configured report for multi-editing of properties that the parameter refers to. Please note that filter fields are only listed here if they are already defined in the report's filter panel and not only as parameter in the query of the configured report for multi-editing of properties. If you select:`SELECTION`, the value of the `REFSTR` of the objects that are currently displayed for editing in the editor of the report are returned to fill the parameter.

12) Click **OK** to close the report assistant and locally save your changes.

13) Click the **Save** button in the toolbar of Alfabet Expand to save your changes to the Alfabet database.

Configuring a Report to Restrict Drop-Down List Content Via a Query

The drop-down lists that are displayed for properties of the type `Reference` and for role types in the editor of a configured report for multi-editing of objects by default display all objects available for the selectable object class. for roles, this is the object class `Person`, for references, this is the target object class of the reference.

It is possible to restrict the number of objects that can be selected in the dropdown list. the selection is defined in a separate configured report of the type `Query` or `NativeSQL` that is then linked to the respective dropdown list in the **Options** tab of the configured report for multi-editing of object data.

The subordinate report must return the following information in the given order:

- The `FIND` class of the Alfabet query or the first `SELECT` argument of the native SQL query must return the `REFSTR` of the object class for that objects shall be listed in the dropdown list.
- The first column in the resulting visible dataset must return the `REFSTR` of an object edited by the user. This column can alternatively return `NULL` if the selection in the combobox shall not depend on the object that is currently edited.
- The second column in the resulting visible dataset must return the property of the object permitted as a reference that will be displayed in the dropdown list to identify the object. Make sure that the property is set for all objects. If it is not set, an empty row will be displayed for the object in the dropdown list.

Additional columns in the report will be ignored.

Note the following about the definition of the secondary report:

- For each drop-down list in the editor of the configured report for multi-editing of object data, results in the secondary report to fill the dropdown list are displayed if the first column in the report returns the REFSTR of the object that is edited via the dropdown list or it returns NULL.
- Results that return NULL in the first column of the report are displayed in the dropdown lists of all edited objects.
- If none of the rows of the secondary report returns either NULL or the REFSTR of the current object, the drop-down list is empty.
- The drop-down list is filled with the results as returned in the secondary report. It is recommended to sort the result dataset according to demands.
- If an object is listed twice in the result dataset of the secondary report, it will also be listed twice in the result dataset.

The report can include parameters in `WHERE` conditions. The parameter values can then be mapped to filter values set in the report for multi-editing of objects and to the current selection of objects in the editor. The secondary configured report must not have an own filter panel defined.

Please note the following:

- The current selection of objects to be edited returns a comma separated list of strings.

  This requires the following synthax of a `WHERE` condition refering to the current selection via a parameter:

  - In native SQL:

    ```
    WHERE CLASSNAME.REFSTR IN (@CurrentSelection)
    ```

  - In Alfabet query language:

    ```
    WHERE ClassName.REFSTR IN (:CurrentSelection)
    ```

- The parameter that refers to the currently selected objects must be mapped to the keyword:`SELECTION` in the configuration of the configured report for multi-editing of objects.
- The parameters in the secondary report must not exceed the number of filter fields plus one (for the selection) defined for the configured report for multi-editing of object properties.
- The names used for the parameters do not have to match the names of the filter fields in the report for multi-editing of objects. The mapping is done in the configuration of the configured report for multi-editing of objects.
- Alfabet query language parameters refering to the curent environment, like `CURRENT_USER`, can be used in the secondary report. The parameter `BASE` can be used in the secondary configured report to refer to the base object selection of the configured report for multi-editing of objects. this is a standard parameter and does not require any mapping in the configuration of the configured report for multi-editing of objects. The secondary report itself must not be applied to a class.

After having defined the secondary configured report and having set the **Report State** of the report to **Active**, the configured report for multi-editing of objects must be defined to use the report for object selection of the target drop-down list:

1) In the report assistant of the configured report for multi-edition of objects, go to the **Options** tab.

2) In the explorer, click the property of the type `Reference` or the role for that you would like to define the dropdown-list content.

3) Set the following attributes:

- **Property enumeration type**: Select `Simple` from the dropdown-list.
- **Enumeration provider name**: Select the name of the configured report providing information about the objects to be found.
- **Parameters mapping**: If your secondary configured report contains filters, click the Browse button of the **Parameters mapping** attribute to open an editor that allows mapping of the parameters in the secondary report with the filter fields or selected objects of the configured report for multi-editing of objects.

The column **Query Parameter Name** lists all parameters defined in the query of the secondary report.

In the column **Control Name**, select the filter field defined for the configured report for multi-editing of properties that the parameter refers to. Please note that filter fields are only listed here if they are already defined in the report's filter panel and not only as parameter in the query of the configured report for multi-editing of properties. If you select:`SELECTION`, the value of the `REFSTR` of the objects that are currently displayed for editing in the editor of the report are returned to fill the parameter.

4) Click **OK** to close the report assistant and locally save your changes.

5) Click the **Save** button in the toolbar of Alfabet Expand to save your changes to the Alfabet database.

Configuring a Report to Restrict Drop-Down List Content Depending on A Master Control

The drop-down lists that are displayed for properties of the type `Reference` and for role types in the editor of a configured report for multi-editing of objects by default display all objects available for the selectable object class. for roles, this is the object class `Person`, for references, this is the target object class of the reference.

It is possible to restrict the number of objects that can be selected in the dropdown list. the selection is defined in a separate configured report of the type `Query` or `NativeSQL` that is then linked to the respective dropdown list in the **Options** tab of the configured report for multi-editing of object data.

The subordinate report must return the following information in the given order:

- The first column in the resulting visible dataset must return the `REFSTR` of the object class for that objects shall be listed in the dropdown list.
- The second column in the resulting visible dataset must return the `REFSTR` of an object edited by the user. This column can alternatively return `NULL` if the selection in the combobox shall not depend on the object that is currently edited.

Please note:

- For each drop-down list in the editor of the configured report for multi-editing of object data, results in the secondary report to fill the dropdown list are displayed if the first column in the report returns the REFSTR of the object that is edited via

the dropdown list or it returns NULL and the second column in the report returns the REFSTR of the object selected in the master field.

- Results that return NULL in the first column of the report are displayed in the dropdown lists of all edited objects.
- If none of the rows of the secondary report returns either NULL or the REFSTR of the current object, the drop-down list is empty.

- The third column in the resulting visible dataset must return the REFSTR of an object that may be or may have been selected in the master field.

  Please note:

  - The master property does not have to be editable or visible in the dataset of the configured report for multi-editing of objects. Any property of the type Reference can be selected as master property.
  - The secondary report is only executed once on opening of the editor. If the master property is editable, the second column of the secondary report shall return not only the REFSTR of objects currently selected in the of the master field, but also take the REFSTR of all objects into account that might be selected by the user editing the master field. If the first column of the secondary report returns the REFSTR of a currently edited object, the combination of the currently edited object with all objects selectable in the master fields must be available in the configured report. It is recommended to set the first column to NULL in case of editable master fields to keep the number of rows in the secondary configured report low.

- The fourth column in the resulting visible dataset must return the property of the object permitted as a reference that will be displayed in the dropdown list to identify the object. Make sure that the property is set for all objects. If it is not set, an empty row will be displayed for the object in the drop-down list.

  Please note:

  - The drop-down list is filled with the results as returned in the secondary report. It is recommended to sort the result dataset according to demands.
  - If an object is listed twice in the result dataset of the secondary report, it will also be listed twice in the result dataset.

Additional columns in the report will be ignored.

The report can include parameters in **WHERE** conditions. The parameter values can then be mapped to filter values set in the report for multi-editing of objects and to the current selection of objects in the editor. The secondary configured report must not have a own filter panel defined.

Please note the following:

- The current selection of objects to be edited returns a comma separated list of strings.

  This requires the following synthax of a `WHERE` condition refering to the current selection via a parameter:

- In native SQL:

  ```
  WHERE CLASSNAME.REFSTR IN (@CurrentSelection)
  ```

- In Alfabet query language:

  ```
  WHERE ClassName.REFSTR IN (:CurrentSelection)
  ```

- The parameter that refers to the currently selected objects must be mapped to the keyword:`SELECTION` in the configuration of the configured report for multi-editing of objects.
- The parameters in the secondary report must not exceed the number of filter fields plus one (for the selection) defined for the configured report for multi-editing of object properties.
- The names used for the parameters do not have to match the names of the filter fields in the report for multi-editing of objects. The mapping is done in the configuration of the configured report for multi-editing of objects.
- Alfabet query language parameters refering to the current environment, like `CURRENT_USER`, can be used in the secondary report. The parameter `BASE` can be used in the secondary configured report to refer to the base object selection of the configured report for multi-editing of objects. this is a standard parameter and does not require any mapping in the configuration of the configured report for multi-editing of objects. The secondary report itself must not be applied to a class.

After having defined the secondary configured report and having set the **Report State** of the report to **Active**, the configured report for multi-editing of objects must be defined to use the report for object selection of the target drop-down list:

1) In the report assistant of the configured report for multi-editing of objects, go to the **Options** tab.
2) In the explorer, click the property of the type `Reference` or the role for that you would like to define the dropdown-list content.
3) Set the following attributes:
   - **Property enumeration type**: Select `Dependent` from the dropdown-list.
   - **Enumeration provider name**: Select the name of the configured report providing information about the objects to be found.
   - **Master Field**: Select the master property from the dropdown list of the attribute. The list also includes properties that are excluded from display and editability of the configured report for multi-editing of properties. The dependency is also evaluated for non-visible properties.
   - **Parameters mapping**: f your secondary configured report contains filters, click the Browse button of the **Parameters mapping** attribute to open an editor that allows mapping of the parameters in the secondary report with the filter fields or selected objects of the configured report for multi-editing of objects.

The column **Query Parameter Name** lists all parameters defined in the query of the secondary report.

In the column **Control Name**, select the filter field defined for the configured report for multi-editing of properties that the parameter refers to. Please note that filter fields are only listed here if they are already defined in the report's filter panel and not only as parameter in the query of the configured report for multi-editing of properties. If you select:`SELECTION`, the value of the `REFSTR` of the objects that are currently displayed for editing in the editor of the report are returned to fill the parameter.

4) Click **OK** to close the report assistant and locally save your changes.

5) Click the **Save**  button in the toolbar of Alfabet Expand to save your changes to the Alfabet database.

Considering Access Permissions in Configured Reports for Multi-Editing of Object Class Properties

Various settings in the configured report as well as in the Alfabet meta-model are available to ensure that the edit permissions of a user for objects and for individual properties are taken into account:

- Edit Permissions for Objects
- Edit Permissions for Object Class Properties

Edit Permissions for Objects

Edit permissions of the user are only taken into account if the configured report is configured to evaluate edit permissions.

In the dataset, this is done via the query that may For example, restrict display to objects for that the current user is the authorized user. If the query of the configured report does not take editability of the object for the current user into account, the table will also display objects that are not editable.

In the editor, access permissions are taken into account by default. If the user selects objects in the dataset and opens the editor, only the subset of the selected objects that are editable by the user are displayed in the editor. If the user selects only objects that are not editable for him/her, an empty editor opens. If no objects are selected, the **Edit** button is deactivated.

In the **Options** tab of the report assistant of the configured report, the validation of edit permissions for the current user can be deactivated by setting the attribute **Validate Edit Permissions** to `True`. The user can then edit objects that he/she has no edit permissions for according to the implemented access permission concepts in Alfabet.

Edit Permissions for Object Class Properties

By default, all object class properties, indicators and roles of a selected object class are visible and editable in the configured report for multi-editing of object class properties. The following methods are available to exclude individual object class properties from beeing editable:

- In the **Default Layout** tab of the report assistant, a checkmark can be set in the column Exclude to exclude the property from the report's dataset and the editor and the **Set All** functionalities.
- In the **Default Layout** tab of the report assistant, the checkmark in the column **Show in Editor** can be deselected to exclude the property from the editor and the **Set All** functionalities without excluding it from the dataset.
- In the **Default Layout** tab of the report assistant, the checkmark **View Only** can be selected in combination with the **Show in Editor** checkmark to include the property view only into the editor. The property will not be available in the the **Set All** functionalities.

- By default, object class properties that are defined in the **Default Layout** tab of the report assistant to be editable are editable in the configured report even if the user has no edit permissions for the object class property via an editor or wizard. This behavior can be changed by setting one of the following attributes of the root node of the **Options** tab of the report assistant. the options:
  - **Enforce Property Editability Rules**: If set to `True`, the editability of the properties in the editor will depend on the editability of the property in the editor or wizard for the base object class used in the class settings for the object profile. If the **Read-Only** attribute of the editor interface control is set ot `True`, the property will not be editable for all objects, even if explicitly defined as editable in the configured report. If a condition defined in the **Read-Only Condition** attribute of the editor inhibits editing for a specific object, the property will not be editable for the specific object. The default is `False`.

    Please note the following:
    - Evaluation of conditions requires a lot of computing capacity. Therefore, the number of objects that are simultaneously editable should be set to a small number with the attribute **Max Number of Records** if **Enforce Property Editability Rules** is set to `True`.
    - The restrictions based editability in editors and wizards are not applied to editing in the **Set All** functionality.
  - **Restrict Properties to Editor/Wizard Definition**: If set to `True`, properties not editable to the user via an editor or wizard will also be automatically set to view only in the editor of the configured report. This is independent of the editability setting in the **Default Layout** tab. The restrictions based editability in editors and wizards are not applied to editing in the **Set All** functionality.
- If a custom object class property shall not be editable in any configured report for multi-editing of object class properties, even if the user can edit the property in an editor and wizard, the attribute object class property **Disable Mass Update** of the object class property can be set to `True`. The column **View Only** cannot be deselected for the property in any report assistant for configured reports for mass update of object class properties. The property will not be editable in the editor an not be available in the **Set All** functionalities. The **Disable Mass Update** attribute can only be set for custom properties. For private and protected standard Alfabet object class properties, this attribute cannot be set and is `False` by default.

Configuring Kanban Reports for Maintenance of Relationships between Objects

The report is configured in the report assistant opening for configured reports based on the template `KanbanReport`. For information about creating the report and opening the report assistant, see Creating a New Report for Multi-Editing of Objects.

The content and layout of a Kanban report is defined by adding elements to the explorer of the **Report Assistant** and setting the attributes in the attribute pane of the **Report Assistant** window.

The following table lists the explorer node elements that can be configured to specify the content of the report as well as provides information about the purpose of each sub-element:

Explorer Node Element	Required to Configure:
Root Node	Definition of the functionality and layout of the report.
Cells	Definition of the cell content. The element is a container for one or multiple elements ***Query*** that define the objects displayed in the cells of the report. Only one object class can be used for display in cells. If you define multiple queries, they must all return objects of the same class.
Columns	Definition of the column header. The element is a container for one or multiple elements ***Query*** that define the objects displayed in the column header. Only one object class can be used for display in column headers. If you define multiple queries, they must all return objects of the same class.
Rows	Definition of the row header. The element is a container for one or multiple elements ***Query*** that define the objects displayed in the row header. Only one object class can be used for display in row headers. If you define multiple queries, they must all return objects of the same class.

The following sections guide you through the definition of various features of the Kanban report. The definition in the sections XXX and XXX are mandatory to define a Kanban report. All other features are optional.

- Defining the Content and Structure of the Kanban Report
- Defining the Toolbar Buttons Available for the Kanban Report
- Defining the Layout of the Kanban Report
- Defining Tooltips for the Kanban Report
- Displaying Evaluation Aspects in Kanban Reports
- Defining Connections between Objects in the Cells of a Kanban Report
- Defining Navigation from the Kanban to Other Views

Defining the Content and Structure of the Kanban Report

Kanban reports can be defined either to display a tabular layout or a matrix layout.

It is mandatory for the definition of a Kanban report to define at least the column headers of the Kanban and the objects to be displayed in the cells of the Kanban report. The definition of the row headers, generating a matrix layout, is optional.

The cells of the Kanban report can contain objects of a single object class only.

The columns and rows in a Kanban report can represent either of the following:

- Values of an object class property of the objects in the cells.
- Objects referenced by the objects in the cells via an object class property of the type `Reference` or `ReferenceArray` of the objects in the cells.
- Objects of an object class that the objects in the cell are assigned to via an intermediate object class. The following use cases are supported:
  - Alfabet users can be assigned a role for an object. The relation between object and user is established via the intermediate object class Role.
  - The relation between business data and an object that reads, creates, updates, processes, or deletes it is established via the intermediate object class BusinessDataUsage.
  - Objects are related to organizations, market products, business processes and domains via the business support they are providing. This relation can be established via the following intermediate object classes: BusinessSupport, TacticalBusinessSupport, StrategicBusinessSupport, and BusinessAppraisal.
  - Objects can be assigned as relevant architecture to a project, demand, policy, risk mitigation, or value node. These relations are established via the intermediate object classes ProjectArch, DemandArch, PolicyArch, AffectedArch, and ValueNodeArch.

The cell content of the Kanban report is defined via a query. The column and row headers of the Kanban report are defined via a query with the exception of Kanban reports that manage the values of the release status or an enumeration based object class property of the objects in the cells. A mechanism is implemented that fills the header fields without a query definition for the release status and enumeration based object class properties.

Do the following to define the content of the Kanban report:

1) In the explorer of the **Report Assistant**, right-click the ***Cells*** element and select **Add New Query** from the drop-down list.
2) Click the ***Query*** node and define the following attributes:

Attribute	Description
Name	Define the name of the ***Query*** element displayed in the explorer of the **Report Assistant**.
Alfabet Query / **Query as Text** / **Native Sql**	Define a query to find the objects that are displayed in the report, the indicator values that are used to calculate the location of the object shapes in the portfolio, and all optional dynamic design elements of the portfolio.

The query must provide the following information:

- In Alfabet Queries, the `FIND` statement of the Alfabet Query must find objects of the object class to be displayed in the cells of the configured report. In native SQL queries, the first argument of the `SELECT` statement must return the `REFSTR` of the object to be displayed in the cells.

Please note that for objects that are related to the objects in the column header or row header via an intermediate object class, objects of the intermediate object class must be displayed in the cells of the Kanban

report. For example, if you want to define a Kanban report that displays the users that are assigned to an object via a role, the `Role` object class must be selected as object class for the cell.

- A column of the dataset from the query must return the text that shall be displayed in the object boxes placed into the cells of the Kanban.
- A column in the dataset must define the position of the object with respect to the columns of the Kanban. If the column headers represent objects, the `REFSTR` of the object in the column header must be returned. If the column headers represent property values, the property value must be returned.
- If the Kanban shall have row headers, a column in the dataset must define the position of the object with respect to the rows of the Kanban. If the row headers represent objects, the REFSTR of the object in the row header must be returned. If the row headers represent property values, the property value must be returned.

The following information can be returned by the query to define optional features for the portfolio report:

Feature to be implemented	For more information see:
Displaying a tooltip when the customer moves the cursor over the object in a cell.	
Defining the height of the object boxes dynamically	
Coloring of object box background and border dynamically	
Defining a navigation target for navigation from objects in the portfolio	

3) If the column headers shall represent objects in the Alfabet database, right-click the ***Columns*** element in the explorer and select **Add New Query** from the drop-down list.

4) Click the ***Query*** node and define the following attributes:

Attribute	Description
Name	Define the name of the ***Query*** element displayed in the explorer of the **Report Assistant**.
Alfabet Query / **Query as Text** / **Native Sql**	Define a query to find the objects that are displayed in the column headers.

If the headers represent objects referenced by the objects in the cells, the query must provide the following information:

- In Alfabet Queries, the `FIND` statement of the Alfabet Query must find objects of the object class to be displayed in the column headers. In native SQL queries, the first argument of the `SELECT` statement must return the `REFSTR` of the objects to be displayed in the column headers.
- All show properties defined in the Alfaber Query or all other `SELECT` statement arguments defined in the native SQL query are displayed in the column headers as text.

5) If the Kanban report shall have row headers that represent objects in the Alfabet database, right-click the ***Rows*** element in the explorer and select **Add New Query** from the drop-down list.

6) Click the ***Query*** node and define the following attributes:

Attribute	Description
Name	Define the name of the ***Query*** element displayed in the explorer of the **Report Assistant**.
Alfabet Query / **Query as Text** / **Native Sql**	Define a query to find the objects that are displayed in the row headers.

The query must provide the following information:

- In Alfabet Queries, the `FIND` statement of the Alfabet Query must find objects of the object class to be displayed in the row headers. In native SQL queries, the first argument of the `SELECT` statement must return the `REFSTR` of the objects to be displayed in the row headers.
- All show properties defined in the Alfaber Query or all other `SELECT` statement arguments defined in the native SQL query are displayed in the row headers as text.

7) In the root node of the **Report Assistant**, define the following attributes in the given order:

Attribute	Description
Enable Object Creation	This attribute must be set to `True` if the Kanban shall be used to display and manage a relationship via an intermediate object class. The attribute must be set to `False` for all other types of Kanban content.
Item Class	Select the object class that is displayed in the cells of the Kanban report. This attribute is mandatory.
Column Property	Select the object class property of the object class in the cells of the Kanban report that establishes the connection to the objects in the column headers or that returns the release status or enumeration-based string value in the column header. This attribute is mandatory.
Row Property	Select the object class property of the object class in the cells of the Kanban report that establishes the connection to the objects in the column headers

Attribute	Description
	or that returns the release status or enumeration based string value in the column header. This setting is ignored if **Row Reference Column** is not set.
Row Header Source	Select `Query` if the row headers are defined via a query. Select `Property` if the row headers represent the release status or an enumeration based string property of the object class in the cells of the Kanban report. This setting is ignored if **Row Reference Column** is not set.
Column Header Source	Select `Query` if the column headers are defined via a query. Select `Property` if thecolumn headers represent the release status or an enumeration based string property of the object class in the cells of the Kanban report. This attribute is mandatory.
Image Column	Enter the name of the dataset column in the query defined in the ***Cells*** > ***Query*** element that returns the string to be displayed in the object boxes in the cells of the Kanban report. This attribute is mandatory.
Column Reference Column	Enter the name of the dataset column in the query defined in the ***Cells*** > ***Query*** element that returns the `REFSTR` of objects represented by the column headers or the values of the release status or enumeration based string property represented by the column headers. This attribute is mandatory.
Row Reference Column	Enter the name of the dataset column in the query defined in the ***Cells*** > ***Query*** element that returns the `REFSTR` of objects represented by the row headers or the values of the release status or enumeration based string property represented by the row headers.
Header Value Column	
Lexicographic Sorting of Column Header	
Lexicographic Sorting of Row Header	

Defining the Toolbar Buttons Available for the Kanban Report

Kanban reports can be configured to permit users to change the relation of the object displayed in the reports with respect to the information in the column and row headers. If the column and row headers

represent objects, the reference of the object in the cell to the objects in the column and row headers is editable via the Kanban report. If the column and row headers represent the value of an object class property of the objects in the cells of the Kanban report, the value for the object class properties can be changed for the object.

When a user changes the position of an object in the Kanban report, this leads to a change of the data stored about the object in the Alfabet database. You should Therefore, consider carefully which of the available editing options should be activated for the Kanban report.

To activate editing of objects via the Kanban report, set the following attributes in the root node of the **Report Assistant**:

Attribute	Description
Can Create Item	Set this attribute to `True` to allow users to create new objects of the object class displayed in the Kanban cells. This action will create a new object in the Alfabet database. Please note that objects shall only be created via a Kanban if they can be created without a content. If the creation of new objects requires setting of references to other object classes that are usually evaluated from the context the object is created in, the respective drop-down lists for selection of the correct references are empty. The **Can Create Item** attribute should be set to `False` for these object classes. For example,: Creating a feature within a Kanban report that displays features defined for all applications in an application group will fail. The object class property `Object` of the object class `Feature` that is storing the reference to the application the feature belongs to is not set via the **Feature** editor but filled automatically during feature creation with the reference to the application the user is currently working with. In a Kanban, the user is not working in the context of an application and Therefore, the required object class property setting will fail. This only applies to the creation of new objects. Existing references can be changed and features can be moved from one application to the other within a Kanban report.
Can Add Item	Set this attribute to `True` to allow users to add existing objects of the object class displayed in the Kanban cells. This action will change the data of the object managed in the Kanban in the Alfabet database.
Can Delete Item	Set this attribute to `True` to allow users to delete existing objects displayed in the Kanban cells. This action will delete the object irrevocably from the Alfabet database.
Can Detach Item	Set this attribute to `True` to allow users to detach an object from the Kanban report. The object is no longer displayed in the Kanban but still exists in the Alfabet database. This action will change the data of the object managed in the Kanban in the Alfabet database.
Can Move Item	Set this attribute to `True` to allow users to move an object to another cell of the Kanban report. This action will change the data of the object managed in the Kanban in the Alfabet database.

Defining Navigation from the Kanban to Other Views

Configuring Matrices for Multi-Editing of Object Relations or Business Supports

The **Report Assistant** allows you to define the queries for the specification of the row and column headers.

The **Report Assistant** has four tabs:

- **Relationship Table** / **IT MAP Table**: The first tab displays an example of a configured report. The tabs for row and column definition are populated with code for the queries required to build the example.
- **Rows Definition**: The **Rows Definition** tab allows to specify the query to define the objects displayed in the rows of the configured report with either an Alfabet query or a native SQL query:
  - **To define an Alfabet query**: Write the complete Alfabet query, including instructions, if required, into the **Query for Rows** field or click the **Browse** button to open the **Alfabet Query Builder** to specify your Alfabet query.
  - **To define a native SQL query**: Write the native SQL query into the **Query for Rows** field. If you need to define Alfabet instructions in combination with the native SQL query, For example, to create expandable rows or columns, define the instructions separately in the **Query Instructions (for native SQL only)** field.

More information about the specification of rows is given in the section General Rules for the Specification of Rows and Columns.

- **Columns Definition**: The **Columns Definition** tab allows to specify the query to define the objects displayed in the columns of the configured report with either an Alfabet query or a native SQL query as described above for the definition of rows.

By default, column headers are as long as the longest content of a field. If the column headers defined with the query are very long, this leads to column headers requiring great part of the screen space. You can restrict the size of vertically displayed the column header to avoid oversized column headers. If the content of the column header cell is longer than the allowed size, it is cropped. To restrict the length of a column,

define the maximum number of characters for the column header in the field **Max. Length of Vertical Column Names**. Enter -1 for unrestricted display of text.

More information about the specification of rows is given in the section General Rules for the Specification of Rows and Columns.

- **Relationship Definition/Business Support**: The last tab allows you to specify the content of the matrix cells. You can define which information in the rows and which information of the columns is related to each other and how the relationship is defined in Alfabet. Detailed information about the definition of relationships is given in the separate sections Defining Matrices for Multi-Editing of Object Relationships and Defining Matrices for Multi-Editing of Business Supports.

General Rules for the Specification of Rows and Columns

The displayed row as well as the column headers are both the output result of a query based tabular report. All options that are available for a single configured report are also available for the definition of the matrix rows or columns:

- The text in the row/column headers is defined by the Show properties of the Alfabet query or the `SELECT` properties of the native SQL query. Each Show/`SELECT` property defined in the query leads to a new field in the row/column headers. You can use the `JOINCOLUMNS` Alfabet instruction to display multiple properties in one field, For example, to combine information about Name and Version of an Application in one field.

  The text for column and row headers should be short. The header fields have a size limit to ensure readability of the configured report. Header texts that are too long are truncated.

- The size of the row/column header fields depends on the content of the cells in the row/column. If you want to restrict the size of the header cells For example, because of long object names, you must define the configured report using native SQL and use the truncate functionality available for native SQL or display any other property, like For example, the short name of an object, to identify the object.
- The rows and columns can be defined as an expandable report table. In the rows, the configured report than looks like a usual expandable report table and rows can be displayed or hidden using the + sign in front of a row.

In the column headers, grouping of report results lead to grouping of the column sub-headers in sections that correspond to the objects of the superordinate class in the `GROUPBY_EX` Alfabet instruction grouping the configured report. It is not possible to expand or collapse sections, but sections and the sub-headers thereof can be hidden by right-clicking a section header. If a section is hidden, the right-click menu of any of the other sections allows to unhide that section header.

- Filters can be defined for the row and column specifications. Above the matrix table, all filter fields for both row and column specification are displayed in a combined filter. Filters that are implied by the use of the Alfabet parameter `BASE` are created automatically. For filter fields resulting from conditions with parameters, the filters must be added to the custom report view manually. For more information about defining filters see the section Defining Filters for Configured Reports and Selectors in the chapter Defining Queries.

The method to create filter fields automatically by creating a new custom report view must not be used for this type of configured report. Deleting of the custom report view to create a new one after the configured report was specified will delete all specifications made with the **Report Assistant**. Therefore, filters can only be defined manually after including parameters into the conditions of the query.

- If the configured report is applied to a class (it depends on a base object of the selected class) and the user does not have edit rights to the base object, the **Edit** button in the matrix report will be disabled. If the user has edit rights to the object or the configured report is not applied to a class, the user will be able to create or delete business supports or object relationships for all objects displayed in the matrix. The query defined to find the objects displayed in the rows or columns of the configured report should Therefore, take access permissions for the current user into account.

Defining Matrices for Multi-Editing of Object Relationships

The configured report can handle two types of relationships:

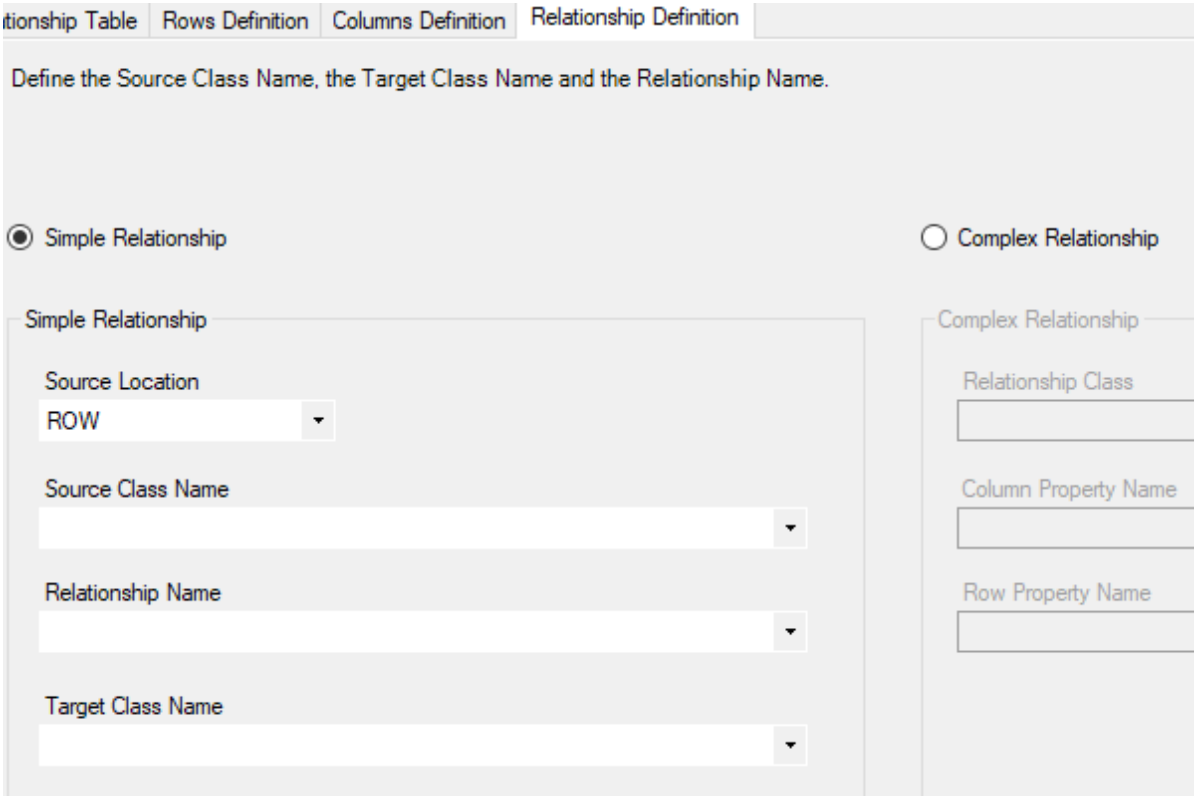
- **Simple Relationships**: Relationships between objects are defined in properties of the type `Reference` or `ReferenceArray`. The configured report for multi-editing of relationships is a two-dimensional matrix that displays the objects that have the property establishing the relationship in one dimension and the objects to that the relationship is built in the second dimension.
- **Complex Relationships**: The relation between two objects is stored in a third, intermediate object, that is exclusively used to store a relation between two objects in two properties of the type `Reference`. The configured report for multi-editing of relationships is a two-dimensional matrix that displays the objects the intermediate object class is referencing with one property in one dimension and the object class that the intermediate object is referencing in the second property in the other dimension.

Intermediate object classes that are designed to define relationships between two other object classes are:

Object class storing the relation	Relation of ... (property storing the relation)	to ... (property storing the relation)
`BusinessDataUsage`	Business data, business object (Data)	Object using the business data/business object (Object)
`DemandArch`	Demand (Demand)	Objects assigned to the demand as affected architecture (Object)
`PlatformElementDependency`	Platform element (Element)	Another platform element depending on the platform element (Dependent Element)
`ProjectArch`	Project (Project)	Objects assigned to the project as affected architecture (Object)

Object class storing the relation	Relation of ... (property storing the relation)	to ... (property storing the relation)
ValueNode	Value node (ValueNode)	Objects assigned to the value node (Object)

The content of the rows and columns of the relationship matrix is customizable and is defined by an Alfabet query or a native SQL query in the **Row** and **Column** tab of the **Report Assistant** as specified above. The relationship defined by the user when clicking a field in the matrix is specified in the fourth tab of the **Report Assistant**:



To define a simple relationship, edit the following fields:

- **Simple Relationship**: Select the checkbox to activate the configuration of a simple relationship.
- **Source Class Name**: Select the object class with the property establishing the solution from the drop-down list.
- **Source Location**: Define, whether objects of the Source Class are specified in the rows or columns of the configured report by selecting the respective location form the drop-down list.
- **Relationship Name**: Select the property that establishes the relationship from the drop-down list. The drop-down list includes all properties of the object class selected on the field **From Class Name**.
- **Target Class Name**: Select the object class to that a relation is specified from the drop-down list. The drop-down list displays the names of all object classes to that the property selected in the **Relationship Name** field specifies a relation.

To define a complex relationship, edit the following fields:

- **Complex Relationship**: Select the checkbox to activate the configuration of a complex relationship.
- **Relationship Class**: Select the intermediate object class that establishes the relation between the objects defined for the rows and columns of the configured report from the dropdown list.
- **Column Property Name**: Select the property of the intermediate object class that stores the information about the relation to the object class in the column definition.
- **Row Property Name**: Select the property of the intermediate object class that stores the information about the relation to the object class in the row definition.

Please note that the columns and rows of the matrix can show information about multiple object classes, but a relation can only be established to the class of the row or column definition that is the base class. The following rules apply:

- In a simple tabular output, the base class is the `FIND` class of the Alfabet query or the class for that the `REFSTR` is defined as first argument in the `SELECT` statement of the native SQL query.
- In a grouped dataset, the base class is the object class defined as lowest level of the dataset.

These rules should be regarded carefully because otherwise relations to object classes that are not allowed as relationship target are established. For example, you want to define a relationship between applications and business processes via the property Applications of the business process, and you want to display information about the ICT object the application is assigned to in the rows defining the applications. Make sure to define the applications as the base class in the respective query for a simple dataset or as subordinate class in a grouped dataset. Otherwise the setting of a relation within the matrix will store the `REFSTR` of the ICT object in the Applications property of the business process.

Defining Matrices for Multi-Editing of Business Supports

A business support describes the use of a specific application by an organization in support of a specific business process or domain. Therefore, a business support has three dimensions.

The configured report for multi-editing of business supports is a two-dimensional matrix. One dimension is specified in the row and one in the column definition. To specify the third dimension, there are two possible options:

- either the row or the column definition can include the third dimension.

For example, the column of the configured report shows business processes, while the row definition shows an expandable table with organizations as a first level and ICT objects owned by the organizations on the second level. When a user clicks a cell in the matrix, a business support is created that defines the use of the selected ICT object by the organization owning the ICT object to support the selected business process.

- the object the user is currently working with when opening the matrix is the third dimension of the business support. If the configured report includes the current object as the third dimension, a filter will be created automatically at the top of the configured report so that the user can select another object of the object class as the base object.

For example, business support shall be specified that is provided by the application the user is currently working with. The matrix based report for multi-editing of objects is added as page view to the object profile of the class application. The matrix is designed to display organizations on one axis and business processes on the other axis. When clicking a cell in the matrix, a business support is created that defines the use of the current application by the selected organization to support the selected business process. The user can use the filter on top of the configured report to select another application and define business support for the selected application.

The content of the rows and columns is customizable and is defined by an Alfabet query or a native SQL query in the **Row** and **Column** tab of the **Report Assistant** as specified above. The row and column header definition is generated based on a query. Each Show property of the Alfabet query or `SELECT` property of the native SQL query creates a column in the header definitions. Object relationships can be reflected in the column and row definitions and can be structured by creating an expandable result table in the row or column definition.

In the example below, the row definition displays organizations, sub-organizations thereof and ICT objects owned by the sub-organizations in a three-level expandable table. The column definitions display business processes grouped by subordinate business processes. In the **Report Assistant**, the root level of a column definition is named `COL1`, the second level `COL2` and so on. Rows are named accordingly as `ROW<number>`.

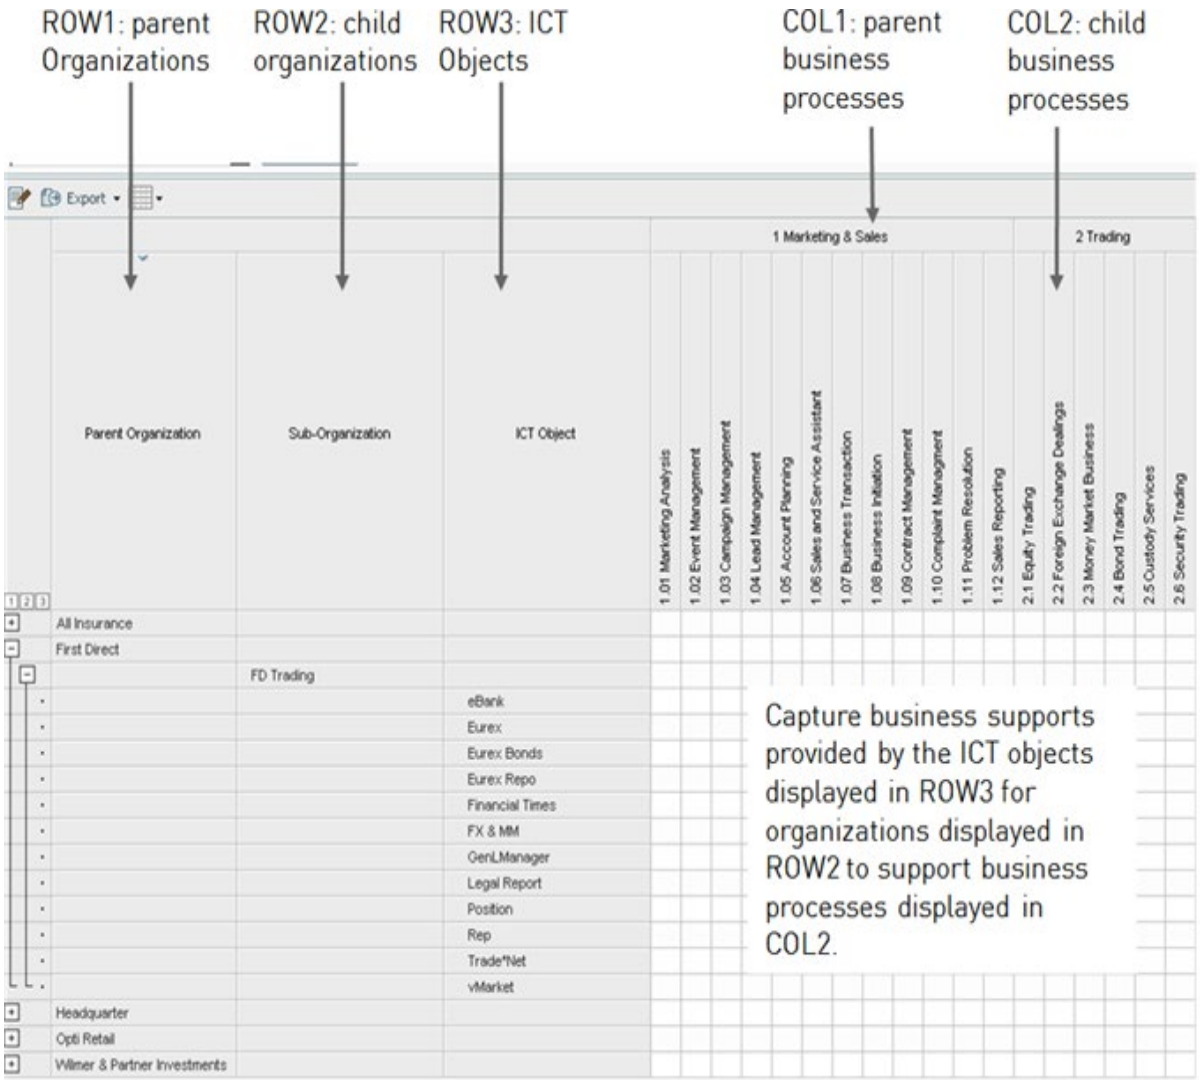


FIGURE: Example of a matrix for multi-editing of business supports

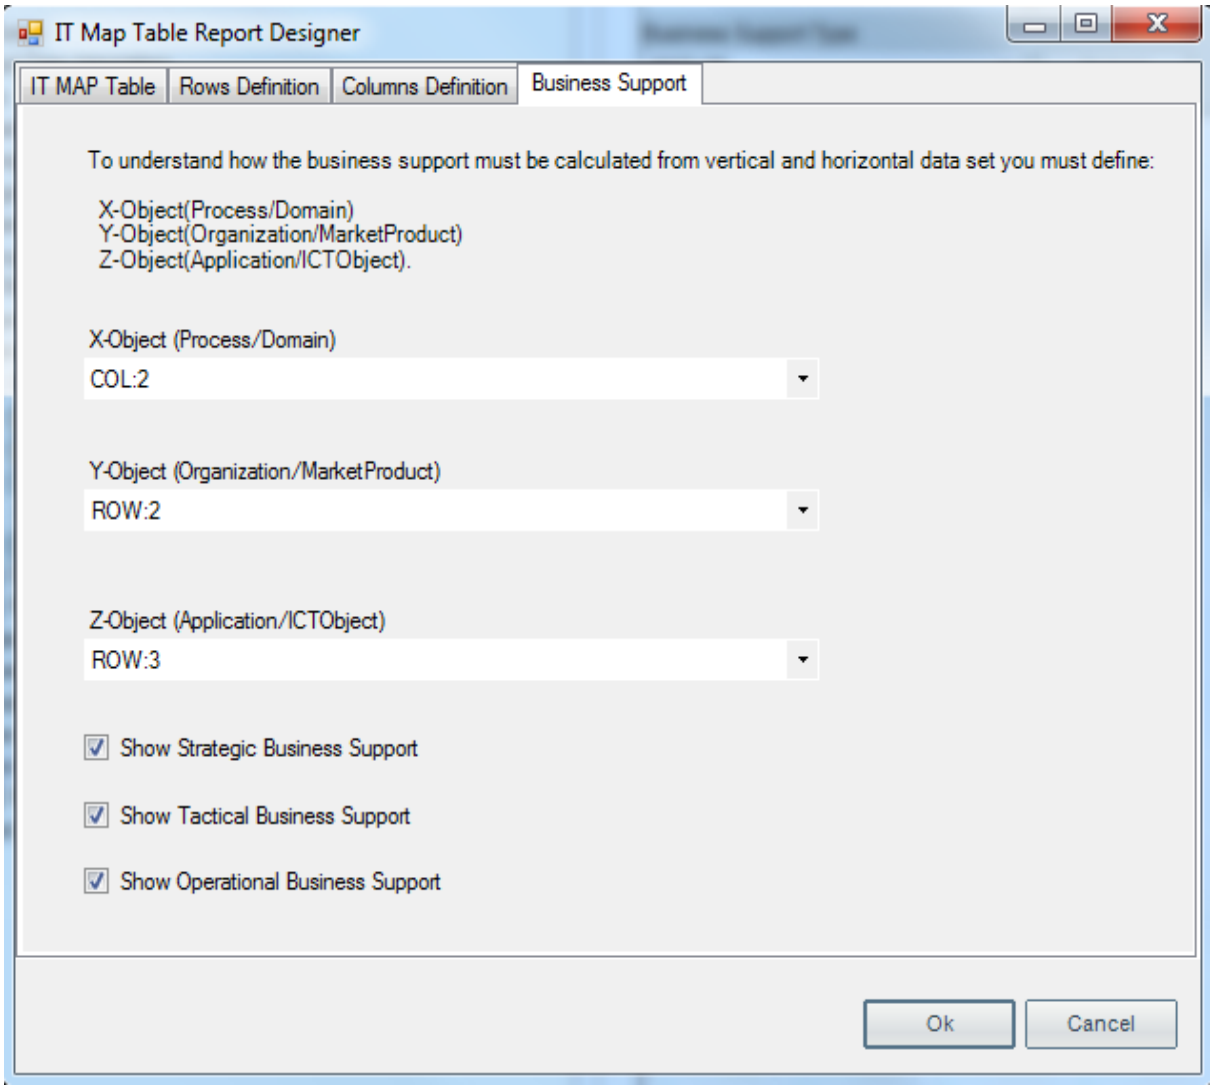
The business support defined by the user when clicking a cell in the matrix is specified in the fourth tab of the **Report Assistant**:



To define the relationship, edit the following fields:

- **X-Object (Process/Domain)**: Define where the business process or domain supported by the business support are specified in the matrix report. If business processes or domains are specified in one of the row or column header fields, select the respective row or column. If the base object is the supported business process or domain, select `BASE`.

  The term X-Object refers to the dimension of the business support and not to the display of objects in the matrix report. For this and the following settings, objects can be specified in any of the row and column specifications. It is even possible to select two dimensions of the business support from a row specification or a column specification. In the example above, organizations (Y-Object) and ICT objects (Z-object) are both specified in the column definition of the matrix.

- **Y-Object (Organization/Market Product)**: Define where the organization or market product using the business support are specified in the matrix report. If organizations or market products are

specified in one of the row or column header fields, select the respective row or column. If the base object is the supported organization or market product, select `BASE`.

- **Z-Object (Application/ICTObject)**: Define where the application or ICT object providing the business support are specified in the matrix report. If applications or ICT objects are specified in one of the row or column header fields, select the respective row or column. If the base object is the application or ICT object providing the business support, select `BASE`.
- **Show <Strategic/Tactical/Operational > Business Support**: Select which type of business support can be created in the matrix. You can select more than one type of business support. If more than one type is selected, a filter on top of the configured matrix allows the user to decide which type of business support he wants to define when working with the matrix.

Filters are created automatically on top of the matrix that allow the user to define the additional parameters to define the selected type of business support. For example, filter fields for the selection of master plan maps or strategy maps must be set prior to working with the matrix. The filter fields defined depend on the selection of business support types in the **Report Assistant**.

Configuring a Report for Multi-Editing of Indicators

The **Report Assistant** displays an explorer and an attribute window on the right of the explorer. The name of the explorer root node is identical to the name of the configured report you are currently designing. The attribute window displays the attributes of the selected element in the explorer. The attributes allow to define the look and content of elements of the configured report.

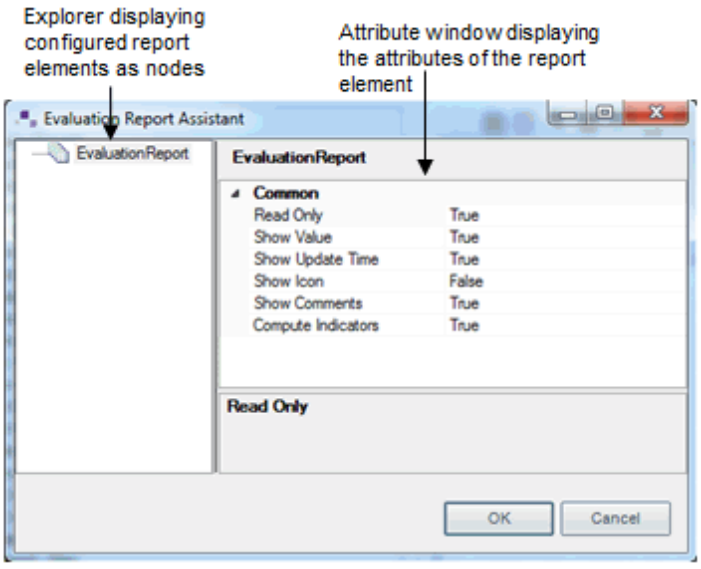


FIGURE: Interface of the Report Assistant for an evaluation report

When you right-click a node in the explorer, the context menu of the selected element opens and allows you to add new elements as child elements of the current element, if applicable.

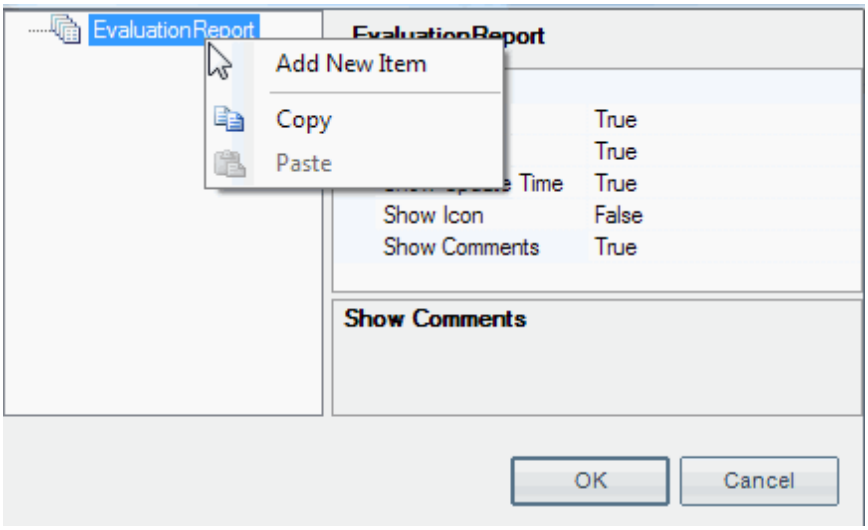

FIGURE: The context menu of the explorer root node of an evaluation report

The context menu also offers a copy and paste functionality to ease re-use of elements within a configured report or between configured reports.

If you copy an element, the element, its attributes and all child elements are copied. You can paste the copied element into another element of the same or a parallel configured report using the paste functionality of the context menu of the proposed parent element.

Defining the Column Display and Editability of the Evaluation Report

The general design of the configured report is defined via the attributes of the root node element. The root node attributes define which columns are displayed in the configured report and whether indicator values can be edited in the configured report.

To edit the attributes of the root node, click the root node in the explorer and edit the attributes described below in the attribute window:

Attribute	Description
Read Only	If set to `false`, the configured report allows to change indicator values and comments. If set to `true`, the configured report is view only. Please note that the report will be ReadOnly if embedded in object cockpits, regardless of the setting of the attribute.
Show Value	Defines whether the indicator value is shown in a column **Value** of the configured report. This attribute must be set to `true` if the user shall be able to edit indicator values directly in the columns of the configured report.
Show Comments	Defines whether the indicator comment is shown in a column **Comments** of the configured report. This attribute must be set to `true` if the user shall be able to edit indicator comments directly in the columns of the configured report.

Attribute	Description
Show Icon	Defines whether the indicator icon is shown in a column **Icon** of the configured report. **Note:** An icon can only be displayed in the configured report if the indicator type has been configured to display icons rather than numerical values. Indicator types are specified in the **Evaluations and Portfolios** functionality of Alfabet. For information about the configuration of indicator types and the icon gallery used to visualize their values, see *Defining an Indicator Type for an Evaluation Type* in the reference manual *Configuring Evaluation and Reference Data in Alfabet*.
Show Update Time	Defines whether the time the indicator was last changed is displayed in the configured report in a column.
Compute Indicators	Defines how computed indicators that are included in the configured report are updated. Computed indicators are calculated automatically and cannot be edited by the user. If **Compute Indicators** is set to `False`, computed indicator are updated when the user selects the option **Action** > **Compute Indicators for All Objects in the Report** in the configured report. If **Compute Indicators** is set to `True`, computed indicator are updated each time the user clicks the **Save** button in the toolbar of the configured report. The option **Action** > **Compute Indicators for All Objects in the Report** is not available in configured reports that are configured to recalculate computed indicators on each saving of indicator values.
Compute All Indicators	If set to `True`, re-calculation of computed indicators triggered via the configured evaluation report includes all computed indicators in the Alfabet database. If set to `False`, only computed indicators visible in the configured evaluation report are re-calculated. For performance reasons it is recommended to set this attribute to `False` if the database contains a high number of computed indicators.
Input Controls Limit	This setting is only taken into account if **Read Only** is set to `False`. It limits the number of input controls that may be displayed in the configured evaluation report. If the configured report exceeds the maximum number of input controls, the user is informed that he/she shall refine the search to reduce the tabular display to the allowed number of input controls. If this attribute is set, the configured evaluation report should have filters for refining the display.
Report Row Limit	This setting is only taken into account if **Read Only** is set to `False`. It limits the number of rows that may be displayed in the configured evaluation report. If the configured report exceeds the maximum number of rows, the user is informed that he/she shall refine the search to reduce the tabular display to the allowed number of rows. If this attribute is set, the configured evaluation report should have filters for refining the display.

Defining the Hierarchy of the Objects and Indicators Displayed in the Evaluation Report

The root node element can contain one or multiple **Item** elements. These first level **Item** elements must have a query definition in their attribute specifications to find the objects displayed in the configured report.

Only objects of artifact bject classes representing an artifact in the IT landscape can be selected to build evaluation reports.

The query can either be a native SQL query or an Alfabet query.

If you are not familiar with Alfabet queries, see the chapter Defining Queries.

For special rules that apply to the definition of native SQL queries in the context of configurations for Alfabet, see the section Defining Native SQL Queries.

The information displayed in the **Object** column of the evaluation report is identical to the column headers that would result from a tabular output of the defined query.

Report columns that are defined for technical reasons are not displayed in the object boxes in the configured report. This includes:

- The first column of the output of a native SQL query. This column must specify the `REFSTR` of the object for technical reasons and is ignored in the visible output.

The configured report can either display a flat list of objects and their indicators, or a grouped report can be configured. There are two methods to configure a grouped report:

- The complete content of the configured report is defined in one query resulting in a grouped dataset.
- A separate query is added to the report configuration for each object class added to one of the levels of the configured report.

When separate queries are defined for each level, a high number of queries must be executed by the database to display the configured report. This can lead to performance issues. Therefore, it is recommended to built the configured report on a grouped dataset defined in a single query. Nevertheless for some use cases, like For example, defining different indicators for objects assigned to the same level, it is required to define multiple queries for the configured report.

Defining a Grouped Report on Basis of a Single Query

A query resulting in a grouped tabular report can be defined for the first level **Item** element to define a grouped report. For a grouped report, the **Object** column of the evaluation report displays the information defined for the column headers of the respective group.

Grouped reports are defined via `GroupBy_Ex` Alfabet instructions defined in Alfabet query language. Alfabet instructions can also be combined with native SQL queries.

A detailed description about how to define a grouped report using the `GroupBy_Ex` c Alfabet instruction is given in the section Grouping Query Results in Expandable Reports in the chapter Defining Queries.

If the query output results in a grouped report, an **Item** element without a query specification must be added to the explorer tree for each grouping level in a hierarchical structure, that means each subordinate level **Item** element as child of the superordinate **Item** element. The hierarchy of **Item** elements correspond to the grouping levels. To enhance the overview over the report structure, an attribute **Name** is available for the item elements that allow to rename the **Item** explorer nodes.

Each element **Item** contains an attribute **Evaluation Types** that defines the evaluation types for that indicators are displayed and optionally can be edited in the configured report.

Please note the following when defining evaluation types for **Item** elements.

- The evaluation type must be assigned to the object class displayed in the level of the grouped report the **Item** element is defined for. For information about the assignment of evaluation types to object classes, see the chapter *Configuring Evaluations, Prioritization Schemes, and Portfolios* in the reference manual *Configuring Evaluation and Reference Data in Alfabet*.
- **Item** elements are not defined per object class but per grouping level. You can define grouped datasets with more than one object class per level, but in that case, the evaluation types selected in the **Item** element for the level must be assigned for all object classes.

The attribute **Visible** of the **Item** element allows you to define rows that are not displayed in the configured report. This is useful to display the indicators of objects that are related to the first level object via an intermediate object without displaying the information about the intermediate object class.

The following example shows a configured report that allows selected indicators to be edited for applications assigned to projects via the project architecture. The configured report also displays indicators for the project that the application is assigned to. The indicators on the project level are aggregated indicators and cannot be edited in the configured report and are Therefore, displayed as colored rows. To recompute the aggregated indicators, click **Action** > **Compute indicators for all objects in report**.

Please note that only one of the indicators for an application is configured to display an icon. Therefore, the column **Icon** will only display an icon in the row of that indicator.

Applications are assigned to projects via the object class `ProjectArch` that defines the relation between a project and an object. The grouped dataset of the example Therefore, has three levels of related object classes: `Project`, `ProjectArch` and `Application`. The configured report can For example, be created on basis of the following Alfabet query:

```
ALFABET_QUERY_500
FIND Project
   InnerJoin ProjectArch ON ProjectArch.Project = Project.REFSTR
   InnerJoin Application ON ProjectArch.Object = Application.REFSTR
Instructions
   JoinColumns("Application.REFSTR,BusinessProcess.REFSTR","Applicat
   ion.REFSTR"," ");
   GroupBy_Ex("Project.Name","ProjectArch.REFSTR","Project",0);
   GroupBy_Ex("ProjectArch.REFSTR","Application.REFSTR","ProjectArch
   ",1);
   RemoveColumns("Application.REFSTR,ProjectArch.REFSTR");
EndOfInstructions
AUTODSINFO
QUERY_XML
<QueryDef>
   <ShowProperty Type="Property" ClassName="Project" Name="Name" />
   <ShowProperty Type="Property" ClassName="ProjectArch"
   Name="REFSTR" />
   <ShowProperty Type="Property" ClassName="Application" Name="Name"
   />
```

```
        <ShowProperty Type="Property" ClassName="Application"
        Name="Version" />

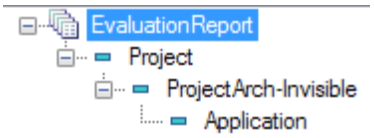
        <ShowProperty Type="Property" ClassName="Application"
        Name="REFSTR" />

        <SortProperty Type="Property" ClassName="Project" Name="Name" />

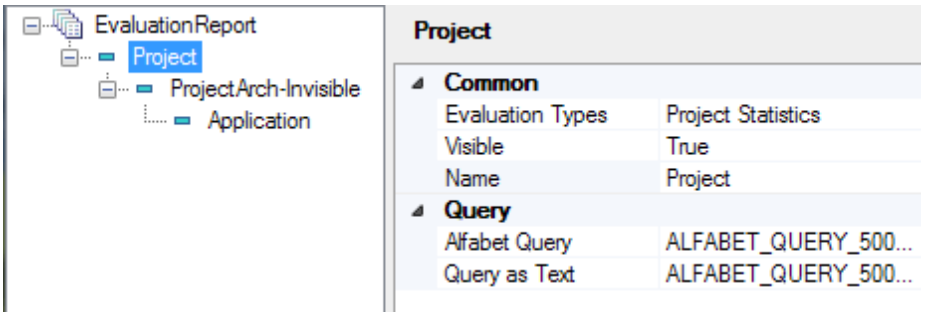
        <SortProperty Type="Property" ClassName="ProjectArch"
        Name="REFSTR" />

    </QueryDef>
```

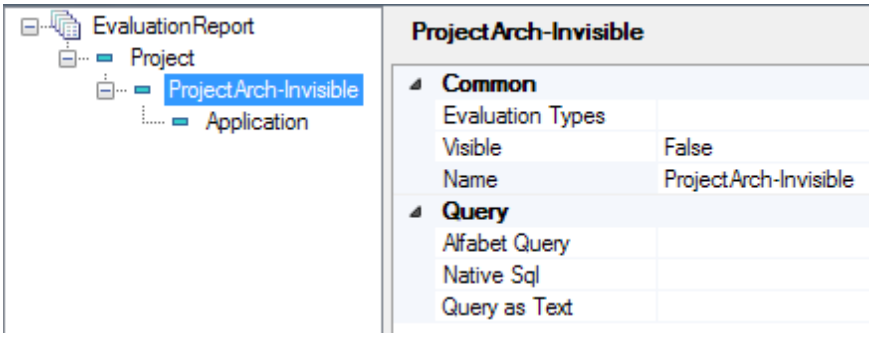
In the **Report Assistant** of the configured report, one Item element must be added to the root node for the definition of the first level. The first level Item element contains a second level Item element which contains the third level Item element:



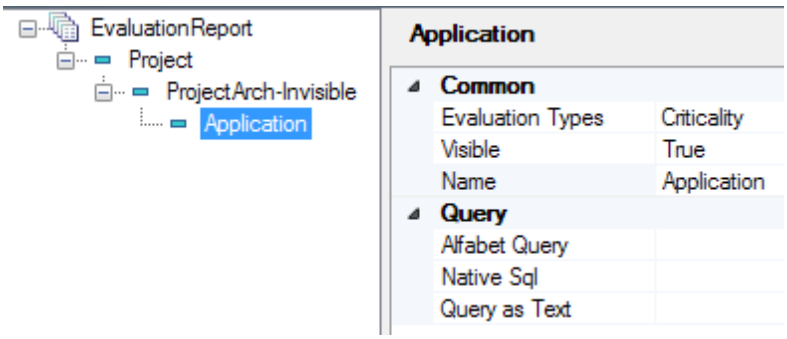
The Alfabet query defining the grouped dataset is defined in the attributes of the first level **Item** element. The first level element also contains the definition of evaluation types that shall be displayed for the projects displayed as first level:



The second grouping level of the configured report displays information about the objects of the object class `ProjectArch` that establish the relation between projects and applications. This level shall not be displayed in the configured report. The attribute **Visible** of the **Item** element in the second level is Therefore, set to `False`.



The third grouping level display applications. The evaluation type for that indicators shall be added in the configured report is defined in the third level **Item** element.



Defining a Grouped Report on Basis of One Query Per Object Class

Item elements can be structured hierarchically. If an element **Item** contains a child element **Item**, for each row added to the configured report on basis of the definition in the parent **Item** element, subordinate rows are added to the configured report on basis of the definition in the child element **Item**. To enhance the overview over the report structure, an attribute **Name** is available for the **Item** elements that allow to re-name the **Item** explorer nodes.

For each element **Item** a query defined in the attributes of the **Item** element specifies for which objects rows are added to the configured report on basis of an Alfabet query or a native SQL query.

The information displayed in the **Object** column of the evaluation report is identical to the column headers that would result from a tabular output of the defined query.

Report columns that are defined for technical reasons are not displayed in the object boxes in the configured report. This includes:

- The first column of the output of a native SQL query. This column must specify the `REFSTR` of the object for technical reasons and is ignored in the visible output.

The attribute **Visible** of the **Item** element allows you to define rows that are not displayed in the configured report. This is useful to display the indicators of objects that are related to an object via an intermediate object without displaying the information about the intermediate object class.

For each element **Item** the display of the indicators of the objects can be defined by setting the attribute ***Evaluation Types*** of the **Item** element.

Note the following when defining the query for the **Item** element:

- If an element **Item** is child of a parent **Item** element, the query defined for the **Item** element must contain the Alfabet parameter:`BASE` in a `WHERE` clause to map the objects of this layer to the objects in the parent layer. `BASE` is identical to the `REFSTR` of the object in the parent layer.

  This specification is not mandatory for the top layer objects. The Alfabet parameter `BASE` can only be used in the Alfabet query or native SQL query defining the top layer objects if the configured report is assigned to an object class with the attribute **Apply To Class**.

- The information displayed in the **Object** column of the evaluation report is identical to the column headers that would result from a tabular output of the defined query.

Report columns that are defined for technical reasons are not displayed in the object boxes in the configured report. This includes:

- The first column of the output of a native SQL query. This column must specify the `REFSTR` of the object for technical reasons and is ignored in the visible output.

Defining the Attributes of the Item Element

The table below lists all attributes of the **Item** element: .

Attribute	Description
Evaluation Types	Click in the field to display the **Browse** button and click the button to open a selector. Select evaluation types to add all indicators based on indicator types that are assigned to the listed evaluation types to the configured report. **NOTE**: The evaluation type must be assigned to the relevant object class. For information about the assignment of evaluation types to object classes, see the chapter *Configuring Evaluations, Prioritization Schemes, and Portfolios* in the reference manual *Configuring Evaluation and Reference Data in Alfabet*.
Visible	Select `True` if you want objects to be visible in the configured report. Select `False` if you do not want the objects to be visible in the configured report.
Name	Define a name for the **Item** element. The name is used in the explorer tree as name for the **Item** node.
Alfabet Query / **Query as Text** / **Native Sql**	Defines the objects displayed in the configured report via an Alfabet query or a native SQL query. For each object found by the query a line is added to the configured report. If you want to define an Alfabet query, you can either use the **Alfabet Query Builder** available via the **Alfabet Query** attribute or write the Alfabet query into a text editor available via the **Query as Text** attribute. If you want to define a native SQL query, use the text editor available via the **Native Sql** attribute. The text editor has separate tabs for the definition of the native SQL query and the definition of Alfabet query language instructions that can be used in combination with native SQL queries to built a grouped dataset. To open an editor, click in the respective attribute field to display the **Browse** button and click the button.

Configuring a Report for Multi-Editing of Aspect Indicators

This configured report provides a matrix view on aspect indicators and an editor for changing indicator values and comments. An aspect indicator is an indicator for the evaluation of an object in a specific context. For example, an application may be evaluated differently in the context of different business processes the application is providing services for. The business process is then the aspect for the evaluation.

An aspect indicator stores a value for a specific combination of evaluated object and aspect object for a defined indicator type and evaluation type.

Standard views for the definition of aspect indicators are only available for the object classes application, and component and project. For all other object classes the configured report is required to set the aspect indicators on the Alfabet user interface.

For general information about aspect indicators, see in the reference manual *Configuring Evaluation and Reference Data in Alfabet*.

The report is configured in the report assistant opening for configured reports based on the template `Report`. For information about creating the report and opening the report assistant, see Creating a New Report for Multi-Editing of Objects

The content and layout of configured report is defined by setting the attributes in the attribute pane of the elements in the explorer of the **Report Assistant** window.

The following table lists the explorer node elements that can be configured to specify the content of the report as well as provides information about the purpose of each sub-element:

Explorer Node Element	Required to Configure:
Root Node	Definition of the layout for the report.
Aspects	Definition of the aspects that indicators shall be defined for.
Indicators	Definition of the indicator typess for that indicators shall be edited for each combination of aspect and object.
Objects	Definition of the objects the indicators shall be defined for.

The following information is available about the configuration of the configured report:

- Defining the Objects, Aspects and Indicators for the Evaluation
- Defining the Layout of the Aspect Indicator Report

Defining the Objects, Aspects and Indicators for the Evaluation

The report displays a matrix for setting combinations of aspects and indicators for either a single base object or a defined set of objects.

The aspect indicator is stored in the object class `Indicator`. The following object class properties of the object class indicator are relevant for the report:

- ***Object***: A reference to the object which is evaluated. In the configured report, either a number of objects or a single object can be evaluated:
    - If indicators shall be set for multiple objects, a query must be defined for the report as sub-node of the ***Objects*** explorer node of the report assistant. The objects returned in the query will be displayed as row headers in the matrix of the aspect indicator report. Details of the query definition are provided below.
    - If indicators shall be set for one object only, the **Apply to Class** attribute of the configured report must be set to the object class of the object that shall be evaluated. The report can then be added to object cockpits or a wizard for the object class it is assigned to and will allow the user to set indicators for the object he/she is currently working with. If the configured report is opened without a context providing a base object, a filter for selection of a base object will be automatically added above the configured report.
- ***Aspect***: A reference to the object that is the aspect of the evaluation. In the configured report, a query must be defined as sub-node of the ***Aspects*** node of the report assistant to specify the aspect objects. The aspect objects will be displayed as column headers or additional level of row headers in the matrix, dependent on the configuration of the aspect indicator report. Details of the query definition are provided below.
- ***IndicatorType***: A reference to the indicator type of the indicator. In the configured report, a query must be defined as sub-node of the ***Indicators*** node to specify the indicator types for that indicators shall be defined in the configured report. The indicator types will be displayed as column headers or additional level of row headers in the matrix, dependent on the configuration of the aspect indicator report. Details of the query definition are provided below.
- ***Value***/***SemanticValue***: The semantic value is displayed in the configured report and the editor. Both attributes are set if a change is made via the editor of the configured report.
- ***Comments***: The comment a user has entered when setting the indicator. The comment can optionally be shown in the report. It is always shown in the editor and editable for the user.
- UpdateTime: The time and date of the last update of the indicator. The information can optinally be shown in the report and is always shown read-only in the editor.

To define objects, aspects and indicators in the report assistant:

- Right-click the node ***Objects***, ***Aspects***, or ***Indicators***and select **Add New Query**.
- Define the query in the attributes of the configured report. The attribute **Query As Text** opens a simple editor to type in either a native SQL query or an Alfabet query. The attributes **Native SQL Query** and **Alfabet Query** open editors specific for the respective query language.

Note the following about the query:

- Depending on the parent node, the query must find objects of the classes `IndicatorType`, the evaluated object class, or the object class that represents the aspect. That means that

this class must be the `FIND` class of an Alfabet query. In native SQL queries, the first `SELECT` argument must return the `REFSTR` values of objects of the respective class.

- The text that shall be displayed in the row headers or column headers must be returned in a single column of the query dataset. The column name for that column must be identical in all return datasets of all queries defined for the aspect indicator report.

For more information about defining queries, see Defining Queries.

- After having defined all queries for the aspect indicator report, click the root node of the report assistant and enter the name of the column of the query dataset returning the text to be displayed in the **Image Column** attribute.

Defining the Layout of the Aspect Indicator Report

The following image shows the default layout of an aspect indicator report:

			API - Open Bank Partner			GTM Partner		
	Object	Indicator Type	Value	Comments	Last Update	Value	Comments	Last Update
1	Corporate Planning	Cost Competitiveness	2 - medium		18/08/2021 10:52:...	2 - medi...		18/08/2021 10:52:...
2		Investment	3 - high		18/08/2021 10:52:...	3 - high		18/08/2021 10:52:...
3		Outcome	3 - high	perfectly matching demand	18/08/2021 10:52:...	2 - medi...		18/08/2021 10:52:...
4		Process Quality	3 - high		18/08/2021 10:52:...	3 - high		18/08/2021 10:52:...
5		Skill	2 - medium		18/08/2021 10:52:...	1 - low		18/08/2021 10:52:...
6		Technology	2 - medium		18/08/2021 10:52:...	2 - medi...		18/08/2021 10:52:...
7	Collaboration	Cost Competitiveness	3 - high		18/08/2021 10:56:...	3 - high		18/08/2021 10:56:...
8		Investment	1 - low		18/08/2021 10:56:...	1 - low		18/08/2021 10:56:...
9		Outcome	3 - high		18/08/2021 10:56:...	2 - medi...	not matching all of our demands	18/08/2021 10:56:...
10		Process Quality	3 - high		18/08/2021 10:56:...	2 - medi...		18/08/2021 10:56:...
11		Skill	1 - low	can be used without training	18/08/2021 10:56:...	2 - medi...		18/08/2021 10:56:...
12		Technology	3 - high		18/08/2021 10:56:...	2 - medi...		18/08/2021 10:56:...

The report shows a matrix with the following structure:

- **Row headers**: The object to be evaluated is displayed in the first column of the report. The second column lists the indicator type for that the indicators are displayed in the current matrix. The row header columns are frozen, which means that they will remain visible on scrolling horizontally.
- **Column headers**: The first level row headers are listing the aspects relevant for the evaluation. For each aspect, three rows providing information about the value, comment and last update time of the aspect indicator are displayed.

This default layout can be changed via the attributes of the root node of the report assistant.

Attribute	Description
Report Layout	By default, this attribute is set to `Compact` and a static table is displayed with all rows visible. Set this attribute to `Tree` to change the layout to a collapsible dataset with the rows defined by the second row header level being collapsible: Indicator Grouping	This attribute defines the grouping of the aspect indicators in the report dataset and in the editor. Select one of the following: • `By Aspect`: Indicator types are used as row headers while aspects are used as column headers. This is the default layout. • `ByIndicatorType`: Aspects are used as row headers while indicator types are used as column headers. 
Object Leading	This attribute defines the order of row headers. By default, it is set to `True` and the first level of row headers displays the objects to be evaluated. Set this attribute to `False` to revers the order of row headers and sort by object in the second level. The first level will then sort by either indicator type or aspect, depending on the setting of the **Indicator Grouping** attribute. 

Attribute	Description
	Please note that this setting also changes the content of the editor. The editor will open for all aspect indicators available for the first level column header for that a row is currently selected in the matrix. In the example above, a user selecting any row beneath `Cost Competitiveness` will be able to set the `Cost Competitiveness` for all combinations of object and aspect. In contrast, the default setting of the report will provide an editor for setting all aspect indicators for a selected object for all combinations of indicator type and aspect.
Comment Visible	Set the attribute to `False` to hide the **Comments** columns from the dataset. If comments are hidden from the dataset, they are nevertheless displayed and editable in the editor.
Last Update Visible	Set the attribute to `False` to hide the **Last Update** columns from the dataset.
Show As Icon	If set to `True`, indicators will be displayed as icons in the report dataset. Please note that indicators must be based on indicator types with an icon definition to show icons in the configured report. For information about configuring indicators to be represented as icons, see *Configuring Indicator Types for an Evaluation Type* in the reference manual *Configuring Evaluation and Reference Data in Alfabet*.
Single Object	

Configuring a Report for Multi-Editing of Questionnaire Indicators

The report is configured in the report assistant opening for configured reports based on the template `QuestionnaireEvaluationReport`. For information about creating the report and opening the report assistant, see Creating a New Report for Multi-Editing of Objects.

The content and layout of configured report is defined by setting the attributes in the attribute pane of the elements in the explorer of the **Report Assistant** window.

The following table lists the explorer node elements that can be configured to specify the content of the report as well as provides information about the purpose of each sub-element:

Explorer Node Element	Required to Configure:
Root Node	Definition of the functionality and layout of the report.
Item	Definition of the information displayed in the tabular dataset of the configured report.

Defining the Tabular Dataset of the Questionnaire Evaluation Report

Define the following attributes of the ***Item*** note in the **Report Assistant** to select the data to be displayed in the tabular dataset of the questionnaire evaluation report:

Attribute	Description
Alfabet Query/Native SQL Query / Query as Text	Define either an Alfabet Query or a native SQL query finding objects of the object class `QuestionaryIndicator`. Note the following about the query definition: • Alfabet query: The `FIND` class must be `QuestionaryIndicator`. A definition of show properties is ignored. The return dataset is defined via the **Show Properties** attribute described below. • Native SQL query: The first argument of the `SELECT` statement must return the `REFSTR` of the object class `QuestionaryIndicator`. All other arguments of the `SELECT` statement are not relevant to define the return dataset. The return dataset is defined via the **Show Properties** attribute described below. • The sort order of results returned by the query is not relevant for the sort order of rows in the table of the configured report. Results are by default sorted first by question set, then by question and then by object. The user can change the sort order of the report at runtime to sort by question set, then object, and then question. • WHERE conditions can be defined to define which questionnaire indicators shall be included into the dataset. • Alfabet parameters can be used to define filters, or to refer to the current object or the current user.
Show Properties	Click the **Browse**  button at the right of the attribute field to open the **Select and Reorder Entries** window. Select the checkbox of all object class properties that you would like to add to the tabular dataset of the report. Note the following about the selection: • If you select an object class property establishing a reference to a target object, the object class properties defined in the **Image Properties** attribute in the

Attribute	Description

	class settings for the target object class will be displayed in the tabular dataset of the configured report.
	• The header of the column in the result dataset will be concatenated from object class caption and object class property caption. Some of the data is available two times in the list. For example, selection of `QuestionaryIndicator.Questionary` and `Questionary.Name` will both add a column providing information about the name of the questionnaire the questionnaire indicator belongs to. But the column header will be **Questionnaire Indicator Questionnaire** for the selection of `QuestionaryIndicator.Questionary` or **Questionnaire Name** for the selection of **Questionary.Name**.
	• The selection of the following properties will add a link to the dataset that allows to navigate to the object profile of the selected object:
	  • Questionnary.Name and QuestionaryIndicator.Questionary provide a link to the object profile of the questionnaire.
	  • QuestionaryIndicator.Object provides a link to the object profile of the object the question targets.
	  • QuestionaryIndicator.Question provides a link to the object profile of the question.
	  • QuestionnaireEvaluation.ID and QuestionnaireEvaluation.Name provide a link to the object profile of the questionnaire evaluation. Questionnaire evaluations cannot be performed via button interactions in the configured questionnaire evaluation report. The link is required to provide the ability to evaluate the questionnaire.
	• The sort order of columns in the result dataset from left to right is identical to the sort order of the entries in the selector from top to bottom. The order of entries can be changed with the up and down buttons on the right of the object class property selection field.

Name	Optionally, change the name of the **Item** element in the explorer of the report assistant.

Creating a Configured Report Displaying an Object Profile or Object Cockpit

To define a configured report of the type `ObjectView`:

- In the **Reports** explorer of the **Reports** tab of Alfabet Expand, create a new configured report and define the general attributes for the configured report and the attributes specific for configured reports of the type `ObjectView`. This step is described in this chapter.
- Set the **Report State** of the configured report to `Active`. For information on how to change theattribute of the configured report, see.
- Define access rights for the configured report in the **Reports Administration** functionality of Alfabet. By default, access is possible for all users. For more information, see the chapter *Defining and Managing User Access to Configured Reports* in the reference manual *User and Solution Administration*.

To create a new configured report in Alfabet Expand with a reference to an object profile or an existing object cockpit of an object of a specified object class:

1) In the **Reports** tab, right-click the **Reports** folder or a sub-folder thereof and select **Create New Report**. You will see the new configured report listed below the selected folder.

As an alternative to defining all attributes for a new configured report, you can copy and paste an existing configured report and make modifications, as needed. To do so, right-click the existing configured report that you want to copy and select **Copy**. Right-click the new configured report and select **Paste**. Modify the necessary attributes described below.

2) In the attribute window, select `ObjectView` in the **Type** field.
3) In the attribute window, define the following attributes for the configured report:

- **Name**: Optionally, change the technical name of the configured report. The technical name of the configured report must be unique.

The technical name is used for identification of the configured report in the context of technical processes such as merging the report configuration with a report configuration saved as an XML file. Therefore, the following is required when defining the name of a configured report:

- The name must be unique. The name must be unique regardless of the report folder it is structured in.
- The name may not be changed once a configured report has been created.
- A validation mechanism checks for correct syntax when defining a technical name. Please note that names may not begin with an empty space nor include special characters. For a list of the special characters that are not

allowed, see the section Defining Attributes for Configuration Objects in the chapter Getting Started with Alfabet Expand.

- If the technical name of the configured report is changed, the name will be correctly updated in other configuration objects referencing the changed report during design time.

Please note that the name of a changed configuration object will not be updated in guide pages or guide views. If you plan to change the name of a configuration object, the reference in the navigation page should be changed prior to changing the configuration object name. You can use the **Show Usage** functionality in the context menu of the configured report to evaluate whether the configured report has been added to a guide view or guide page.

- **Caption**: Enter a caption for the configured report. The name you define here will be displayed in the **Reports Administration** functionality, the **Configured Reports** functionality or the **Configured Reports** page view in object profiles.
- **Description**: Provide information about the configured report that is useful to users. This comment will be displayed in the **Description** field for the configured report in the **Reports Administration** functionality in the **Administration** module, the **Configured Reports** functionality or the **Configured Reports** page view in object profiles.
- **Report State**: The **Report State** attribute is view only and is set to `Plan` for new configured reports. The configured report can only be edited when the **Report State** attribute is set to `Plan`. After finishing all configuration steps described in the following, the **Report State** attribute must be set to `Active` as described in the section General Guidelines for Creating Configured Reports. The configured report is then visible to users in the Alfabet user interface.
- **Apply to Class**: Click the **Browse** button to open a dialog box and select the object class or object class stereotype for which you want to display the object view. A selector that is automatically added at the top of the configured report allows the user to select an object of the object class or object class stereotype the configured report is applied to and view the object profile or object cockpit for the selected object.

  For configured reports of the type `ObjectView`, the **Apply to Class** attribute is mandatory. However, the attribute does not make the configured report available in the object profile of the selected object class, as is the case for the other types of configured report. The configured report is available to users in the **Configured Reports** functionality of the **Search** module only.

  If the configured report is applied to an object class stereotype, the filter field for selection of the base object will use the caption of the object class stereotype as caption of the filter field and the selector defined in the class settings for the object class stereotype for selection of the base object.

- **View**: Select an object view from the drop-down list. The object profile must display data about the object class specified in the **Apply to Class** field.
- **Object View Presentation Type**: Select `Normal` to display the object profile in the configured report. Select `Dashboard` to display the object cockpit in the configured report. The default object cockpit assigned to the view scheme used by the user profile the user is currently logged in with when opening the configured report is displayed.

- **Help Index**: Specify the location of the external Help file using the following syntax:(For example,:). The external help file will be displayed when the user clicks the context-sensitive Help link in the standardHelp menu.

  Server variables can be used in the Help links. Server variables allow you to define all or part of the URL definition in the server alias configuration of the Alfabet Server instead of directly defining it in the configuration in Alfabet Expand. Use of server variables is useful, For example, in order to change a Web server name defined in multiple URL definitions in Alfabet Expand. Instead of changing all URL definitions, only the variable value in the server alias configuration must be updated. The use of server variables is described in the section Using Server Variables in Web Link and Database Server-Related Specifications in the chapter Configuring Reports.

- **Selector Behavior**: The attribute can be used to exclude configured reports that are defined for special purposes, like For example, triggering of data export via the RESTful API, from being selectable in the **Configured Reports** table. By default, the attribute is set to `Visible` and the configured report is visible in the selector for adding configured reports to the **Configured Reports** table if all other conditions for access to the configured report apply. If the attribute is set to `NotVisible`, the configured report is excluded from the selector for adding configured reports to the **Configured Reports** functionality. Please note however, that this setting is not excluding the configured report from any standard views or customer configured views and selectors, but exclusively from the standard selector for configured reports implemented in Alfabet.

The attribute cannot be edited in the attribute window directly. To change the setting, right-click the configured report and select **Set Report Selector Behavior to 'Not Visible'** or **Set Report Selector Behavior to 'Visible'** respectively.

- **Applicable for AlfaBot**: Specify whether the configured report is accessible via the AlfaBot. By default, the attribute will be set to `True` for new reports. Set the attribute to `False` if the configured report should not be opened outside of a specific context. For example, this may be relevant for reports that are specifically designed to be embedded in an object cockpit.

  This attribute is only relevant if the AlfaBot is implemented. For information about the implementation of the AlfaBot, see Implementing the AlfaBot for Navigation via a Full-Text Command.

- **Business Problem Statement**: Optionally enter a description that will help users to search for the configured report in the AlfaBot. The text is not displayed in the user interface, but it is of special relevance for the search mechanisms implemented for the AlfaBot. If the report caption entered by the user in the AlfaBot for a request to open a configured report does not match the caption of one of the available configured reports, the AlfaBot will split the caption entered by the user into keywords and will perform a keyword search on the **Caption**, **Description** and the **Business Problem Statement** attributes of the configured reports that are accessible via the AlfaBot. In addition to a keyword search, a synonym search is performed on the text provided in the **Business Problem Statement** attribute.

  This attribute is only relevant if the AlfaBot is implemented. For information about the implementation of the AlfaBot, see Implementing the AlfaBot for Navigation via a Full-Text Command.

- **Base Classes**: Define the object classes that must be available to run the configured report. If this attribute is set, the Alfabet Server checks whether the object classes specified as base

classes are excluded from the view scheme used to access the configured report. If the user does not have access permissions to one of the base classes, the configured report will be disabled. To set the attribute, click the **Browse** button to select the object classes that are required to run the configured report and click **OK**.

4) In the toolbar, click the **Save** button to save your changes.

Creating an Alfabet Configured Report That Opens an External Report

To define a configured report of the type `Extern`:

- Generate an external report independent of Alfabet by means of a reporting tool or script and make it available via a URL. If the external report shall display data from the Alfabet database or link to the Alfabet interface, consult the section *Accessing the Alfabet Database with External Applications* in the reference manual *System Administration* for details about the required interfaces with Alfabet.
- In the **Reports** explorer of the **Reports** tab of Alfabet Expand, create a new configured report and define the general attributes for the configured report and the attributes specific for external reports. This step is described below.
- Set the **Report State** of the configured report to `Active`. For information on how to change theattribute of the configured report, see.
- Define access permission for the configured report in the **Reports Administration** functionality of Alfabet. By default, access is possible for all users. For more information, see the chapter *Defining and Managing User Access to Configured Reports* in the reference manual *User and Solution Administration*.

To create a new configured report with a reference to an existing external report that was configured with an external reporting tool:

1) In the **Reports** tab, right-click the **Reports** folder or a sub-folder and select **Create New Report**. You will see the new configured report listed below the selected folder.

   As an alternative to defining all attributes for a new configured report, you can copy and paste an existing configured report and make modifications, as needed. To do so, right-click the existing configured report that you want to copy and select **Copy**. Right-click the new configured report and select **Paste**. Modify the necessary attributes described below.

2) In the attribute window, select `Extern` in the **Type** field.
3) In the attribute window, define the following attributes for the configured report:
   - **Name**: Optionally, change the technical name of the configured report. The technical name of the configured report must be unique.

     The technical name is used for identification of the configured report in the context of technical processes such as merging the report configuration with a report

configuration saved as an XML file. Therefore, the following is required when defining the name of a configured report:

- The name must be unique. The name must be unique regardless of the report folder it is structured in.
- The name may not be changed once a configured report has been created.
- A validation mechanism checks for correct syntax when defining a technical name. Please note that names may not begin with an empty space nor include special characters. For a list of the special characters that are not allowed, see the section Defining Attributes for Configuration Objects in the chapter Getting Started with Alfabet Expand.
- If the technical name of the configured report is changed, the name will be correctly updated in other configuration objects referencing the changed report during design time.

Please note that the name of a changed configuration object will not be updated in guide pages or guide views. If you plan to change the name of a configuration object, the reference in the navigation page should be changed prior to changing the configuration object name. You can use the **Show Usage** functionality in the context menu of the configured report to evaluate whether the configured report has been added to a guide view or guide page.

- **Caption**: Enter a caption for the external report that will be accessible via the URL definition. The name you define here will be displayed in the **Reports Administration** functionality and the **Configured Reports** views of the Alfabet interface. When the configured report is assigned to an object profile as a page view, the text is displayed by default as page view caption
- **Description**: Provide information about the external report that is useful to users. This comment will be displayed in the **Description** field for the external report in the **Reports Administration** functionality in the **Administration** application, the **Configured Reports** functionality. When the configured report is assigned to an object profile as a page view, the text is displayed beneath the page view caption as short description.
- **Report State**: The **Report State** attribute is view only and is set to `Plan` for new configured reports. The configured report can only be edited when the **Report State** attribute is set to `Plan`. After finishing all configuration steps described in the following, the **Report State** attribute must be set to `Active` as described in the section General Guidelines for Creating Configured Reports. The configured report is then visible to users in the Alfabet user interface.
- **URL**: Enter the URL targeting the location where the relevant external report is located.

  It is possible to specify part or all of the URL definition in the AlfabetMS.xml configuration file as server variable and reference the appropriate server variable in the URL definition of the external report. For information about how to use server variables see the section Using Server Variables in Web Link and Database Server-Related Specifications.

- **Help Index**: Specify the location of the external Help file using the following syntax:(For example,:). The external help file will be displayed when the user clicks the context-sensitive Help link in the standardHelp menu.

Server variables can be used in the Help links. Server variables allow you to define all or part of the URL definition in the server alias configuration of the Alfabet Server instead of directly defining it in the configuration in Alfabet Expand. Use of server variables is useful, For example, in order to change a Web server name defined in multiple URL definitions in Alfabet Expand. Instead of changing all URL definitions, only the variable value in the server alias configuration must be updated. The use of server variables is described in the section Using Server Variables in Web Link and Database Server-Related Specifications in the chapter Configuring Reports.

- **Selector Behavior**: The attribute can be used to exclude configured reports that are defined for special purposes, like For example, triggering of data export via the RESTful API, from being selectable in the **Configured Reports** table. By default, the attribute is set to `Visible` and the configured report is visible in the selector for adding configured reports to the **Configured Reports** table if all other conditions for access to the configured report apply. If the attribute is set to `NotVisible`, the configured report is excluded from the selector for adding configured reports to the **Configured Reports** functionality. Please note however, that this setting is not excluding the configured report from any standard views or customer configured views and selectors, but exclusively from the standard selector for configured reports implemented in Alfabet.

The attribute cannot be edited in the attribute window directly. To change the setting, right-click the configured report and select **Set Report Selector Behavior to 'Not Visible'** or **Set Report Selector Behavior to 'Visible'** respectively.

- **Applicable for AlfaBot**: Specify whether the configured report is accessible via the AlfaBot. By default, the attribute will be set to `True` for new reports. Set the attribute to `False` if the configured report should not be opened outside of a specific context. For example, this may be relevant for reports that are specifically designed to be embedded in an object cockpit.

  This attribute is only relevant if the AlfaBot is implemented. For information about the implementation of the AlfaBot, see Implementing the AlfaBot for Navigation via a Full-Text Command.

- **Business Problem Statement**: Optionally enter a description that will help users to search for the configured report in the AlfaBot. The text is not displayed in the user interface, but it is of special relevance for the search mechanisms implemented for the AlfaBot. If the report caption entered by the user in the AlfaBot for a request to open a configured report does not match the caption of one of the available configured reports, the AlfaBot will split the caption entered by the user into keywords and will perform a keyword search on the **Caption**, **Description** and the **Business Problem Statement** attributes of the configured reports that are accessible via the AlfaBot. In addition to a keyword search, a synonym search is performed on the text provided in the **Business Problem Statement** attribute.

  This attribute is only relevant if the AlfaBot is implemented. For information about the implementation of the AlfaBot, see Implementing the AlfaBot for Navigation via a Full-Text Command.

- **Base Classes**: Define the object classes that must be available to run the configured report. If this attribute is set, the Alfabet Server checks whether the object classes specified as base classes are excluded from the view scheme used to access the configured report. If the user does not have access permissions to one of the base classes, the configured report will be disabled. To set the attribute, click the **Browse** button to select the object classes that are required to run the configured report and click **OK**.

4) In the toolbar, click the **Save**  button to save your changes.

Creating Configured Reports That Are Containers for Multiple Configured Reports

You can define configured reports that are cockpits for display of multiple configured reports displaying data for the same context. There are two ways to define a configured report on basis of multiple existing configured reports:

- Console Reports

Console reports consist of multiple configured reports and optionally an attribute section. The attribute section is only applicable if the configured report is defined for a single base object.

On top of the configured reports, a filter can be defined that is valid for all configured reports subordinate to the console report.

- Cascading Reports

Cascading reports consist of multiple configured reports that refer to each other. A subordinate configured report can be defined as master of another subordinate configured report. When the user selects an object in the master report, the content of the subordinate configured report displays data about the selected object.

When the configured reports that shall be displayed in a single configured report are all about a defined object, and no further filter is required, you can define an object cockpit for the object profile of the object class the objects belong to instead of defining a console or cascading report. For more information about defining object cockpits, see Configuring Object Cockpits for a Custom Object View.

Creating Console Reports

A console report displays an object cockpit with a filter area. Filter settings done in the filter area of the console report can be applied to all configured reports in the object cockpit.

To generate a console report that displays an object cockpit with a filter:

1) In the **Reports** tab, right-click the **Reports** folder or a sub-folder thereof and select **Create New Report**. You will see the new configured report listed below the selected folder.

As an alternative to defining all attributes for a new configured report, you can copy and paste an existing configured report and make modifications, as needed. To do so, right-click the existing configured report that you want to copy and select **Copy**. Right-click the new configured report and select **Paste**. Modify the necessary attributes described below.

2) In the attribute window, select `Custom` in the **Type** field.

3) The following attribute settings are required to create a valid console report:

- **Base Object Query**: For a console report with a filter that is applied to all subordinate configured reports assigned to the console report, the base object query must find the `UserGlobalData` instance that is assigned to the current user. You can use the following queries.

In native SQL:

```
SELECT REFSTR, USERREF
FROM USERGLOBALDATA
WHERE USERREF = @CURRENT_USER
```

In Alfabet query language:

```
ALFABET_QUERY_500
FIND UserGlobalData
WHERE UserGlobalData.USERREF = @CURRENT_USER
```

- **Template**: This attribute must be left empty.

4) Optionally, you can define the following attributes for the configured report:

- **Name**: Optionally, change the technical name of the configured report. The technical name of the configured report must be unique.

  The technical name is used for identification of the configured report in the context of technical processes such as merging the report configuration with a report configuration saved as an XML file. Therefore, the following is required when defining the name of a configured report:

  - The name must be unique. The name must be unique regardless of the report folder it is structured in.
  - The name may not be changed once a configured report has been created.
  - A validation mechanism checks for correct syntax when defining a technical name. Please note that names may not begin with an empty space nor include special characters. For a list of the special characters that are not allowed, see the section Defining Attributes for Configuration Objects in the chapter Getting Started with Alfabet Expand.
  - If the technical name of the configured report is changed, the name will be correctly updated in other configuration objects referencing the changed report during design time.

  Please note that the name of a changed configuration object will not be updated in guide pages or guide views. If you plan to change the name of a configuration object, the reference in the navigation page should be changed prior to changing the configuration object name. You can use the **Show Usage** functionality in the context menu of the configured report to evaluate whether the configured report has been added to a guide view or guide page.

- **Caption**: Enter a caption for the configured report. The caption you define here will be displayed in the **Reports Administration** functionality in the **Administration** module and the **Configured Reports** views of the Alfabet interface. If the configured report is assigned to an object view as a page view, the text will be displayed as the page view caption in the object view. The caption of the configured report may exceed the conventional 64 character limit.

- **Description**: Provide a short information about the configured report that is useful to Alfabet users. This comment will be displayed on the Alfabet user interface in the header of the configured report in a single line under the report caption and the **Description** field for the configured report in the table of all views listing configured reports, like the **Configured Reports** views of the **Search** functionalities. If the configured report is assigned to an object view as a page view, the text will be displayed under the page view caption as short description in the object view.

  In the configured report, the description will be truncated if it is longer than one line on the screen. Therefore, the description should be short to ensure complete display in the configured report header.

- **Usage Guideline**: Provide information that helps users to execute and interpret the configured report. This information will not be displayed directly on the user interface. The user can access the information using the following mechanisms:

  - If the user moves the cursor over the description provided for the configured report with the attribute **Description**, a tooltip opens that includes both the description and the usage guideline.
  - The **Options** button will be displayed on the upper right with an option **Help On Filter Fields** to open a new window displaying the usage guideline in addition to any filter field hints, if configured.

    For views that have filters defined, the **Options** button will only be displayed if the filter panel either allows batch clearing of filter fields or collapsing and expanding of the filter panel. For more information about the configuration of these functionalities, see Configuring the Complete Filter Area to be Collapsible and Allowing the User to Clear the Filter Area.

- **Technical Comment**: Provide information that is useful for solution designers working with Alfabet Expand in order to better understand the configured report from a technical perspective. The **Technical Comment** will not be displayed in the user interface. Nevertheless, you can configure the interface to display the information in, For example, the attribute section of the configured report's object profile in the **Reports Administration** functionality.
- **Report State**: The **Report State** attribute is view only and is set to `Plan` for new configured reports. The configured report can only be edited when the **Report State** attribute is set to `Plan`. After finishing all configuration steps described in the following, the **Report State** attribute must be set to `Active` as described in the section General Guidelines for Creating Configured Reports. The configured report is then visible to users in the Alfabet user interface.
- **Help Index**: Specify the location of the external Help file using the following syntax:(For example,:). The external help file will be displayed when the user clicks the context-sensitive Help link in the standardHelp menu.

  Server variables can be used in the Help links. Server variables allow you to define all or part of the URL definition in the server alias configuration of the Alfabet Server instead of directly defining it in the configuration in Alfabet Expand. Use of server variables is useful, For example, in order to change a Web server name defined in multiple URL definitions in Alfabet Expand. Instead of changing all URL definitions,

only the variable value in the server alias configuration must be updated. The use of server variables is described in the section Using Server Variables in Web Link and Database Server-Related Specifications in the chapter Configuring Reports.

- **Selector Behavior**: The attribute can be used to exclude configured reports that are defined for special purposes, like For example, triggering of data export via the RESTful API, from being selectable in the **Configured Reports** table. By default, the attribute is set to `Visible` and the configured report is visible in the selector for adding configured reports to the **Configured Reports** table if all other conditions for access to the configured report apply. If the attribute is set to `NotVisible`, the configured report is excluded from the selector for adding configured reports to the **Configured Reports** functionality. Please note however, that this setting is not excluding the configured report from any standard views or customer configured views and selectors, but exclusively from the standard selector for configured reports implemented in Alfabet.

The attribute cannot be edited in the attribute window directly. To change the setting, right-click the configured report and select **Set Report Selector Behavior to 'Not Visible'** or **Set Report Selector Behavior to 'Visible'** respectively.

- **Applicable for AlfaBot**: Specify whether the configured report is accessible via the AlfaBot. By default, the attribute will be set to `True` for new reports. Set the attribute to `False` if the configured report should not be opened outside of a specific context. For example, this may be relevant for reports that are specifically designed to be embedded in an object cockpit.

  This attribute is only relevant if the AlfaBot is implemented. For information about the implementation of the AlfaBot, see Implementing the AlfaBot for Navigation via a Full-Text Command.

- **Business Problem Statement**: Optionally enter a description that will help users to search for the configured report in the AlfaBot. The text is not displayed in the user interface, but it is of special relevance for the search mechanisms implemented for the AlfaBot. If the report caption entered by the user in the AlfaBot for a request to open a configured report does not match the caption of one of the available configured reports, the AlfaBot will split the caption entered by the user into keywords and will perform a keyword search on the **Caption**, **Description** and the **Business Problem Statement** attributes of the configured reports that are accessible via the AlfaBot. In addition to a keyword search, a synonym search is performed on the text provided in the **Business Problem Statement** attribute.

  This attribute is only relevant if the AlfaBot is implemented. For information about the implementation of the AlfaBot, see Implementing the AlfaBot for Navigation via a Full-Text Command.

- **Base Classes**: Define the object classes that must be available to run the configured report. If this attribute is set, the Alfabet Server checks whether the object classes specified as base classes are excluded from the view scheme used to access the configured report. If the user does not have access permissions to one of the base classes, the configured report will be disabled. To set the attribute, click the **Browse** button to select the object classes that are required to run the configured report and click **OK**.

- **Can Create Express View**: Select `True` if an express view may be created for the report. Select `False` if an express view may not be created for the report. Please note that for reports that have a custom report view, the setting must be consistent with the setting of the attribute **Can Create Express View** of the custom report view.

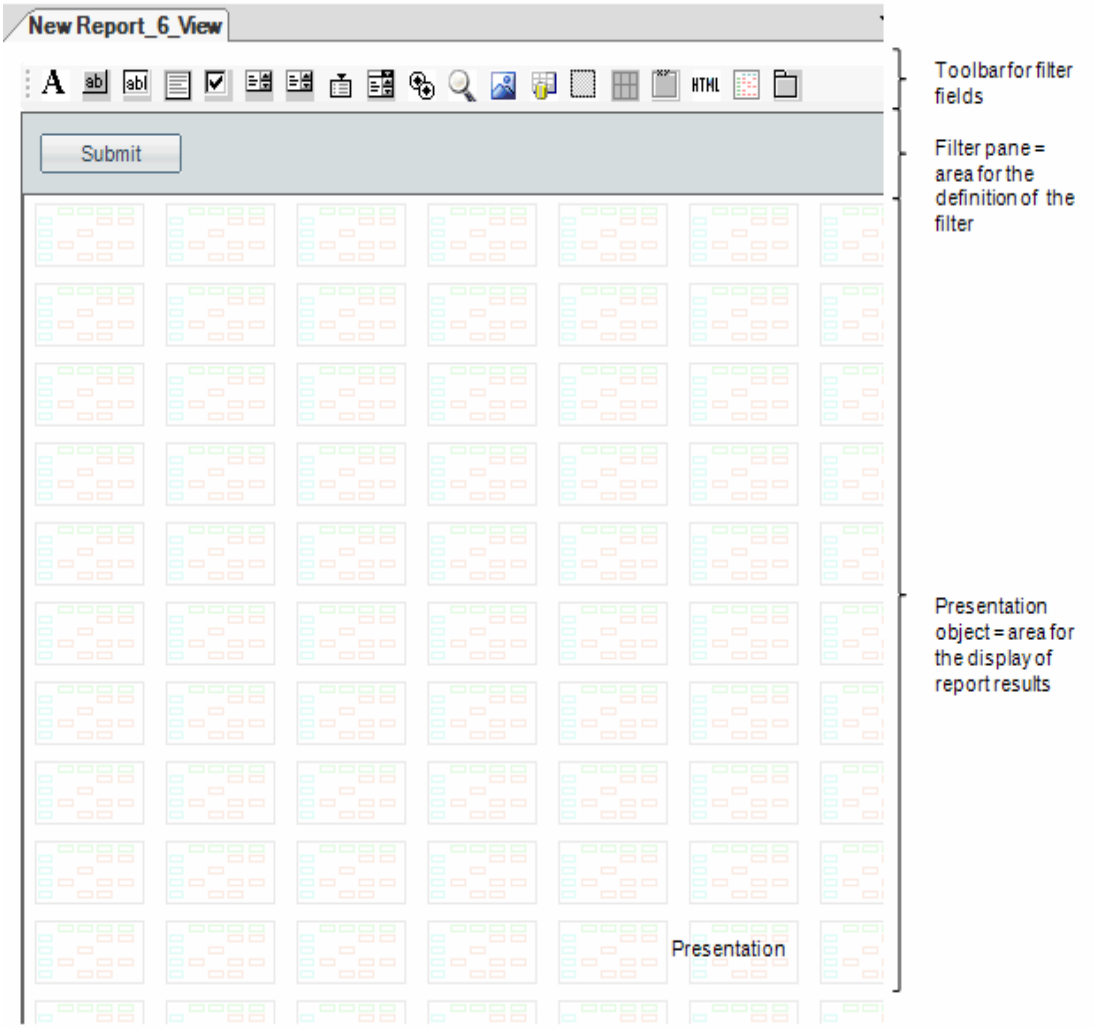
An express view is a link to a specific Alfabet view displaying data that allows individuals inside or outside of the user community to view information in Alfabet. When the express view is created, an email notification is automatically mailed to a specified recipient. The recipient receives a URL that allows him/her to access the current page view in Alfabet. For more information, see the section *Sending and Receiving Express Views* in the reference manual *Getting Started with Alfabet*.

5) In the explorer, right-click the configured report and select **Create Custom Report View**. The view editor opens. In the explorer, the custom report view is displayed as a subordinate object of the configured report. The attributes for the custom report view are displayed in the attribute window. You can optionally edit the following attributes:

- **Name**: Optionally you can change the name for the custom report view. The **Name** must be unique for custom report views.
- **Can Create Bookmark**: Select `True` if a bookmark may be created for the configured report. Select `False` if a bookmark may not be created for the configured report.
- **Can Create Express View**: Select `True` if an express view may be created for the configured report. Select `False` if an express view may not be created for the configured report. Please note that the setting must be consistent with the setting of the attribute **Can Create Express View** of the configured report.

An express view is a link to a specific Alfabet view displaying data that allows individuals inside or outside of the user community to view Alfabet information. When the express view is created, an e-mail notification is automatically mailed to the specified recipient who receives a URL that allows him/her to access the current page view via an Alfabet Web Client. For more information, see *Sending and Receiving Express Views* in the reference manual *Getting Started with Alfabet*.

6) In the view editor, define the filter in the filter panel on top of the panel named ***Presentation***.



The filter must be defined to store data into a custom property of the object class `UserGlobal-Data`. Follow the configuration steps to configure reusable filter settings described in the section Configuring Reusability of Filter Settings Across Reports in the Chapter Defining Queries.

For general information about the definition of the filter panel and the filter fields in the panel, see Defining Filters for Configured Reports and Selectors in the chapter Defining Queries.

7) In the view editor, click inside the presentation object named ***Presentation***.

8) Right-click inside the view and select **Delete** . The ***Presentation*** pane is deleted.

9) In the toolbar of the view editor, click the **Flow Panel** or **Table Layout Panel** button and click in the custom report view pane where you want to place it. The element is added to the pane.

It is recommended to use the **Flow Panel** design which has the advantage that object cockpits are not squeezed, stretched, or truncated when the interface is resized. Group boxes containing attributes and presentation objects (views and reports) will be dynamically positioned according to the current width of the Alfabet Web interface. When resizing the interface, the content displayed in object cockpits will be redistributed in the available space and the content will not be cut-off. The flow panel ensures that a configured view or set of views will be bumped down and placed below the preceding view or

set of views. Business graphics embedded in an object cockpit will be automatically scaled down in size to fit in the available screen space of the device the user is using.

Console reports rendered in static **Table Layout Panel** interface control that does not allow for dynamic positioning of the interface controls based on the width of the software interface. This method is available for reasons of backward compatibility however it is not recommended to use the **Table Layout Panel** interface control because the data in the object cockpit may be squeezed, stretched, or truncated when the interface is resized.

10) Design the object cockpits by adding elements as described in the section Configuring the Object Cockpit By Means of a Flow Panel or Configuring the Object Cockpit By Means of a Table Grid in the chapter Configuring Object Views.

The following special requirements apply to the configuration of object cockpits in a console report:

- Only configured reports and standard Alfabet views can be added to the pane. Presentation objects cannot be added to a console report.
- After having added a configured report to the cockpit, click the presentation object of the configured report in the pane, and in the attribute window, set the **Refresh on Submit** attribute of the presentation object to `True`. This setting is required to update the configured report on submit of the filter settings.
- If **Value Control** elements of the **Sub Type** `Property` are added to the console report, the **Refresh On Submit** attribute of the controls must be set to `True` to update values on submit of the filter settings.

11) In the toolbar, click the **Save**  button to save your changes.

12) In the explorer, right-click the console report and select **Review Report**. The console report opens in a web browser. If the results are not as expected, you can edit the console report until the output of the console report meets your expectations.

The **Review Report** functionality also allows the visibility of toolbar buttons of the configured report to be defined for different view schemes. For more information, see Refining Visibility Issues in the View Scheme.

After having created the configured report, you can define access rights for the configured report in the **Reports Administration** functionality of Alfabet. By default, access is possible for all users. For more information, see the chapter *Defining and Managing User Access to Configured Reports* in the reference manual *User and Solution Administration*.

Creating Cascading Reports

In a cascading report, at least two configured reports are added to the custom report view and one of the configured reports is defined to display data about a single object in the other configured report when a user clicks the object in the configured report.

To define a cascading report with one master report and a second configured report subordinate to the master report, you must define three configured reports, the master report, the subordinate configured report and the cascading report that combines the two configured reports.

1) Define the master report. The master report can be any configured report of the type `Query`, `NativeSQL` or `Custom`.

   For information about the definition of the configured report see the sections Creating a Tabular Configured Report of the Type Query, Creating a Tabular Configured Report of the Type NativeSQL,Creating a Graphic Report.

2) Define the subordinate configured report. The subordinate configured report can be any configured report of the type `Query`, `NativeSQL` or `Custom`. Define the dependency with the master report by using the Alfabet parameter `MASTEROBJECT` in at least one `WHERE` clause of the query that specifies the content of the subordinate configured report. The Alfabet parameter `MASTEROBJECT` returns the `REFSTR` of the object that the user currently selected in the master report during runtime.

   For general information about the definition of the configured report see the sections Creating a Tabular Configured Report of the Type Query, Creating a Tabular Configured Report of the Type NativeSQL, Creating a Graphic Report.

   For general information about the use of Alfabet parameters in queries, see Referring to the Current Alfabet Context in a WHERE Condition and Using Alfabet Parameters in Native SQL Queries in the chapter Defining Queries.

3) Set the **Report State** attribute of both master and subordinate configured report to `Active` before performing the next steps.

4) To define the cascading report that combines the master report with the subordinate configured report, right-click the **Reports** folder or a sub-folder thereof and select **Create New Report**. You will see the new configured report listed below the selected folder.

5) In the attribute window, select `Custom` in the **Type** field.

6) Optionally, you can define the following attributes for the configured report:

   - **Name**: Optionally, change the technical name of the configured report. The technical name of the configured report must be unique.

     The technical name is used for identification of the configured report in the context of technical processes such as merging the report configuration with a report configuration saved as an XML file. Therefore, the following is required when defining the name of a configured report:

     - The name must be unique. The name must be unique regardless of the report folder it is structured in.
     - The name may not be changed once a configured report has been created.
     - A validation mechanism checks for correct syntax when defining a technical name. Please note that names may not begin with an empty space nor include special characters. For a list of the special characters that are not allowed, see the section Defining Attributes for Configuration Objects in the chapter Getting Started with Alfabet Expand.

- If the technical name of the configured report is changed, the name will be correctly updated in other configuration objects referencing the changed report during design time.

Please note that the name of a changed configuration object will not be updated in guide pages or guide views. If you plan to change the name of a configuration object, the reference in the navigation page should be changed prior to changing the configuration object name. You can use the **Show Usage** functionality in the context menu of the configured report to evaluate whether the configured report has been added to a guide view or guide page.

- **Caption**: Enter a caption for the configured report. The caption you define here will be displayed in the **Reports Administration** functionality in the **Administration** module and the **Configured Reports** views of the Alfabet interface. If the configured report is assigned to an object view as a page view, the text will be displayed as the page view caption in the object view. The caption of the configured report may exceed the conventional 64 character limit.
- **Description**: Provide a short information about the configured report that is useful to Alfabet users. This comment will be displayed on the Alfabet user interface in the header of the configured report in a single line under the report caption and the **Description** field for the configured report in the table of all views listing configured reports, like the **Configured Reports** views of the **Search** functionalities. If the configured report is assigned to an object view as a page view, the text will be displayed under the page view caption as short description in the object view.

  In the configured report, the description will be truncated if it is longer than one line on the screen. Therefore, the description should be short to ensure complete display in the configured report header.

- **Usage Guideline**: Provide information that helps users to execute and interpret the configured report. This information will not be displayed directly on the user interface. The user can access the information using the following mechanisms:
  - If the user moves the cursor over the description provided for the configured report with the attribute **Description**, a tooltip opens that includes both the description and the usage guideline.
  - The **Options** button will be displayed on the upper right with an option **Help On Filter Fields** to open a new window displaying the usage guideline in addition to any filter field hints, if configured.

    For views that have filters defined, the **Options** button will only be displayed if the filter panel either allows batch clearing of filter fields or collapsing and expanding of the filter panel. For more information about the configuration of these functionalities, see Configuring the Complete Filter Area to be Collapsible and Allowing the User to Clear the Filter Area.

- **Technical Comment**: Provide information that is useful for solution designers working with Alfabet Expand in order to better understand the configured report from a technical perspective. The **Technical Comment** will not be displayed in the user interface. Nevertheless, you can configure the interface to display the information in, For example, the attribute section of the configured report's object profile in the **Reports Administration** functionality.

- **Report State**: The **Report State** attribute is view only and is set to `Plan` for new configured reports. The configured report can only be edited when the **Report State** attribute is set to `Plan`. After finishing all configuration steps described in the following, the **Report State** attribute must be set to `Active` as described in the section General Guidelines for Creating Configured Reports. The configured report is then visible to users in the Alfabet user interface.

- **Apply to Class**: When the configured report is applied to an object class or object class stereotype, a base object can be selected for the configured report. A filter for selection of a base object will automatically be set on top of the configured report. When configuring queries for the configured report, you can use the Alfabet parameter `BASE` to refer to the object selected in the filter and define search conditions dependent on the base object. To apply the configured report to a base class, click the **Browse** button to open a dialog box and select the object class to which you want to apply the configured report and click **OK**

  Note the following:

  - If the configured report is assigned to the object view of an object of the class it is applied to, the configured report will automatically open with the current object selected as base object, even if **Apply to Class** is not set.
  - If the configured report is applied to an object class stereotype, the filter field for selection of the base object will use the caption of the object class stereotype as caption of the filter field and the selector defined in the class settings for the object class stereotype for selection of the base object.
  - Alternatively, the base object of a configured report can be set with the attribute **Base Query**. While the attribute **Apply to Class** enables the user to determine the current base object by setting a filter, the **Base Query** evaluates the base object by execution of a query when opening the configured report. A filter field is not available and the user cannot change the base object.
  - The parameter **Apply to Class** also influences the availability of the configured report on the Alfabet interface. Select a class to make the configured report available in the **Configured Reports** page view on the object view of objects of the selected object class. If you do not set the attribute, the configured report is only available in the **Configured Reports** functionality. The configured report can be assigned to object views and wizards independent from the parameter.

- **Execute on Enter**: Set to `True` to execute the configured report with empty filter settings when the user opens the configured report on the Alfabet interface. Set to `False` to open the configured report without execution of the Alfabet query with empty filter settings. By default, this attribute is set to `True`. It should only be set to `False` when a configured report would result in an exceedingly big dataset when executed with empty filter settings.

  When you set **Execute on Enter** to `False`, you must make sure that the **Submit** button is available in the custom report view of the configured report. If the **Submit** button is deleted from the custom report view, the configured report cannot be displayed. The setting and execution of the **Execute on Enter** attribute is independent from the definition of filters for a configured report. A configured report without

filters must nevertheless have a **Submit** button when **Execute on Enter** is set to `False`.

- **Help Index**: Specify the location of the external Help file using the following syntax:(For example,:). The external help file will be displayed when the user clicks the context-sensitive Help link in the standardHelp menu.

  Server variables can be used in the Help links. Server variables allow you to define all or part of the URL definition in the server alias configuration of the Alfabet Server instead of directly defining it in the configuration in Alfabet Expand. Use of server variables is useful, For example, in order to change a Web server name defined in multiple URL definitions in Alfabet Expand. Instead of changing all URL definitions, only the variable value in the server alias configuration must be updated. The use of server variables is described in the section Using Server Variables in Web Link and Database Server-Related Specifications in the chapter Configuring Reports.

- **Selector Behavior**: The attribute can be used to exclude configured reports that are defined for special purposes, like For example, triggering of data export via the RESTful API, from being selectable in the **Configured Reports** table. By default, the attribute is set to `Visible` and the configured report is visible in the selector for adding configured reports to the **Configured Reports** table if all other conditions for access to the configured report apply. If the attribute is set to `NotVisible`, the configured report is excluded from the selector for adding configured reports to the **Configured Reports** functionality. Please note however, that this setting is not excluding the configured report from any standard views or customer configured views and selectors, but exclusively from the standard selector for configured reports implemented in Alfabet.

The attribute cannot be edited in the attribute window directly. To change the setting, right-click the configured report and select **Set Report Selector Behavior to 'Not Visible'** or **Set Report Selector Behavior to 'Visible'** respectively.

- **Base Classes**: Define the object classes that must be available to run the configured report. If this attribute is set, the Alfabet Server checks whether the object classes specified as base classes are excluded from the view scheme used to access the configured report. If the user does not have access permissions to one of the base classes, the configured report will be disabled. To set the attribute, click the **Browse** button to select the object classes that are required to run the configured report and click **OK**.
- **Can Create Express View**: Select `True` if an express view may be created for the report. Select `False` if an express view may not be created for the report. Please note that for reports that have a custom report view, the setting must be consistent with the setting of the attribute **Can Create Express View** of the custom report view.

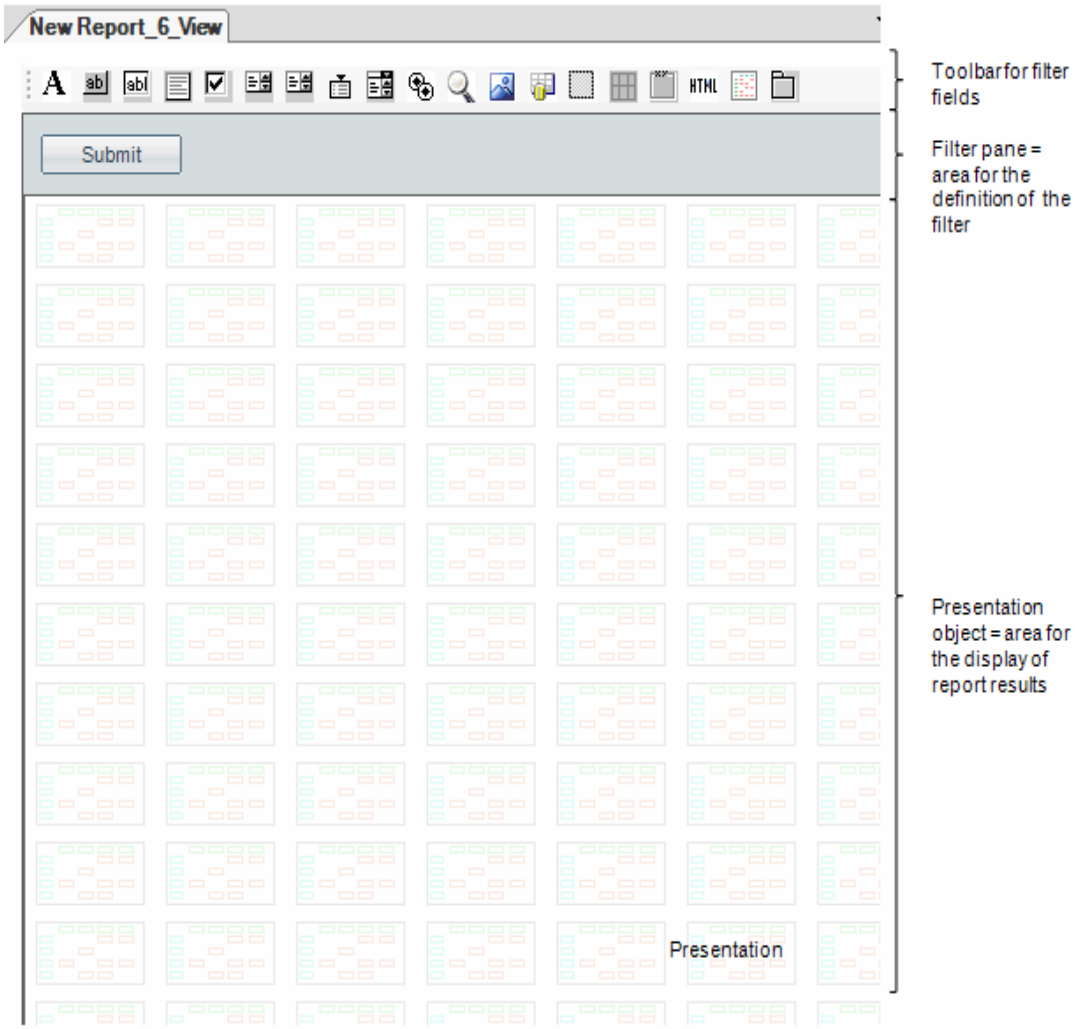
  An express view is a link to a specific Alfabet view displaying data that allows individuals inside or outside of the user community to view information in Alfabet. When the express view is created, an email notification is automatically mailed to a specified recipient. The recipient receives a URL that allows him/her to access the current page view in Alfabet. For more information, see the section *Sending and Receiving Express Views* in the reference manual *Getting Started with Alfabet*.

7) In the explorer, right-click the configured report and select **Create Custom Report View**. The view editor opens. In the explorer, the custom report view is displayed as a subordinate object of the configured report. The attributes for the custom report view are displayed in the attribute window. You can optionally edit the following attributes:

- **Name**: Optionally you can change the name for the custom report view. The **Name** must be unique for custom report views.
- **Can Create Bookmark**: Select `True` if a bookmark may be created for the configured report. Select `False` if a bookmark may not be created for the configured report.
- **Can Create Express View**: Select `True` if an express view may be created for the configured report. Select `False` if an express view may not be created for the configured report. Please note that the setting must be consistent with the setting of the attribute **Can Create Express View** of the configured report.

  An express view is a link to a specific Alfabet view displaying data that allows individuals inside or outside of the user community to view Alfabet information. When the express view is created, an e-mail notification is automatically mailed to the specified recipient who receives a URL that allows him/her to access the current page view via an Alfabet Web Client. For more information, see *Sending and Receiving Express Views* in the reference manual *Getting Started with Alfabet*.

8) In the view editor, either define a filter in the filter panel on top of the panel named ***Presentation*** or delete the filter pane if no filter is required and the attribute **Execute on Enter** of the configured report is not set to `False`.



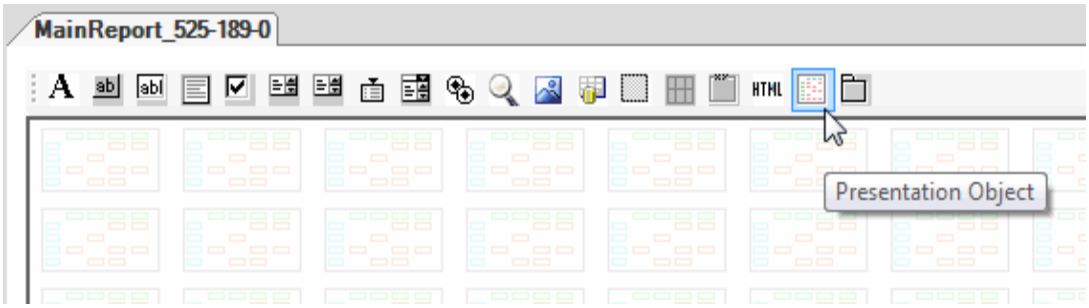
For general information about the definition of the filter panel and the filter fields in the panel, see Defining Filters for Configured Reports and Selectors in the chapter Defining Queries.

9) In the view editor, click inside the presentation object named ***Presentation***.

10) In the attribute window, set the attribute **Dock** of the presentation object to `Top`.

11) Alter the size and position of the presentation object to the size the master report should have in the custom report view. The size and position can be altered using the **Coordinates** attributes in the attribute window or by directly resizing and moving the graphic object in the custom report view.

12) In the toolbar, click the **Presentation Object** button, and then click on the position where the presentation object should be located in the custom report view. The presentation object is added to the custom report view and can be resized and moved to the correct position.

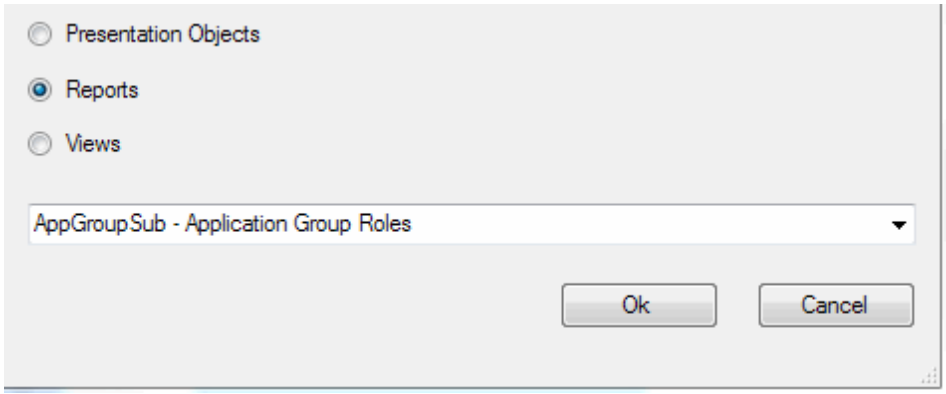


13) In the attribute window, set the attribute **Dock** of the presentation object to `Fill`.

A validation mechanism checks for inconsistencies in the layout and docking definition of interface controls in guide views, configured reports, and other configured views. Please note that an error message will be displayed when the user attempts to open an incorrectly configured view if two or more interface controls have no docking defined in the view. The error message will provide detailed information about the faulty configuration.

14) For both presentation objects, set the following attributes in the attribute window that opens when you click on the presentation object:

- **Name**: The name of the presentation object of the master report is used instead of the configured report name to set the master in the subordinate configured reports. The name of the presentation object should be altered to a string that makes it easy to identify the underlying report configuration. The name is a technical name and shall not contain whitespaces or special characters.
- **Refresh on Submit**: Select `True`.
- **Sub Type**: Select `View`.
- **Source**: Click the button on the right of the field. A selector window opens. Select configured reports and select the configured report that shall be displayed in the drop-down list of available configured reports. Click **OK** to save your selection.



15) For the presentation object of the subordinate configured report, set the following attribute:

- **Master Control**: Click the button on the right of the field. A selector window opens. Select the checkbox of the presentation object containing the master report. Click **OK** to save your selection.

16) In the toolbar, click the **Save** button to save your changes.

17) Right-click the configured report and select **Review Report**. The configured report opens in a Web browser. If the result is not as expected, alter the settings for your configured reports until the configured report is correctly displayed.

The **Review Report** functionality also allows the visibility of toolbar buttons of the configured report to be defined for different view schemes. For more information, see Refining Visibility Issues in the View Scheme.

18) Set the **Report State** attribute of the configured report to `Active`.

After having created the configured report, you can define access rights for the configured report in the **Reports Administration** functionality of Alfabet. By default, access is possible for all users. For more information, see the chapter *Defining and Managing User Access to Configured Reports* in the reference manual *User and Solution Administration*.

Testing Configured Reports

You can test the outcome of your report configuration by opening the configured report directly from Alfabet Expand:

Access of Alfabet Expand to a running Alfabet Web Application must be configured in the server alias of Alfabet Expand to use this feature. For information about the configuration of the server alias, see the section *Installation and Configuration of Alfabet Expand and the Guide Pages Designer* in the reference manual *System Administration*.

1) Prior to using the test functionality, all current changes to the meta-model must be saved to the Alfabet database. If applicable, click the **Save** button to save all changes.

2) In the explorer of the **Reports** tab, right click the configured report that you want to test and select **Review Report** from the context menu.

The configured report opens in a web interface rendered by a running Alfabet Web Application.

Please note the following about the test view for configured reports opened via Alfabet Expand:

- No menu buttons are displayed.
- Navigation from cells or graphic elements in a configured report to views or editors in Alfabet is disabled. These configurations cannot be tested via the **Review Report** function.
- For performance reasons, the web server used to render the report for the **Review Report** function caches part of the meta-model information. If you use the function, change the report and re-use the function within a short time interval, de-synchronization of the cached data and the content stored in the Alfabet database might occur and you might see a message informing you that the design page is not valid any more. If this message is displayed, close the window and re-use the **Review Report** option in the context menu of the configured report to repeat the test. The view then opens with the correct content.

Managing and Structuring Your Configured Reports in Folders

You can organize your configured reports in folders and sub-folders. A report folder can have multiple sub-folders and multiple levels of sub-folders. A configured report can be assigned to any root level folder or sub-folder.

The hierarchy that you define in Alfabet Expand in the **Reports** explorer is also used to present the configured reports to users in the **Configured Reports** functionality and the **Configured Reports** page view in object profiles. Therefore, the names of report folders and the structure should be carefully considered so that they are easily understandable for relevant users.

Creating a New Report Folder

To create a new report folder:

1) In the **Reports** explorer, right-click the root node to create a new folder at the top level of the hierarchy or right-click an existing report folder to add a sub-folder to that report folder.
2) Select **Create New Folder**. The new report folder is added to the explorer tree with a default name.
3) Click the new report folder to open the attribute window. Define the following attributes:
   - **Name**: Enter a unique name for the report folder. This name is used to identify the report folder in technical processes, For example, when merging two configurations.
   - **Caption**: Enter a caption for the report folder. This caption is displayed to the users in the **Configured Reports** view for the report folder.
   - **Description**: Enter a meaningful description that will clarify the purpose of the report folder for the users looking for a configured report.
   - **Technical Comment**: Provide information that is useful for solution designers working with Alfabet Expand. The **Technical Comment** will not be displayed on the user interface. Nevertheless, you can configure the interface to display the information For example, in the attribute section of the report folder's object profile in the **Reports Administration** functionality.

4) Click **OK** to save your report folder or **Cancel** to exit without saving the data.

You will see the new report folder in the table with a + or - symbol next to it. You can now add configured reports to the folder or create additional levels of sub-folders to the reports folder.

Moving Configured Reports and Report Folders in the Hierarchy

You can move an existing report folder or configured report in the hierarchy via drag and drop.

You can only move a report folder or configured report to another report folder. It is not possible to change the order of the report folders within one report folder using drag and drop or copy and paste.

To move a configured report or report folder using drag and drop:

1) In the **Reports** explorer tree of the **Reports** tab, click the configured report or report folder that you want to move and drag it to the new location.

Adding Existing Configured Reports to Report Folders

You can move an existing configured report in the hierarchy using cut and paste or copy an existing configured report to a new location using copy and paste:

1) In the **Reports** explorer tree of the **Reports** tab, right-click the configured report that you want to copy or move and select
   - **Copy** to make a copy of the configured report. The original configured report will remain at the old location.
   - **Cut** to remove the configured report from the old location.
2) Right-click the report folder that you want to add the configured report to and select **Paste**.
3) Right-click the **Reports** root folder and select **Rescan Tree**. If you used cut and paste, the configured report is now removed from the old location and only displayed at the new location.

Deleting a Configured Report or Report Folder

You can delete configured reports that are in the **Report State** `Plan` or `Retired`. It is not possible to delete configured reports in the **Report State** `Active`. If you want to delete a report folder, all configured reports in the folder must have the **Report State** attribute set to `Plan` or `Retired`.

If you delete a configured report or a report folder, the configured report or report folder will be irrevocably deleted from the Alfabet database.

If you delete a report folder that contains configured reports or sub-folders, the configured reports and sub-folders are also deleted irrevocably from the Alfabet database.

To delete an existing configured report or report folder:

1) In the **Reports** explorer in the **Reports** tab, right-click the configured report or report folder that you want to delete and select **Delete**.

2) Confirm the warning by clicking **Yes**, or click **No** to exit without saving your changes.

Alfabet Expand also offers mechanisms to batch delete configured reports on the root level. You can either delete all report folders and their configured reports and sub-folders or delete only configured reports that are created directly at the root level. This mechanism is useful, For example, to manage Ad-Hoc reports that are created to answer one-time requests for information. If all configured reports created for long-term availability on the Alfabet interface are stored in report folders, and Ad-Hoc reports are stored on the root level of the **Reports** tree, the Ad-Hoc reports can be batch deleted without affecting the long-term configured reports.

To batch delete configured reports or report folders on the root level:

1) In the **Reports** explorer in the **Reports** tab, right-click the **Reports** root folder and select one of the following:
   - **Delete All Root Reports** to delete all configured reports that are located directly under the root level folder.
   - **Delete All Folders** to delete all report folders and their sub-folders and configured reports.
2) Confirm the warning by clicking **Yes,** or click **No** to exit without saving your changes.

Changing the Settings for all Configured Reports in a Report Folder on the Report Folder Level

The context menu of the report folder contains options that are also available in the context menu of the configured report. If you select one of these context menu options on the report folder level, the change is performed for all configured reports that are located in the report folder or sub-folders thereof. Please note that changes are applied independent of the setting of the attribute **Report State** of the configured report.

The following option of the configured report can be set for all reports in a report folder:

- Changing the attribute **Report State** of the configured reports subordinate to the report folder.
- Changing the attribute **Selector Behavior** of the configured reports subordinate to the report folder.
- Updating the translation changed for the description and caption of the configured reports subordinate to the configured report folder in the Alfabet database.

Once the **Caption** and **Description** attributes have been specified for a configured report, they will be automatically added to the vocabularies available in Alfabet Expand. Once they are available in the vocabularies, they can be translated like any other string in the **Translation Editor** or exported to a Microsoft Excel file and translated there. For more information, see the section Modifying, Translating and Managing the Vocabularies in the chapter Localization and Multi-Language Support for the Alfabet Interface.

For technical reasons, the translation of report captions and descriptions is coupled with the mechanisms of object data translation. Therefore, the translation provided via the vocabularies is only displayed in the Alfabet interface if data translation is enabled for the object class `ALFA_REPORT` and the option **Update Translation** in the context menu of the configured report was used.

Understanding Private Report Folders

A number of private report folders is available in the **Reports** explorer of any Alfabet installation. The content of these folders is provided by Software AG for storage of preconfigured or automatically generated report required for the following functionalities:

Private report folder	Supported functionality
AlfaBotReports	This folder contains preconfigured reports specifying the configured reports that are included into the faceted search for the Analyze intent of the AlfaBot. For basic information about the `Analyze` intent, see *Using the AlfaBot User Assistance* in the reference manual *Getting Started with Alfabet*. For more information about the configuration required to use the functionality, see Implementing the AlfaBot for Navigation via a Full-Text Command.
Analysis Intent Ad-Hoc Reports	This folder contains reports that are automatically generated to answer questions users are entering into the faceted search view of the `Analyze` intent of the AlfaBot. For basic information about the `Analyze` intent, see *Using the AlfaBot User Assistance* in the reference manual *Getting Started with Alfabet*. For more information about the configuration required to use the functionality, see Implementing the AlfaBot for Navigation via a Full-Text Command. Please note that this folder may contain a high number of reports and shall be cleaned up in regular intervals. The cleanup process is part of the configuration described for implementing the AlfaBot.
DataImport-IntoARIS	This folder contains preconfigured reports for data export from Alfabet to ARIS via the ARIS - Alfabet Interoperability Interface. For more information, see *Configuring Data Export from Alfabet* in the reference manual *ARIS - Alfabet Interoperability*.

You cannot edit the content of private folders.

Integration of Configured Reports in the Alfabet Interface

There are two concepts that allow the integration of configured reports in the Alfabet interface:

- Configured reports can be displayed separate from the standard reports in Alfabet so that they are clearly identifiable as configured reports. They can then be accessed by the user in the standard **Configured Reports** functionality and/or in the **Configured Reports** page view available in the object profile of selected object classes.
- Standard and configured reports can be included in custom object views or object cockpits, wizards and workflows. Hyperlinks to standard and configured reports can be implemented in guide pages. No distinction between a standard or configured report in the guide page, object profile, workflow step or wizard view is visible to the user.

Only configured reports for which the **Report State** attribute is set to `Active` can be executed in the Alfabet interface. When the **Report State** attribute is reset to `Plan` or `Retired`, the user will not be able to access the configured report via a link from a guide page, an object profile, workflow step or wizard view. A respective error message will inform the user that the configured report is currently not available.

Display of Configured Reports in a Separate Functionality

Users can access configured reports in the Alfabet interface either in the **Configured Reports** functionality or in the **Configured Reports** page view available in the relevant object view. Both views provide a table that displays the configured reports structured in folders. These report folders are also created in Alfabet Expand. The user will see the configured reports exactly as structured in the Alfabet Expand explorer.

The table describes the type of configured report and displays the name and the description specified for the configured report. To view the configured report, the user must select a configured report in the table and click the **Go to Report** button in the toolbar. If the configured report is an external report, the specified URL of the report will open in a new window. All other types of configured reports open directly in the Alfabet interface.

User access to a configured report in the **Configured Reports** view will depend on the following:

- **The definition of the Report State attribute of the report.**

Configured reports can have the **Report State** attribute set to `Plan`, `Active` or `Retired`. Configured reports with the **Report State** attribute set to `Plan` are not included in the table. This state is reserved for configured reports that are currently being configured. Only configured reports with the **Report State** attribute set to `Active` will be available to users. Configured reports that are obsolete are set to the state `Retired`. These configured reports are displayed in red in the **Configured Reports** table for the users that have access to the configured report.

- **The definition of the Apply to Class attribute of the configured report.**

Users can access all configured reports via the **Configured Reports** functionality available in the **Search** module. If the **Type** attribute of the configured report is set to `Custom` or `Query` and the **Apply to Class** attribute is defined, the configured report will also be available in the **Configured Reports** page view in the **Configured Reports** workspace of the object view of the specified object class.

Configured reports that are defined for an object class may display results about objects that are completely independent of the object the user is currently working with. For example, an external report defined for the object class Application might show a contact list of all application architects in the enterprise. However, it is also possible to configure the configured report to display results that are specific to the object that the user is currently working with. For example, a configured report might display the projects where the current application is defined as part of the affected architecture.

- **The definition of access permissions configured for the configured report in the Reports Administration functionality of the Administration application in Alfabet .**

Access permissions can be restricted to the configured authorized user and authorized user groups or granted to users logged in with a specified object view, or users that are members of a specified user group.

The administrator can either configure the configured report to be included automatically in the table of reports in the **Configured Reports** view or to be included only when explicitly added to the **Configured Reports** view.

- **The definition of the Selector Behavior attribute of the report.**

The **Selector Behavior** attribute can be used to exclude configured reports that are defined for special purposes (such as triggering data export via the RESTful API) from being selectable in the **Configured Reports** table. By default, the attribute is set to `Visible` and the configured report is visible in the selector used to add configured reports to the **Configured Reports** table if all other conditions for access to the configured report apply. If the attribute is set to `NotVisible`, the configured report will be excluded from the selector used to add configured reports to the **Configured Reports** functionality. The **Selector Behavior** attribute is not set directly in the attribute window of the configured report, but rather by triggering the respective action in the context menu of the configured report. The action can also be triggered for a report folder in order to exclude all reports in a report folder. Please note that this only excludes the configured report from the standard selector for configured reports that are used per default in the **Configured Report** views. If a custom selector is used, the configured report might be selectable if not otherwise defined by the solution designer. The **Selector Behavior** attribute has no impact on the display of the configured report in the Alfabet user interface. The report may even be visible in the **Configured Reports** table if it already has been added to the view or if the configured report has been defined to be added per default to the **Configured Report** table for a user without prior selection by the user.

For detailed information about the configuration of access permissions for configured reports, see the chapter *Defining and Managing User Access to Configured Reports* in the reference manual *User and Solution Administration*.

Integration of Configured Reports as Page Views in Custom Object Views or Object Cockpits

Alfabet is highly customizable. Customization can be performed on the level of explorers, object profiles (object views), editors and page views. Object profiles provide information about the attributes of the current object, allow editing of the object, and provide links to all relevant page views for the object. Page views either allow the user to edit the object or display non-editable data about the objects.

When configuring a custom object view or an object cockpit for a custom object view, the list of relevant views for the object can include standard Alfabet page views as well as configured reports. In the object profile, the configured reports are displayed and accessed as standard page views. The user will not be able to distinguish between standard Alfabet views or configured reports.

For a description of the configuration of object views and object cockpits including the assignment of configured reports to the object profile, see the section Configuring Object Views.

Keep the following in mind when assigning configured reports to custom object views:

- Only configured reports of the type `Query`, `NativeSQL` or `Custom` can be assigned to custom object views or object cockpits.
- Configured reports of the type `Custom` that are based on the template `EvaluationReport` are always ReadOnly if assigned to object views or object cockpits. The editability of this type of configured report has been designed for use in wizards only.

- In the object view, the **Caption** property of the configured report is displayed as the default caption for the configured report and the Description property of the configured report is displayed as the page view description for the configured report. The report caption displayed in the object view can be overwritten by setting a property **Caption** for the respective report icon in the object view.
- When the user opens the configured report from the object view, the caption of the report displays the information about the current object. The **Description** property of the configured report is displayed as a page view description below the caption. If the current object is not the base object of the configured report, the caption is identical to the **Caption** property of the configured report. If the caption has been changed in the object view configuration, this has no effect on the caption displayed in the configured report itself. Therefore, the caption can be different in the object view and the configured report.
- Only configured reports with the **Report State** attribute set to `Active` can be executed in the Alfabet interface. When a configured report is assigned to an object view or object cockpit and the **Report State** attribute is reset to `Plan` or `Retired`, the user will not be able to access the configured report. An error message will inform the user that the configured report is currently not available.
- Configured reports that are assigned to an object view are automatically applied to the object view's class without setting the **Apply To Class** attribute of the configured report. The Alfabet parameter `BASE` can be used in the query of the configured report to specify the object the user is currently working with even if **Apply To Class** is not set. When **Apply To Class** is not set, the user cannot change to another `BASE` object via an automatically generated filter field on top of the configured report but the configured report is limited to results about the current object. Please note that if **Apply To Class** is not set, the configured report can only be used in a context that predefines a `BASE` object, like in an object profile. It cannot longer be used For example, in the **Configured Reports** view of the **Search** functionalities, because this view is not called in the context of working with an object.

Integration of Configured Reports in Wizard Views in Custom Wizards

A wizard is a series of Alfabet editors and/or views that guides users through each step of a multi-step operation. A wizard usually contains multiple Alfabet views that allow you to capture a specific set of data about various aspects of an object. Wizards are typically created in order to standardize the capture of data about an object or for use in the workflow capability.

Configured eports of the type `Query`, `NativeSQL`, or `Custom` can be integrated in a wizard along with the editors and page views assigned to the wizard. For example, a configured report can be useful in a wizard in order to provide additional information that is required about an object or to provide a means to control and review data.

For a description of the configuration of wizards, see the chapter Configuring Wizards.

Integration of Configured Reports in Workflow Steps in Workflows

A workflow is a collaborative process made up of workflow steps that are typically carried out by one or more users. A workflow is based on a configured workflow template that determines a sequence of

workflow steps that are to be performed by specified users. Workflow steps are sequenced in a workflow but they may have specific pre-conditions and post-conditions that determine different branches to take in the workflow depending on the conditions that are or are not met.

A Alfabet view type is defined for each workflow step in order to specify the view that is presented to the user when opening the workflow step. For example, this view can be an editor, a wizard or a standard Alfabet page view. A configured report of the type `Query`, `Native SQL`, or `Custom` can also be added as a workflow step. For example, if objects are assigned to the base object edited in the workflow in one workflow step, the following workflow step might display a configured report that lists all relevant objects that the user can then navigate to.

For a description of the configuration of workflows, see the chapter Configuring Workflows.

Integration of Configured Reports in Custom Explorers

Custom explorers are configurable by the customer in Alfabet Expand. Each node in the explorer except the root node represents an object in the Alfabet database. When you click a node representing an object, the object profile of the object opens. The explorer can optionally be configured to show a graphic view or a configured report when you click the root node.

For a description of the configuration of custom explorers, see the chapter Configuring Standard Business Functions and Custom Explorers.

Integration of Configured Reports in Guide Pages and Guide Views

A guide page is a customized HTML file with hyperlinks that provide users access to the software and support them in their work. A guide view offers enhanced flexibility in designing the view without using a predefined HTML template. A guide page or guide view could serve as the start page for the software and can include, For example, informational text or images about enterprise-specific workflows in the Alfabet solution, links to specific functionalities in Alfabet, URL links to internal documents or the Web, or hyperlinks to other navigation pages.

Guide pages and guide views can provide links to a configured report, including the ability to pre-set the filters to defined values when a user opens the configured report from the guide page or guide view. Configured reports can also be embedded into guide pages and guide views to be displayed directly on the start page.

The configuration of guide pages and guide views is carried out in the tool Guide Pages Designer. For detailed information about how to configure guide pages and guide views for the user profiles in your user community, see the reference manual *Designing Guide Pages for Alfabet*.

In order to display a guide page or guide view as a start page in the Alfabet interface, you must assign it to the relevant user profile. For detailed information about how to assign guide pages to user profiles, see Defining Access to the Functionalities via a Guide Page in the section Configuring User Profiles for the User Community.

Integration of Configured Reports as Report Collection Into Tabular Configured Reports

For each object class and object class stereotype a number of configured reports can be configured that shall be available via tabs in all tabular configured reports finding objects of this object class (stereotype). The report collection available via tabs display information about all objects listed in the tabular configured report they are opened from. They can be used to provide aditional information about the objects listed in the tabular configured report. For example, for a tabular configured report listing a number of application groups, a portfolio can be available via a tab that informs about the criticality and business relevance of all applications in all application groups listed in the table. Via a second tab users can open a gantt chart informing about the lifecycle of the applications in all application groups.

This feature requires the following configuration:

- Defining a Category for Report Collections
- Defining Reports to be Opened in Report Collections
- Making the Report Collection Available for an Object Class or Object Class Stereotype
- Configuring Tabular Reports to Show the Report Collection

Defining a Category for Report Collections

A category must be assigned to configured reports that shall be used in a report collection. Prior to defining the configured reports, you must define the category in the XML object ***UseCaseCategories***:

1) In the **Presentation** tab of Alfabet Expand, expand the explorer node **XML Objects**.
2) Right-click on the XML object ***UseCaseCategories*** in the explorer and select **Edit XML** from the context menu. The XML object opens in the middle pane.
3) In the XML object, add an XML element `UseCaseInfo` as child element of the root XML element `UseCaseCategories` with the following XML attributes and child elements:

   ```
   <UseCaseInfo UseCase="CustomChartViews">
   <ScopeInfo Scope="Report" Categories="CommaSeparatedListOfCategories" />
   </UseCaseInfo>
   ```

   CommaSeparatedListOfCategories must be substituted with at least one category name. This name will be selectable in the attribute **Category** of configured reports to mark them as part of a report collection. If you enter more than one name comma separated, all names will be valid as category name.

4) In the toolbar, click the **Save** button.

Defining Reports to be Opened in Report Collections

You can add any type of configured report to a report collection. Reports for report collection must have the following configuration in addition to the general configuration requirements for the specific type of configured report:

- The **Category** attribute must be set to the category defined in the XML object ***UseCaseCategories*** for the `CustomChartViews` use case.
- The **Apply to Class** attribute must not be set.
- The query or queries the configured report is based on must be defined using the Alfabet query parameter `CVREFS` that returns the list of `REFSTR` values for all objects currently displayed in the tabular dataset the report will be opened from via a tab in the report collection.

  The following parameter shows a `WHERE` clause for a report that shall be added to the report collection of the object class Application in native SQL:

  ```
  WHERE APPLICATION.REFSTR IN (@CVREFS)
  ```

- A report view must be created for the configured report.
- The report must not have any filters. For configured reports of the type `Query` or `NativeSQL` the automatically generated filter field for the `CVREFS` parameter must be deleted from the report view.

Making the Report Collection Available for an Object Class or Object Class Stereotype

The number and order of tabs available as report collection are defined in the class settings of the object class or object class stereotype in Alfabet Expand:

1) Go to the **Presentation** tab and expand the **Class Settings** node.
2) Expand the node of the object class or object class stereotype to which you want to add a report collection and click the relevant class setting.
3) In the attribute window, click the **Browse** button in the **Supplementary Reports** attribute in the **Custom Chart Views** section.
4) In the editor that opens, all configured reports that are assigned to the category of the `CustomChartViews` use case are listed. Click a configured report to select the checkbox. Optionally, you can then move the position of the configured report in the list using the up and down buttons on the right of the report list field. The order of tabs in the report collection on the Alfabet user interface is identical to the order of configured reports in the field.

   You can sort the reports in the list lexicographically by selecting the checkbox **Sort Lexicographically**. Please note that the lexicographic order applies to the names of the reports and not to the report caption. As the text of the tabs is identical to the caption of the configured report, lexicographic sorting via this mechanism might not result in an lexicographic sorting in the user interface. Nevertheless you can use the functionality to find configured reports in a long list of configured reports.

Configuring Tabular Reports to Show the Report Collection

A report collection configured for an object class or object class stereotype is only displayed in configured reports with the following configuration:

- The **Type** attribute of the configured report is set to either `Query` or `NativeSQL`.

- The configured report finds objects of the object class or object class stereotype for that a report collection is defined in the class settings.
- The following attributes of the configured report are set to activate the report collection:
  - **Chart Views Mode**: The attribute is set to `Custom`. By default, the attribute is set to `Standard`, and standard page views providing additional information about the objects in the tabular dataset will be accessible via a button in the toolbar. For more information, see Display of Results in Standard Alfabet Report Formats. The attribute can be set to `None` to provide neither standard chart views nor a report collection.
  - **Custom Chart View Base Class**: This attribute is only visible if the **Chart Views Mode** attribute is set to `Custom`. Select the object class or object class stereotype for which the tabs opening the configured reports for the report collection shall be displayed. Please note that the selected object class must be identical to the object class found in the tabular dataset of the configured report you are currently configuring. If the objects found in the tabular dataset do not match the setting, the report will not show the tabular dataset, but an error message about the incorrect setting in the configuration.

Integration of Quality Widgets in Configured Reports, Object Cockpits and Wizards

Additional information about data in a configured report, object cockpit, or wizard/wizard step can be provided via a quality widget displayed in a pop-up window. The quality widget is either a configured widget report or a configured business chart or Gantt chart report that can be assigned to multiple configured reports, object cockpits, and wizard/wizard steps. When the user opens or loads the configured report, object cockpit, or wizard/wizard step that the quality widget is assigned to, the quality widget will be displayed in a separate pop-up window that opens for a short time. The quality widget pop-up window opens by default in the upper-right corner of the Alfabet user interface below the main menu. This position is configurable. In the case of a wizard/wizard step, the quality widget will be appended to the upper-right edge of the wizard.

Depending on the configuration of the primary configured report, either the complete quality widget will be displayed or only the caption will be displayed in a title bar and the user can click the title to open the quality widget.

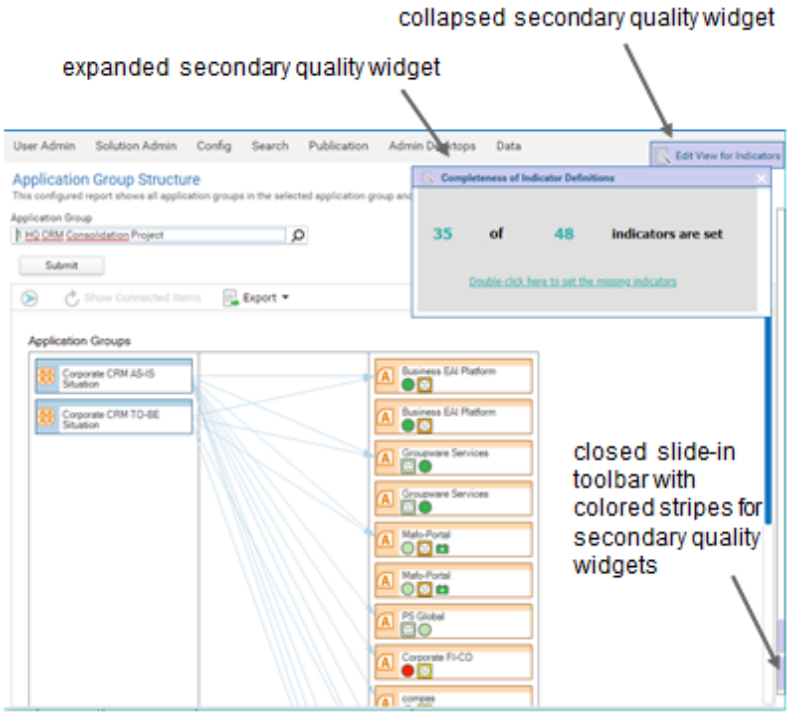


FIGURE: Configured report with a collapsed and an expanded quality widget

If the user does not click the quality widget during the short time that it is visible, the quality widget view will automatically drop into the slide-in toolbar on the right edge of the Alfabet user interface. The slide-in toolbar displays a colored notch for each of the available quality widgets (as well as for other forms of user assistance). The user can access the quality widget anytime by pointing to the notch in the slide-in toolbar and then clicking the quality widget icon to open it. The quality widget will remain open until the user clicks outside of the pop-up window or clicks the close button.

If navigation is configured from the quality widget view to another configured report or graphic view, the navigation target will open in a new browser tab.

A typical use case for quality widgets is a widget report that opens to provide information to the user about the quality of the data in the current configured report, object cockpit, or wizard/wizard step. For example, if objects displayed in a configured report are colored according to an indicator value, the user could be provided with information about the completeness of the indicators specified for the objects in the configured report. A configured link available in the quality widget could then open a view that allows the user to provide the missing data and thus correct the issue. When the user clicks the link available in the quality widget report, the view will open in a new browser tab. The user can then define the relevant indicators and reload the original view with the updated data.

For more information about assigning the configured report as a quality widget to an object cockpit, see the section Adding Data Quality Widgets to Object Cockpits. For more information about assigning the configured report as a quality widget to a wizard or wizard view, see the section Adding Data Quality Widgets to Object Cockpits.

Please note the following for the specification of a configured report that shall be integrated into the Alfabet user interface as a quality widget:

- The configured report must be of the type `Custom` and based on either of the templates `WidgetReport`, `GanttReport` or `BusinessChartReport`.

For more information about defining widget reports, see Defining Widget Reports. For more information about defining business chart reports, see Defining Chart Reports. For more information about defining Gantt chart reports, see Defining Gantt Chart Reports.

- The Alfabet query language parameter `BASE` can be used in the query or queries that the configured quality widget report is based on. The parameter will be substituted with the `REFSTR` of the object that the user is currently working with in the object view. If the quality widget opens for a configured report and the configured report is assigned to a base class with the attribute **Apply To Class**, the parameter `BASE` is substituted with the `REFSTR` of the current object that the user is opening the configured report for.

The configured report used as the quality widget should not be assigned to a base class with the **Apply To Class** attribute. It is automatically assigned to the base class of the view it opens for.

- The configured report must not have filters nor toolbar buttons nor drill-down defined.

The visualization of secondary window skins is configured via the **Quality Widget** attributes for a GUI scheme. For more information, see the section Configuring GUI Scheme Definitions for the Alfabet Interface as well as the section *Attributes Displayed in the Grid Section: Secondary Window Skins* in the reference manual *Configuring Alfabet with Alfabet Expand - Appendix*.

To assign a quality widget to an existing configured report or object cockpit:

1) Right-click the configured report or object cockpit and select **Add Secondary View** . A secondary view is added to the explorer and the attributes of the secondary view are displayed in the attribute window.
2) Define the following attributes of the secondary view:
   - **Name**: Enter a unique name for the secondary view. The name is a technical name and shall not contain special characters or whitespaces. The technical name is not displayed in the user interface.
   - **Caption**: Enter a caption for the secondary view that shall be displayed in the title bar of the secondary view in the Alfabet user interface and in the tooltip displayed for the icon of the secondary view in the slide-in toolbar. Please note that the caption should be short. It will not be displayed in the title bar if it is too long.
   - **Role**: Select `QualityWidget`.
   - **View Type**: Select `Report`.
   - **View Name**: Select the configured report that shall be displayed as secondary view. The drop-down list displays the names of all available configured reports of the allowed report types widget report, gantt chart report, and business chart report.
   - **Show Automatically**: Select `True` if you would like the secondary view to be fully displayed for a few seconds when the user accesses the object cockpit or configured report that the secondary view is defined for. Select `False` if only the caption of the secondary view shall be displayed in a title bar for a few seconds when the user accesses the object cockpit or configured report that the secondary view is defined for. The secondary view will then open if the user clicks the title bar.
   - **Position**: Select the position of the open quality widget on the Alfabet user interface. The quality widget window can be placed in the center of the Alfabet user interface or in one of

the corners of the user interface beneath the main toolbar. The quality widget pop-up window opens by default in the upper-right corner of the Alfabet user interface below the main menu.

- **Height**: Define the inner height of the quality widget window in pixel. This is the height available for the display of the configured report opened in the window.
- **Width**: Define the inner width of the quality widget window in pixel. This is the width available for the display of the configured report opened in the window.

3) In the toolbar, click the **Save**  button.

Translating Configured Reports

Alfabet provides a multi-language capability. This allows users to display the Alfabet interface in a secondary languages that are used in your enterprise. For a detailed description of how to implement multi-language support in Alfabet, see the chapter Localization and Multi-Language Support for the Alfabet Interface.

If your enterprises requires the Alfabet interface to be displayed in any of the secondary supported languages, then you must explicitly ensure that the data displayed in configured reports is also translated to the relevant language. The following must be carried out in order to translate the content of a configured report:

- For each report configured in Alfabet Expand, the **Caption** and **Description** attributes will be displayed in the Alfabet interface. These attributes can be translated as described below in the section Translating the Caption and Description of a Configured Report.
- For relevant configured reports configured in Alfabet Expand, the column headers of tabular reports are created based on either the alias definitions in the `Show` properties of the Alfabet query, the `SELECT` clause of the native SQL query, or the instructions defined for the query. The column headers can be translated as described in the section Translating Column Headers or Captions of a Configured Report.
- String values in a graphic report that have been defined directly in an attribute of the report assistant are usually added automatically to the vocabulary files. This includes, For example, the captions for lanes in lane reports, the names of color rules and indicator rules that are used as legend headers, static text definitions in widget reports, or the graphic title, X-axis title, and Y-axis title of business chart reports or portfolio reports. For gauge and map chart reports, this also includes the captions defined for color range members. For general information about vocabulary translation, see Modifying, Translating and Managing the Vocabularies.
- Text defined for the cell tooltip in the `LinkAssignment_Edit` instruction as well as text defined as legend text in the Alfabet query language instructions `ColorAssignment`, `PictureAssignment`, `RowColorAssignment`, `FontStyleAssignment`, `FontStyleColorAssignment` are added automatically to the vocabulary files. For general information about vocabulary translation, see Modifying, Translating and Managing the Vocabularies.
- In the case of configured portfolio, lane, and grid reports, the graphic title, X-axis title, and Y-axis will not be added automatically to the vocabulary files. Texts provided for the calculation of a total value for pie charts will also not be added automatically to vocabulary files. These values can be translated as described in the section Translating Column Headers or Captions of a Configured Report.

Please note that the labels displayed in configured portfolio charts and gauge reports and the labels for enterprise milestones in configured Gantt chart reports cannot be translated.

If configured reports are translated to Arabic, you should be aware that the text is right-aligned instead of left-aligned in user interface elements. For example, for the display of a **Caption** defined for a **Lane** in a lane report, you will see the text above the lanes instead of above the object boxes because the space for the caption spans both object boxes and lanes. To display a caption above the object boxes, you must define the caption in the **Caption** attribute of the **Node** element below the **Lane** element.

If the Alfabet user interface is rendered in Arabic language, the order of columns and display of graphic elements in graphic reports is changed to right to left instead of left to right, as for all other supported languages. Only configured reports based on the template `MatrixMapReport` that have the subtype `Diagram` and Pivot Grids rendered with the embedded DevExpress® component are still displayed left to right.

- For Alfabet objects displayed in a configured report, the translation of relevant object properties is read from the database tables. The following object class properties are translatable and can be displayed in a secondary language:
  - Predefined protected properties such as the object's **Name** and **Description** properties as well as custom properties of the type `String` and `Text`. These properties will be displayed in the target language if the **Support Data Translation** attribute of the relevant culture is set to `True`, and a translation has been made in the relevant object class editor in the Alfabet user interface. The translated values for object data will be displayed automatically in configured reports based on Alfabet query language. For native SQL queries, however, a special code triggering the translation must be added to native SQL queries in order to enable the display of translation values for object data. For more information, see Displaying Translated Object Data In the Current Language of the User Interface in the chapter Defining Queries. For more information about object data translation, see the section Configuring the Translation of Object Data.
  - The caption of the object class and object class stereotype. These captions can be added to a configured report via instructions. If this is the case, the captions of the object class and object class stereotype can be displayed in a target language if they are translated in the vocabularies available in Alfabet Expand. For general information about vocabulary translation, see Configuring the Translation of Object Data.
  - Values defined for object states, release statuses, indicator values, enterprise releases, project milestones, and enumerations. These values can be displayed in a target language if the following applies:
    - The **Enable Data Translation** attribute of the relevant object class property (properties of the type `String` or `Text`) is set to `Manual` or `ManualAndAutomated`.
    - Translations are provided in the vocabularies available in Alfabet Expand. For more information about vocabulary translation, see Configuring the Translation of Object Data.
    - The values are not automatically displayed translated in configured reports. An instruction triggering the translation must be added to queries to enable the display of translation values. For more information, see Translating Enumerations, Object States, Release Statuses, and Indicator Values in a Configured Report.

Status values that are editable in the **Report** editor in the **Reports Administration** functionality available in the Alfabet interface is neither a release status, object state, nor based on an enumeration and Therefore, cannot be translated in the **Report** editor.

Translating the Caption and Description of a Configured Report

The **Caption** and **Description** attributes will be displayed in the Alfabet interface for each report configured in Alfabet Expand. These attributes can be translated to the languages supported by your enterprise.

Once the **Caption** and **Description** attributes have been specified for a configured report, they will be automatically added to the vocabularies available in Alfabet Expand. Once they are available in the vocabularies, they can be translated like any other string in the **Translation Editor** or exported to a Microsoft Excel file and translated there. For more information about this process, see the section Modifying, Translating and Managing the Vocabularies.

For technical reasons, the translation of report captions and descriptions is coupled with the mechanisms of object data translation. Therefore, the translation provided via the vocabularies is only displayed in the Alfabet interface if the following applies:

- The **Support Data Translation** attribute must be set to `True` for the respective culture.
- The translation must be updated in the data translation columns of the database table of the object class `Report`. To write the translated **Caption** and **Description** attributes to the database table of the object class `Report`:
  1) Set the **Report State** attribute for the configured report to `Plan`.
  2) Right-click the configured report and select **Update Translation**.

     To batch update the translation of multiple configured reports, right-click the **Reports** node and select **Update Translation**. The captions and descriptions for all configured reports for which the **Report State** attribute is set to **Plan** will be updated.

  3) Set the **Report State** attribute for the configured report to `Active`.

Translating Enumerations, Object States, Release Statuses, and Indicator Values in a Configured Report

Configured reports require the specification of instructions to display the translated values. Two new Alfabet instructions are available that trigger the display of translated values for indicator ranges, enumerations, object states, and status definition values:

- To display enumeration, object state, and release status values in the translated language, the following Alfabet instruction must be added to the query. The `ColumnName` is the name of the column containing the information that shall be translated:

```
TranslateEnums("ColumnName,ColumnName,..");
```

- To display indicator range values in the translated language, the following Alfabet instruction must be added to the query. The `ColumnName` is the name of the column containing the information that shall be translated:

  ```
  TranslateIndicators("ColumnName,ColumnName,..");
  ```

For detailed information about the definition of the Alfabet instructions see Displaying Translated Values of Enumerations, Object States, Statuses, Milestones and Indicators in Configured Reports in the section Using Instructions to Format the Results of an Alfabet or Native SQL Query.

Translating Column Headers or Captions of a Configured Report

The definition of column header or graphic report elements in a native SQL query or Alfabet query is typically a complex process. This is the case, For example, for a native SQL query containing a `WITH` statement or if instructions are used for renaming and restructuring the results of the query. In such cases, it is not possible to automatically scan the query definitions for strings that need to be translated.

Therefore, if you want to translate column headers, you must write the column header strings in the XML object ***VocXML***. The strings defined in the XML object ***VocXML*** are automatically added to the meta-model section of the vocabularies and can be translated to a defined target language as described in the section Modifying, Translating and Managing the Vocabularies.

Strings that are defined directly in report assistants such as the caption of lane reports or strings that are explicit in the query definition such as column headers defined in `SetColumnShowName` instructions are automatically added to the translation tables. You can check the vocabularies prior to adding strings to the XML object ***VocXML*** to evaluate which strings have already been added automatically to the vocabulary.

To add column headers to the translation table of the Alfabet vocabularies:

1) In the **Presentation** tab of Alfabet Expand, expand the **XML Objects** node and double click the XML object ***VocXML***. The XML object ***VocXML*** opens in the center pane. The editor automatically displays the root XML element `VocXml` of the XML object.
2) For each column header, enter a child element `Entry` to the `VocXml` root element. In the `Entry` element, write the string of the column header in the original language.

   Alfabet vocabularies are string-based. Therefore, if two configured report have the same column header, you must only add the string once to the XML object t ***VocXML***. If the header column string is identical to a string that is used somewhere else in the configuration of the Alfabet meta-model (For example, if the header column is identical to the caption of an object class property), the string will already exist in the vocabulary and does not need to be entered in the XML object t ***VocXML***. If you enter a duplicate string in the XML object ***VocXML*** it will be ignored.

3) In the toolbar, click the **Save**  button to save your changes.

For example, a configured report is based on the following native SQL query:

```
SELECT proj.REFSTR, proj.NAME AS 'Project Name',proj.STEREOTYPE
FROM PROJECT proj
```

The query is combined with the following Alfabet instructions:

```
InsertColumn("1","StereotypeCaption");
SetColumnShowName("StereotypeCaption","Project Stereotype");
SetStereotypeCaption("REFSTR","STEREOTYPE", "StereotypeCaption");
RemoveColumns("STEREOTYPE");
```

The resulting configured report will have two column headers:

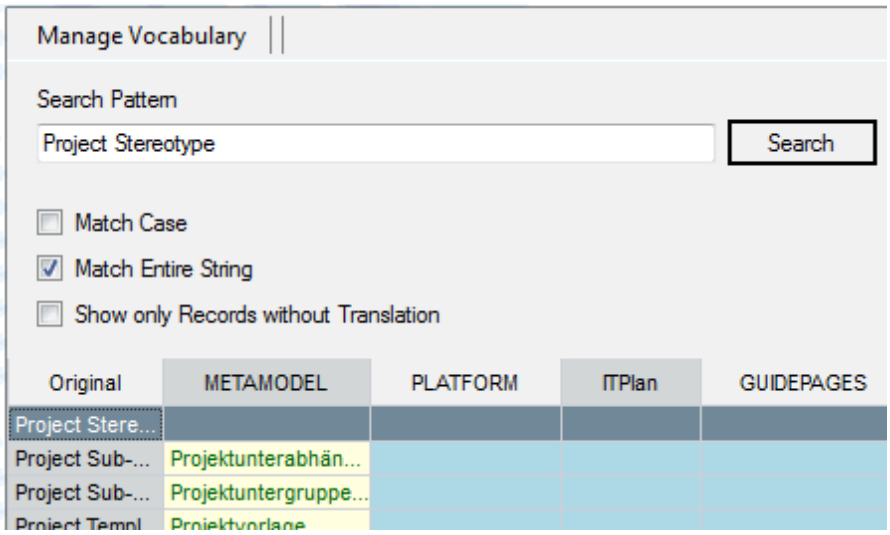
- "Project Name", derived from the alias definition in the `SELECT` clause of the native SQL query
- "Project Stereotype" defined via the `SetColumnShowName` instruction.

	Project Name	Project Stereotype
1	Consolidate Trading Applications	Program
2	Retire GL Applications	Project
3	Upgrade GenLManager	Project
4	Reshape Core Trading Applications	Project
5	Enhance TradeNet	Project
6	Implement Unified Trade Solution	Project
7	UTS phase 1	Project Step
8	UTS phase 2	Project Step
9	UTS phase 3	Project Step
10	Streamline CRM Applications	Program
11	Migrate CRM Opti Retail to CRM CSS	Project
12	Integrate CRM with SAP	Project
13	Retire GL Applications Solution	Project

To translate the headers of the configured report, the two definitions must be written in the XML object ***VocXML***:

```
<VocXml>
   <Entry>Project Name</Entry>
   <Entry>Project Stereotype</Entry>
</VocXml>
```

The terms are then translated to the target language (in this case, German) in the **Translation Editor** of Alfabet Expand:



The translations will be displayed if German is selected as the base culture for th---e culture displayed in the Alfabet interface.

	Projektname	Projekt-Stereotyp
1	Consolidate Trading Applications	Programm
2	Retire GL Applications	Projekt
3	Upgrade GenLManager	Projekt
4	Reshape Core Trading Applications	Projekt
5	Enhance TradeNet	Projekt
6	Implement Unified Trade Solution	Projekt
7	UTS phase 1	Projektschritt
8	UTS phase 2	Projektschritt

Please note: You can see from the example that the content of the configured report is also only partially translated. The project names are displayed in English because data translation has not yet been activated. The stereotype captions are automatically added to the vocabulary and have been translated. Therefore, the translated values are displayed in the configured report. For more information about data translation, see the section Configuring the Translation of Object Data.

Control Report Usage to Remove Unused Configured Reports

Alfabet provides a mechanism to control whether configured reports are still in use. A report can be displayed in Alfabet Expand that informs you about the number of users currently accessing the configured report. When the configured report is not used at all, you can remove the configured report from your configuration. The activity tracking of report usage is not done by default but must be explicitly activated. The usage report only shows data evaluated after activation of activity tracking.

The following workflow is recommended to limit your report configuration to currently active configured reports:

- Activate Usage Tracking to enable count of access to individual configured reports. For more information, see Activating Activity Tracking.

- When you want to decide about retiring configured reports, consult the activity report to evaluate which configured reports are no longer used. For more information, see Reading the Activity Tracking Report.
- Retire the configured reports and remove them from the current configuration before deleting them. For more information, see Removing the Configured Report From the Configuration.

Activity tracking is managed via the Alfabet Server and only configured reports accessed by users working in client-server-mode are included into the tracking report. When the configured report is accessed by a tool with direct access to the Alfabet database, For example, when working with Alfabet Expand in standalone mode, is not taken into account.

Activating Activity Tracking

Report activity tracking is based on the same mechanisms as the usage tracking mechanism that is implemented for metered contracts. Usage tracking must be activated to enable report activity tracking.

For more information about usage tracking, see the section *Usage Tracking* in the *Technical Requirements*.

When usage tracking is activated, activity tracking information is written into *.dat files in the directory defined as **Track Usage Directory** field of the server alias configuration. The information is stored in encrypted form and can only be accessed via the activity tracking report in Alfabet Expand.

Reading the Activity Tracking Report

Do the following to open the Activity Tracking report:

1) Open Alfabet Expand.
2) In Alfabet Expand, go to the **Reports** tab and right-click the **Reports** root node.
3) In the context menu, select **Open Usage Activity Tracking**. The report opens in the middle pane of the user interface of Alfabet Expand.
4) Optionally, you can export the report to Microsoft Excel format to save and view the report outside of Alfabet Expand. Click the **Export** button and select a location to save the report in the explorer that opens to create a Microsoft Excel version of the report.

The report displays all report folders and configured reports available in the **Reports** explorer.

The report is an expandable dataset. Expanded nodes show a + sign and can be collapsed by clicking the + sign. Collapsed nodes are showing a - sign and can be expanded by clicking the - sign.

Report folders and configured reports can be identified in the activity tracking report via their name and caption.

For each configured report, the last usage data is displayed. The number of users that accessed the report is given for four different time periods: The current month, the last 3 month, the last 6 month and the last 12 month.

The report displays the number of users that access the configured report and not the number of times the configured report was used. When a user accesses the configured report multiple times during a defined period, even with different user profiles, this is only raising the number of users displayed for the defined period by one.

The numbers displayed for a report folder are the sum of numbers calculated for the configured reports subordinate to the report folder.

Removing the Configured Report From the Configuration

When a configured report is not used any longer, it can be deactivated by setting the **Report State** to `Retired`. Retired configured reports cannot be accessed any longer on the Alfabet interface. The configured report is displayed struck-through in tables listing available configured reports and when a user tries to access the configured report from For example, an object view, an error message is thrown.

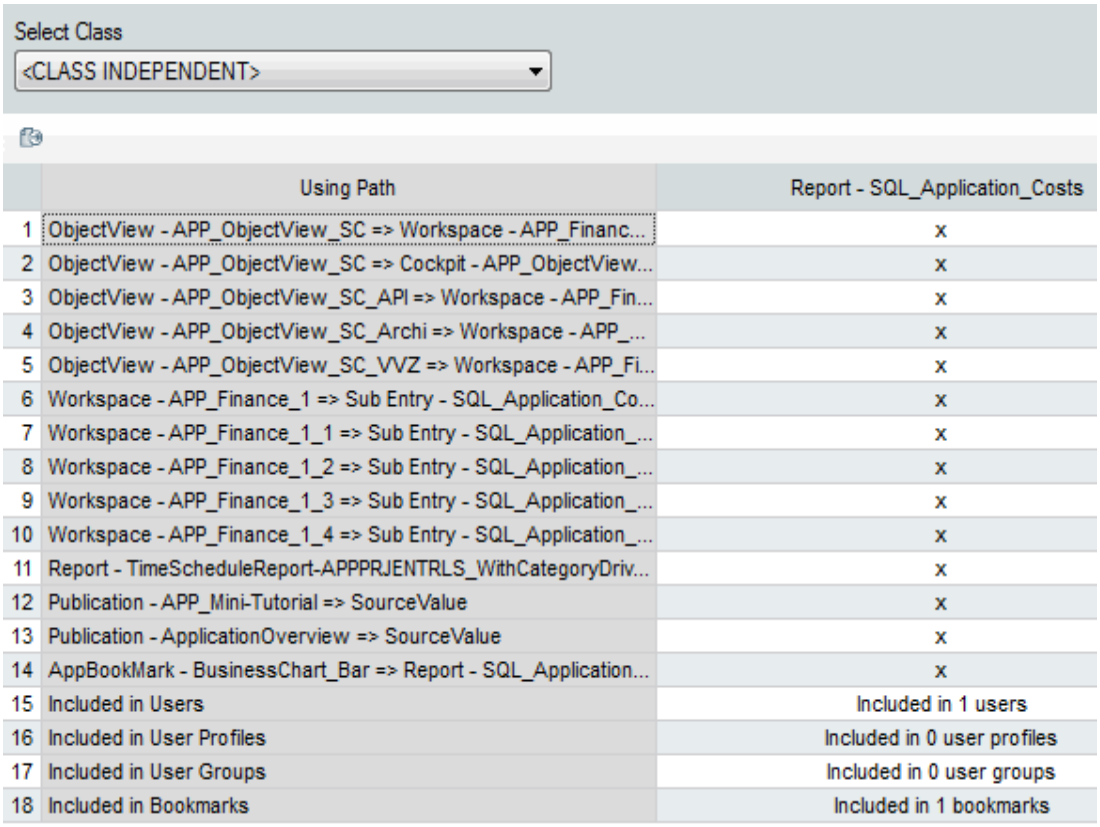
You can decide whether the configured report shall still be kept in the report configuration for future reuse or as template for similar configuration or whether it shall be deleted.

Prior to retiring and optionally deleting a configured report, the configured report must be removed from the configuration. Configured reports can be assigned to object views and object cockpits, wizards, workflows and custom explorers. They can also be assigned directly to a user, user profile or user group in the **Reports Administration** functionality of Alfabet. Guide pages and guide views may include links to the configured report.

A report is available that lists the usage of a configured report in the configuration.

Do the following to delete a configured report from the configuration:

1) In the **Reports** tab of Alfabet Expand, right-click the configured report in the explorer and select **Show Usage** from the context menu. A new window opens displaying the usage of the configured report in the configuration.



Select Class

<CLASS INDEPENDENT>

	Using Path	Report - SQL_Application_Costs
1	ObjectView - APP_ObjectView_SC => Workspace - APP_Financ...	x
2	ObjectView - APP_ObjectView_SC => Cockpit - APP_ObjectView...	x
3	ObjectView - APP_ObjectView_SC_API => Workspace - APP_Fin...	x
4	ObjectView - APP_ObjectView_SC_Archi => Workspace - APP_...	x
5	ObjectView - APP_ObjectView_SC_VVZ => Workspace - APP_Fi...	x
6	Workspace - APP_Finance_1 => Sub Entry - SQL_Application_Co...	x
7	Workspace - APP_Finance_1_1 => Sub Entry - SQL_Application_...	x
8	Workspace - APP_Finance_1_2 => Sub Entry - SQL_Application_...	x
9	Workspace - APP_Finance_1_3 => Sub Entry - SQL_Application_...	x
10	Workspace - APP_Finance_1_4 => Sub Entry - SQL_Application_...	x
11	Report - TimeScheduleReport-APPPRJENTRLS_WithCategoryDriv...	x
12	Publication - APP_Mini-Tutorial => SourceValue	x
13	Publication - ApplicationOverview => SourceValue	x
14	AppBookMark - BusinessChart_Bar => Report - SQL_Application...	x
15	Included in Users	Included in 1 users
16	Included in User Profiles	Included in 0 user profiles
17	Included in User Groups	Included in 0 user groups
18	Included in Bookmarks	Included in 1 bookmarks

The report provides the following information:

- For each configuration object in Alfabet Expand and for each guide page or guide view the configured report is assigned to there is a row in the report that displays the type and name of the configuration object and location of the configured report in the implementation of the configuration object. If the configured report is not assigned to any configuration object, you will not see any configuration object rows in the report.
- The rows **Included By Users**, **Included In Profiles** and **Included In User Groups** are always displayed in the report. They inform about the assignment of configured reports to the **Configured Reports** page view of users in Alfabet. The assignment of configured reports is done in the **Reports Administration** functionality. A configured report may be configured to be available to a user on request only. In that case, the **Show Usage** table shows the number of users that actively added the configured report to their **Configured Reports** page view.
- The row **Included in Bookmarks** is always displayed in the report. It informs about the number of bookmarks created by any user that open the report.
- The **Select Class** filter on top of the **Show Usage** table allows to limit the display to configuration objects that are assigned to the selected class. Configuration objects that are not assigned to any class and the information of usage by person, user profile or user group are always displayed. It is recommended to set the filter to `<CLASS INDEPENDENT>` in this context to make sure that the report is removed from all configuration objects prior to retiring it.

2) In Alfabet Expand, remove the configured report from the object profiles, wizards, workflows and custom explorers the configured report is assigned to.

If a configured report selected in the **Supplementary Reports** attribute of class settings is deleted, it will be removed from the **Supplementary Reports** attribute automatically without any user interaction required.

3) In the **Reports Administration** functionality of Alfabet remove the configured report from all users, user profiles and user groups it is assigned to.
4) In the **Reports** tab of Alfabet Expand, right-click the configured report in the explorer and select **Set Report State to Retired**. The configured report cannot be accessed any longer by users in the Alfabet interface but is still available in the **Reports** explorer of Alfabet Expand.
5) Optionally, right-click the configured report and select **Delete**. The configured report node is irrevocably removed from the explorer.

Chapter 18: Publishing Data In Microsoft® Word Format

The Alfabet Publication Framework (APF) allows you to publish Microsoft® Word documents containing data from the Alfabet database.

APF allows you to select objects via customer-defined queries and define the data that shall be published for an object via Word templates defined directly in Microsoft® Word. Attribute data, data about related objects, and reports available for an object can be added to the published output. The publication can include data about multiple object classes, and a different template can be used to publish data for the different object classes. For example, the publication about the applications in an application group can include the name of the application group and the application portfolio report for the application group. For each application in the application group, the application's name and version and **Evaluations** page view can be added to the publication.

Publication definitions are specified in the configuration tool Alfabet Expand. The definition of the publication includes the following

- The objects for which data will be published. The objects can be selected via a query or a user can select one or multiple objects for publication directly in the Alfabet user interface.
- The Word template used to publish data about the object(s).
- The mapping of the object data to bookmarks defined as placeholders in the Word template
- Which related objects shall also be published.
- The Word template used to publish data about the related objects
- The mapping of the object data of related objects to bookmarks defined as placeholders in the Word template

Publications can be triggered by a batch utility or by the user accessing a report configured for publication purposes in the Alfabet interface. There are two methods for users to trigger a publication:

- The user opens a configured report that allows the objects to be selected, a publication to be triggered, and the document to be published.
- The user clicks a button in the toolbar of an object's profile to open a configured report that allows a publication to be triggered and the document to be published.

The figure below displays a configured report that displays a table showing one or more applications that the user can select for publication. The publication can be executed via the buttons below the table.

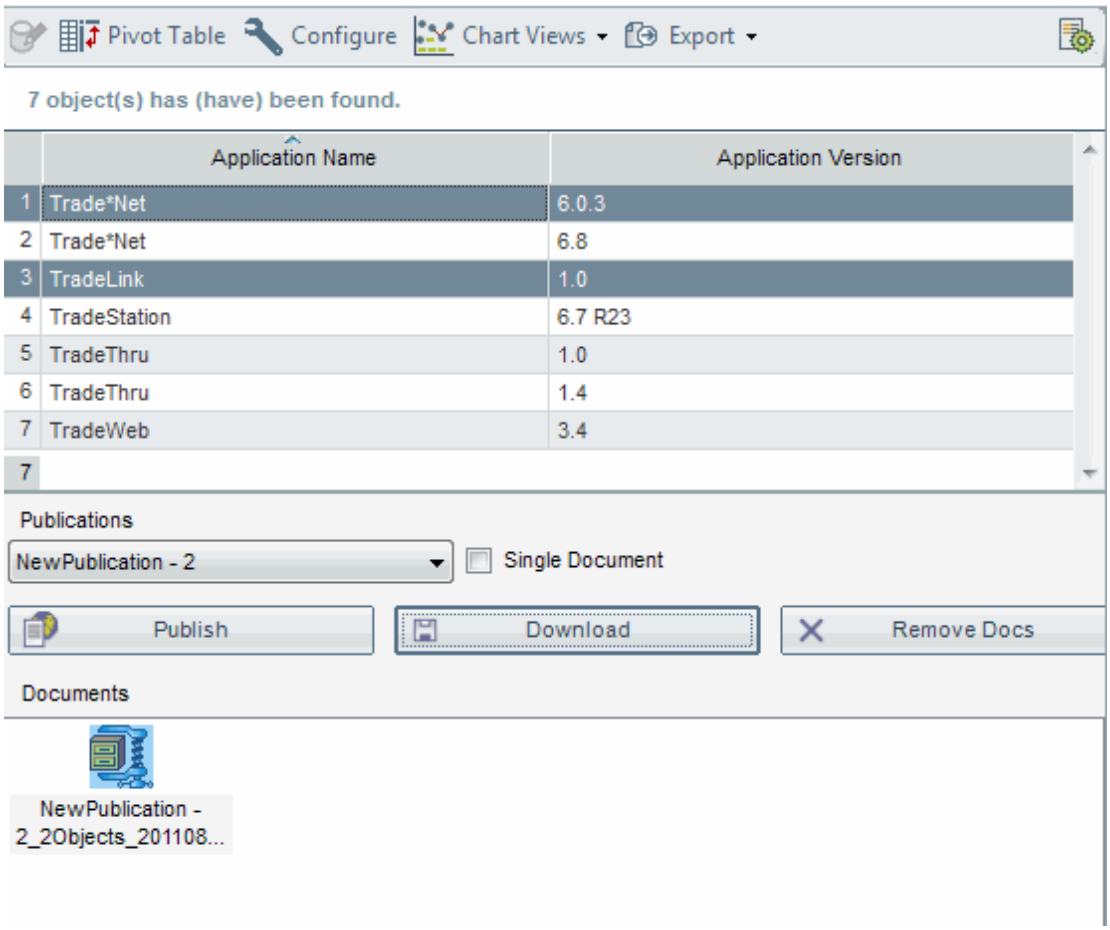


FIGURE: Configured report triggering publications about applications

To trigger a publication, the user must perform the following:

1) Select one or multiple objects in the report.
2) Select a configured publication in the drop-down list in the **Publications** field
3) Optionally, select the checkbox **Single Document** if data about all selected objects shall be published in one document. If the checkbox is not selected, one document will be published per selected base object.

   Publishing data about multiple base objects in a single document may alter the design of the title page of the document. If the Microsoft® Word template is configured to have a title page **without** a header and/or footer while the rest of the document is configured to have a header and footer, the header/footer will be added to all title pages displayed throughout the document.

4) Click the **Publish** button to publish the data. A ZIP file is created with the publication results and the section **Documents** shows an icon for the publication results.

   Alternatively, published documents can be displayed in a table. In the toolbar of the Publications field, select **View** > **Show As List** to display the publications in a table.

5) Click the **Download** button to download the publication results from the Alfabet database to the local file system. Optionally, the documents can be removed from the database after download via the **Remove Docs** button.

In the figure below, a publication is configured to include data about an application group and all applications that are assigned to the application group. The publication definition is mapped to two templates, one for the application group data and one for the applications. To create the document for the single application group, the Word template for application groups will be filled with the data for the application group. The document is then amended with data for each application in the application group. For each application found, the Word template for the applications is filled with the appropriate data for the application and added to the document.

If data is not available for a view that is configured to be added for a bookmark, the publication will display a message stating that no data is available for the report.

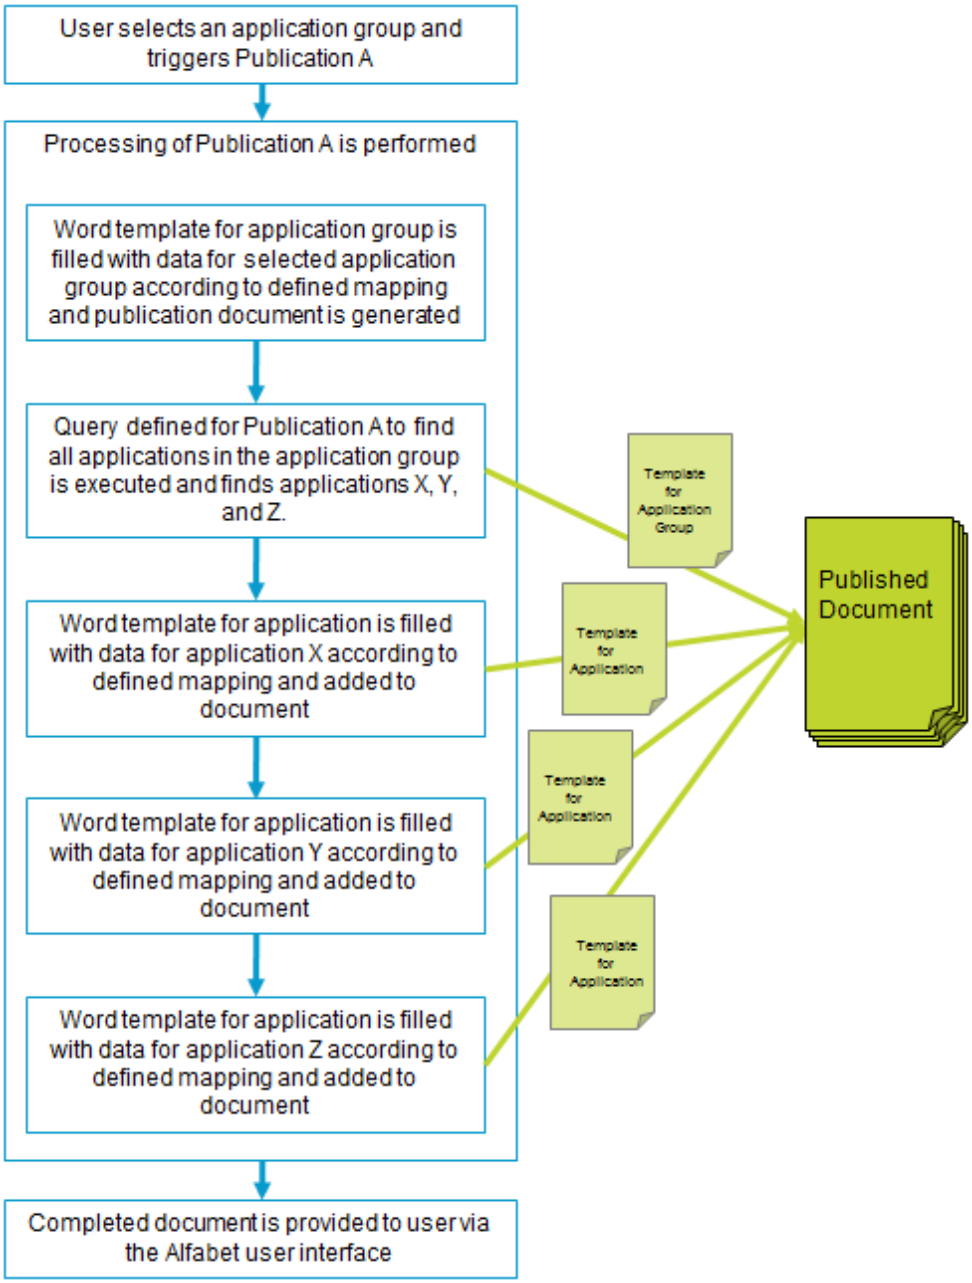

FIGURE: Generation of a Word document with data about an application group

The output is a ZIP file that contains either a document with all relevant data or a set of documents with information about each relevant object.

The name of the published documents and the ZIP file will depend on the number of base objects selected to trigger the report:

- If data about one object is published, the file naming convention will be: <publication name>_<object name>_<timestamp>
- If data about multiple objects is published, the file naming convention will be: <publication name>_<number of objects on first level of publication>_<timestamp>
- If no base objects are selected and data is published on basis of a query definition independent from a current object selection, the file naming convention will be: <publication name>_<timestamp>
- Constraints on the generation of ZIP files may result in a deviation from the naming convention for APF publications:
  - File names may not exceed 256 characters. If the file name is too long, the <object name> will be shortened, or, if applicable, left out. If the file name is still too long, the <publication name> will be shortened.
  - File names must not contain characters other than letters, numbers, underscores, or hyphens. If the object name or publication name contains a special character, the special character will be replaced with an underscore.

The timestamp includes the current date and time in the format: YYYYMMDD_hhmmssmmmm.

The following is required to configure Alfabet to allow users to trigger data publication:

- Design at least one template for the publication in Microsoft® Word. For more information, see the section *Defining Microsoft® Word Templates for Publication*.
- Define the mapping of data in the Alfabet database using the Word templates. This includes the definition of the queries that find the relevant objects for the publication. For more information, see the section *Mapping Alfabet Data to Word Templates*.
- Configure the user interface to allow users to trigger a publication. For more information, see the section *Configuring Access to the Publication Functionality*.

Alternatively, publications can be triggered by a batch job.

Defining Microsoft® Word Templates for Publication

The first step to set up a publication in the APF is the definition of at least one publication template in Microsoft® Word DOT or DOTX format.

Publications can be configured to include information not only about one object or multiple objects of the same object class, but also about related objects. The publication definition can be regarded as a tree. Each node in the tree must be mapped to a Microsoft® Word template. Multiple nodes in the tree can be mapped to the same Word template provided that the same data structure applies to the publication of the data about the objects found for the node.

The mapping of object data to a Word template is defined per node in the publication definition (and not per object class). You can use different Word templates for data about the same object class if the objects of the respective object class are found via different nodes in your publication definition.

The publication templates are defined directly in Microsoft® Word. They are simple Microsoft® Word documents that can be formatted according to your needs using the mechanisms available in Microsoft® Word.

The Word template consists of plain text that will be published for each object found for the node in the publication definition. Microsoft® Word bookmarks can be used in the text as placeholders for data that is to be added about the object.

The following object information can be added to a publication:

- Object class property values
- Graphic views
- Configured reports
- Datasets that are the result of a query defined in the publication definition.

To define a Microsoft® Word template:

1) Open the Microsoft® Word program installed on your computer.
2) Create a document that matches the desired publication in content and style and save it as Word template (*.dot or *.dotx).
3) Add bookmarks to the document wherever you want Alfabet data to be added as follows:
   - Add the name of the bookmark as text to the document.
   - Mark the bookmark name in the text and add a bookmark that is applied to the text with a name identical to the marked text.

Note the following about adding bookmarks to the document:

- The Word template can only be used in the Alfabet Publication Framework (APF) if the text and the name of the bookmarks match identically.
- If you want to add a configured report or standard Alfabet page view including a legend to the document, you must add separate bookmarks for the configured report/page view and for the legend of the configured report/page view.
- If you add a configured report or page view via a bookmark, the report will be inserted as a graphic. The image is resized to fit the document width. If the length of the graphic supersedes the space available on the page, the lower part of the image may be hidden behind the footer defined for the document. This is the standard graphic import behavior of Microsoft Word and cannot be changed by Software AG.
- Other than the table of contents feature, you must not user any other Microsoft Word bookmark field functions in the document.

Using Microsoft Word, you can insert a table of contents in the document by defining the hierarchy of heading levels that are to be included. When creating and updating the table of contents, the information about the document content will be

automatically included in the table of contents. This mechanism can only be used if the formatting of the headings is based on styles.

You can add a table of contents to your template via two methods:

- Use the Microsoft Word mechanisms to add a table of contents anywhere in the Word template. The publication will have a table of contents at the specified position that reflects the current content.
- If you create the Word template without a table of contents, you can configure the publication definition in Alfabet Expand to add a table of contents to the document during publication. The table of contents will be inserted before the Word template. This method is not recommended for templates containing a title page because the table of contents will be located before the title page.

For information about the configuration of the publication definition to include a table of contents in the document, see *Mapping Alfabet Data to Word Templates*.

For either method, the table of contents will not be automatically filled during document creation. When a user opens a publication, he/she will see the text "TOC" where the table of contents has been added. The user must update the table of contents manually to view the contents. To do so, the user must click the word "TOC" and press F9 on his/her keyboard.

Mapping Alfabet Data to Word Templates

The mapping of Alfabet data to bookmarks in Word templates is carried out in the configuration tool Alfabet Expand.

Each publication definition is configured by creating explorer elements as sub-nodes of the **Publications** root node in the **Publications** tab. A publication consists of a publication node with the following child elements:

- A **Templates** folder that contains at least one template element. Each template element corresponds to a Word template. The template assigned to the template element is uploaded to the Alfabet database.
- A publication entry element that assigns the Word template to objects of a defined object class in the Alfabet meta-model. The entry element can contain the following sub-elements:
  - A **Mappings** folder must be available that contains one mapping element for each bookmark
  - Optionally, child publication entry elements can be added to define a hierarchy of publication steps

To configure mapping of data to a Word template:

1) In Alfabet Expand, go to the **Reports** tab.
2) In the explorer, right-click the root node **Publications** and select **Add publication**. A new node is added to the explorer and the attribute window displays the attributes of the new publication.
3) Define the following attributes of the new publication:

- **Name**: Enter a unique name for the publication. The name is a technical name and should not contain whitespaces and special characters.
- **Caption**: Enter a caption for the publication. The caption is displayed in the Alfabet user interface in the drop-down list of the publication selector. The **Name** attribute of the publication will be displayed if no caption is defined.
- **Comments**: Optionally enter a description for the publication.
- **Debug Arguments**: You can define a default for the parameter settings if:
  - publication is to be executed with the command line utility `PublicationConsole.exe`, and
  - the queries defined for the publication contain Alfabet parameters that are to be substituted with values defined for the Alfabet parameters via the command line.

  

  The required syntax is <parameter name>=<value>. If you want to define multiple parameter values, the entries must be comma-separated. The value must be defined in the exact syntax required to define the Alfabet parameter value in the query. For example, if strings are written in inverted commas in a query, the inverted commas must be part of the Alfabet parameter value. The parameter name is the name of the Alfabet parameter without the prefix @ or:

  For more information about the definition of Alfabet parameter values in the command line of the publication console application, see Defining Publication Output In the Command Line of the Batch Utility.

- **Data Culture**: Select the culture for the publication in the drop-down list. If no culture is selected, the default language English will be used for the publication. The **Data Culture** attribute is only required if object data translation has been activated for the **Support Data Translation** attribute of the relevant culture . If object data translation is activated for a culture, the **Name** and **Description** property of Alfabet may be translated to the language associated with the currently selected culture. Translated strings are stored in the database table of the object class in a separate column. For more information about the specification of cultures and translation, see the chapter Localization and Multi-Language Support for the Alfabet Interface.
- **Document Format**: If you select `Word`, the result of the publication will be a Microsoft Word document. If you select `PDF`, the result of the publication will be a PDF document.
- **Group**: You can optionally structure and organize publications in publication group folders. To create a publication group, enter a name for the publication group in the **Group** field and press ENTER. The publication group appears as a folder ascendant to the publication. If other publications are already structured in publication groups, existing publication groups can be selected from a drop-down list in the **Group** attribute. If an existing publication group is selected, the publication will be added to the selected publication group folder.
- **Insert Table of Contents**: Optionally, you can trigger the generation of a table of contents for the document by setting this attribute to `True`.

  

  In Microsoft Word you can insert a table of contents in the document by defining a hierarchy of the heading levels that are to be included. When creating and updating the table of contents, the information about the document content will be automatically included in the table of contents. This mechanism can only be used if the formatting of the headings is based on styles.

You can add a table of contents to your template via two methods:

- Use the Microsoft Word mechanisms to add a table of contents anywhere in the Word template. The publication will have a table of contents at the specified position that reflects the current content.
- If the Word template has been created without a table of contents, set the attribute **Insert Table Of Contents** of the publication definition to `True` to add a table of contents to the document during publication. The table of contents will be inserted before the Word template. This method is not recommended for Word templates containing a title page because the table of contents will be located before the title page.

With both methods, the table of contents will not be automatically filled during document creation. When a user opens a publication, he/she will see the text "TOC" where the table of contents has been added. The user must update the table of contents manually to view the contents. To update the table of contents, the user must click the word "TOC" and press F9 on the keyboard.

If you specify `True` for the **Insert Table of Contents** attribute, you should also expand the section **TOC Info** and edit the following attributes:

- **Start Level**: Define the first heading level that shall be included in the table of contents.
- **End Level**: Define the last heading level that shall be included in the table of contents.
- **Heading**: Enter the text that shall be displayed as heading text above the table of contents.
- **Heading Style Name**: Enter the style name that shall be used to format the heading of the table of contents. The style must exist in the style configuration of your Word template.
- **Separate Page**: Select `True` if a page break shall be inserted after the table of contents.

4) Expand the new publication node in the explorer and right-click the **Templates** folder.
5) In the context menu, select **Add template**.
6) In the explorer that opens, select the Word template that you want to use for the publication of data. The Word template is added as a new sub-node to the **Templates** folder.

The template is uploaded to the database when you select it in the explorer. Once the template is uploaded to the database, the following is possible by right-clicking the template node:

- **Show Publication Template**: Select this option to open a preview of the template in Alfabet Expand. Please note that only one template can be displayed in the middle pane. If you use the option on a publication template while another publication template is aready displayed, the preview of previously displayed template is substituted with the preview of the selected publication template.
- **Reload Publication Template**: Select to update changes made to the template stored in the local file system. Any changes performed after the template has been assigned to the publication configuration must be reloaded in order to be

updated to the solution configuration. If you select **Reload Template**, an explorer will open that allows you to select the changed document in the local file system. After upload, the mapping nodes of an existing configuration will be automatically adapted to the new template without any loss to the existing configuration. Renaming a bookmark requires re-configuration of the bookmark mapping because the old bookmark will be regarded as deleted and the new name will be interpreted as a new bookmark.

- **Save Publication Template to Disk**: Select this option to export a copy of the uploaded template to the local file system.
- **Delete**: Select this option to delete the uploaded template from the database. If you delete a template, the mapping for the template will also be deleted. All mapping nodes and the configuration in the nodes will be removed from the publication node.

Information about the creation and last update performed on the Word template node are available in the attribute window of the template node. Expand the **Tech Info** attribute to view the information.

7) In the attribute window, define a unique name for the Word template in the **Name** attribute The name is a technical name and should not contain whitespaces and special characters.
8) Right-click the publication node and select **Add Publication Entry**. The publication entry is added as a new sub-node to the publication node and the attributes are displayed in the attribute window.
9) In the attribute window, define the following attributes:
   - **Name**: Enter a unique name for the publication entry.
   - **Parameter Name**: Enter a name that can be used as parameter name in queries. The parameter name can be used for any publication entries in the publication configuration to refer to the `REFSTR` of the current object found for this publication entry.

     

     For more information about how to define Alfabet parameters in Alfabet queries, see the section Referring to the Current Alfabet Context in a WHERE Condition in the chapter Defining Queries.

     For more information about how to define Alfabet parameters in native SQL queries, see the section Using Alfabet Parameters in the section Defining Native SQL Queries of the chapter Defining Queries.

   - **Source Type**: Select one of the following:
     - `None`: Select this option if you want to publish data about the base object of the publication. The base object is the object that the user selects to trigger the publication for in a configured report or the object the user is currently working with if he/she triggers the publication via a configured button in the object profile.
     - `Query`: Select this option if you want to publish data about the objects found by the Alfabet query. If this option is selected, the Alfabet query must be configured to find the base objects for the publication in either the **Alfabet Query** attribute or the **Alfabet Query as Text** attribute.

- `NativeSql`: Select this option if you want to publish data about the objects found by a native SQL query. If this option is selected, the native SQL query must be configured to find the base objects for the publication in the **Native Query** attribute.

  If the **Source Type** attribute is set to `None`, the publications can neither be tested in Alfabet Expand nor published with the publication console application. If you want to test a report that should be based on a base object selected by the user (**Source Type** attribute = `None`), you must simulate the user selection during the configuration: To do so, select `Query` or `NativeSql` in the **Source Type** attribute and define a query that finds one single object of the base object class. After successful testing, you can change the **Source Type** attribute to `None`. If you want a publication to be executed with the publication console application with the selection of a different base object for each publication, you can select the option `Query` or `NativeSql` in the **Source Type** attribute and define an Alfabet parameter in the query. Current Alfabet parameter values can be selected in the command line of the publication console application. For more information, see the section Defining Publication Output In the Command Line of the Batch Utility.

- **Native Query** / **Alfabet Query** / **Alfabet Query as Text**: If the **Source Type** attribute is set to `Query` or `NativeSql`, you must define a query that finds the object(s) for which data should be published. The parameter `BASE` can be used in the query to refer to the `REFSTR` of the object that the user has currently selected for publication.

  For more information about how to define Alfabet queries or native SQL queries in the context of Alfabet configurations, see the chapter Defining Queries.

- **Template**: Select the Word template to use for the publication of data. The drop-down list displays all uploaded Word templates.

- **Use separate page**: Select `True` if you want a line break to be added to the document when starting publication of a new object of this level.

10) After having selected a Word template for the **Template** attribute of the publication entry, a **Mappings** folder with one mapping node for each bookmark found in the Word template will be added automatically to the publication entry node.

    To check the position of the bookmark you are currently mapping to the Word template, right-click the mapping node and select **Show bookmark in template**. A document preview opens in the center pane displaying the page that contains the currently selected bookmark.

    In the **Source Type** attribute of the mapping node, map the bookmark to the Alfabet data:

- `Property`: Select to display the current value of a defined object class property.

- `GraphicView`: Select to display a graphic view with the current object as base object. If the graphic view should have a legend in the publication, the legend must be added with a separate bookmark mapped to a graphic view legend.

- `GraphicViewLegend`: Select to display the legend of a standard graphic view.

- `CustomReport`: Select to display a configured report with content for the current object as base object. Configured reports must be applied to an object class to be displayed in a publication. If the report should have a legend in the publication, the legend must be added with a separate bookmark mapped to a configured report legend.

Console Reports, that means reports that display a number of subordinate reports in a table layout, cannot be added to publications. When a console report is added to a publication, the first subordinate report in the console report is displayed in the publication and all other reports are ignored.

- `CustomReportLegend`: Select to display the legend of a configured report.
- `Query`: Select to display the dataset returned by an Alfabet query defined in the **Alfabet Query** attribute or the **Alfabet Query as Text** attribute.
- `NativeQuery`: Select to display the dataset returned by an SQL query defined in the **Native Query** attribute.

11) Define the attributes required for the value selected in the **Source Type** attribute for the mapping node. Only the relevant values for the selected **Source Type** attribute will be displayed in the **Source** section of the attribute window:

- **Property Path**: Define the object class property for which the current value should be published. The object class property to be displayed can be an object class property of the current object or an object class property of a related object. Each object class must be defined by the **Parameter Name** specified in the publication entry. The object class and object class property must be separated by a period.

  To display an object class property of the object class defined in the current publication entry, define < **Parameter Name** value>.<object class property name> (For example, the start date of the current application with a **Parameter Name** definition of `App` in the current publication entry):

  ```
  App.StartDate
  ```

  To display a property of a superordinate object in the hierarchy (For example, the name of the application group that the application is assigned to with a parent publication entry that defines the **Parameter Name** of the application group as `AppGroup`):

  ```
  AppGroup.Name
  ```

- **View**: Select the Alfabet page view that you want to display. The drop-down list includes all views available for Alfabet. You must ensure that the selected view is relevant for the current object.

  To evaluate which page views are relevant for an object class, you can consult the object view definition of the object class. The standard object views for an object class that are visible in the **Object View** explorer node in the **Presentation** tab in Alfabet Expand contain the relevant page views for the respective object class.

  Note the following about the display of views in the publication:

  - If a view has filters, the view will be executed with empty filter fields. If a default is available for a filter setting, the default will be used. The filter settings currently stored for the user triggering the publications will be ignored. If a report shall be executed with defined filter settings, you can either use a configured report that returns a dataset that would result from the filter settings on the standard view or define a query to return the required result via either the **Alfabet Query** attribute, **Alfabet Query as Text**

attribute, or **Native Query** attribute. If you define the return dataset via a query, you can use Alfabet parameters to refer to variables that are specified either in the command line of the batch job triggering the publication or in the **Debug Arguments** attribute of the report. This allows filters to be simulated for a report when triggering the publication via the command line.

- Grouped views allow the user to expand or collapse sections of the report to view or hide subordinate information. These are displayed with all collapsible levels expanded to display all available information in the publication. This applies to Gantt charts and expandable tabular reports, For example,.
- The scaling of graphic reports is identical to the scaling used in the Alfabet user interface if the resulting image size fits on the document page. If the image is larger then the width of the document page, the image is resized to fit the page.

- **Apply to Class**: If you want to map the bookmark to a configured report applied to an object class via the **Apply to Class** attribute of the configured report, you must first select the object class that the configured report is applied to.
- **Custom Report**: Select a configured report to map the bookmark to a configured report. If you select an object class in the **Apply to Class** attribute, the drop-down list will display all configured reports that apply to the defined class. If the attribute **Apply to Class** is not specified, the drop-down list will display all configured reports that are not applied to the class Reports.

  Note the following when adding a configured report to a publication:

  - Reports that are configured to trigger publications cannot be selected.
  - The rules that apply to the display of standard Alfabet views (listed above) also apply to the display of configured reports.

- **Alfabet Query/Alfabet Query as Text**: Define an Alfabet query either in the **Alfabet Query** attribute using the **Alfabet Query Builder** or in the **Alfabet Query as Text** attribute using a text editor. The dataset returned by the Alfabet query is displayed in the publication. The attributes available in the **Source** section allow you to format the display of the dataset. The **Parameter Name** values of this or any other publication entry in the publication definition can be used in the query as a parameter in order to return the `REFSTR` of the current object of the respective publication level.

  For more information about how to define Alfabet queries, see the chapter Defining Queries.

- **Native Query**: Define a native SQL query. The dataset returned by the native SQL query is displayed in the publication. The attributes available in the **Source** section allow you to format the display of the dataset. The **Parameter Name** values of this or any other publication entry in the publication definition can be used in the query as a parameter in order to return the `REFSTR` of the current object of the respective publication level.

  For more information about how to define native SQL queries in the context of Alfabet configurations, see the section Defining Native SQL Queries in the chapter Defining Queries.

- **String Formatting Type**: Select one of the following types of formatting for the dataset returned by the defined query:
  - `DataSet`: Select to display a tabular output of the query results.
  - `DelimitedString`: Select to display search results in a string with a defined delimiter between each column value of the returned dataset. Whether data is displayed in a new row for each dataset or without line breaks between the returned datasets will depend on the setting of the **Use New Line For Each Row** attribute
  - `FormattedString`: Select to display search results as variable part of a static string defined with the attribute **Format String**.
- **Format String**: Define the string that shall be displayed for the search results of the defined query. To display current query results in the string, add a variable in the format {dataset column name}.

  

  The name and caption of a dataset column are not necessarily identical. Which value must be taken over depends on how the Alfabet query or a native SQL query is defined. For more information about how to identify the correct technical name of a dataset column, see the section Defining Column Names and Captions in the chapter Defining Queries.

  

  For example, data about an application is to be published. For the current bookmark, the name of the ICT object that the application is assigned to shall be published as part of a sentence. The ICT object is found by a native SQL query definition:

  ```
  SELECT icto.REFSTR, icto.NAME as "ICTObject"
  FROM ICTOBJECT icto, APPLICATION app
  WHERE app.REFSTR = @BASE
  AND app.ICTOBJECT = icto.REFSTR
  ```

  The text string is defined as follows to include the name of the ICT object:

  ```
  The application is assigned to the ICT object {ICTObject}.
  ```

- **Delimiter**: Define the delimiter between values within a dataset. By default, values are delimited with a space.
- **Use New Line for Each Row**: Select `True` to display each dataset returned by the query in a new line. Select `False` to display all results without line breaks between datasets.

12) You can optionally add additional entries to the publication either in parallel to the first publication entry or as sub-elements of the already configured publication entry. Note the following when configuring publications with multiple entries:

- Only publication entries of the first level can have the **Source Type** attribute set to `None`.
- Publication entries that are child elements of parent publication entries must have the **Source Type** attribute set to `Query` or `NativeSql`. An Alfabet query or native SQL query must be defined by means of the respective **Alfabet Query (as Text)** attribute or **Native Query** attribute. The query must relate the objects found for the current level with the objects found for the parent level. The Alfabet query language parameters (For example, the parameter `BASE`) that refers to the current object of the parent level can be used in the query.

In addition, the query can refer to any ancestor object in the hierarchy of publication entries using the value defined in the **Parameter Name** attribute as the parameter to refer to the `REFSTR` of the ancestor object.

13) In the toolbar of Alfabet Expand, click the **Save** button to save your changes.

14) In the explorer, right-click the publication node and select **Test Publication**. If the publication configuration is incorrect, an error message will be displayed that provides information about the location of the error. If the publication configuration is correct, a process information will be displayed. When you confirm the process protocol, the word document with the current data from the Alfabet database will open in Microsoft® Word. If the results are not as expected, you can edit the publication configuration until the output of the publication meets your expectations.

Please note that the publishing protocol dialog is displayed in the language set in the **Data Culture** attribute of the publication independent from the language settings selected for the Alfabet Expand user interface.

15) Click the publication node and select **Set Publication State to 'Active'**. Only publications with a **Publication State** attribute set to **Active** can be displayed and accessed in the Alfabet user interface.

Publications with the **State** attribute set to `Active` cannot be edited in Alfabet Expand. If you want to change a publication configuration that is currently `Active` and used on the Alfabet user interface, re-set the **Publication State** attribute to `Plan` by right-clicking the publication node. The publication configuration can then be edited. As long as the **Publication State** attribute is set to `Plan`, the publication will not be available in the Alfabet user interface. It will not be displayed in drop-down lists displaying available configurations. Functionalities that directly execute the publication will throw an error message informing the user that the publication is currently inactive. Publications in with the **Publication State** attribute set to `Retired` can neither be executed in the Alfabet user interface nor edited in Alfabet Expand.

The options to change the state of publications are also available on publication group folders. If you use the options on the publication group folder, the status change will be applied to all publications in the publication group folder.

Publishing Documents in Different Languages

Alfabet can be configured to translate strings displayed on the user interface and the **Name** and **Description** properties of objects defined by the Alfabet user community. When the user logs in to the Alfabet user interface, the user interface will display the language associated with the default culture defined either in the user's personal settings or defined in the server alias configuration used for login to the Alfabet Web Application. The user can switch to a different culture via the **Language** button in the upper-right corner of the Alfabet interface.

If multi-language support is available for your Alfabet user community, then the publications should also be available in the various languages that are supported. A separate publication must be configured for each language for which you want to provide a translated publication.

The following is recommended to generate a language version for a publication configuration:

1) Create a copy of the Word template(s) assigned to the original publication definition and translate all static content to the target language.

2) Open Alfabet Expand and go to the **Reports** tab.

3) Right-click the original publication and select **Copy**.

4) Right-click the new **Publications** root node and select **Paste**. A copy of the original publication is added to the explorer tree with the name **<source publication name> - 1**.

5) If the **State** attribute of the new publication is not set to `Plan`, right-click the new publication and select **Set State to Plan**.

6) Define the following attributes of the new publication:

   - **Name**: Enter a unique name for the publication. The name is a technical name and should not contain whitespaces and special characters. The name should reflect that the publication is a language version of the original publication (For example, by defining <source publication name>-<language code>).

   - **Caption**: Enter a caption for the publication. The caption is displayed in the Alfabet user interface in the drop-down list available for the **Publication** field. The **Name** attribute will be displayed if no caption is defined. It is recommended that you define a name that allows the publication to be identified as a language version of the source publication (For example, "Publication X (German)"). The caption can be defined in the base language of the meta-model (which is English). It can later be translated to other languages via the **Translation Editor** available in Alfabet Expand. For more information about the translation capability available in Alfabet Expand, see the chapter Localization and Multi-Language Support for the Alfabet Interface.

   - **Comments**: Optionally enter a description for the publication. The description can be defined in the base language of the meta-model. It will later be translated to other languages via the translation editor of Alfabet Expand.

   - **Data Culture**: Select the culture for the publication in the drop-down list. If no culture is selected, the default language English will be used for the publication. The **Data Culture** attribute is only required if instance translation has been activated for the **Support Data Translation** attribute of the relevant culture. If instance translation is activated for a culture, the **Name** and **Description** property of Alfabet may be translated to the language associated with the currently selected culture. Translated strings are stored in the database table of the object class in a separate column. For more information about the specification of cultures, see the chapter Localization and Multi-Language Support for the Alfabet Interface.

   - **Group**: You can optionally structure and organize publications in publication group folders. To create a publication group, enter a name for the publication group in the **Group** field and press ENTER. The publication group appears as a folder ascendant to the publication. If other publications are already structured in publication groups, existing publication groups can be selected from a drop-down list in the **Group** attribute. If an existing publication group is selected, the publication is added to the selected publication group folder.

7) Expand the new publication node in the explorer and expand the **Templates** node.

8) Right-click a Word template and select **Reload template**.

9) In the explorer that opens, select the translated version of the Word template. The Word template is substituted with the language version.

The template is uploaded to the database when you select it in the explorer. Once the template is uploaded to the database, the following is possible by right-clicking the template node:

- **Show Publication Template**: Select this option to open a preview of the template in Alfabet Expand. Please note that only one template can be displayed in the middle pane. If you use the option on a publication template while another publication template is aready displayed, the preview of previously displayed template is substituted with the preview of the selected publication template.
- **Reload Publication Template**: Select to update changes made to the template stored in the local file system. Any changes performed after the template has been assigned to the publication configuration must be reloaded in order to be updated to the solution configuration. If you select **Reload Template**, an explorer will open that allows you to select the changed document in the local file system. After upload, the mapping nodes of an existing configuration will be automatically adapted to the new template without any loss to the existing configuration. Renaming a bookmark requires re-configuration of the bookmark mapping because the old bookmark will be regarded as deleted and the new name will be interpreted as a new bookmark.
- **Save Publication Template to Disk**: Select this option to export a copy of the uploaded template to the local file system.
- **Delete**: Select this option to delete the uploaded template from the database. If you delete a template, the mapping for the template will also be deleted. All mapping nodes and the configuration in the nodes will be removed from the publication node.

Information about the creation and last update performed on the Word template node are available in the attribute window of the template node. Expand the **Tech Info** attribute to view the information.

10) If the publication shall be triggered via a configured report, go to the **Reports** section of the explorer and select the configured report that triggers the publication in the user interface.
11) Right-click the **Publications** sub-folder of the report node and select **Add Publication**. Select the newly created language version of the publication and click **OK**. The language version of the publication is now available for selection in the report.
12) In the **Translation Editor** available in Alfabet Expand, **translate the caption and description of the original and the language version of the publication to the language of the translated publication.** For more information about the translation of strings available in the Alfabet user interface, see the section Modifying, Translating and Managing the Vocabularies in the chapter Localization and Multi-Language Support for the Alfabet Interface..

Configuring Access to the Publication Functionality

After the publication definition based on Word templates has been configured, you must define a configured report that allows the user to trigger the publication. The publication functionality can be included directly in a configured report that displays the report results or the report can be configured to trigger publications only.

Publication can be performed in the Alfabet interface using one of the following methods:

- A configured report of the type `Query`, `NativeSql`, or `Custom` that displays a dataset that is returned by the query. The user can select one or multiple objects in the dataset and then trigger a

publication. The publication functionality is displayed below the dataset and includes the necessary buttons to trigger the publication.

The objects selected in the dataset are the base objects for the publication. For first level publication nodes with a **Source Type** attribute set to `None`, the data about the selected object will be published. For first level publication entries with a **Source Type** attribute set to `Query` or `NativeQuery`, the selected objects can be referenced by means of the parameter `BASE` in the query defined for the publication entry.

- A configured report that displays only the publication functionality. The user can trigger the publication for base objects that are selected by one of the following methods:
  - The first level publication entries of the publication has the **Source Type** attribute set to `Query` or `NativeSql` and the query defines the objects to be selected without a reference to a base object (in other words, without using the parameter `BASE`).
  - The configured report is assigned to an object class via the **Apply to Class** attribute of the configured report. A selector is then displayed in the publication interface that allows an object to be selected as the base object for the configured report. The first level publication entries of the publication can either have the **Source Type** attribute set to `None` and configured to publish data about the current object, or have the **Source Type** attribute set to `Query` or `NativeQuery`. The query references the selected base object using the parameter `BASE`.
  - A custom button is configured for an object profile that opens the configured report triggering the publication and the **Operation Apply To** attribute of the button is set to `BaseInstance`. The object the user is currently working with is the base object of the report. The first level publication entries of the publication can either have the **Source Type** attribute set to `None` and configured to publish data about the current object, or have the **Source Type** attribute set to `Query` or `NativeSql`. The query can reference the selected base object using the parameter `BASE`.

For information about the creation of custom buttons to open a configured report, see the ssection Configuring Custom Buttons for the Toolbar of a Custom Object View in the chapter Configuring Object Views.

The following information is available:

- *Defining a Configured Report for Base Object Selection and Publication*
- *Defining a Configured Report to Trigger Publications Only*

Defining a Configured Report for Base Object Selection and Publication

To define a configured report to provide both a report for selection of objects and an interface to trigger publications:

1) In the **Reports** tab of Alfabet Expand, either:
   - Create a new configured report that allows the data to be selected for which you would like to trigger publication, or
   - Go to an existing report that matches the required configuration and make sure that the **State** attribute is set to `Plan`.

For a detailed description of how to configure a configured report, see the chapter Configuring Reports.

2) Right-click the configured report and select **Add Publication**.

3) In the selector that opens, select one or multiple publication configurations that should be triggered from the configured report. A folder **Publications** is added to the configured report with the publication configurations added as sub-nodes to the folder.

To add additional publication configurations to the configured report, right-click the **Publications** folder and select **Add Publication**.

To remove a publication configuration from the configured report, right-click the publication configuration node in the **Publications** folder and select **Detach Publication**.

4) Right-click the configured report and select **Add Publication Control**. A new window opens.

5) In the **Add Publication Control** window, select the position of the publication interface in the configured report with the **Dock** attribute.

6) In the toolbar of Alfabet Expand, click the **Save** button to save your changes.

7) Optionally, right-click the report view node and select **Design View**. The report view opens in the center pane and shows both the presentation object of the configured report and the presentation object for the publication interface. You can resize the presentation objects, if necessary.

8) In the toolbar, click the **Save** button to save your changes.

9) Right-click the configured report and select **Set State to Active**.

Defining a Configured Report to Trigger Publications Only

To define a configured report that only provides an interface to trigger publications:

1) In the **Reports** tab, right-click the **Reports** folder or a sub-folder and select **Create New Report**. You will see the new configured report listed below the selected folder.

As an alternative to defining all attributes for a new configured report, you can copy and paste an existing configured report and make modifications, as needed. To do so, right-click the existing configured report that you want to copy and select **Copy**. Right-click the new configured report and select **Paste**. Modify the necessary attributes described below.

2) In the property window, define the following attributes for the configured report:

- **Name**: Optionally, change the technical name of the configured report. The technical name of the configured report must be unique.

The technical name is used for identification of the configured report in the context of technical processes such as merging the report configuration with a report configuration saved as an XML file. Therefore, the following is required when defining the name of a configured report:

- The name must be unique. The name must be unique regardless of the report folder it is structured in.
- The name may not be changed once a configured report has been created.
- A validation mechanism checks for correct syntax when defining a technical name. Please note that names may not begin with an empty space nor include special characters. For a list of the special characters that are not allowed, see the section Defining Attributes for Configuration Objects in the chapter Getting Started with Alfabet Expand.
- If the technical name of the configured report is changed, the name will be correctly updated in other configuration objects referencing the changed report during design time.

Please note that the name of a changed configuration object will not be updated in guide pages or guide views. If you plan to change the name of a configuration object, the reference in the navigation page should be changed prior to changing the configuration object name. You can use the **Show Usage** functionality in the context menu of the configured report to evaluate whether the configured report has been added to a guide view or guide page.

- **Caption**: Enter a caption for the configured report. The caption you define here will be displayed in the **Reports Administration** functionality in the **Administration** module and the **Configured Reports** views of the Alfabet interface. If the configured report is assigned to an object view as a page view, the text will be displayed as the page view caption in the object view. The caption of the configured report may exceed the conventional 64 character limit.
- **Description**: Provide a short information about the configured report that is useful to Alfabet users. This comment will be displayed on the Alfabet user interface in the header of the configured report in a single line under the report caption and the **Description** field for the configured report in the table of all views listing configured reports, like the **Configured Reports** views of the **Search** functionalities. If the configured report is assigned to an object view as a page view, the text will be displayed under the page view caption as short description in the object view.

  In the configured report, the description will be truncated if it is longer than one line on the screen. Therefore, the description should be short to ensure complete display in the configured report header.

- **Usage Guideline**: Provide information that helps users to execute and interpret the configured report. This information will not be displayed directly on the user interface. The user can access the information using the following mechanisms:
  - If the user moves the cursor over the description provided for the configured report with the attribute **Description**, a tooltip opens that includes both the description and the usage guideline.
  - The **Options** button will be displayed on the upper right with an option **Help On Filter Fields** to open a new window displaying the usage guideline in addition to any filter field hints, if configured.

    For views that have filters defined, the **Options** button will only be displayed if the filter panel either allows batch clearing of filter fields or collapsing

and expanding of the filter panel. For more information about the configuration of these functionalities, see Configuring the Complete Filter Area to be Collapsible and Allowing the User to Clear the Filter Area.

- **Technical Comment**: Provide information that is useful for solution designers working with Alfabet Expand in order to better understand the configured report from a technical perspective. The **Technical Comment** will not be displayed in the user interface. Nevertheless, you can configure the interface to display the information in, For example, the attribute section of the configured report's object profile in the **Reports Administration** functionality.
- **Type**: Select `Query`. This is the default for new configured reports.
- **Report State**: The **Report State** attribute is view only and is set to `Plan` for new configured reports. The configured report can only be edited when the **Report State** attribute is set to `Plan`. After finishing all configuration steps described in the following, the **Report State** attribute must be set to `Active` as described in the section General Guidelines for Creating Configured Reports. The configured report is then visible to users in the Alfabet user interface.
- **Help Index**: Specify the location of the external Help file using the following syntax:(For example,:). The external help file will be displayed when the user clicks the context-sensitive Help link in the standardHelp menu.

  Server variables can be used in the Help links. Server variables allow you to define all or part of the URL definition in the server alias configuration of the Alfabet Server instead of directly defining it in the configuration in Alfabet Expand. Use of server variables is useful, For example, in order to change a Web server name defined in multiple URL definitions in Alfabet Expand. Instead of changing all URL definitions, only the variable value in the server alias configuration must be updated. The use of server variables is described in the section Using Server Variables in Web Link and Database Server-Related Specifications in the chapter Configuring Reports.

- **Apply to Class**: To apply the configured report to one specified object class, click the **Browse** button to open a dialog box and select the object class to which you want to apply the configured report and click **OK**. If you set the attribute, a selector will be displayed at the top of the configured report. The user can select a base object for the report in the selector.
- **Base Classes**: Define the object classes that must be available to run the configured report. If this attribute is set, the Alfabet Server checks whether the object classes specified as base classes are excluded from the view scheme used to access the configured report. If the user does not have access permissions to one of the base classes, the configured report will be disabled. To set the attribute, click the **Browse** button to select the object classes that are required to run the configured report and click **OK**.

3) Right-click the configured report and select **Add Publication**.
4) In the selector that opens select one or multiple publication configurations that should be triggered via the configured report. A **Publications** folder is added to the configured report. The publication configurations are added as sub-nodes to the folder.

   To add additional publication configurations to the configured report, right-click the **Publications** folder and select **Add Publication**.

To remove a publication configuration from the configured report, right-click the publication configuration node in the **Publications** folder and select **Detach Publication**.

5) Right-click the configured report and select **Create Custom Report View**. The configured report view is added to the configured report and opens in the center pane.
6) Delete all controls and elements from the report view.
7) In the toolbar of Alfabet Expand, click the **Save** button to save your changes.
8) Right-click the configured report and select **Add Publication Control**. A new window opens.
9) In the **Add Publication Control** window, set **Dock** to `Fill`. All other fields must be left empty.
10) Click **OK** to apply your changes.

The new control is only visible in the report view displayed in the center pane if you close and reopen the report view in the middle pane.

11) In the toolbar of Alfabet Expand, click the **Save** button to save your changes.

Triggering Publication Via a Batch Utility

APF allows you to directly publish data to the local file system using a batch utility.

Software AG provides a Windows® command line tool `PublicationConsole.exe` that allows a publication to be triggered via a command line or by means of a Windows® batch job.

A publication must be completely configured and the **State** attribute set to `Active` before starting a publication job. The publication must be defined in the Alfabet database that the Alfabet Server connects to and must be defined to be independent of the selection of a base object. If you want to publish data about different objects with the same publication via the batch job, you can define Alfabet parameters in the queries of the publication definition that are substituted with values defined in the command line when starting the publication console.

For information about running a publication job with `PublicationConsole.exe`, see *Batch Processes Relevant for the Alfabet Publication Framework* in the reference manual *System Administration*.

Defining Publication Output In the Command Line of the Batch Utility

If a publication is to be triggered via the `PublicationConsole.exe`, the selection of the base objects of the publication must be specified in a query in the publication definition. This results in a publication that returns results for the same set of base objects each time it is executed.

If you want to select different base objects for each publication with `PublicationConsole.exe`, you can use Alfabet parameters in the queries selecting the base object as well as in the queries defining the data to be published about the objects. The value of the Alfabet parameter is then defined in the command line of the publication console application when triggering a publication.

For more information about how to define Alfabet parameters in Alfabet queries, see Referring to the Current Alfabet Context in a WHERE Condition in the chapter Defining Queries.

For more information about how to define Alfabet parameters in native SQL queries, see Using Alfabet Parameters in the section Defining Native SQL Queries of the chapter Defining Queries.

The following configuration is required to use Alfabet parameters in the command line:

- When defining the publication, define queries that contain Alfabet parameters in `WHERE` conditions.
- Optionally, define a default value for each Alfabet parameter in the **Debug Arguments** attribute of the publication. The definition must be defined in the following syntax:
  - Each default must be defined as <parameter name>=<value>.
  - When multiple default values are added, they must be comma-separated.
  - The <parameter name> does not include the prefix @ or: of the Alfabet parameter.
  - The <value> must be written in the attribute as if defined in a query. For example, if a string is written in inverted commas in the query, the inverted commas must be part of the value specification.
- When starting the command line application, the value substituting the Alfabet parameter must be defined in the command line as -<parameter name> <value>. The parameter name is the Alfabet parameter without the prefix @ or: and the value must be defined as required by the query syntax. In other words, a string written in inverted commas in the query must be defined with the inverted commas.

A publication triggers the publication of data about a number of applications found via their name. The query finding the application is defined in the publication entry as:

```
ALFABET_QUERY_500

FIND Application

WHERE Application.Name LIKE:AppName
```

The **Debug Arguments** attribute of the publication definition specifies a default value for the application name. If no parameter value is defined in the command line, the publication will be created for all applications with a name that starts with `CMS`:

```
AppName='CMS%'
```

If you were to start the `PublicationConsole.exe` in order to create the publication about an application named "`Central Server`", the command line must look like this:

```
PublicationConsole.exe -msalias Production -alfaLoginName
SystemAdmin -alfaLoginPassword AdminPassword -publication
ApplicationData -outputfile CentralServer.zip -AppName 'Central
Server'
```

Chapter 19: Defining Queries

Queries allow for objects to be efficiently searched for and retrieved in Alfabet based on object attributes and relationships. Queries can be implemented in a wide variety of contexts, thus allowing the solution to be customized for many of the Alfabet capabilities. Queries can be written in either the Alfabet query language or in native SQL. The table below provides an overview of when native SQL and the Alfabet query language can be used.

Query Context	Description	Native SQL	Alfabet Query Language
Custom Reports	The reports functionality allows you to configure customized reports about objects in the Alfabet database. Queries in configured reports are also used to allow users to quickly and efficiently search for objects via custom filters. For detailed information about configuring reports, see Configuring Reports.	Yes	Yes
Custom Selectors	Queries in custom selectors are used to allow users to quickly and efficiently search for objects via custom filters. For detailed information about configuring custom selectors, see the section Configuring a Custom Selector for Search Functionalities.	Yes	Yes
Custom Editors	Queries in custom editors are used to specify the content in various filter options such as combo-boxes, checked list boxes, edit searches, and radio group buttons. For detailed information about configuring custom selectors, see the section Configuring Custom Editors.	Yes	Yes
Workflows	The workflow functionality may require queries in order to find objects that are the target of a workflow, users responsible to perform a workflow step, pre-conditions or post-conditions for a workflow step, or objects to be updated in the context of the workflow. For detailed information about configuring workflows, see the chapter Configuring Workflows.	Yes **NOTE**: For specific information about the use of native SQL queries in the context of workflows, see the section Special Rules for the Specification of Native SQL in the Context of Alfabet Configurations.	Yes
Wizards	The wizard functionality may require queries in order to change the target object of the wizard, pre-conditions or post-conditions for a wizard step, or objects to be updated in the context of the workflow. For detailed information about	Yes **NOTE**: For specific information about the use of native SQL queries in the	Yes

Query Context	Description	Native SQL	Alfabet Query Language
	configuring wizards, see the section Configuring Wizards.	context of wizards, see the section Special Rules for the Specification of Native SQL in the Context of Alfabet Configurations.	
Object Views	Queries can be specified to find a property to display in the **Attributes** section that is not a standard. For detailed information about the configuration of object views and their object cockpits, see the section Configuring Object Views.	No	Yes
Object Cockpits	Queries can be specified to fetch a property or validate complete data via a check entry in the object cockpit. For detailed information about the configuration of object views and their object cockpits, see the section Configuring Object Cockpits for a Custom Object View in the chapter Configuring Object Views.	Yes	Yes
Custom Explorer	Queries are specified to determine the content of explorer nodes in custom explorers. For information about configuring custom explorers, see the section Configuring Standard Business Functions and Custom Explorers.	Yes. **NOTE**: For specific information about the use of native SQL queries in the context of custom explorers, see the section Special Rules for the Specification of Native SQL in the Context of Alfabet Configurations.	Yes
Rule-Based Access Permissions	Read/Write access to objects can be granted by means of permission rules based on a query. Permission rules are defined in the XML object ***AlfaRightsManager*** in Alfabet Expand. For more information, see the section Configuring Permission Rules for Access to Objects.	Yes **NOTE**: For specific information about the use of native SQL queries in the context of rule-based access permissions, see the section Special Rules for the Specification of Native SQL in the Context of Alfabet Configurations.	Yes

Query Context	Description	Native SQL	Alfabet Query Language
Full-Text Search	Queries are required in order to find the objects indexed for the full-text search. For more information, see the section Configuring the Full-Text Search Capability.	Yes	Yes
Compliance Policy	Compliance policies determine the rules to find the objects to be targeted in a compliance project and the users responsible to provide information about the objects. Alfabet queries can be defined in order to search for the objects and persons relevant for the compliance project. For more information about the configuration of a compliance policy, see the section Configuring Queries for Compliance Policies in the chapter Configuring Alfabet Functionalities Implemented in the Solution Environment.	Yes	Yes
Computation Rules	A computation rule may be based on a query that allows for the traversal across object relationships to find content to be evaluated. For detailed information about defining computation rules, see the section *Specifying Computation Rules for Indicator Types* in the reference manual *Configuring Evaluation and Reference Data in Alfabet*.	Yes	Yes
Color Rules	A color rule consists of one or more Alfabet query-based rules that highlight a found set of objects. Color rules can be configured to be applied to objects in several matrix reports available for the object class Map View as well as to objects displayed in standard Alfabet diagrams in which a diagram view is selected. For more information about the configuration and implementation of color rules, see the *Configuring Color Rules for Map Views and Diagram Views* in the reference manual *Configuring Evaluation and Reference Data in Alfabet*.	Yes	Yes
Text Templates	Queries can be added to text templates in order to add content to the text such as a document link, list of relevant objects, or contact information about the sender or recipient of the email. For more information about the configuration of text templates, see the section Configuring Text Templates for Email Notifications in	Yes	Yes

Query Context	Description	Native SQL	Alfabet Query Language
	the chapter Configuring Alfabet Functionalities Implemented in the Solution Environment..		
Notification Monitors	A notification monitor alerts users about objects. Queries define the properties of an object class that are monitored as well as the users who are the recipients of the notification sent when the monitor is triggered. For more information about the configuration of notification monitors, see the section *Defining Notification Monitors* in the reference manual *User and Solution Administration*.	Yes	Yes
Consistency Monitors	A consistency monitor is based on a query that defines the object classes targeted by the query as well as the inconsistent properties to be detected. For more information about the configuration of consistency monitors, see the section *Defining Consistency Monitors* in the reference manual *User and Solution Administration*.	Yes	Yes
Technical Environment Items	A technical environment describes a specific area of the technology required to support the development, maintenance, operation, or testing of an object. The query searches for a set of objects that may be defined as elements in the technical architecture definition. For more information about the configuration of notification monitors, see the section *Configuring Technical Environment Definitions* in the reference manual *User and Solution Administration*.	No	Yes
Alfabet Publication Framework (APF)	Queries are used in APF to select objects and define the data to be published in Microsoft® Word®.	Yes	Yes
Alfabet Data Integration Framework (ADIF)	Queries are used in ADIF for the batch import, export, and manipulation of data in the Alfabet database.	Yes	No

The following information is available:

- Defining Alfabet Queries

Defining Alfabet Queries

By means of a class-oriented query language, Alfabet users can efficiently search for objects by defining Alfabet queries. This query language uses the CODBI (Class Oriented Database Interface) standard, which allows direct access to the model structure. Knowledge of the SQL language is not necessary to create or use Alfabet queries. Once an Alfabet query is defined, the Alfabet platform will translate the Alfabet query into native SQL and send it to the database. The Alfabet query searches for the relevant objects and generates a result list comprised of the objects and relevant properties.

The method to build Alfabet queries is similar in all contexts mentioned above. This chapter provides a general instruction about the Alfabet query language/syntax as well as how to operate the tool **Alfabet Query Builder** that supports the definition of valid Alfabet queries.

In Alfabet Expand, Alfabet queries are generally defined in the attribute window of a configuration object. The following example displays the property window of a report:

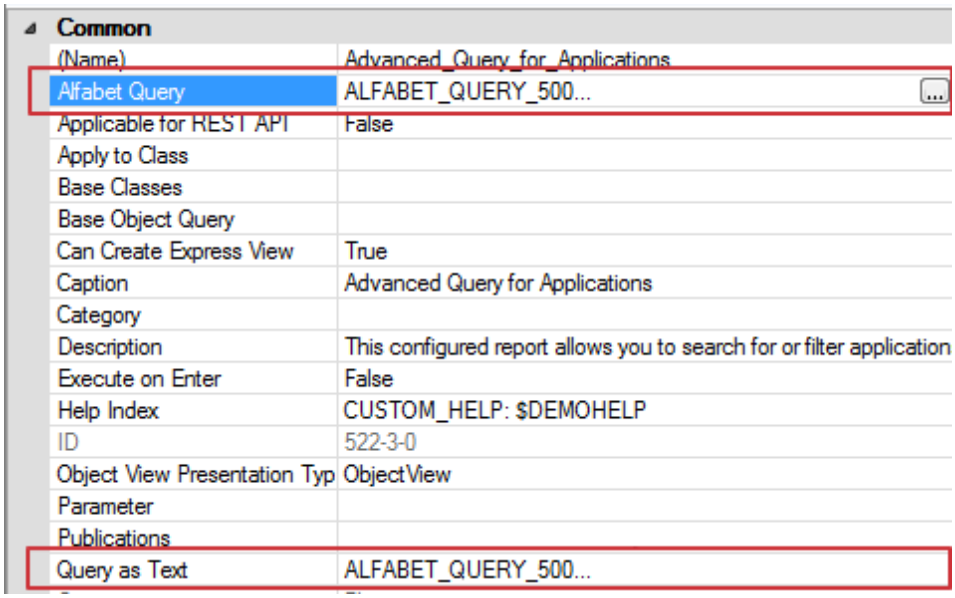

FIGURE: Property grid supporting query definition

For reports, For example, you can configure the Alfabet query using either the **Alfabet Query Builder** or the text editor. You can switch between the text editor and the **Alfabet Query Builder**, as needed:

- **Defining Alfabet queries in the Alfabet Query Builder**: Click the **Browse** button in the **Alfabet Query** field to open the **Alfabet Query Builder**.
- **Defining Alfabet queries in a text editor**: Click the **Browse** button in the **Alfabet Query as Text** field to open a text editor. You can write the Alfabet query based on the Alfabet query language directly in the editor.

Please note that the query that you define with the Alfabet Query Builder is only saved if you close the Alfabet Query Builder by clicking on the button **OK**. If you close the Alfabet Query Builder by clicking the **X** on the upper right corner of the window will close the Alfabet Query Builder without saving your changes. A query defined in the context of a configuration must additionally be saved to the Alfabet database by clicking the Save button of the Alfabet Expand Web menu after having closed the Alfabet Query Builder.

The following section provides an overview of the basic structure of the Alfabet query and the Alfabet query language and its display in the **Alfabet Query Builder**. Thereafter follows a section that will guide you through the steps required to configure a simple Alfabet query. Detailed information will follow that provides specific information about the individual elements of the Alfabet query language.

- Understanding Alfabet Queries
- *Building an Alfabet Query*
- Specifying WHERE Clauses in Alfabet Queries
- Specifying JOINs in Alfabet Queries
- Specifying Show and Sort Properties in Alfabet Queries
- Defining Filters for Configured Reports and Selectors
- Using Instructions to Format the Results of an Alfabet or Native SQL Query

- Defining Queries in XML Elements
- Testing Queries for Compliance with the Current Release
- *Creating an Index to Improve Performance for Query Searches in Database Tables*

Understanding Alfabet Queries

If you open an Alfabet query with the **Alfabet Query Builder**, you will see an interface with three main workspaces that represent the main structure of an Alfabet query written in Alfabet query language.

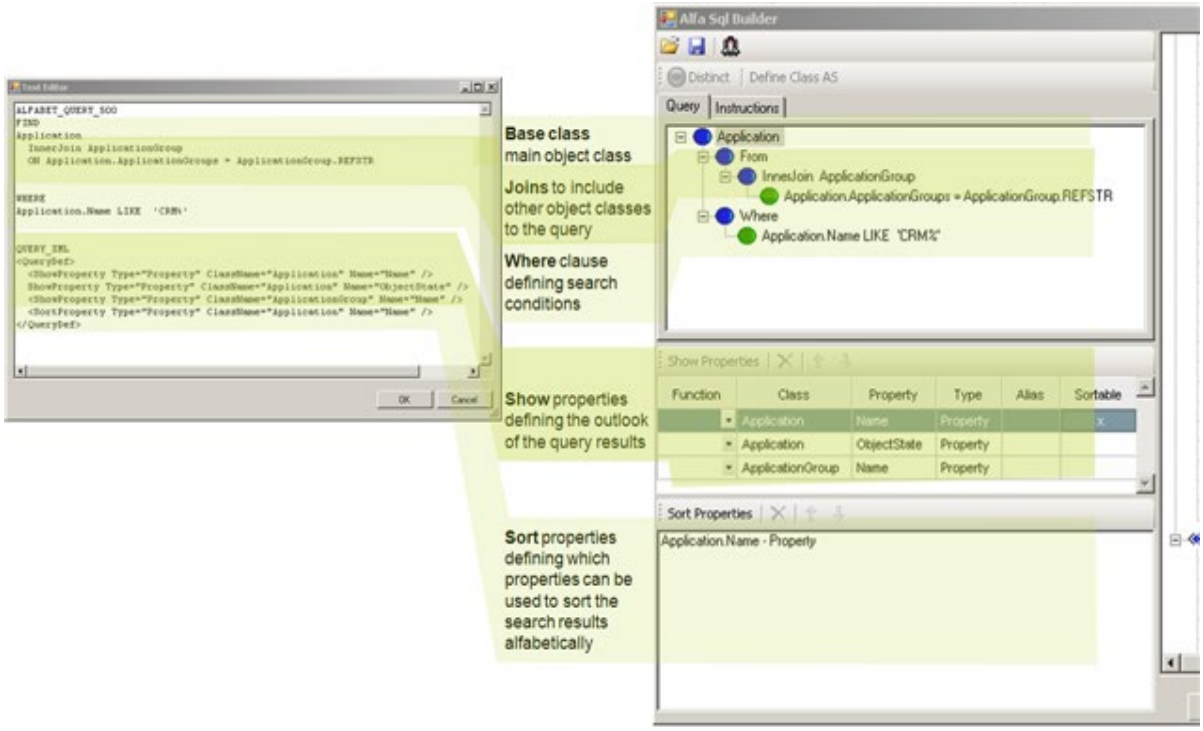

FIGURE: Alfabet query displayed in the text editor (left) and the same query displayed in the Alfabet Query Builder (right)

- The first section of the Alfabet query defines the objects to be searched for in the Alfabet database.
  - The Alfabet query starts with the base class, which is the class that is being searched for. In a report, the user can navigate to the object profile of this object class by clicking on an object displayed in the search results. In the example above, the base class is `Application`.
  - A `JOIN` allows you to include other object classes in the Alfabet query. The **Alfabet Query Builder** specifies the `JOIN`s in a `FROM` clause. If your search shall include data from object classes other than the base object class, you must define the relation between that object class and the base object class with a join. For example, to create a report about the applications that are assigned to a defined application group, you must define the relation between applications and application groups in a `JOIN`.

    Please note that whereas the **Alfabet Query Builder** specifies `JOIN`s via a `FROM` clause, the Alfabet query language does not use the expression `FROM` for a `JOIN`.

- A `WHERE` clause allows you to define the conditions that objects must meet to be included in the search condition. For example, you can search for applications that are assigned to a specific ICT object or that are members of a specific application group.

- In the **Show Properties** window, you can define which properties of the objects found by your Alfabet query shall be displayed in the resulting report or delivered as output to the processing functionality. If the output of your Alfabet query is a report table, you must define the columns of the report in **Show Properties** window. A column is added to the report for each show property defined.

- In the **Sort Properties** window, you can define the sort order of your Alfabet query results. You can sort the results in alpha-numerical order for any property included in the **Show Properties** section

A typical tabular report based on an Alfabet query is shown below:

Application Name	Assignment Name	Assignment Status	Assignment AssignmentType	Assignment TargetDate	Person Name
Mortgage Register Ma	Check if this application	Accepted	Optional	8/8/2008	Administrator
alfabet SITM	Applications ending late	Created	Mandatory	10/14/2008	Ngombe
Mortgage Register Ma	Please check if the life-	Created	Optional	7/30/2008	Administrator
SAP International	Outdated Compliance C	Created	Mandatory	11/24/2008	Picard
TradeWeb	Outdated Compliance C	Created	Mandatory	11/24/2008	Customer
alfabet SITM	Applications starting ear	Created	Mandatory	10/14/2008	Ngombe
Customer Manager	Please check if this app	In Progress	Mandatory	7/10/2008	Administrator
Credits&Loans BO	Please check the busin	Re-Assigned	Optional	6/30/2008	Gossarah

FIGURE: Report results based on an Alfabet query

Show properties define the number and content of the columns in the report. The **Sort properties** define the columns that can be sorted. These columns are underlined. The user can click the column header to sort the results as needed.

Each result found by the Alfabet query is displayed in its own row in the report. The user can double-click a row in the results table to navigate to the base class object. In the example above, the base class is the class Application. Double-clicking the second row will open the object profile of the application `alfabet SITM`.

Tables in tabular reports are displayed with a default height of one line of text. If the search result includes a line break, you can see only the first line of the results. To see the following lines, click the lower border of the table cell and drag it to increase the size of the table.

Building an Alfabet Query

The following steps are required to build an Alfabet query:

- *Identifying the Requirements for the Alfabet Query Output*
- *Defining the Base Class*

- *Defining Show Properties* to test the output of the Alfabet query.
- Defining the complete show properties for the data output.
- *Defining WHERE Conditions to Filter Search Results*
- *Defining Sort Conditions to Structure the Output*.

In the EBNF code writing standard, any variable that is exchanged with a specific value when writing the code is defined in angle brackets. In the code examples for Alfabet queries in this chapter, any term that is variable and must be exchanged with a specific value is written in italics rather than angle brackets This is done to distinguish variables from XML elements that are also used in Alfabet queries.

When a code is specified as:

```
ALFABET_QUERY_500
FIND
NameOfObjectClass
```

`NameOfObjectClass` must be substituted with the name of the object class when writing the following example query:

```
ALFABET_QUERY_500
FIND
Application
```

Identifying the Requirements for the Alfabet Query Output

Before you start defining an Alfabet query, it is recommended that you make a rough sketch of the requirements informing the query. Changing an existing Alfabet query because you discover that the results do not fulfill your expectations may be time-consuming and complicated.

The following questions may influence the way you need to define the Alfabet query:

- What is the expected result of my report, custom explorer, rule-based access permission, etc.?
- Which object classes are required in the report, custom explorer, rule-based access permission, etc. ?
- Which of these object classes is the base class?
- Starting with the base class, what are the relationships between the required classes?
- Which conditions apply to searching for objects in the defined object classes in order to get the expected result?

In the following, an example will accompany the description of the definition of an Alfabet query. In the example, a tabular report will be generated to allow users to check which applications in an application group have the status Draft.

The report will display:

- The name of the application.

- The version of the application.
- The name of the assigned application group(s)

The user shall be able to navigate to the application to edit relevant data. Therefore, the object class `Application` is the base class.

The report must show the following properties of the following classes:

- Class `Application`: properties `Name`, `Version`
- Class `ApplicationGroup`: property `Name`

Defining the Base Class

The base class defines the primary object class of the Alfabet query. The search for objects in the database starts with the database table of the base class. All objects that are to be found by the Alfabet query must either belong to the base class or must have a relation to the base class that is specified in the Alfabet query.

If the output of the Alfabet query is a report, the user can only navigate to the base class objects from the report. For example, when the search results display data about an application including its assignments and responsible users, and a user double-clicks a row in the results, the object view of the application displayed in that row will open even if the cursor is in a field displaying other referenced data.

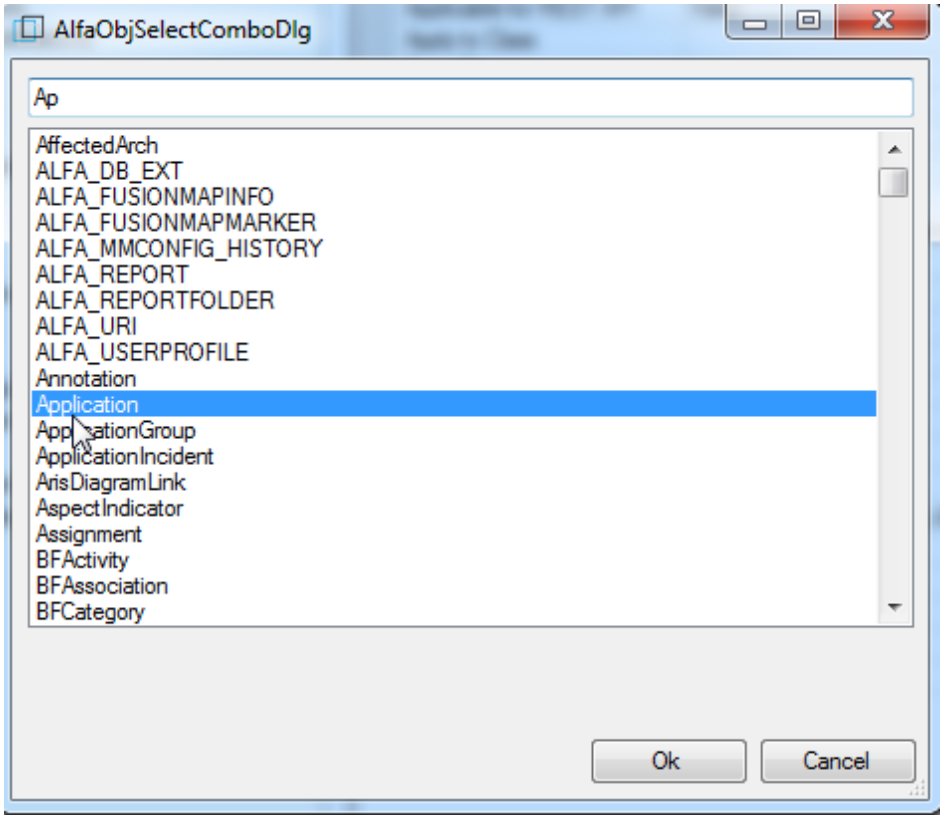
Navigation to the base class object view from a report is limited to object classes that represent artifacts in the meta-model.

When you open the **Alfabet Query Builder** to build a new Alfabet query, you will first see a dialog box listing all available object classes that can be specified as the base class of an Alfabet query.

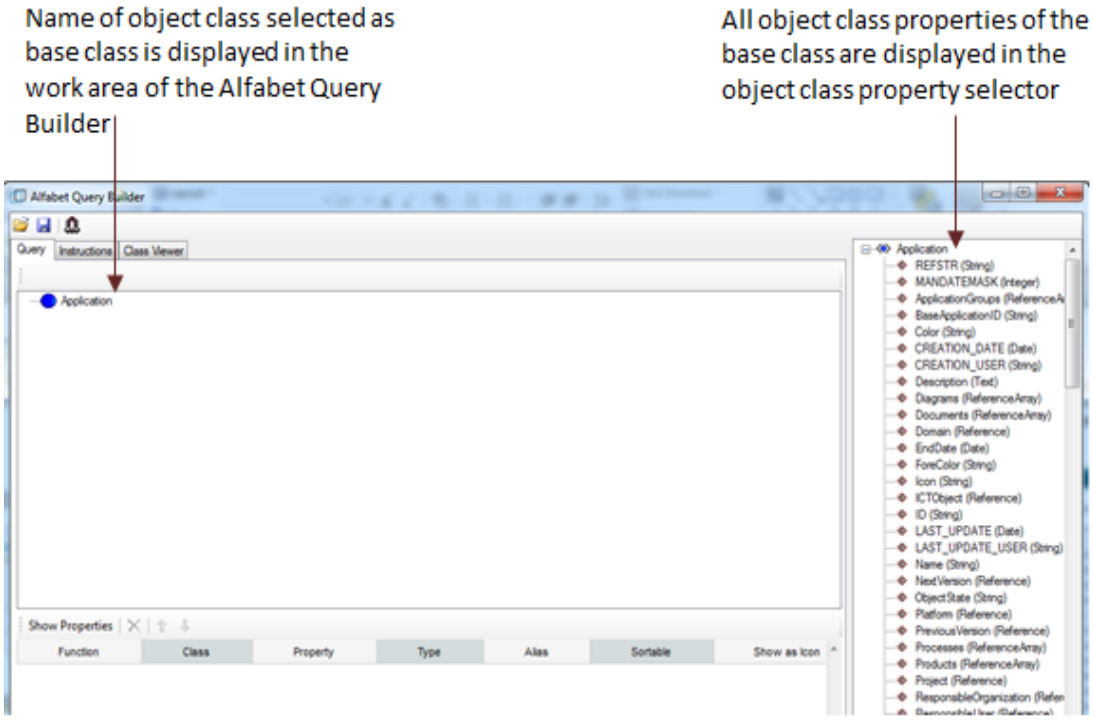
Select the base object class for your Alfabet query:

1) Click the name of the object class in the list or write the name of the object class in the upper field.

   If you start writing a name into the upper field, the cursor will move to the first search result matching your text in the list of classes.



2) Click **OK**. The **Alfabet Query Builder** opens with the base class displayed as the root node of the Alfabet query. On the right, all object class properties of the base class are listed in a separate pane, which is called the object class property selector.



To define a new Alfabet query and its base class in a text editor, enter the following lines of code:

```
ALFABET_QUERY_500
FIND
NameOfBaseClass
```

The Alfabet query must start with the header line `ALFABET_QUERY_500` followed by a `FIND` clause defining the base class. It is not possible to define more than one `FIND` clause in an Alfabet query.

Defining Show Properties

The Alfabet query finds objects in the Alfabet database that match specific criteria. To display the output in a report, the object class properties that shall be shown for each object found by the Alfabet query must be defined.

All object class properties that can be selected as Show properties are listed in the object class property selector in the right pane of the **Alfabet Query Builder**. The object class property selector lists all object class properties of all object classes that are included in the Alfabet query as a base class or in a `JOIN`. You can select the following:

Object class properties of the object class. When you select an object class property, the value of the object class property is displayed in the results.

Role type assigned to the object class in the **Configuration** module in Alfabet. When you select a role type, the name of the user to which the role is assigned for the object is displayed in the results. The name of the user is displayed as Name followed by First Name.

Indicator types assigned via evaluation types to the object class in the **Configuration** module in Alfabet. When you select an indicator type, the value for the indicator is displayed in the results.

The **Show Properties** section of the **Alfabet Query Builder** displays all object class properties defined to be displayed in the output of the Alfabet query in a table that has the following columns:

- **Function**: Select a function that shall be applied to the values of the show property prior to display. For example, the function `SUM` returns the sum of a set of numeric values. For more information, see the section *Defining Show Properties*.
- **Class**: Displays the name of the object class.
- **Property**: Displays the name of the object class property.
- **Type**: Displays the type of show property to display. The type can be:
  - `Property`: An object class property of the object class in the class model.
  - `Indicator`: An indicator of the object class.
  - `Role`: A role specified for the object class.

- **Alias**: Text written into a cell in this column is displayed as column caption in the tabular output of the Alfabet query.
- **Sortable**: Click a cell in this column to make the property represented by the row sortable for the user opening a tabular report..

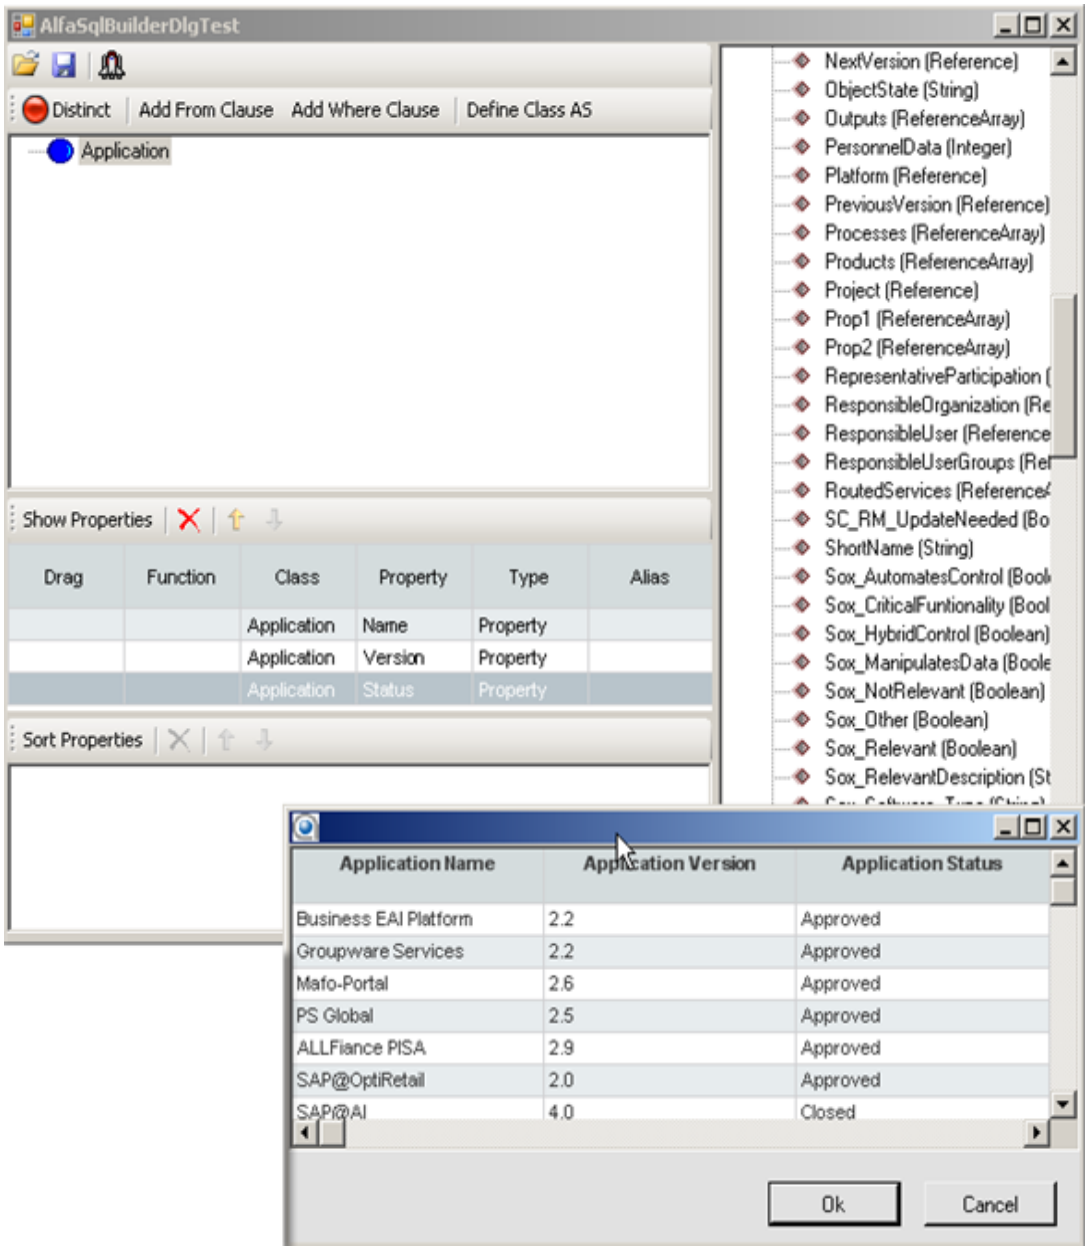
To define the Show properties in the report:

1) Click an object class property of the base class in the object class property selector and drag it to the **Show Properties** section of the **Alfabet Query Builder**. The columns **Class**, **Property** and **Type** are automatically filled.

   Object class properties that specify references to objects of other object classes (of the data type `Reference` or `ReferenceArray`) cannot be added to the Show properties. A `JOIN` is required to add references to query results.

2) Repeat step 1) for all properties of the base class that you want to display in the report.
3) Optionally, enter a column header for the property in the resulting report in the **Alias** column. By default, the column headers display the class name followed by the property name.
4) Optionally, sort the columns in the report. The columns are displayed in the order they are defined in the **Show Properties** section. To change the position of a column in the result data set, click the respective row in the **Show Properties** section and use the **Up** and **Down** buttons in the toolbar of the **Show Properties** section to change the position in the list.
5) Click the **Test Query** button. The list of all available objects of the base class is listed in a separate table.

For the example, the base class properties `Name` and `Version` are selected as well as the property `Status` in order to control the `WHERE` condition for the Alfabet query defined in one of the following steps. The resulting report shows all applications independent of the Release Status they are in:



To define show properties for an Alfabet query in a text editor, you can define the show properties either in an XML element or with a `SHOW` statement. The automatic code generated by the **Alfabet Query Builder** generates the XML definition of the show properties. Nevertheless, you might also require alternative syntax (For example, to specify an Alfabet query within an XML definition or when defining treemap reports).

For more information about the definition of show properties in the Alfabet query language, see the section Specifying Show and Sort Properties in Alfabet Queries which includes the following information:

- Defining Show and Sort Properties in an XML Element
- Displaying Users/Organizations Defined for a Role in Alfabet Query Results
- Displaying Indicator Values in Alfabet Query Results

- Calculating Values in Alfabet Query Results

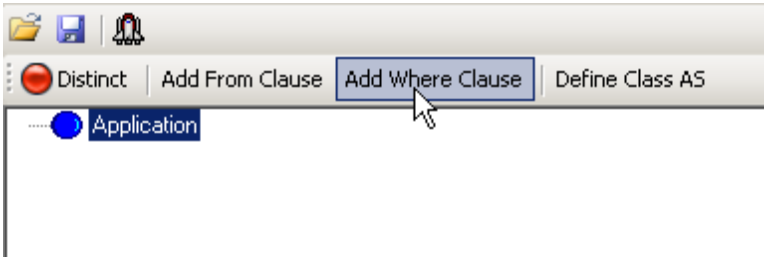
Defining WHERE Conditions to Filter Search Results

`WHERE` clauses limit the search output to a subset of the available objects in the database table of an object class that match a condition specified in the `WHERE` clause.

In the example, the result of the report shall display only objects of the class Application that are in the release status Draft.

To add a `WHERE` clause to the Alfabet query:

1) In the **Alfabet Query Builder**, click the base class in the main area.



2) In the toolbar, select **Add Where Clause**. In the **Alfabet Query Builder**, the parameter ***Where*** is written below the base class and the node ***And*** is written below the parameter ***Where***.
3) In the Alfabet query, click ***And***. The buttons in the toolbar change to the available types of `WHERE` clauses.
4) In the toolbar, select **Property**. The **Properties Browser** opens
5) Drag an obect class property to the lower pane of the **Properties Browser** and click **OK**. The object class property is displayed in the Alfabet query nested below the `WHERE` clause.
6) In the Alfabet query, click the property in the `WHERE` clause. The buttons in the toolbar change to the available operators for the selected object class property type.

   For information about the meaning of each operator, see the Operators for WHERE Clauses Dependent on Property Data Type.

7) In the toolbar, select an operator. A dialog box will open for all operators except the operators `IS NULL` and `IS NOT NULL`.
8) In the dialog box, enter the value that the selected object class property should have and click **OK** . The condition is displayed in the `WHERE` clause in the Alfabet query.
9) Click the **Test Query**  button. The list of all found objects of the base class is displayed in a separate table.

You can change the conditions for the selected property later. Click the condition and carry out one of the following procedures: To change the operator, select the new operator in the toolbar. If the value of the condition is an object property, the operator will be changed and the toolbar will be cleared. To see the toolbar buttons again, you must click the condition again. If the

condition is a string or parameter, the dialog box for the condition value will open after selecting the new operator and you can change the value.

- To change the condition value, you must proceed differently for comparisons with object properties vs. string values or parameters.
  - If you want to change an object property, drag the new property from the property selector window to the condition.
  - If you want to change a property value that is a string, select the current operator in the toolbar. The dialog box for the value specification opens and allows to edit the value.

To define a `WHERE` clause for an Alfabet query in the text editor, write the following lines of code under the `FIND` statement:

```
WHERE
ObjectClassName.PropertyName Operator OperatorValue
```

The `WHERE` clause must start with `WHERE` followed by the specification of an object class property of an object class and the condition that has to apply to the object class property. When the condition is a string, it must be written in single quotes. For example,:

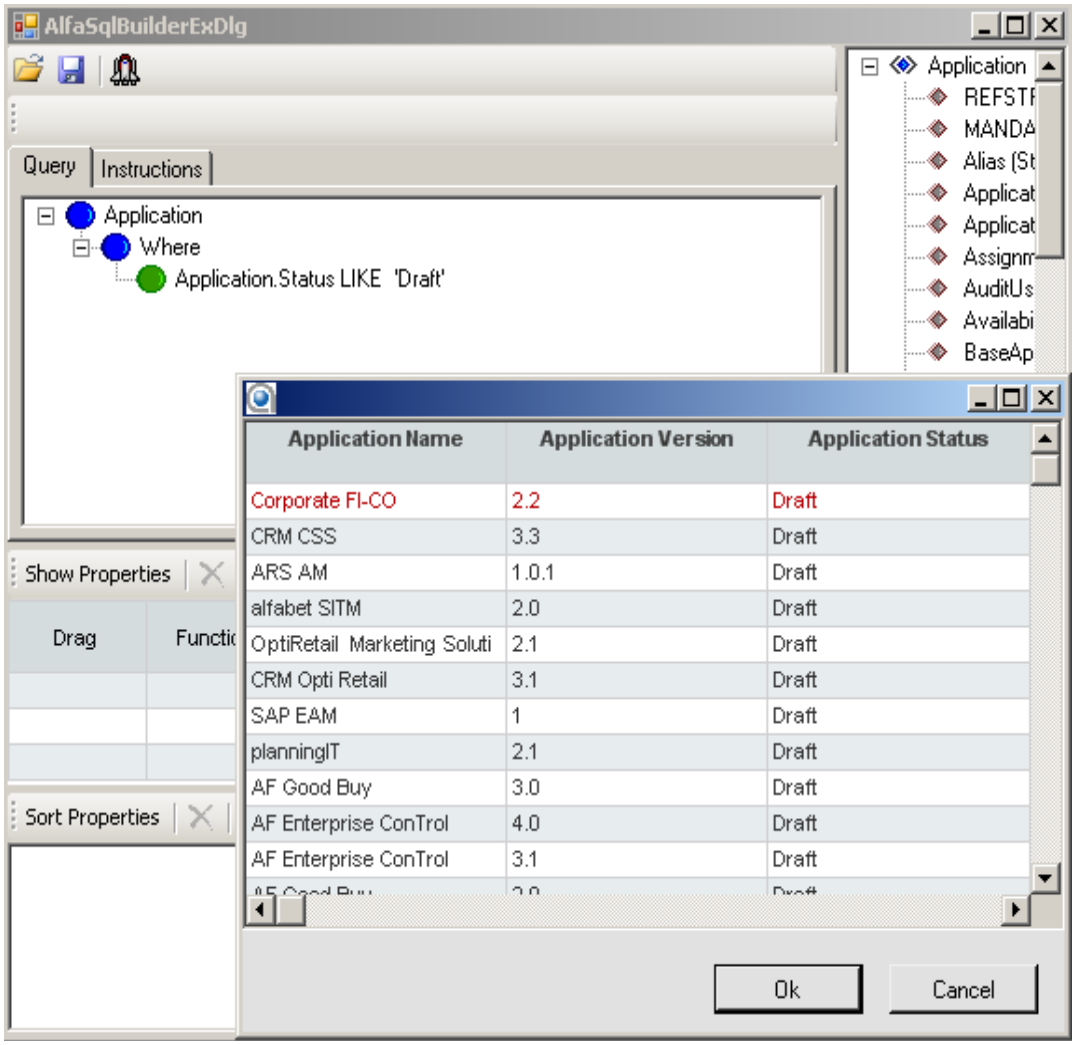
```
WHERE
Application.Status LIKE 'DRAFT'
```

The operators that can be used depend on the data type of the object class property. For detailed information about the available `WHERE` operators, see Operators for WHERE Clauses Dependent on Property Data Type in the section Specifying WHERE Clauses in Alfabet Queries.

For example, the `WHERE` condition specifies that the object class property `Status` (Release Status) of the object class `Application` is `Draft`.

```
WHERE
Application.Status LIKE 'DRAFT'
```

The resulting report now shows only applications that are in the release status `Draft`:



You can add multiple `WHERE` conditions to the `WHERE` clause of an Alfabet query. For more information see the section Adding Multiple WHERE Conditions to an Alfabet Query. If you define ony one `WHERE` clause and you close and reopen the Alfabet Query Builder, the And node is removed from the query definition.

For detailed information about the definition of `WHERE` clauses in Alfabet queries, see the following:

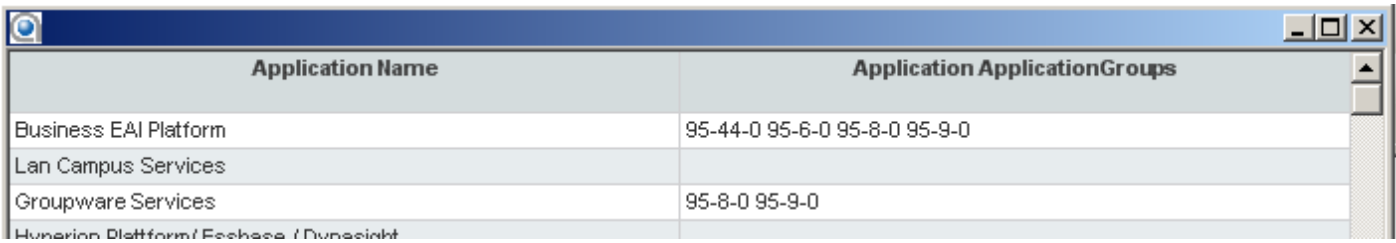
- Specifying WHERE Clauses in Alfabet Queries
  - Operators for WHERE Clauses Dependent on Property Data Type
  - Booleans in WHERE Clauses
  - Specification of Dates
  - Using Wildcards in WHERE Conditions
  - Using Special Characters in WHERE Conditions
  - Defining Case-Sensitivity for WHERE Clauses
  - Comparing Property Values with Other Property Values
  - Referring to the Current Alfabet Context in a WHERE Condition

- Adding Multiple WHERE Conditions to an Alfabet Query
- Creating a Filter Field with a WHERE Clause

Defining JOINs

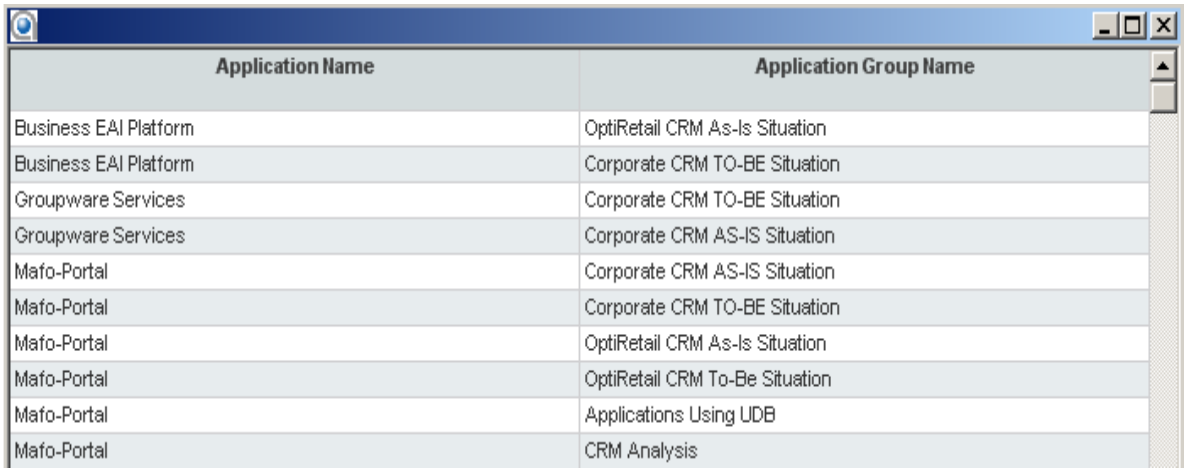
By defining one or more `JOIN`s, you can add objects from other object classes that are related to the base class through relationships defined in the meta-model. If you do not join other object classes to your Alfabet query, you will only find and display objects in the base object class in the Alfabet query results.

Relationships to other object classes are specified in object class properties of the type `Reference` or `ReferenceArray`. If a report should display all application groups that the application is assigned to, you cannot simply add the property `ApplicationGroup` to the show properties of the Alfabet query because you would then get a list of reference strings for internal database identification of the reference:



Application Name	Application ApplicationGroups
Business EAI Platform	95-44-0 95-6-0 95-8-0 95-9-0
Lan Campus Services	
Groupware Services	95-8-0 95-9-0
Hyperion Plattform/ Essbase / Dynasight	

To display the name of the referenced application groups, you must add a `JOIN` to the Alfabet query. The join specifies that application groups are added to a query result if they are referenced in the object class property `ApplicationGroups` (Application Groups). If multiple application groups are referenced by the application, a separate line is displayed in the results for each relation found:



Application Name	Application Group Name
Business EAI Platform	OptiRetail CRM As-Is Situation
Business EAI Platform	Corporate CRM TO-BE Situation
Groupware Services	Corporate CRM TO-BE Situation
Groupware Services	Corporate CRM AS-IS Situation
Mafo-Portal	Corporate CRM AS-IS Situation
Mafo-Portal	Corporate CRM TO-BE Situation
Mafo-Portal	OptiRetail CRM As-Is Situation
Mafo-Portal	OptiRetail CRM To-Be Situation
Mafo-Portal	Applications Using UDB
Mafo-Portal	CRM Analysis

The properties of the object class `ApplicationGroup` (Application Group) are then displayed in the property selector of the **Alfabet Query Builder** and you can add the property `Name` of the class `ApplicationGroup` to the show properties.

Deciding About the Type of JOIN to Use

If an object class A references the object class B, a relation exists between objects of both classes. But there are normally also objects of object class A that do not reference object of the object class B and objects of the object class B that are not referenced by object class A. In the example above, you will find applications assigned to application groups, but also applications that are not assigned to an application group. There are also application groups in the Alfabet database that only include other application groups and have no applications directly assigned.

If you join an object class to your base object class in the Alfabet query, you can use four different kinds of `JOINS` to select a different subset of objects:

InnerJoin	FullJoin	LeftJoin	RightJoin
Selects all instances from both classes that are related to each other	Selects all instances from both classes	Selects all instances from both classes that are related to each other and all instances from A that do not have a reference to B.	Selects all instances from both classes that are related to each other and all instances from B that are not referenced by A.

Application	Application Group
A 1	AG 1
A 2	
A 3	AG 2
A 4	
	AG 3

Application	Application Group
A 1	AG 1
A 2	
A 3	AG 2
A 4	
	AG 3

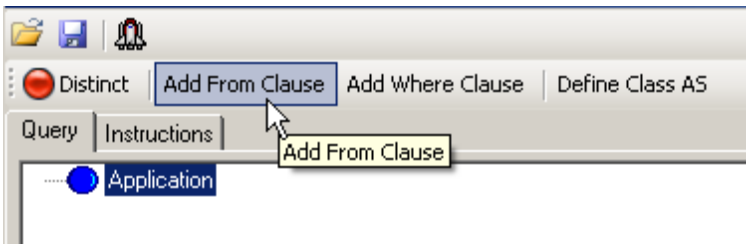
Application	Application Group
A 1	AG 1
A 2	
A 3	AG 2
A 4	
	AG 3

Application	Application Group
A 1	AG 1
A 2	
A 3	AG 2
A 4	
	AG 3

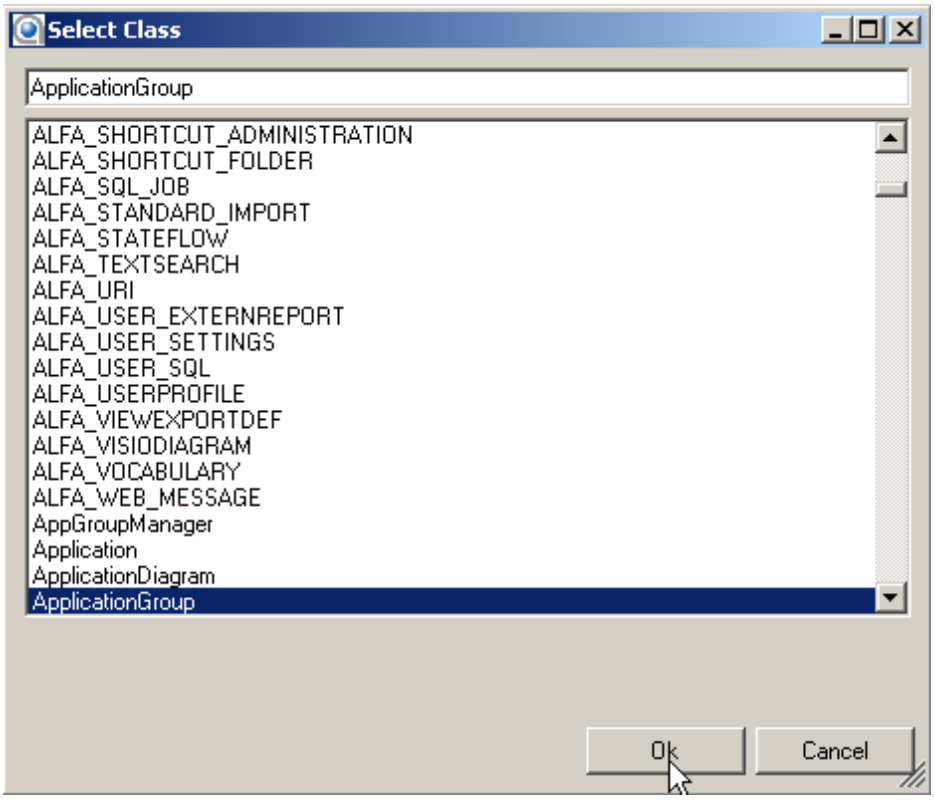
Defining JOINS in the Alfabet Query Builder

In the **Alfabet Query builder**, a `JOIN` is a sub-clause of a `FROM` clause. An Alfabet query can have only one `FROM` clause. The `FROM` clause must include all defined `JOINS`.

1) In the **Alfabet Query Builder**, click the base class of the Alfabet query.
2) In the toolbar, select `Add From Clause`.

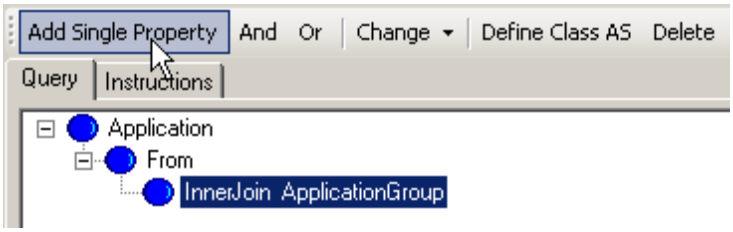


The **Select Class** dialog box opens.

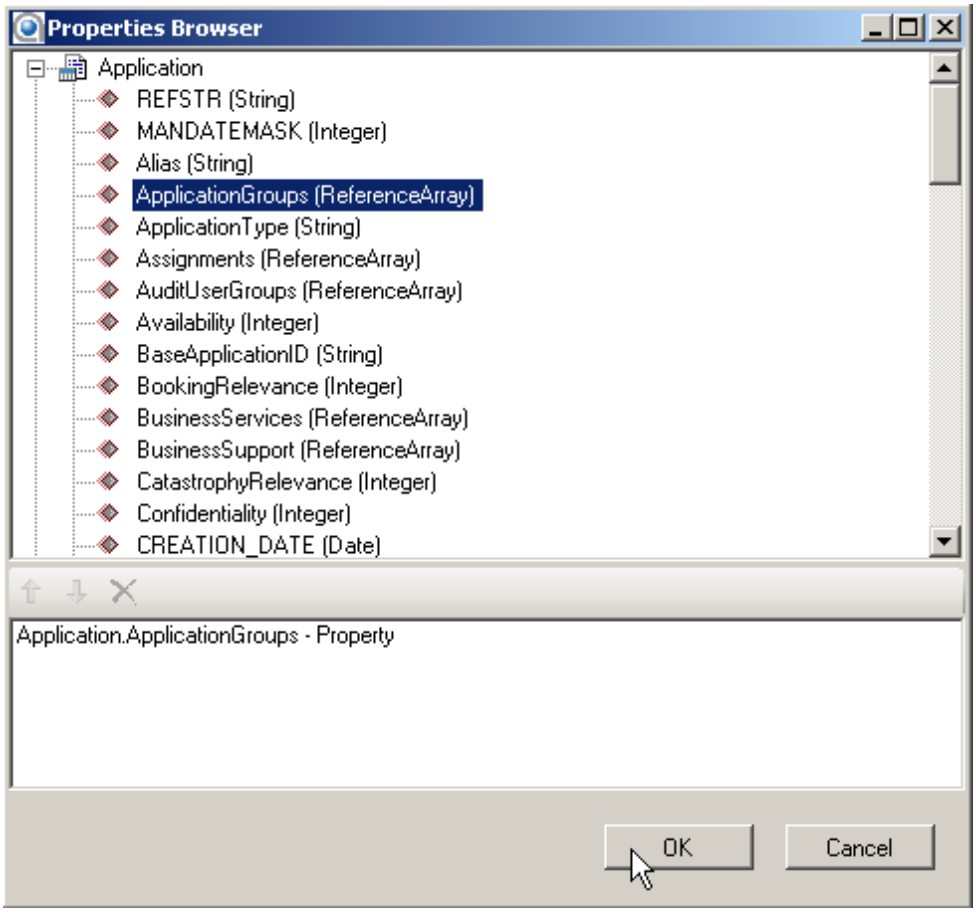


3) In the dialog box, select the class that you want to add and click **OK** . An `InnerJoin` referencing the selected object class is added to the Alfabet query

4) If you do not want to specify an `InnerJoin`, click the **Change** button in the toolbar and select the required type of `JOIN` in the drop-down list.



5) In the toolbar, select **Add Single Property**. The **Properties Browser** opens



6) In the **Properties Browser**, expand the object class properties of the object class with the object class property referencing the other object class. In the example, this is the object class `Application`. Select the object class property specifying the reference and drag it to the lower pane of the **Properties Browser**.

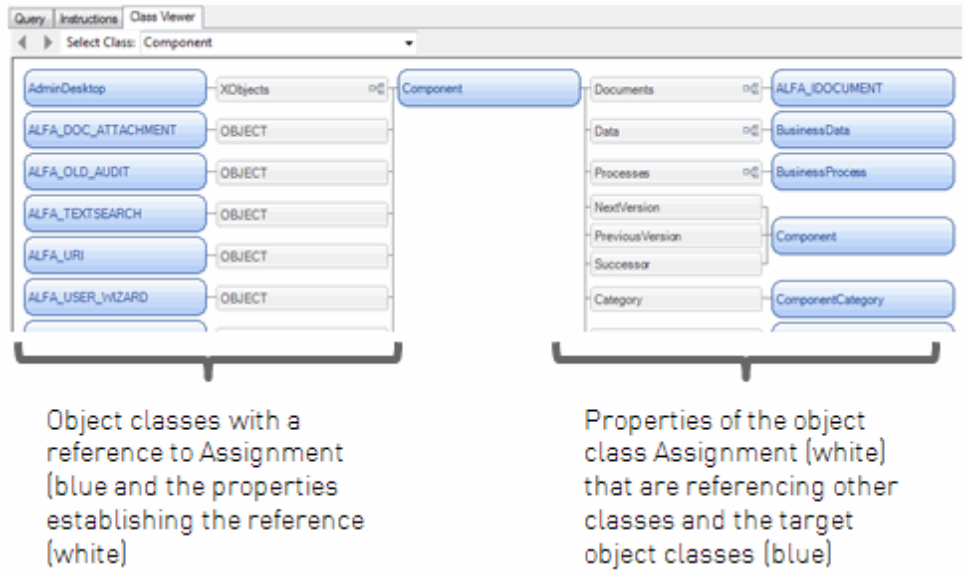
The object class property establishing the reference is not necessarily an object class property of the base class or an object class already joined to the Alfabet query. It can also be a property of the object class that you want to join referencing an already joined class.

For the example given, it would also be possible to select the object class property `Applications` of the class `ApplicationGroup` that you currently want to join and specify that it has to contain the `REFSTR` of the application.

It is also possible to specify `JOIN`s by comparing object class properties of two object classes in `JOIN`s without one object class property referencing the other object class. For more information, see Operators for the Definition of JOIN Conditions.

If you do not know which object class property references which object class, go to the **Class Viewer** tab in the **Alfabet Query Builder**.

The base class of your Alfabet query is displayed in the top center of the graphic. On the left, all object classes referencing the selected base class via one or multiple of their object class properties are listed in blue boxes. The object class property that establishes the reference is displayed in a white box between the object classes. On the right, all object class properties of the selected object class that store references to other object classes are listed. The target object classes are listed in the blue boxes on the right.



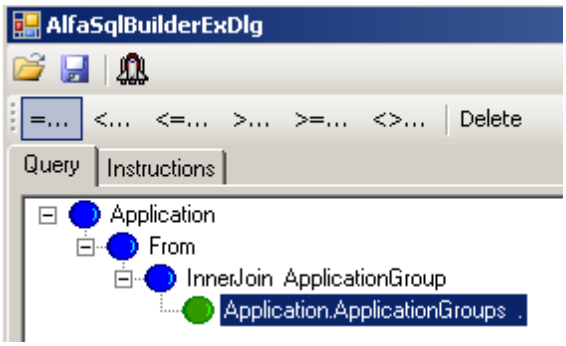
When you double-click a referenced object class in the graphic, a new tab opens that displays the references of this object class to other object classes.

You can select another object class whose references you want to see in the **Select Class** field.

The arrow  buttons next to the **Select Class** field allow navigation to previously shown object class relations.

7) Click **OK** to save your selection. The object class property is displayed in the **Query** tab in the **Alfabet Query Builder**.

8) Click the object class property name. The toolbar displays all available operators for the object class property's data type.



9) From the toolbar, select an operator. The **Properties Browser** opens.

10) In the **Properties Browser**, expand the properties of the object class that is referenced by the object class property displayed in the `JOIN`. In the example, this is `ApplicationGroup`. Select the referenced object class property and drag it to the lower pane of the **Properties Browser** . In the example, this is the `REFSTR` property of the class `ApplicationGroup`.

11) Click **OK** to save your selection. The object class property is displayed in the **Query** tab of the **Alfabet Query Builder**.

12) If you want to display object class properties of the joined class in the query results, add the desired object class properties to your show properties. For information on how to add a show property, see *Defining Show Properties*.

13) Click the **Test Query**  button. You will see the selected object class properties of your joined object class in the report. Test whether the results are as expected. If this is not the case, you should check whether you have chosen the wrong type of `JOIN` or whether results must be filtered by another `WHERE` condition that specifies a condition for an object class property of the joined object class.

When you want to join a second class to the Alfabet query, you can click ***From*** in the Alfabet query displayed in the **Alfabet Query Builder** and directly select the type of `JOIN`. All `JOIN`s are written to the same `FROM` clause.

You can change the conditions for the selected property later. Click the condition and carry out one of the following procedures: To change the operator, select the new operator in the toolbar. If the value of the condition is an object property, the operator will be changed, and the toolbar will be cleared. To see the toolbar buttons again, you must click the condition again. If the condition is a string or parameter, the dialog box for the condition value will open after selecting the new operator and you can change the value.

- To change the condition value, you must proceed differently for comparisons with object properties vs. string values or parameters.
  - If you want to change an object property, drag the new property from the property selector window to the condition.
  - If you want to change a property value that is a string, select the current operator in the toolbar. The dialog box for the value specification opens and allows to edit the value.

It is not possible to delete an intermediate `JOIN` in a query with two or more `JOIN`s. For example, if a query joins class 1 to the base class, class 2 to class 1 and class 3 to class 2, the `JOIN` of class 2 to class 1 cannot be deleted.

To add a `JOIN` to an object class for an Alfabet query defined in a text editor, you must specify the `JOIN` under the base class definition with the following line of code:

```
JoinTypeNameOfClassToJoinON
ObjectClassName.PropertyNameOperatorObjectClassName.PropertyName
```

In case the `JOIN` is specified to link an object class that is referenced by an object class property of the type `ReferenceArray` or `Reference`, the `JOIN` is defined as:

```
JoinTypeNameOfClassToJoinONNameOfReferencingClass.NameofPropertythatReferencesToTheOtherClass=NameofReferencedClass.REFSTR
```

The type of `JOIN` can be `InnerJoin, OuterJoin, LeftJoin`, and `RightJoin`. For more information about `JOIN` types, see *Deciding About the Type of JOIN to Use*.

In the example, the object class `ApplicationGroup` is added via an `InnerJoin` to the base class `Application` because only applications that are assigned to application groups are relevant for the report and vice versa.

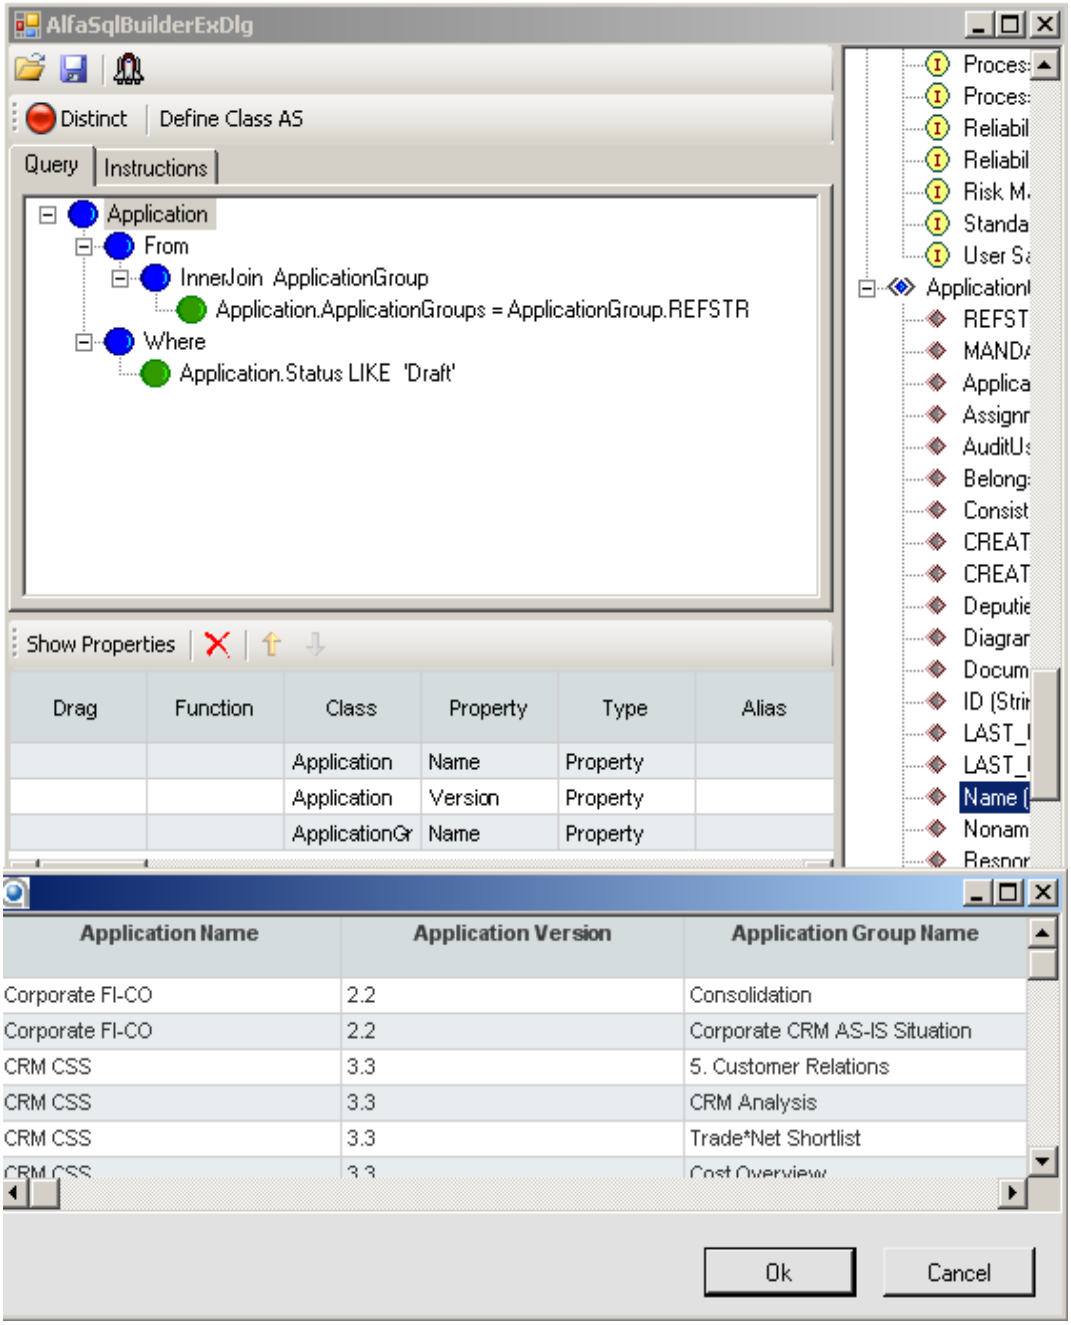
```
ALFABET_QUERY_500

FIND

Application
```

```
InnerJoin ApplicationGroup ON Application.ApplicationGroups =
ApplicationGroup.REFSTR
```

In the example, the object class property `Status` of the object class `Application` is deleted from the Show properties section because it is no longer required and the object class property `Name` of the class `ApplicationGroup` is added:



For detailed information about the definition of `JOIN`s in Alfabet queries, see the section Specifying JOINs in Alfabet Queries. The following information is addressed:

- Operators for the Definition of JOIN Conditions
- Specifying Multiple JOIN Conditions for one JOIN

- Joining Classes Already Specified in the Alfabet Query
- Defining JOINs for Roles
- Defining JOINs for Indicators
- Defining JOINs Between Value Nodes, Projects, or Demands and the Affected Architecture
- Defining JOINs to Object Class Stereotypes

Defining Sort Conditions to Structure the Output

The results of an Alfabet query are listed in the order that they are found in the database. However, you may want the results to be sorted alphanumerically based on the values of selected columns in the result table.

Sort conditions in Alfabet queries allow you to define the columns in the report that are to be sorted in ascending alphanumeric order during execution of the Alfabet query. All rows with an equal value are then sorted according to the second criteria, and so on. The user can change the sort order of the rows in the report by clicking any column header of the report. The report is then sorted in ascending alphanumeric order based on the values in the selected column. If he/she clicks the column header of a column that is already used for sorting, the sorting order is reverted from ascending to descending alphanumeric order and vice versa.

You can define multiple Sort properties in one Alfabet query. Sort properties cannot be defined for roles and indicators directly added to the Show properties via the object class property selector.

To define Sort conditions in the **Alfabet Query Builder**:

1) In the **Show Properties** section, click the cell in the column **Sortable** of the object class property that you want to select as `SORT` property. An x is displayed in the cell and the object class property is added to the **Sort Properties** section.

To define Sort properties for an Alfabet query in a text editor, you can define the Sort properties either in an XML element or with a `SORT` statement. The automatic code generated by the **Alfabet Query Builder** generates the XML definition of the Sort properties. Nevertheless, you might also require alternative syntax (For example, to specify an Alfabet query within an XML definition or when defining treemap reports).

The following information about the definition of Sort properties is available:, see the section Specifying Show and Sort Properties in Alfabet Queries.

- Specifying Show and Sort Properties in Alfabet Queries
  - Defining Show and Sort Properties in an XML Element
  - Displaying Users/Organizations Defined for a Role in Alfabet Query Results
  - Displaying Indicator Values in Alfabet Query Results
  - Calculating Values in Alfabet Query Results

Specifying WHERE Clauses in Alfabet Queries

A WHERE clause can be added to Alfabet queries to limit the search results to a subset of the objects defined for the base class or the object classes added to an Alfabet query by means of a JOIN. An object class property of an object class is compared to a given value in a WHERE clause. For example, you can limit the search output to objects with a name starting with "A" or with a start date before the current date.

A WHERE clause consists of the object class property, the operator defining the compare mode, and the value with which the object class property is compared:

```
WHERE
ObjectClassName.PropertyNameOperatorValue
```

```
WHERE
Application.Name LIKE 'A%'
```

Information about how to add a WHERE clause to an Alfabet query in the **Alfabet Query Builder** is provided in *Defining WHERE Conditions to Filter Search Results* in the section *Building an Alfabet Query*.

This chapter provides information about the different kind of WHERE clauses that can be specified. The following information is available:

- Operators for WHERE Clauses Dependent on Property Data Type
- Booleans in WHERE Clauses
- Specification of Dates
- Using Wildcards in WHERE Conditions
- Defining Case-Sensitivity for WHERE Clauses
- Comparing Property Values with Other Property Values
- Referring to the Current Alfabet Context in a WHERE Condition
- Adding Multiple WHERE Conditions to an Alfabet Query
- Creating a Filter Field with a WHERE Clause

Operators for WHERE Clauses Dependent on Property Data Type

The following list provides an overview of the operators that are allowed in Alfabet queries for different data types.

Note the following about the use of operators in Alfabet queries:

- If you define the Alfabet query with the **Alfabet Query Builder**, only the allowed operators will be displayed in the menu when you click the property defined in a WHERE clause. For some special properties (For example, the REFSTR or the MANDATEMASK property), you can use only a subset of the operators specified in the table below. The table lists the default for the use of the operators per data type.

- The range of allowed operators for a data type includes combinations that are only relevant for special contexts. Not all allowed combinations of data type or operator may be meaningful for the context you are working with.
- `WHERE` clauses can only be built on properties of the data type `ReferenceArray` if the object class property's attribute **Reference Support** is set to `True` in the Alfabet meta-model. For the rare case that **Reference Support** is set to `False`, the property cannot be used in Alfabet queries.

Operator	Description	For Data Type	Example
`LIKE`	Similar to a defined string.	`String` `StringArray`	`Application.Name LIKE 'A%'` (finds all applications whose names begin with "A")
`NOT LIKE`	Different to a defined string.	`String`	`Application.Name LIKE 'A%'` (finds all applications whose names do not begin with "A")

`CONTAINS`	Similar to.
	NOTE: `CONTAINS` differs from `LIKE` for the generation of filter fields in reports based on Alfabet queries. For more information about the types of filter fields, see Defining Filters for Configured Reports and Selectors.
		`String`
		`StringArray`
		`Reference`
		`ReferenceArray` (with the **Reference Support** attribute set to `True`)
			`Application.Name CONTAINS 'A%'`
			(finds all applications whose names begin with "A")
			NOTE: For properties of the type `StringArray`, only entries exactly matching the defined string will be found. Therefore, if you want to find entries containing only one specific selection, enter 'Selection'. To find entries containing one specific selection and optionally other selections, enter '`%`Selection`%`'. If you want to find entries all with at least two defined selections, enter '`%`Selection1`%`Selection2`%`'. The selections must be listed in the order they are listed in the enumeration.

`CONTAINSOR`	The object class property value is to be found in the values of a list. The list is enclosed in inverted commas and the individual values are separated by a comma.
	NOTE: `CONTAINSOR` can be used to create multi-select
		`String`
		`StringArray`
		`Reference`
		`ReferenceArray` (with **Reference Support** set to `True`)
			`Person.Name CONTAINSOR 'Miller,Young,Singer'`
			(finds all users with the name Miller, Young or Singer)
			NOTE: In the **Alfabet Query Builder**, the comma-separated list of values must be defined in the dialog box for entering values without the inverted commas.

Operator	Description	For Data Type	Example
	combo-box filters. For more information about the types of filter fields, see Defining Filters for Configured Reports and Selectors.		
IN ()	The object class property value is to be found in the values of a list. The list is enclosed in a parenthesis (). The individual values are comma-separated and each written into inverted commas.	Integer Real Reference **NOTE**: The operator IN can also be used to compare the REFSTR property of an object class with a list of values.	Project.ReportProgress IN ('10','20',30') (finds all projects with a report progress of 10, 20, or 30) **NOTE**: In the **Alfabet Query Builder**, the list of values must be defined in the dialog box for entering values without the parenthesis, separating commas and inverted comma. Instead, values must be separated with a whitespace. The list of integers in the example above must be written into the field as: 10 20 30
NOT IN ()	The object class property value is not to be found in the values of a list. The list is enclosed in a parenthesis (). The individual values are comma-separated and each written into inverted commas	Integer Real Reference **NOTE**: The operator IN can also be used to compare the REFSTR property of an object class with a list of values.	Project.ReportProgress NOT IN ('10','20','30') (finds all projects with a report progress of 10, 20, or 30) **NOTE**: In the **Alfabet Query Builder**, the list of values must be defined in the dialog box for entering values without the parenthesis, separating commas and inverted commas. Instead, values must be separated with a whitespace. The list of integers in the example above must be written into the field as: 10 20 30
BETWEEN	Selection of a value range. The value is specified in the format: *LowerLimit*AND*UpperLimit*	Date Integer Real	ProjectGroup.SpendLimit BETWEEN 0 AND 10000 (finds projects with a spend limit higher than 0 and lower than 10000) **NOTE**: If the condition is written in the Alfabet query language as text and the values are dates, they must be written in inverted commas:

Operator	Description	For Data Type	Example
			`Appliation.StartDate BETWEEN '25/03/2008' AND '28/03/2008'` (finds applications with a start date between March 25th, 2008 and March 28th, 2008) **NOTE**: In the **Alfabet Query Builder**, the upper and lower limit of the range must be defined in the dialog box for entering values without the `AND`, but only separated with a whitespace. Dates are not written in inverted commas in this dialog box.

`NOT BETWEEN`	The object class property value is not to be found in a selection of a value range. The value is specified in the format:
	
	LowerLimit`AND`*UpperLimit*
		`Date`
		
		`Integer`
		
		`Real`
			`ProjectGroup.SpendLimit NOT BETWEEN 0 AND 10000`
			
			(finds projects with a spend limit higher than 10000)
			
			NOTE: If the condition is written in the Alfabet query language as text and the values are dates, they must be written in inverted commas:
			
			`Application.StartDate NOT BETWEEN '25/03/2008' AND '28/03/2008'`
			
			(finds applications with a start date before March 25th, 2008 and after March 28th, 2008)
			
			NOTE: in the **Alfabet Query Builder**, the upper and lower limit of the range must be defined in the dialog box for entering values without the `AND`, but only separated with a whitespace. Dates are not written in inverted commas in this dialog box.

=	Equal to.
	
	If the object class property value is of the type `String`, `Date` or `Boolean`, it must be written in inverted commas in the Alfabet query.
		`String`
		
		`Date`
		
		`Integer`
		
		`Real`
		
		`Boolean`
		
		`Reference`
		
		`ReferenceArray` (with **Reference Support** set to `True`)
			`Application.StartDate = '28/03/2008'`
			
			(finds applications with a start date of March 28th, 2008)
			
			NOTE: Wildcards are not allowed in value specifications for this operator.
			
			NOTE: In the **Alfabet Query Builder**, the value of any data type is written without inverted commas into the dialog box for entering values.

<	Lesser than.
	
	If the object class property value is
		`String`
		
		`Date`
			`Application.StartDate <= '28/03/2008'`

Operator	Description	For Data Type	Example
	of the type `String` or `Date`, it must be written in inverted commas in the Alfabet query.	`Integer` `Real`	(finds applications with a start date before March 28th, 2008) **NOTE**: In the **Alfabet Query Builder**, the value of any data type is written without inverted commas into the dialog box for entering values.

<=	Lesser than or equal to.
	If the object class property value is of the type `String` or `Date`, it must be written in inverted commas in the Alfabet query.
		`String`
		`Date`
		`Integer`
		`Real`
			`Application.StartDate <= '28/03/2008'`
			(finds applications with a start date of March 28th, 2008 and before)
			NOTE: In the **Alfabet Query Builder**, the value of any data type is written without inverted commas into the dialog box for entering values.

>	Greater than.
	If the object class property value is of the type `String` or `Date`, it must be written in inverted commas in the Alfabet query.
		`String`
		`Date`
		`Integer`
		`Real`
			`Application.StartDate > '28/03/2008'`
			(finds applications with a start date after March 28th, 2008)
			NOTE: In the **Alfabet Query Builder**, the value of any data type is written without inverted commas into the dialog box for entering values.

>=	Greater than or equal to.
	If the object class property value is of the type `String` or `Date`, it must be written in inverted commas in the Alfabet query.
		`String`
		`Date`
		`Integer`
		`Real`
			`Application.StartDate >= '28/03/2008'`
			(finds applications with a start date of March 28th, 2008 and higher)
			NOTE: In the **Alfabet Query Builder**, the value of any data type is written without inverted commas into the dialog box for entering values.

<>	Not equal to.
	If the object class property value is of the type `String` or `Date`, it must be written in inverted
		`String`
		`Date`
		`Integer`
		`Real`
			`Application.StartDate <> '28/03/2008'`
			(finds applications with a start date other than March 28th, 2008)

Operator	Description	For Data Type	Example
	commas in the Alfabet query.		**NOTE**: In the **Alfabet Query Builder**, the value of any data type is written without inverted commas into the dialog box for entering values.

`IS NULL`	The object class property is undefined. It has either not yet been assigned a value or a previous value has been deleted by the user.
	The operator has no value specification.
		`String`
		`Date`
		`Integer`
		`Real`
		`Reference`
		`ReferenceArray`
		`Boolean`
			`Application.ApplicationGroups IS NULL`
			(finds all applications that are not assigned to an application group)

`IS NOT NULL`	A value has been assigned to the object class property.
	The operator has no value specification.
		`String`
		`Date`
		`Integer`
		`Real`
		`Reference`
		`ReferenceArray`
		`Boolean`
			`Application.ApplicationGroups IS NOT NULL`
			(finds all applications that are assigned to at least one application group)

Booleans in WHERE Clauses

Boolean values are stored as `0` for false or `1` for true. To limit search results to objects for which a specific property of the data type `Boolean` is either false or true, you can use any of the following `WHERE` conditions:

For property = true	For property = false

`WHERE ClassName.PropertyName = 1`
`WHERE ClassName.PropertyName = true`
`WHERE ClassName.PropertyName = True`
	`WHERE ClassName.PropertyName = 0`
	`WHERE ClassName.PropertyName = false`
	`WHERE ClassName.PropertyName = False`

Please note that properties of the data type boolean can have three values:

- `0` = the value is set to false
- `1` = the value is set to true
- `Null` = the value is not set

In the Alfabet query language, a property that is `Null`, that means not set, is regarded as set to false and included into the results accordingly.

Specification of Dates

The format for dates is a string written as follows: DD/MM/YYYY. For example, a valid Alfabet query condition would be `Application.Startdate` = '27/09/2005'. The majority of date properties can be written like this, but there are a few system properties that save not only the date, but an actual timestamp that records the date and the time in milliseconds.

In the example `Application.CREATION_DATE` = '27/09/2005', it is likely that nothing will be returned even though it is a valid condition. But because every creation date is stored as a timestamp, it will only return applications that were created on the 27th of September in the year 2005 at exactly 12:00:00.000 pm (which is highly unlikely). However, you could theoretically write a condition like `Application.CREATION_DATE` = '27/09/2005 09:13:04.568 am', if you know the exact timestamp when the application you seek was created. Alternatively, you can find applications created on a specific date with a `WHERE` condition using a `BETWEEN` operator, For example, `Application.CREATION_DATE BETWEEN` '26/09/2005' `AND` '28/09/2005'.

Using Wildcards in WHERE Conditions

You can use the `%` symbol as a wildcard in the specification of `WHERE` clauses. For example,:

```
FIND
Application
WHERE Application.Name LIKE 'A%'
```

finds all application with a name starting with "A".

```
FIND
Application
WHERE Application.Name LIKE '%a%'
```

finds all application with a name containing an "a" at any position in the name.

You should take case-sensitivity into account when specifying `WHERE` clauses to search for a string or part of a string. For more information, see Defining Case-Sensitivity for WHERE Clauses.

Using Special Characters in WHERE Conditions

When the value specified for your `WHERE` clause contains special characters, the results might not be as expected because the characters are treated as operators rather than characters in a string. For example, the symbol `%` is used as a wildcard in the Alfabet query language. Therefore, the `WHERE` clause

```
WHERE ObjectClassName.PropertyName LIKE '10%'
```

will not limit search results to all values that equal "10%" but all values containing "10" followed by any characters.

You cannot search for the following special characters in Alfabet queries:

- %
- _
- *

Defining Case-Sensitivity for WHERE Clauses

By default, the specification of strings as values is case sensitive in `WHERE` conditions. However, case sensitivity also depends on the database server used and the specific setup. The definition of

```
WHERE Application.Name LIKE '%m%'
```

and

```
WHERE Application.Name LIKE '%M%'
```

will typically result in different output. The first definition finds all applications that have a lower-case m in their names and the second definition finds all applications that have an upper-case M in their names.

Per default, properties of the data type text (For example, descriptions) are read by the Alfabet query as all upper-case letters.

If you want to make the specification case-insensitive, you can define the Alfabet query to read all strings in the Alfabet database as written in upper-case letters only or in lower-case letters only and compare the results with the specified value.

To specify the comparison of the specified value to object class property values read in upper-case or lower-case letters for an existing `WHERE` condition in the **Alfabet Query Builder**:

1) In the **Query** tab of the **Alfabet Query Builder**, select the `WHERE` condition that you want to make case-insensitive.
2) In the toolbar, select either:
   - **To Upper**: To read all property values in upper-case letters.
   - **To Lower**: To read all property values in lower-case letters.

You can undo the choice by selecting **No Conversion** in the toolbar.

In the Alfabet query language, the conversion of property values to upper-case or lower-case letters is specified as:

```
WHERE (UPPERObjectClassName.PropertyName)OperatorValue
```

or

```
WHERE (LOWERObjectClassName.PropertyName)OperatorValue
```

With the `WHERE` clause:

```
WHERE (LOWER Application.Name) LIKE '%m%'
```

the Alfabet finds all applications with a lower-case "m" or an upper-case "M" in their name.

Reading all letters in a string as lower-case or upper-case letters is not case-insensitive. You must take this into account when specifying the value for your `WHERE` condition.

When you specify

```
WHERE (UPPER Application.Name) LIKE '%m%'
```

you will get no results because you are looking for an application with a lowercase "m" in the name while at the same time reading all letters in all application names as upper-case letters.

Comparing Property Values with Other Property Values

You can define a `WHERE` clause that checks whether the value of an object class property is identical to the value of another object class property. In the **Alfabet Query Builder**, the object class property you want to define as a value for the operator in the `WHERE` clause cannot be specified in the dialog box used to specify values for `WHERE` conditions.

To compare two properties in the **Alfabet Query Builder**:

1) In the **Query** tab of the **Alfabet Query Builder**, define a `WHERE` clause with an object class property in the usual way:

2) Select the object class property that you want to compare the defined object class property with in the object class property selector pane of the **Alfabet Query Builder** and drag it to the object class property name specification in the `WHERE` condition. The two properties are compared with the "=" operator.

3) To change the operator, click the `WHERE` condition and select the operator from the toolbar. The dialog box to enter a value opens.

4) Leave the fields in the dialog box empty and click **OK** . The operator in the `WHERE` condition has changed.

To compare two properties in the Alfabet query language as text, the value of the WHERE clause must be specified as ObjectClassName.PropertyName. The value is not written in inverted commas.

The following WHERE condition defines that only applications with an end date after the end date of the assigned ICT object are displayed in the report:

```
WHERE
Application.EndDate > ICTObject.EndDate
```

Referring to the Current Alfabet Context in a WHERE Condition

The Alfabet query language allows the specification of Alfabet parameters that refer to the current context in the Alfabet interface (For example, the object the user is currently working with, the user executing the report, the current workflow being executed).

In the Alfabet query language, Alfabet parameters are written as follows:

```
:ParameterName
```

or

```
@ParameterName
```

For example,:

```
FIND
ApplicationGroup
WHERE ApplicationGroup.BelongsTo CONTAINS:BASE
```

finds all application groups subordinate to the application group the user is currently working with.

During execution of the Alfabet query, the Alfabet parameter is substituted with the current return value. If no value is returned, the Alfabet query is executed without the WHERE statement.

The **Test Query**  button of the **Alfabet Query Builder** cannot be used to test queries with Alfabet parameters. If you define a configured report, you can test the query using the **Review Report** option of the context menu of the report.

The following Alfabet parameters can be used for Alfabet queries:

Parameter Name	Description
CURRENT_PROFILE	Returns the value of the REFSTR property of the current user profile
CURRENT_USER	Returns the value of the REFSTR property of the current user.

Parameter Name	Description

CURRENT_MANDATE	Returns the current mandate of the user. The Alfabet parameter can be used For example, to limit search results to objects that are assigned to the mandate the user is currently logged in with, For example,:
	`ALFABET_QUERY_500`
	`FIND ICTObject`
	`WHERE ICTObject.MANDATEMASK CONTAINS:CURRENT_MANDATE`
	NOTE: The parameter CURRENT_MANDATE (and the whole statement it is used in) is ignored if the user has no mandate assigned or is working as mandate master.

CURRENT_CULTURE	Returns the Microsoft® Windows® Locale identifier (LCID) of the current culture. Please note that the culture that is selected as default culture is always returned as 127, which means default, independent from the LCID of the culture.
TODAY	Returns the current date.
BASE	Returns the value of the REFSTR property of the current object.
ALFA_SERVER_URL	Returns the value of the attribute **Web Server** of the server alias configuration of the Alfabet component processing the query. The attribute Web Server is editable in the **Overview** tab of the server alias configuration editor.
BASE<number>	For queries defined in the context of layered diagrams and grid reports only! If the report is configured to allow cascading queries, and more than one level of related objects us defined, BASE0 returns the value of the REFSTR property of the parent object in the directly superordinate level of the diagram. BASE1 returns the ancestor object in the level superordinate to the parent object level etc.
WIZARDBASE	For queries defined in the context of wizard configuration only! Return the value of the REFSTR property of the base object of the wizard. The base object of the wizard can be different from the base object of a wizard step. This parameter allows to refer to the base object of the wizard For example, in pre-conditions of steps that have a different base object than the overall wizard.
WORKFLOW	For queries defined in the context of workflow configuration only! Returns the value of the REFSTR property of the workflow. Each workflow corresponds to an object Workflow in the Alfabet database. The parameter is useful when defining queries that refer to properties of the class Workflow, like For example, the workflow owner or the workflow initiator. For more information, see Defining the Users Responsible for a Workflow Step.

Parameter Name	Description
WORKFLOWBASE	For queries defined in the context of workflow configuration only! Returns the value of the REFSTR property of the base object of the workflow. The base object of the workflow can be different from the base object of a workflow step. This parameter allows to refer to the base object of the workflow For example, in pre-conditions of steps that have a different base object than the overall workflow.
LAST_EXECUTION	For queries defined in the context of monitors only. Returns the date of the last execution of the monitor.

Adding Multiple WHERE Conditions to an Alfabet Query

You can add multiple WHERE conditions to the WHERE clause of an Alfabet query. When you do so, you must specify in the WHERE clause whether the WHERE conditions are AND or OR related:

AND: Returns True when all expressions are true.

OR: Returns True when at least one expression is true.

More than two WHERE conditions can be related with each other in an AND or OR relationship.

You can combine multiple AND and OR conditions hierarchically. For example, you can define that condition A and either condition B or condition C should apply.

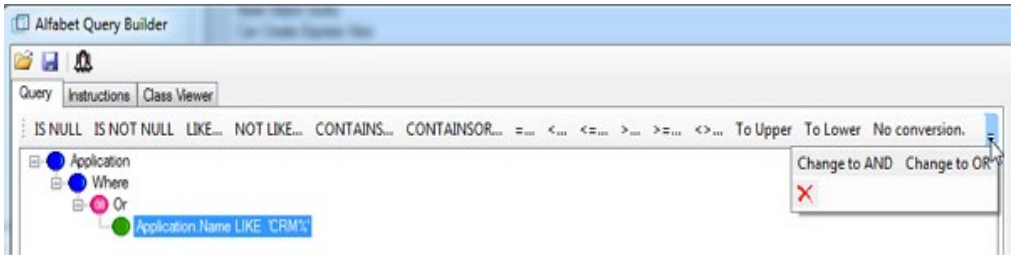
All WHERE conditions of an Alfabet query are written in the same WHERE clause. It is not allowed to specify multiple WHERE clauses in an Alfabet query.

In the **Alfabet Query Builder**, the relation ***And*** is automatically added to the WHERE clause upon definition of the first WHERE condition.

When you close and re-open the **Alfabet Query Builder** while a single condition is defined, the node And is removed from the Alfabet query. If you want to add another condition, you can re-establish the And node or create an Or node:

1) In the **Query** tab of the **Alfabet Query Builder**, click the condition in the WHERE clause.
2) In the toolbar, select **Change to AND** to add an ***And*** relation or **Change to OR** to add an ***Or*** relation.

If a high number of operators is available for the condition, you might not see the options **Change to AND** and **Change to OR** in the toolbar because there is not sufficient space to display all options. Click on the small field on the right of the toolbar to open a drop-down menu with the menu options that were hidden.



You can do one of the following to build a hierarchy of related conditions:

- To add a condition to an ***And*** or ***Or*** node, click the node and select **Property** from the toolbar.
- To add a subordinate condition to an ***And*** or ***Or*** node, click the node and select **AND** or **OR** from the toolbar.
- To change an ***And*** node to an ***Or*** node, click the node and select **Change to OR** from the toolbar.
- To change an ***Or*** node to an ***And*** node, click the node and select **Change to AND** from the toolbar.
- To delete an ***And*** node, an ***Or*** node, a condition or the complete `WHERE` clause from the Alfabet query, click the respective node and select **Delete** from the toolbar.

In the Alfabet query language, multiple `WHERE` conditions in an Alfabet query are defined as:

```
WHERE
    (AND|OR
        Condition1
        Condition2
    )
```

The expression:

```
WHERE
    (AND
        Application.ResponsibleUser IS NULL
        Application.Status = 'Approved'
    )
```

finds all applications with the status `Approved` and no responsible user assigned.

In the Alfabet query language as text, the combination of `AND` or `OR` relations results in a code like the following:

```
WHERE
    (AND|OR
        Condition1
        (AND|OR
            Condition2
            Condition3
```

```
        )
    )
```

Creating a Filter Field with a WHERE Clause

You can allow users to select the output of a configured report at runtime by means of filters that you configure. The definition of filters is described in detail in the section Defining Filters for Configured Reports and Selectors.

Specifying JOINs in Alfabet Queries

Basic information about `JOIN`s is provided in the section *Building an Alfabet Query*:

- *Defining JOINs*
- *Deciding About the Type of JOIN to Use*

This section provides additional information on how to add special classes to Alfabet queries or how to add `JOIN`s for specific circumstances. The following information is available:

- Operators for the Definition of JOIN Conditions
- Specifying Multiple JOIN Conditions for one JOIN
- Joining Classes Already Specified in the Alfabet Query
- Using DISTINCT to Avoid Rows with Identical Content in Results
- Defining JOINs for Roles
- Defining JOINs for Indicators
- Defining JOINs Between Value Nodes, Projects, or Demands and the Affected Architecture
- Defining JOINs to Object Class Stereotypes

Operators for the Definition of JOIN Conditions

The general construction of a `JOIN` is:

```
JoinTypeReferencedObjectClassONObjectClassName.PropertyNameRelationalOperatorObjectClassName.PropertyName
```

The most straight-forward relationship between two object classes is one in which an object class property with the data type `Reference` or `ReferenceArray` references another object class. To specify that relation, you must define the `JOIN` as follows:

```
JoinTypeReferencedObjectClassONObjectClassName.ReferencingProperty=ReferencedObjectClassName.RESTR
```

or:

*JoinTypeReferencedObjectClass*ON*ReferencedObjectClassName*.*ReferencingProperty*=*ObjectClassName*.RESTR

For example, the JOIN

```
LeftJoin Application ON BusinessProcess.Applications =
Application.REFSTR
```

adds all applications assigned to the business processes with the property Applications to the search result of the Alfabet query.

The ability to build a JOIN based on properties of the type ReferenceArray depends on the attribute **Reference Support** of the property:

- If **Reference Support** is set to True, the relational operator "=" is used in the expression. It is used in the JOIN as "includes" or "is included in" rather than "is equal to" operator.
- If **Reference Support** is set to False, you cannot build a JOIN on the property.

JOINs can also specify other relations between two objects either instead of or in addition to a direct reference by a property of the type Reference or ReferenceArray. Any property of the joined object class can have a relation with any other property of the base class or an already joined class in the Alfabet query: .

For example, the JOIN

```
FIND Application

InnerJoin ApplicationGroup ON ApplicationGroup.ResponsibleUser =
Application.ResponsibleUser
```

finds all combinations of application groups and applications for that the same user is defined as responsible user.

In most cases, this type of comparison is useful in combination with a JOIN condition based on a direct reference. In the example, it is probable that the user wants to make sure that the person that is responsible for an application group is a supervisor that is not identical with the person responsible for any individual applications in the application group. The information about the responsible user, that has nothing to do with the relation between application group and applications itself, also combines application groups with applications that are not assigned to that application group. A second JOIN condition must be defined that limits the search results to applications that are assigned to the application group. For information about how to join a class with multiple JOIN conditions, see Specifying Multiple JOIN Conditions for one JOIN.

JOIN conditions allow the use of the following operators:

Operator	Description
=	Equal to
<	Lesser than

Operator	Description
<=	Lesser than or equal to
>	Greater than
>=	Greater than or equal to
<>	Not equal to

Specifying Multiple JOIN Conditions for one JOIN

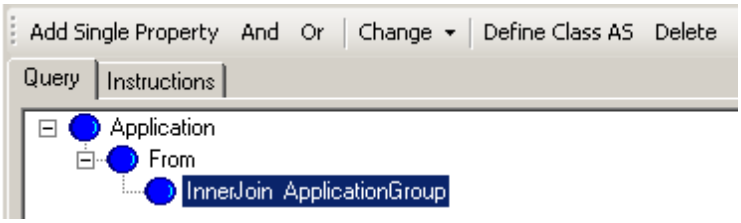
In some cases, you may need to define that more than one property from the first class must match a property of the second class. To do so, you must define all `JOIN` conditions in one `JOIN` and specify in the `JOIN` whether the `JOIN` conditions are `AND` or `OR` related:

`AND`: Returns `True` when all expressions are true.

`OR`: Returns `True` when at least one expression is true.

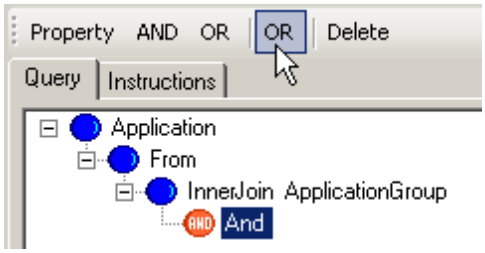
In the **Alfabet Query Builder**, you can decide to use multiple `JOIN` conditions directly after defining the `JOIN`. If a `JOIN` already has a condition, you must first delete that condition to be able to specify multiple conditions.

1) In the **Query** tab of the **Alfabet Query Builder**, click the `JOIN` that has no condition specified.



2) In the toolbar, select either **And** or **Or** to define whether the conditions are `AND` or `OR` related. The selected condition is added to the `JOIN`.
3) In the toolbar, select **Property** and specify the `JOIN` condition as usual.
4) Repeat step 3) to add the second condition.

You can later decide to change the condition from `AND` to `OR` and vice versa. To do so, click the condition in the Alfabet query. You will see the buttons **Property**, **AND**, and **OR** in the toolbar and behind that another button for the condition that you might want to change to. Click that button to change the condition.



In the Alfabet query language, multiple `JOIN` conditions in an Alfabet query are defined as follows:

```
JoinTypeObjectClassNameON (And|OrCondition1Condition2)
```

The expression:

```
InnerJoin ApplicationGroup ON (And Application.ApplicationGroups=
ApplicationGroup.RESTR Application.MANDATEMASK
<>ApplicationGroup.MANDATEMASK)
```

finds all application groups that the application is assigned to and that have a different mandate specification as the application.

More than two `JOIN` conditions can be related with each other in an `AND` or `OR` relationship.

You can combine multiple `AND` and `OR` conditions hierarchically. For example, you can define that condition A and either condition B or condition C should apply.

In the **Alfabet Query Builder**, you can select a new `AND` or `OR` relation from the toolbar when you click an existing `AND` or `OR` relation in the Alfabet query.

In the **Alfabet Query Builder**, the combination of `AND` or `OR` relations results in a code similar to the following:

```
JoinTypeObjectClassNameON (And|OrCondition1 (And|OrCondition2Condition3))
```

The expression:

```
InnerJoin ApplicationGroup ON (And
Application.ApplicationGroups=ApplicationGroup.RESTR (Or
Application.MANDATEMASK<>ApplicationGroup.MANDATEMASK
Application.ResponsibleUser<>ApplicationGroup.ResponsibleUser))
```

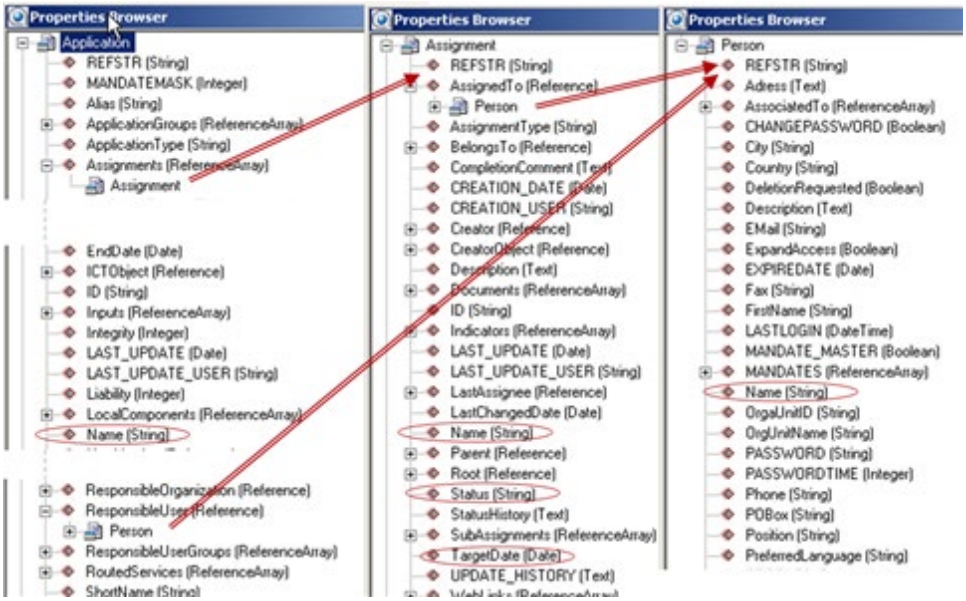
finds all application groups that the application is assigned to and that have either a different mandate specification or a different responsible user as the application.

Joining Classes Already Specified in the Alfabet Query

For some queries, it is necessary to join the same object class two times with different `JOIN` conditions.

For example, an Alfabet query is defined for a report about assignments for applications. The name and responsible user of the application, the name of the assignment, and the status, target date and user responsible for the assignment shall be displayed in the report.

JOINs to the classes Assignment and Person must be added to the Alfabet query in order to find the relevant assignments of the query and the users that are the originators and the responsible users/organizations for the assignment.



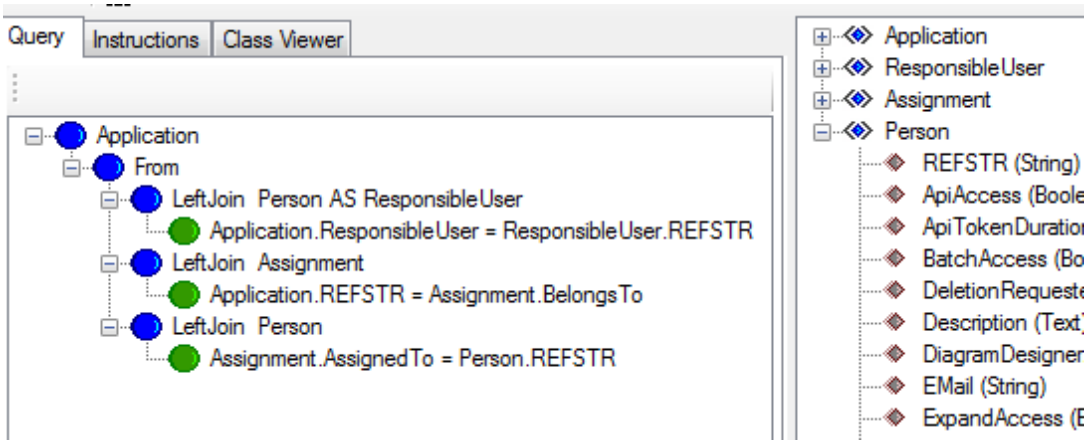
The Assignments property of the class Application references the class Assignment. The attribute ResponsibleUser of the class Application and the attribute AssignedTo of the class Assignment reference the class Person. That means that the class Person is referenced twice in the Alfabet query, each JOIN finding a different subset of objects of the class Person. The name of the person shall be displayed twice in the report: in a column for responsible user and in a column for the assignment's responsible person/organization.

To specify two different JOINs to the same object class, you must define an alias for the object class in the first JOIN before adding the second JOIN. The alias can contain letters and numbers, but no special characters or whitespaces. The alias will be used as the object class name for the object classes matching the specified JOIN conditions. You must use the alias instead of the original object class name in the specification of the JOIN condition, WHERE clauses, and Show and Sort properties.

To define the alias for a joined class in the **Alfabet Query Builder**:

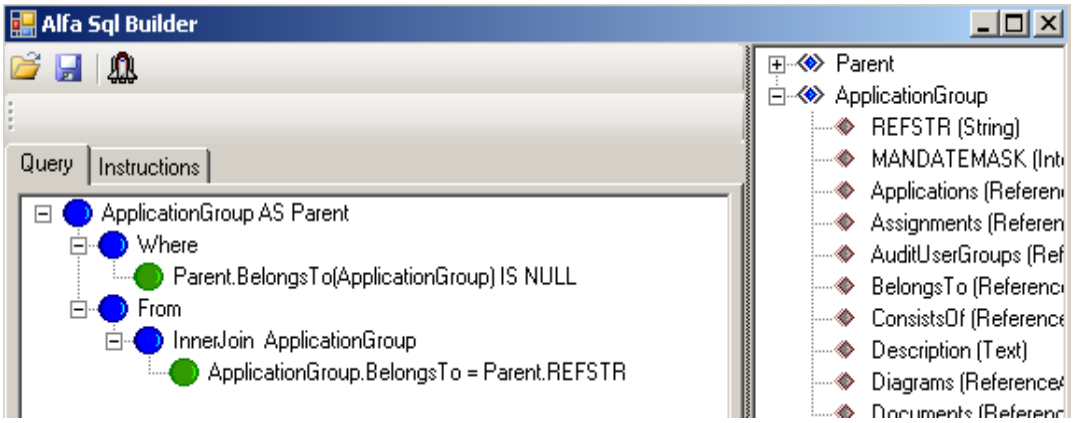
1) In the **Query** tab of the **Alfabet Query Builder**, add a JOIN for the object class.
2) Click the JOIN and select **Define Class As** in the toolbar. A dialog box opens.
3) Define the alias name in the dialog box and click **OK** . You can see the alias class name in the property selector and, if a condition for the JOIN was already defined, in the JOIN conditions.

In the following example, the class Person is renamed to ResponsibleUser in the specification of the user that is the assigned responsible user for the base class application. The class is not renamed for the JOIN that specifies the relation between the classes Person and Assignment. In the property selector, ResponsibleUser is listed as well as Person. Both sections contain all properties, roles and indicators for the object class Person.



Specification of an alias is also required to add a `JOIN` to the base object class of the Alfabet query. The alias is then required on the base class. In the **Alfabet Query Builder**, an alias on the base class can be specified by clicking the base class instead of the `JOIN` and following the procedure described above.

In the following example, application groups that are assigned to top-level application groups shall be displayed in a report. The base class is `ApplicationGroup`, specified with the alias `Parent`. A `WHERE` clause defines that only application groups with no superordinate application groups are found as parent. Subordinate application groups are defined with a `JOIN` to all objects of the class `ApplicationGroup` that belong to one of the parent application groups.



In the Alfabet query language, the code for the definition of an alias is as follows:

```
ObjectClassNameASAliasName
```

To define an alias for the base class:

```
FIND

ObjectClassNameASAliasName
```

To define an alias for a joined class:

```
JoinTypeReferencedObjectClassASAliasNameONObjectClassName.PropertyNameRelati
onalOperatorAliasName.PropertyName
```

In the XML definition of Show and Sort properties, the original object class name must be defined in the attribute `ClassName` and an additional attribute `ClassAlias` must be added that specifies the alias name.

For example, the following Alfabet query:

```
FIND

Application

LeftJoin Person AS ResponsibleUser ON Application.ResponsibleUser =
ResponsibleUser.REFSTR

LeftJoin Assignment ON Application.REFSTR = Assignment.BelongsTo

LeftJoin Person AS Assignee ON Assignment.AssignedTo =
Assignee.REFSTR

QUERY_XML

<QueryDef>

   <ShowProperty Type="Property" ClassName="Application" Name="Name"
   />

   <ShowProperty Type="Property" ClassName="Person"
   ClassAlias="ResponsibleUser" Name="Name"/>

   <ShowProperty Type="Property" ClassName="Assignment" Name="Name"
   />

   <ShowProperty Type="Property" ClassName="Person"
   ClassAlias="Assignee" Name="Name" />

</QueryDef>
```

finds all applications, their assignments and all users that are defined as the responsible user for an application or assignee of an assignment. In the Show properties, the `Name` property of the object class person is displayed two times. Because of the specification of an alias, the distinction can be made between the responsible user and the assignee.

Using DISTINCT to Avoid Rows with Identical Content in Results

If an object class is joined to the base class by means of multiple joins, and the Show properties do not include data about all of the object classes in the `JOIN`, the results may display multiple rows with identical data. In some cases, the results can be limited to rows with differing content by using a `DISTINCT` clause in the specification of the base class.

For example,:

The Alfabet query finds all business functions that are related to ICT objects. However, business functions are not directly related to ICT objects. Business functions use business services that are provided by applications. Therefore, business functions that use business services by applications that are assigned to an ICT object are the relevant business functions that are related to the ICT object.

The Alfabet query must Therefore, join three object classes: `Application, BusinessService` and `BusinessFunction`. In the example above, ICT objects, applications assigned to the ICT object, and the business functions that use business services of the applications are displayed in the results.

Some business functions use business services from more than one application assigned to an ICT object. As a result, the report contains rows that only differ in the data about the application:

```
ALFABET_QUERY_500

FIND

ICTObject

InnerJoin Application ON Application.ICTObject = ICTObject.REFSTR

InnerJoin BusinessService ON Application.REFSTR =
BusinessService.Object

InnerJoin BusinessFunction ON BusinessService.Function =
BusinessFunction.REFSTR

QUERY_XML

<QueryDef>

   <ShowProperty Type="Property" ClassName="ICTObject" Name="ID" />

   <ShowProperty Type="Property" ClassName="ICTObject" Name="Name"
   />

   <ShowProperty Type="Property" ClassName="Application" Name="ID"
   />

   <ShowProperty Type="Property" ClassName="Application" Name="Name"
   />

   <ShowProperty Type="Property" ClassName="BusinessFunction"
   Name="LevelID" />

   <ShowProperty Type="Property" ClassName="BusinessFunction"
   Name="Name" />

   <SortProperty Type="Property" ClassName="ICTObject" Name="ID" />

   <SortProperty Type="Property" ClassName="ICTObject" Name="Name"
   />

   <SortProperty Type="Property" ClassName="BusinessFunction"
   Name="LevelID" />

   <SortProperty Type="Property" ClassName="BusinessFunction"
   Name="Name" />

</QueryDef>
```

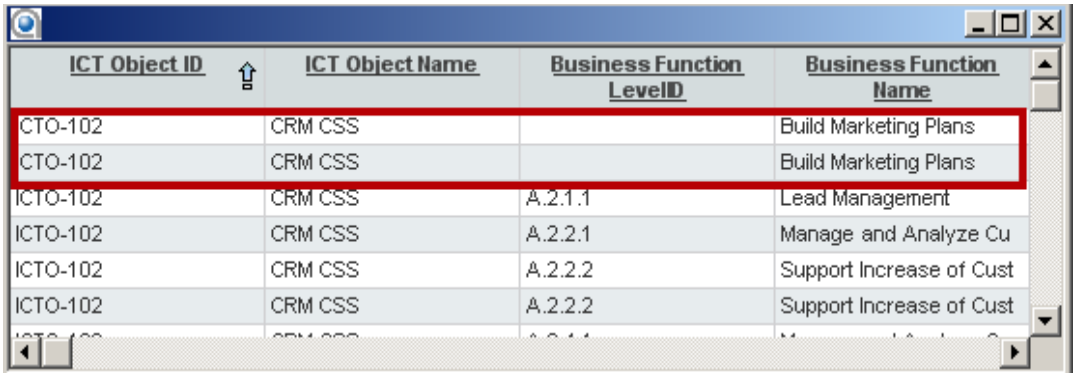
ICTO-102	CRM CSS	APP-2695	CRM CSS	A.2.2.2	Support Increase
ICTO-102	CRM CSS	APP-2694	CRM CSS	A.2.2.2	Support Increase
ICTO-102	CRM CSS	APP-2694	CRM CSS	A.2.4.1	Manage and Ana

If the report displays only data about the ICT object and the business function, you will see a report with rows displaying identical data. The difference in the data set (in this case, the application providing the business service used by the business support) is not visible:



ICT Object ID	ICT Object Name	Business Function LevelID	Business Function Name
CTO-102	CRM CSS		Build Marketing Plans
CTO-102	CRM CSS		Build Marketing Plans
ICTO-102	CRM CSS	A.2.1.1	Lead Management
ICTO-102	CRM CSS	A.2.2.1	Manage and Analyze Cu
ICTO-102	CRM CSS	A.2.2.2	Support Increase of Cust
ICTO-102	CRM CSS	A.2.2.2	Support Increase of Cust

To solve the problem of the duplicate display of data in a scenario as described above, the Alfabet query must have a `DISTINCT` option in the specification of the base class. `DISTINCT` specifies that the resulting report should contain only rows displaying distinct objects. .

For example, if the Alfabet query specified in the example above contains a `DISTINCT` option and no Show properties for applications:

```
ALFABET_QUERY_500

FIND

DISTINCT ICTObject

InnerJoin Application ON Application.ICTObject = ICTObject.REFSTR

InnerJoin BusinessService ON Application.BusinessServices =
BusinessService.REFSTR

InnerJoin BusinessFunction ON BusinessService.Function =
BusinessFunction.REFSTR

QUERY_XML

<QueryDef>

   <ShowProperty Type="Property" ClassName="ICTObject" Name="ID" />

   <ShowProperty Type="Property" ClassName="ICTObject" Name="Name"
   />

   <ShowProperty Type="Property" ClassName="BusinessFunction"
   Name="LevelID" />

   <ShowProperty Type="Property" ClassName="BusinessFunction"
   Name="Name" />

   <SortProperty Type="Property" ClassName="ICTObject" Name="ID" />

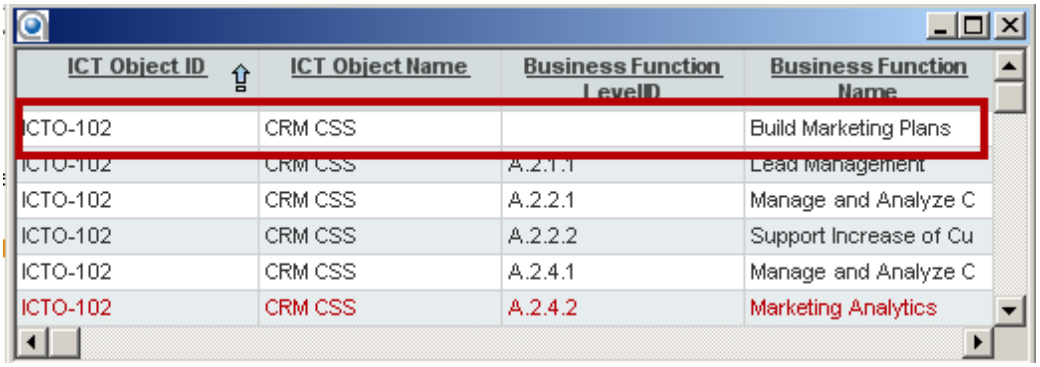
   <SortProperty Type="Property" ClassName="ICTObject" Name="Name"
   />

   <SortProperty Type="Property" ClassName="BusinessFunction"
   Name="LevelID" />

   <SortProperty Type="Property" ClassName="BusinessFunction"
   Name="Name" />

</QueryDef>
```

The resulting report shows only lines with different content:



ICT Object ID	ICT Object Name	Business Function LevelID	Business Function Name
ICTO-102	CRM CSS		Build Marketing Plans
ICTO-102	CRM CSS	A.2.1.1	Lead Management
ICTO-102	CRM CSS	A.2.2.1	Manage and Analyze C
ICTO-102	CRM CSS	A.2.2.2	Support Increase of Cu
ICTO-102	CRM CSS	A.2.4.1	Manage and Analyze C
ICTO-102	CRM CSS	A.2.4.2	Marketing Analytics

Note the following when using `DISTINCT`:

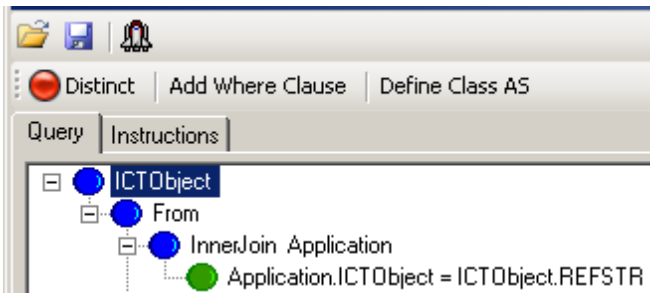
- The parameter `DISTINCT` cannot be used in Alfabet queries that contain object class properties of the **Data Type** `StringArray` or `Text` if the Alfabet database is located on an Oracle® 10g database server.
- In the Alfabet query language, `DISTINCT` forces the display of different objects in each row. This behavior is different from the use of `DISTINCT` in SQL, where `DISTINCT` refers to different object properties.

  For example, if you find applications with the `DISTINCT` option and you only display the name of the application in the report, you may see rows that look identical regardless of the `DISTINCT` setting, because the `Name` property is not unique for applications. Two applications can have the same name as long as they have different versions.

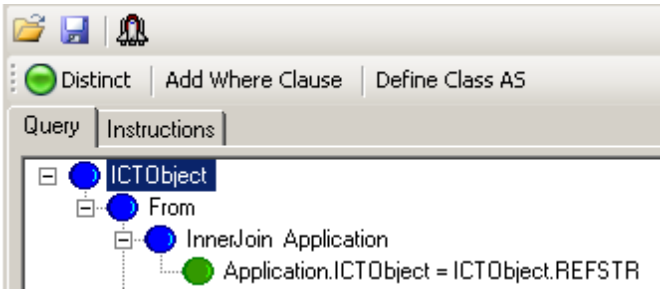
- Also, `DISTINCT` is only applied to the base class of the Alfabet query. If your Alfabet query does not contain any Show properties for the base class, `DISTINCT` will not have any effect.

To add `DISTINCT` to the base class definition in the **Alfabet Query Builder**:

1) In the **Query** tab of the **Alfabet Query Builder**, click the base class. In the toolbar, the **Distinct** button is displayed with a red light, which means that `DISTINCT` is not selected:



2) In the toolbar, click the **Distinct** button. The button now displays a green light which means that `DISTINCT` is selected.



To add `DISTINCT` clause to the base class definition in the Alfabet query language, write `DISTINCT` between `FIND` and the name of the base class:

```
ALFABET_QUERY_500
FIND DISTINCT Application
```

Defining JOINs for Roles

An object of the object class `Role` is created each time a responsibility is defined for an object based on a preconfigured role type.

Role types define the type of responsibility a user or organization has for an object in the Alfabet database. Role types are configured in the **Reference Data** functionality of the **Configuration** module of Alfabet. They are then assigned to object classes in the **Class Configuration** functionality.

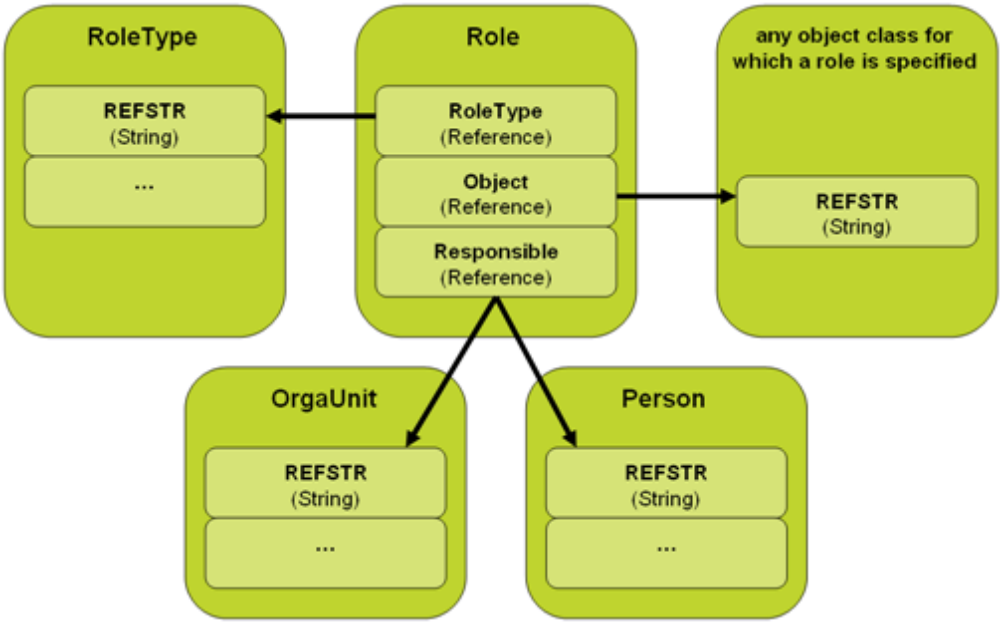
In the **Responsibilities** page view of an object, the user can now create a role by defining a responsibility for either a user or an organization. In the editor for the role definition, the responsible user or organization and the role type that defines the type of responsibility for the object is defined.

The Alfabet query language offers an easy way to include information about responsible users or organizations defined for roles in the results of an Alfabet query. Roles can be specified in the Show properties in an XML definition. The role is automatically interpreted in the XML definition and the name of the responsible user or organization is returned in a separate column per role type. For information about the definition of Show properties for roles, see the section Displaying Users/Organizations Defined for a Role in Alfabet Query Results.

Nevertheless it might be necessary to use `JOIN`s to display the responsible users and organizations defined for roles in reports:

- If the output of the report shall not include the name of the responsible users/organizations, in a separate column per role type. For example, you might want to display users and organizations in different columns, or you might want to add a column showing the role type and a second column showing the responsible for the role type for the object.
- If the output of the report is to be sorted by the user/organization that is responsible for the role. It is not possible to include the role output in the Sort properties without `JOIN`s.

In the Alfabet class model, the relation between the role type, the object, and the responsible person or organization is only specified in the database table for the class `Role`:



To include information about roles in the Alfabet query results, you must first join the class `Role` to the Alfabet query. You can then join all other involved object classes with a relation to the class `Role`.

The property `Responsible` of the class `Role` can reference two object classes: `OrgaUnit` and `Person`. Therefore, you must join both object classes in the Alfabet query to find all roles defined for an object.

For example, to display information about the roles that are defined for objects of a defined object class:

1) Create a `JOIN` to the class `Role` that finds all roles with a reference to objects of the base class in the property `Object`. Create an inner `JOIN` to include only objects with defined roles in the report or a left `JOIN` to find all objects of the base class:

2) Create a `JOIN` to the class `RoleType` that finds all role types that are referenced in the `RoleType` attribute of the roles found in your Alfabet query. You can use a left `JOIN` or an inner `JOIN`. Both results are identical because each role must have a role type defined:

   You can now add the `Name` property of the role type to your Show properties.

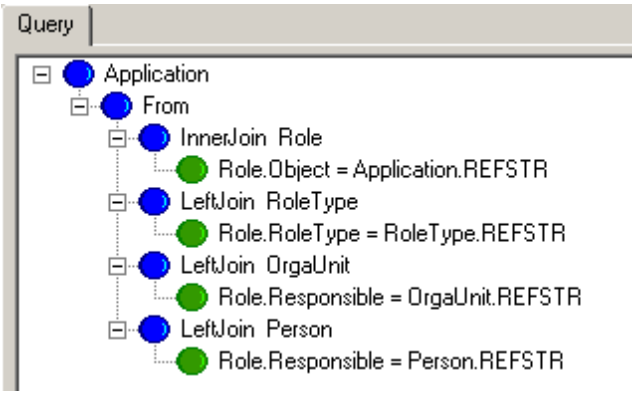
3) Create a left `JOIN` to the class `Organization` that finds all organizations that are referenced in the `Responsible` attribute of the roles found in your Alfabet query. You must define a left `JOIN` to also display applications with responsibilities defined for users instead of organizations. If you are interested in only organizational responsibilities, you can define an inner `JOIN`, but then applications without any roles defined will not be included in the Alfabet query results.

   You can now add the `Name` property or any other properties of the responsible organization to your Show properties.

4) Create a left `JOIN` to the class `Person` that finds all users that are referenced in the `Responsible` attribute of the roles found in your Alfabet query. You must define a left `JOIN` to also display applications with responsibilities defined for organizations instead of users. If you are interested in only user responsibilities, you can define an inner `JOIN`, but then applications without any roles defined will not be included in the Alfabet query results.

You can now add the `Name` property or any other properties of the user to your Show properties.

The resulting Alfabet query will appear as follows:



Defining JOINs for Indicators

In the **Evaluations and Portfolios** functionality in the **Configuration** module in Alfabet, you can define evaluation types that bundle a set of indicator types in order to evaluate objects in Alfabet. The evaluation types are assigned to object classes in the **Class Configuration** functionality.

The indicator types defined for the evaluation types that are assigned to the object class are displayed on the *Evaluation Page View* of each object in the object class. The user can define indicators for the object by defining the value of the indicator type in the *Evaluation Page View*.

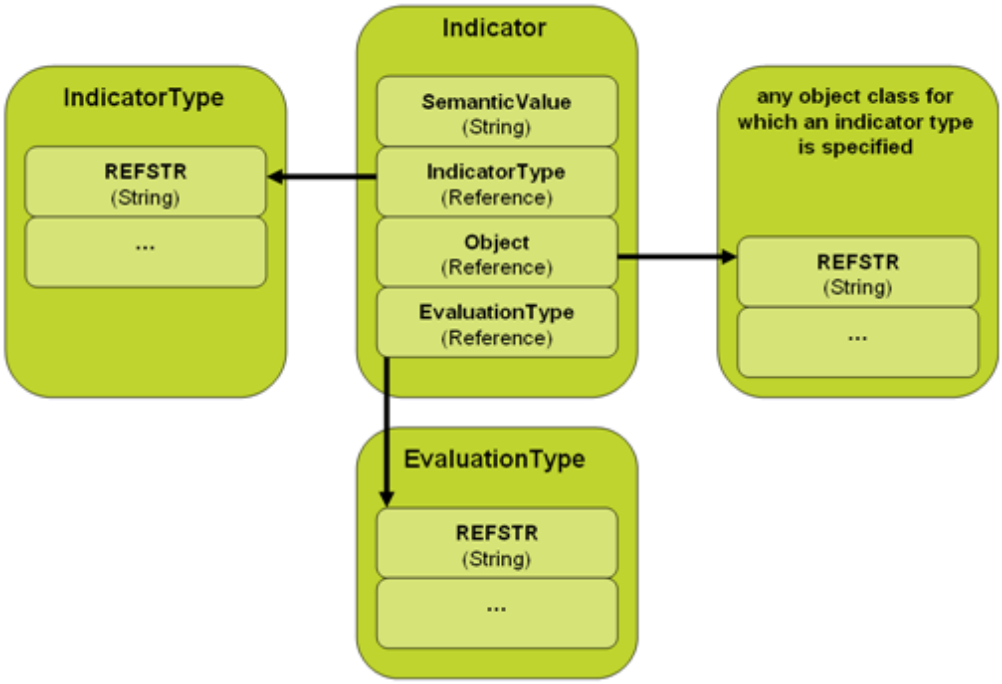
An object of the object class Indicator is created each time a value is entered for an indicator type on the **Evaluations** page view of an object.

The Alfabet query language offers an easy way to include information about indicators in the results of an Alfabet query. Indicators can be specified in the Show properties in XML definition. The indicator is automatically interpreted in the XML definition and the name of the values are returned in a separate column per indicator type. For information about the definition of Show properties for indicator types, see Displaying Users/Organizations Defined for a Role in Alfabet Query Results.

Nevertheless it might be necessary to use `JOIN`s to display indicators in reports:

- If the output of the report shall not display a separate column per indicator type. For example, you might want to display one column for the indicator type and one for the value defined for the indicator type.
- If the output of the report shall be sorted by indicator value. It is not possible to include the indicator output in the Sort properties without `JOIN`s.

In the Alfabet class model, the value defined for an object's indicator type is only specified in the database table for the class `Indicator`. The class `Indicator` specifies the object and the indicator type that each value was defined for and the evaluation type that the indicator type is assigned to:

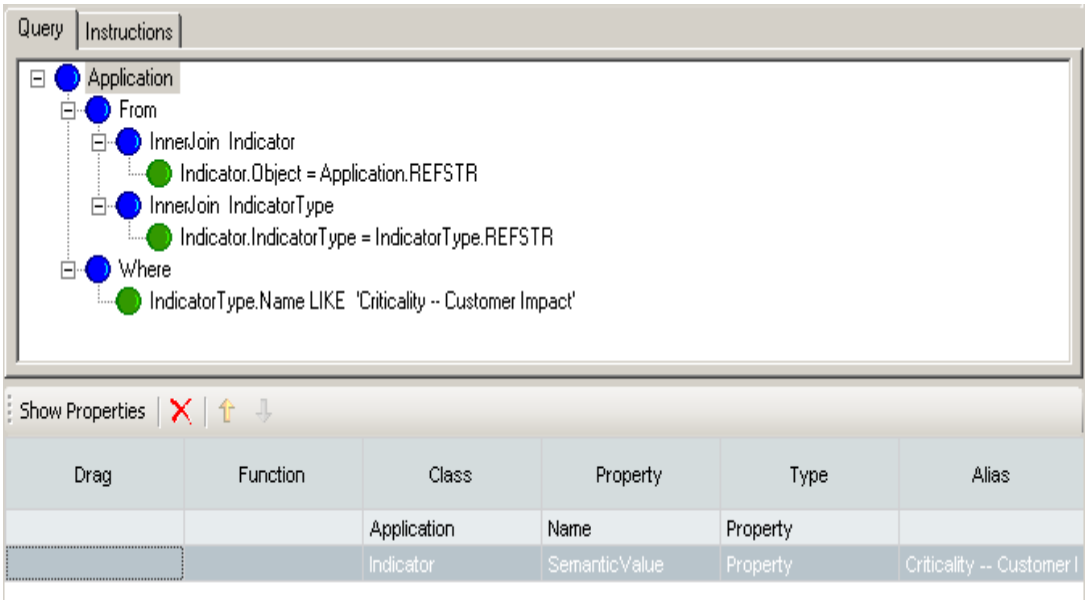


To include information about indicators in the Alfabet query results, you must first join the class `Indicator` to the Alfabet query. You can then join all other relevant object classes via a relation to the class `Indicator`.

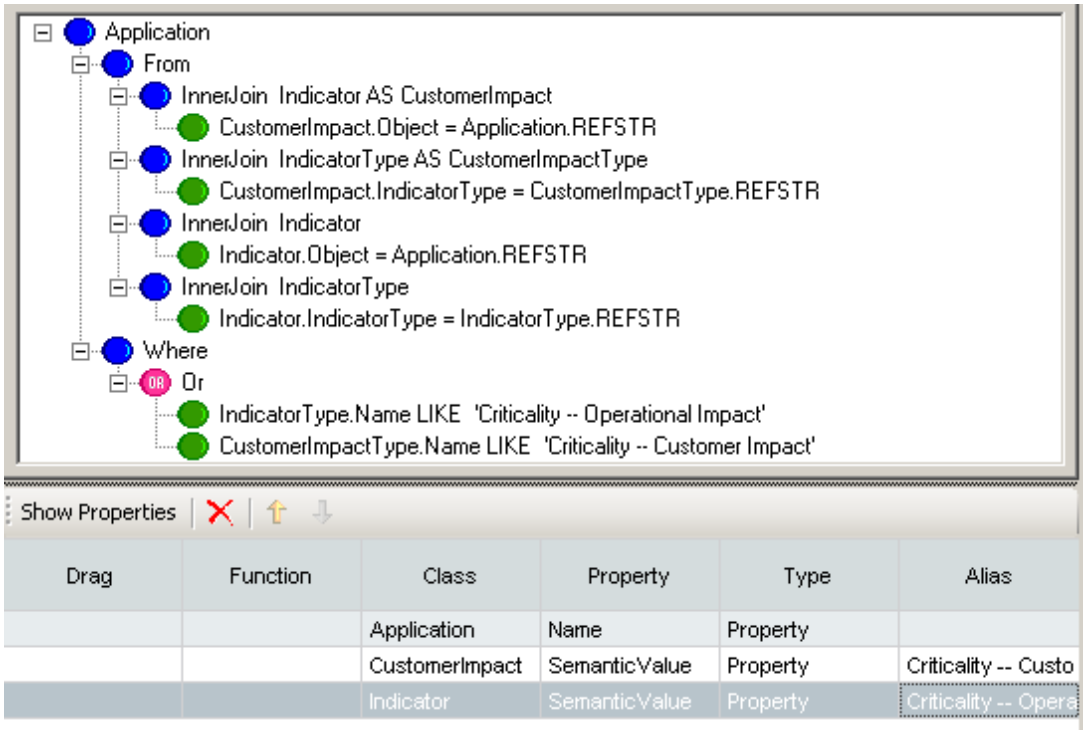
For example, to display information about the values of a specific indicator type that is defined for objects of a defined object class:

1) Create a `JOIN` to the class `Indicator` that finds all Indicators with a reference to objects of the base class in the property `Object`. Create an inner `JOIN` to include only objects with defined indicators in the report or a left `JOIN` to find all objects of the base class:
2) Create a `JOIN` to the class `IndicatorType` that finds all Indicator types that are referenced in the `IndicatorType` property of the indicators found in your Alfabet query. You can use a left `JOIN` or an inner `JOIN`. Both results are identical because each indicator must have an indicator type defined:
3) Add a `WHERE` condition to your Alfabet query that defines that the `Name` property of the indicator type must correspond to the name of the indicator for which you want to display values in the report.
4) Define the property `Name` of the object and the property `SemanticValue` of the indicator as Show properties and change the column caption to the name of the indicator.

The resulting Alfabet query will appear as follows:



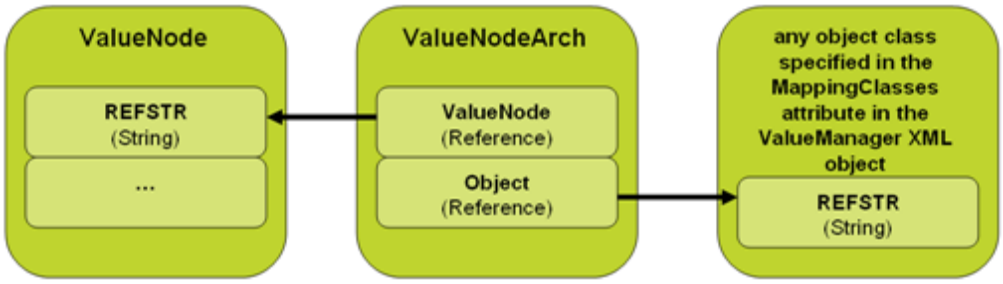
If you want to show the values of more than one indicator type and add one column to your report for each indicator type, you must join the class Indicator two times to your report and specify an alias name for one of the indicators. The same applies to the indicator type `JOIN`. For information on how to join one object class multiple times to an Alfabet query, see the section Joining Classes Already Specified in the Alfabet Query.



Defining JOINs Between Value Nodes, Projects, or Demands and the Affected Architecture

For value nodes, projects and demands, the affected architecture is not defined as a property of the value node, project and demand, but with a special object class `ValueNodeArch`, `DemandArch` and `ProjectArch` respectively. The class `ValueNode` is used to describe the relation to the affected architecture in the following example. The relation between projects or demands and their affected architecture follows the same rules.

An object of the object class `ValueNodeArch` (value node arc) is created each time a user adds an architecture element to the affected architecture of a value node stereotype either on the *Affected Architecture Page View* of the value node stereotype or on the *Impacting Value Nodes Page View* for the architecture object. The relation between the value node and the architecture object is neither stored in the database table of the value node nor in the database table of the architecture object. The relation between the a value node and its affected architecture is only specified in the database table for the class `ValueNodeArch`:



To include information about the affected architecture of a value node or the impacting value nodes assigned to an object in the Alfabet query results, you must first join the class `ValueNodeArch` to the Alfabet query. You can then join all other involved object classes with a relation to the class `ValueNodeArch`:

- Value nodes are based on value node stereotypes. To limit the search results to value nodes of a certain value node stereotype only, you must include a `WHERE` statement as described in the section Defining JOINs to Object Class Stereotypes.
- The property `Object` of the class `ValueNodeArch` can reference objects of any object class that are defined in the `MappingClasses` attribute for a value node stereotype in the XML object ***Value Manager***. To create a `JOIN` to the affected architecture, you must add a `JOIN` to all involved object classes to the Alfabet query. For information about the XML specification for value nodes, see Configuring the Strategy Deduction Capability in the chapter Configuring Alfabet Functionalities Implemented in the Solution Environment.

For example, an Alfabet query shall find all objects of the affected architecture for a value node of the stereotype `Architecture Requirements` that has the following stereotype definition:

```
<ValueStereotype
   Name="Architecture Requirements"
   Level="5"
   MappingClasses="Domain,BusinessProcess,OrgaUnit,MarketProduct"
   Picture="ArchitectureRequirement"/>
```

In the Alfabet query, you must define the following:

1) Define `ValueNode` as the base class.

You can now add the name of the value node to your Show properties.

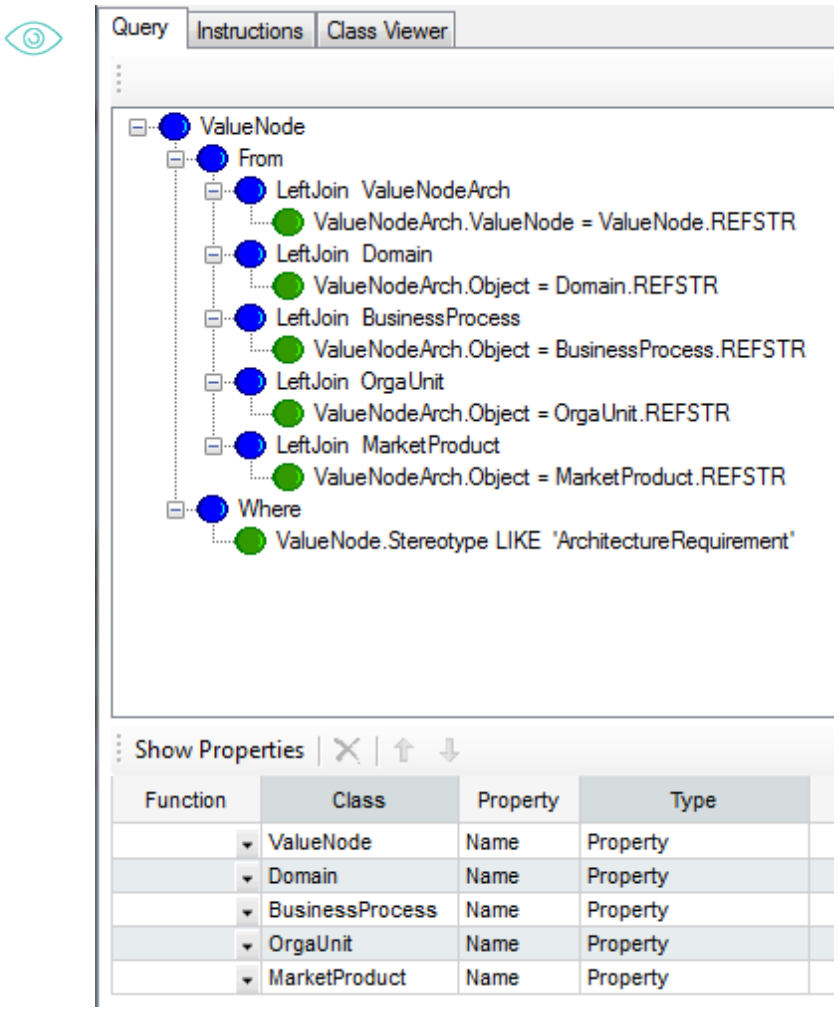
2) Add a `WHERE` clause to the Alfabet query that defines that the `Stereotype` property of the value nodes must have the value "`Architecture Requirements`".

3) Create a `JOIN` to the class `ValueNodeArch` that finds all value node arcs. Create an inner `JOIN` to include only value nodes with defined affected architecture in the report or a left `JOIN` to find all value nodes.

4) Create a `JOIN` to each of the object classes defined as `MappingClasses` in the stereotype definition of the value node. The `JOIN` condition must define that the object class is referenced by the object class property `Object` of the object class `ValueNodeArch`. You can use a left `JOIN` or an inner `JOIN`. Both results are identical because each value node arch must have an object defined.

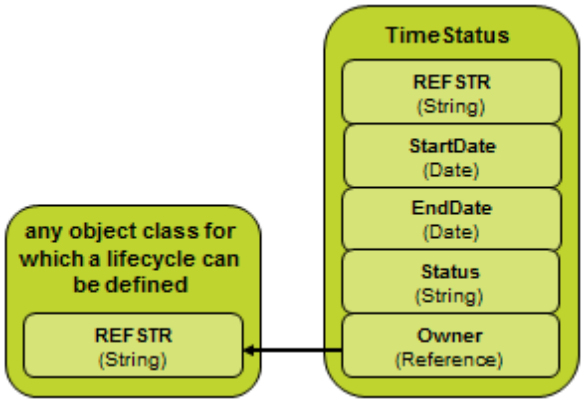
   You can now add the names of the object classes to your Show properties.

The resulting Alfabet query will appear as follows:



Referring to the Lifecycle of an Object in the Alfabet Query

In the Alfabet database, the lifecycle definition and lifecycle phases for an object are stored as objects of the object class `TimeStatus`. Each `TimeStatus` object provides information about the start date, the end date and the lifecycle status of the lifecycle phase stored in the object as well as a reference to the object that the lifecycle phase is defined for in the property `Owner`. The lifecycle status can be any of the names of the lifecycle phases defined for the object class in the XML object ***ObjectLifeCycleManager*** in Alfabet Expand.



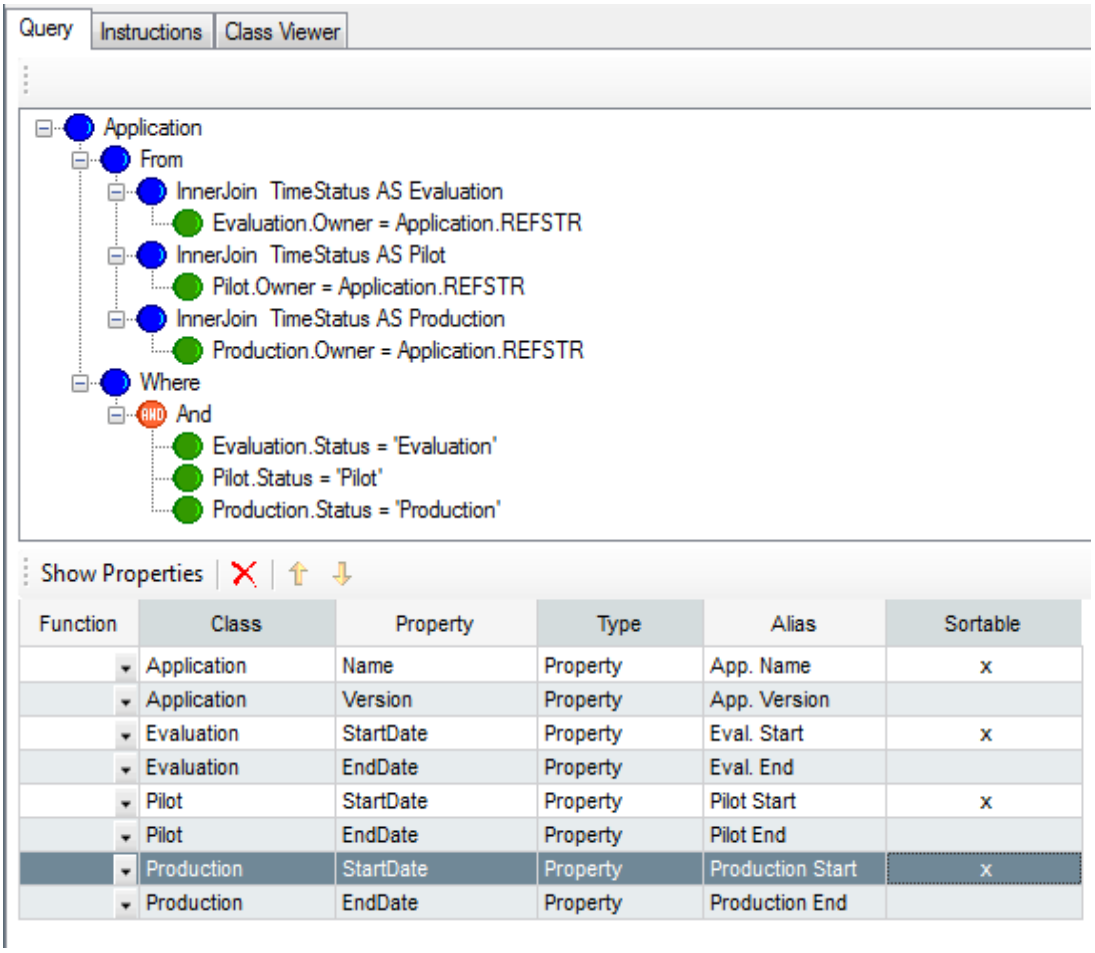
To include information about the lifecycle of an object in the Alfabet query results, you must first join the class `TimeStatus` to the Alfabet query.

For example, a report shall display the start and end dates for the `evaluation`, `pilot` and `production` lifecycle phases for applications:

App. Name	App. Version	Eval. Start	Eval. End	Pilot Start	Pilot End	Production Start	Production End
ACCOUNT	1	30/09/2002	17/06/2003	17/06/2003	20/11/2004	20/11/2004	07/08/2010
ACCOUNT	1.2	28/09/2008	20/05/2009	20/05/2009	02/09/2010	02/09/2010	23/10/2015
Administrative	1.0	29/02/2008	15/11/2008	15/11/2008	21/04/2010	21/04/2010	06/01/2016
AF Enterprise	4.0	30/03/2005	15/12/2005	15/12/2005	21/05/2007	21/05/2007	03/02/2013
AF Enterprise	3.1	15/12/2005	31/03/2006	31/03/2006	29/10/2006	29/10/2006	25/02/2009
AF Good Buy	2.0	08/06/2006	12/09/2006	12/09/2006	25/03/2007	25/03/2007	08/05/2009
AF Good Buy	3.0	31/03/2011	13/07/2011	13/07/2011	06/02/2012	06/02/2012	19/05/2014
AF HR Online	3.0	24/02/2005	14/11/2005	14/11/2005	24/04/2007	24/04/2007	27/01/2013

Each lifecycle phase (`production`, `pilot` and `evaluation`) corresponds to one object of the class `TimeStatus`. Therefore, each row displays information about three different objects of the same class. Therefore, the Alfabet query must include three `JOIN`s to the same object class, using an alias for the object classes as described in the section Defining JOINs for Indicators. `WHERE` clauses must be added to define which value of the object class property `Status` a `TimeStatus` object must have to be displayed in the respective row.

The resulting Alfabet query will appear as follows in the **Alfabet Query Builder**:



Defining JOINs to Object Class Stereotypes

The concept of object class stereotype has been implemented for many object classes. Object class stereotypes differ in name and the range of functionalities available for them. The object class stereotype definition also includes the structure of the stereotypes in the hierarchy.

For an overview of the object classes supporting object class stereotype configuration, see the section Configuring Object Class Stereotypes for Object Classes.

On the user interface, the caption of the object class stereotype is used instead of the caption of the object class. For example, the caption of the object view displays the object class stereotype caption and not the object class name. But in the Alfabet database, all objects of an object class are stored in the same database table regardless of their object class stereotype.

When a user creates an object class stereotype, the information about the configuration applied to the object is stored in the object class property `Stereotype`. The value of the property `Stereotype` is the value of the attribute ***Name*** of the corresponding stereotype configured in the relevant XML object.

To find objects of a specific object class stereotype, you must add the object class for which the object class stereotype is defined to the Alfabet query either as the base class or in a `JOIN`, and you must restrict the search results to the object class stereotype in a `WHERE` clause.

For example, to find projects of the project stereotype `StatementOfWork`:

```
FIND
Project
WHERE Project.Stereotype LIKE 'StatementOfWork'
```

Specifying Show and Sort Properties in Alfabet Queries

Show properties define the object class properties of objects found by the Alfabet query that will be displayed in the results of the Alfabet query.

Sort properties define the subset of Show properties that are relevant for alphanumerical sorting of the results in the result table during execution of the Alfabet query. The results are first sorted in ascending order based on the first Sort property defintion. All rows having an equal value are then sorted according to the second criteria, and so on. The user can change the sort order of the rows in the report by clicking any column header of the report. The report is then sorted in ascending alphanumeric order of the values in the selected column. If he/she clicks the column header of a column that is already used for sorting, the sorting order is reverted from ascending to descending alphanumeric order and vice versa.

Show and Sort properties are only required if the Alfabet query result is displayed on the interface (For example, for Alfabet queries in reports). No Show and Sort property definition is required for Alfabet queries that are used to find objects for further processing by a Alfabet functionality, (For example, Alfabet queries for wizard check entries).

Please note that Show properties cannot be defined for an Alfabet query used in a computation rule.

Information about how to define Show and Sort properties in the **Alfabet Query Builder** is explained in *Defining Show Properties* in the section *Building an Alfabet Query*.

This chapter provides information about the definition of Show properties for object class properties, indicators and roles and Sort properties for object class properties in the Alfabet query language as an XML element. The following information is available:

- Defining Show and Sort Properties in an XML Element
- Displaying Users/Organizations Defined for a Role in Alfabet Query Results
- Displaying Indicator Values in Alfabet Query Results
- Calculating Values in Alfabet Query Results

Defining Show and Sort Properties in an XML Element

The Alfabet query language allows you to specify the Show and Sort properties in an XML element ***QueryDef*** that is written in a ***QUERY_XML*** clause. For each Show property, an XML element ***ShowProperty*** is written into the ***QueryDef*** element. For each Sort property, an XML element ***SortProperty*** is written into the ***QueryDef*** XML element. This is the preferred syntax.

The ***ShowProperty*** XML element has different XML attributes for the definition of object class property values, indicators and names of the users/organizations defined for a role. This section describes the XML attributes that are required to show and sort object class properties in the report results. Show properties for indicators and roles are described in separate sections below.

The general syntax to add a Show property for object class properties to an Alfabet query is:

```
QUERY_XML
<QueryDef>
   <ShowProperty Type="Property" ClassName="ObjectClassName"
   Name="PropertyName" ShowName="ColumnHeaderString" />
</QueryDef>
```

You can define a subset of the selected Show properties as Sort properties by adding an XML element ***SortProperty*** to the ***QueryDef*** XML element.

```
QUERY_XML
<QueryDef>
   <SortProperty Type="Property" ClassName="ObjectClassName"
   Name="PropertyName" />
</QueryDef>
```

The ***SortProperty*** XML element has the same XML attributes as the ***ShowProperty*** element. The XML attributes of the ***SortProperty*** XML element must have identical values to an existing ***ShowProperty*** XML element:

```
QUERY_XML
<QueryDef>
   <ShowProperty Type="Property" ClassName="Application" Name="Name"
   />
   <SortProperty Type="Property" ClassName="Application" Name="Name"
   />
   <ShowProperty Type="Property" ClassName="Domain" Name="Name"
   ShowName="In Domain"/>
   <SortProperty Type="Property" ClassName="Domain" Name="Name"
   ShowName="In Domain"/>
</QueryDef>
```

The table below lists all available XML attributes in the ***ShowProperty*** and ***SortProperty*** XML elements of the type `Property`:

Attribute	Allowed Values	Default	Description
`Type`	`Property` `Role`	**MANDATORY**	Defines the type of Show property. The XML attributes described in this table are for the type `Property` only.

Attribute	Allowed Values	Default	Description
	Indicator		Show properties of the type Property define the display of object class properties in the Alfabet query results. See Displaying Users/Organizations Defined for a Role in Alfabet Query Results and Displaying Indicator Values in Alfabet Query Results for a description of the XML attributes for roles (Type="Role") and indicators (Type="Indicator").
ClassName	Name of object class	**MANDATORY**	The name of the object class that the object class property specified with the attribute Name belongs to.
ClassAlias	Alias name of object class		When multiple JOINs to the same object class are defined in an Alfabet query, the object class is assigned a different alias name in each JOIN in order to distinguish between the objects of that class found by one or the other JOIN. If the role is specified for an object class that has an alias name in the Alfabet query, the alias name must be specified with this XML attribute.
Name	Name of property	**MANDATORY**	The name of the object class property that is displayed in the table results.
ShowName	String	ObjectClassName PropertyName	Optionally the name of the column header can be defined with the attribute ShowName.
Function	AVG SUM MIN MAX COUNT		If set, the specified function will be assigned to the Show property. For information about assigning functions to Show properties, see Calculating Values in Alfabet Query Results

Displaying Users/Organizations Defined for a Role in Alfabet Query Results

An object of the object class Role is created each time a responsibility is defined for an object based on a preconfigured role type.

Information about which user/organization is responsible for a specific role for an object can be added to an Alfabet query directly in the XML definition of Show properties without using JOINs to the involved object classes.

The XML definition of the Show property for a role generates one column in the query output for each role type. The search returns the name and first name of the responsible user or the name of the responsible organization for the role.

The XML definition of Show properties for roles is not always applicable:

- If you specify an Alfabet query in an XML attribute of an XML element, you cannot use the XML definition of Show properties. This is required, For example, for the definition of treemap and layered diagram reports, wizards, workflows and computation rules.
- If you want the role responsibilities in the Alfabet query results to be displayed in another form than the one predefined for XML definitions of Show properties of the type `Role`. For example, if the users/organizations defined for all roles shall be listed in one column and the role type of the role shall be listed in another column.
- If you want to sort the results by responsible. The definition of Sort properties is not possible for XML definitions of Show properties for roles.
- If you want to define an Alfabet query instruction that colors the cell dependent on the availability of a role on the object. For more information about the definition of cell coloring depending on search results, see Defining Coloring for Cells or Rows Containing Specific Data.

If you want to add information about a role to the Alfabet query results without using the XML definition, you must join the relevant object classes and define their object class properties via Show properties. Detailed information about joining roles is provided in the section Defining JOINs for Roles.

The following information is available:

- Defining Roles as Show Properties in the Alfabet Query Builder
- Defining Roles as Show Properties in the XML Element

Defining Roles as Show Properties in the Alfabet Query Builder

To add a role to the Show properties in the **Alfabet Query Builder**:

1) Click a role in the object class property selector and drag it to the **Show Properties** section of the **Alfabet Query Builder**. The columns **Class**, **Property** and **Type** are automatically filled.

   If the object class supports object class stereotype definition, the object class property selector displays all role types assigned to the object class and to any of the defined object class stereotypes. If you are defining a query that finds objects of a given object class stereotype, you may see role types in the list that are not applicable for the stereotype that you are specifying in the Alfabet query.

2) If the role is not defined for the base class of the Alfabet query, but for an object class added with a `JOIN` to the Alfabet query:
   - Drag the `REFSTR` property of the selected object class from the object class property selector to the **Show Properties** section.
   - Select the **Instructions** tab of the **Alfabet Query Builder** and enter:

     ```
     REMOVECOLUMNS("ObjectClassName.REFSTR")
     ```

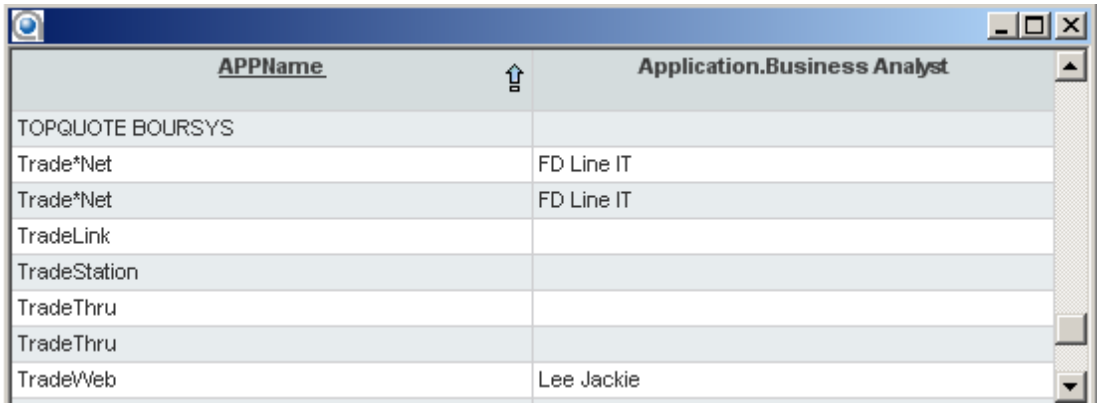
The REFSTR property defined in the Show properties is not displayed in the results table.

If you want to hide REFSTR columns for multiple object classes, the columns can be added to the command in comma-separated format:

```
REMOVECOLUMNS("ObjectClassName.REFSTR","ObjectClassName.REFSTR")
```

Whitespaces are not allowed in the command.

Dragging a role property from the property selector to the **Show Properties** section of the **Alfabet Query Builder** results in the following output:



APPName	Application.Business Analyst
TOPQUOTE BOURSYS	
Trade*Net	FD Line IT
Trade*Net	FD Line IT
TradeLink	
TradeStation	
TradeThru	
TradeThru	
TradeWeb	Lee Jackie

- One column is added to the report showing the responsible users/organizations for the role per object.
- If multiple users/organizations defined for a role have the same role for an object, one row is added to the report for each responsible user/organization.
- Base class objects with no role defined are displayed in the report and the report column is left empty. This corresponds to a left JOIN of the object class Role to the base class.
- Responsible organizations and responsible users are displayed in the same column.
- For responsible organizations, the name of the organization is displayed. For responsible users, the name and first name of the user is displayed.

If you want to change the information that is displayed about the responsible users/organizations in the rows of the report, you can edit the XML show property definition in a text editor. All other changes require the definition of JOINs.

Defining Roles as Show Properties in the XML Element

In the XML definition of Show properties described in the section Defining Show and Sort Properties in an XML Element above, roles are defined in an XML element ***ShowProperty*** of the type Role with the following XML attributes:

```
<ShowProperty Type="Role" ClassName="ObjectClassName" Name="RoleTypeName"
ShowName="ColumnCaption" ImageProps1="PropertiesDisplayedForUser"
ImageProps2="PropertiesDisplayedForOrganization" />
```

Attribute	Allowed Values	Default	Description
Type	Property Role Indicator	**MANDATORY**	Defines the type of show property. The attributes described in this table are for the type Role only. Show properties of the type Role define the display of users/organizations defined for a role for a defined role type without adding JOINs to the Alfabet query.
ClassName	Name of object class	**MANDATORY**	The name of the object class for which the responsible user/organization defined for the role shall be displayed.
ClassAlias	Alias name of object class		When multiple JOINs to the same object class are required in an Alfabet query, the object class is assigned a different alias name in each JOIN to distinguish between the objects of that object class found by one or the other JOIN. If the role is specified for an object class that has an alias name in the Alfabet query, the alias name must be specified with this XML attribute.
Name	RoleTypeName	MANDATORY	The name of the role type for which the responsible users/organizations shall be displayed. This XML attribute is used to identify the role type and also defines the display of the role type in the column header by default. The column header can be overwritten with the XML attribute ShowName.
ImageProps1	PropertyName[, PropertyName]	Name, FirstName	Defines the display of responsible users in the Alfabet query output. One object class property or a comma-separated list of object class properties of the object class Person (User) can be specified. The values of the listed object class properties are displayed in the specified order and separated with whitespace in the results.
ImageProps2	PropertyName[, PropertyName]	Name	Defines the display of responsible organizations in the Alfabet query output. One object class property or a comma-separated list of object class properties of the object class OrgaUnit (Organization) can be specified. The values of the listed object class properties are displayed in the specified order and separated with whitespace in the results.
ShowName	String	ObjectClassName PropertyName	Optionally the caption of the column header can be defined with the XML attribute ShowName. If ShowName is not defined, the name of the role type as specified with the XML attribute Name is displayed in the column header.

If the object class that the role is assigned to is not the base class, the following specifications are additionally required in the Alfabet query:

- The specification of the `REFSTR` property of the class the role is assigned to as show property.
- The specification of an instruction that hides the `REFSTR` property from the report. Instructions are written into a section `Instructions` in the Alfabet query text. If you want to hide multiple columns, you can write the instructions into the same section.

Thus, the complete specification of show properties is:

```
Instructions
REMOVECOLUMNS("ObjectClassName.REFSTR")
EndOfInstructions
QUERY_XML
<QueryDef>
   <ShowProperty Type="Property" ClassName="ObjectClassName" Name="REFSTR"
   />
   <ShowProperty Type="Role" ClassName="ObjectClassName" Name="RoleTypeName"
   ShowName="ColumnCaption" Reference="ReferenceString"
   ImageProps1="PropertiesDisplayedForUser"
   ImageProps2="PropertiesDisplayedForOrganization" />
</QueryDef>
```

If you want to hide `REFSTR` columns for multiple object classes, the columns can be added to the command in comma-separated format:

```
REMOVECOLUMNS("ObjectClassName.REFSTR","ObjectClassName.REFSTR")
```

Whitespaces are not allowed in the command.

Displaying Indicator Values in Alfabet Query Results

In the **Evaluations and Portfolios** functionality in the **Configuration** module in Alfabet, you can define evaluation types that bundle a range of indicator types to evaluate objects in Alfabet. The evaluation types are assigned to object classes in the **Class Configuration** functionality.

The indicator types of the evaluation types assigned to the object class are displayed in the **Evaluations** page view of each object of the class. The user can define indicators for the object by defining the value of the indicator type in the **Evaluations** page view.

Information about the setting of indicators for objects of object class can be added to an Alfabet query directly in the XML definition of Show properties without using `JOIN`s to the involved object classes.

The XML definition generates one column in the output for each indicator type. The search returns the indicator, that means the value of the indicator type for the current object depending on the configuration of the value in the indicator type definition. If an icon gallery is assigned in the **Visualization** tab of the indicator's editor, the icons are displayed. Otherwise the display depends on the **Range** and **Hide Number** settings of the indicator:

- If a **Range** definition exists in the indicator type definition, the display depends on the setting of the property **Hide Number** of the indicator type. If **Hide Number** is activated, only the string defined after the hyphen is displayed, while the complete definition including the numeral and the hyphen is displayed if **Hide Number** is deactivated.

  The semantic value following the hyphen in the **Range** definition of an indicator type is translatable and will be displayed in the language of the cultures currently selected by the user if a translation is provided. The **Range** definitions are included into the vocabularies for interface string translation of Alfabet without the numeral part and the hyphen.

- If a **Range** definition does not exist, the value of the indicator is displayed as follows:
  - if the value contains only numerals, it will be assumed that the value is a number. The numeric value will be displayed in a form appropriate to the specified culture.
  - if the value contains no numerals or a mixture of non numerical characters and numerals, the value is displayed as a string.

The assignment of indicator types to user profiles is not taken into consideration by the XML definition of indicators in Alfabet queries.

The XML definition of Show properties for indicators is not always applicable:

- If you want the indicators in the Alfabet query results to be displayed in another form than the one predefined for XML definitions of Show properties of the type `Indicator`. For example, if the indicators of all indicator types shall be listed in one column and their corresponding indicator types shall be listed in another column.
- If you want to sort the results by indicator. The definition of Sort properties is not possible for XML definitions of Show properties for indicators.
- If you want to restrict the display of indicators to indicator types assigned to the user profile that the user is currently logged in with. The assignment of indicator types to user profiles is not taken into consideration by the XML definition of Show properties for indicators.
- If you want to define an Alfabet query instruction that colors the cell depending on the value of the indicator. For more information about the definition of cell coloring, see Defining Coloring for Cells or Rows Containing Specific Data.
- If you define a query for a configured report displaying a chart.

For this configurations you must add the indicator to the query via `JOIN`s and define the indicator value as a normal Show property.

The following information is available about the definition of Show properties for indicators:

- Defining Indicators as Show Properties in the Alfabet Query Builder
- Defining Indicators as Show properties in the XML Element ShowProperty

Defining Indicators as Show Properties in the Alfabet Query Builder

To add an indicator to the Show properties in the **Alfabet Query Builder**:

1) Click an indicator  in the object class property selector and drag it to the **Show Properties** section of the **Alfabet Query Builder**. The columns **Class**, **Property** and **Type** are automatically filled and an **X** is automatically defined in the column **Show As Icon**.

   If the object class supports stereotype definition, the object class property selector displays all indicators assigned to the object class and to any of the defined stereotypes. If you are defining a query that finds objects of a given stereotype, you may see indicators in the list that are not applicable for the stereotype for which you define the Alfabet query.

2) By default the indicator is represented by icons an icon gallery is assigned in the **Visualization** tab of the indicator's editor. If you want to display semantic values instead, click in the **Show As Icon** cell to remove the **X**.

3) If the indicator is not defined for the base class of the Alfabet query, but for an object class added with a `JOIN` to the Alfabet query:

   - Drag the `REFSTR` property of the selected object class from the object class property selector to the **Show Properties** section.
   - Select the **Instructions** tab of the **Alfabet Query Builder** and enter:

     ```
     REMOVECOLUMNS("ObjectClassName.REFSTR")
     ```

The `REFSTR` property defined in the show properties is not displayed in the results table.

If you want to hide `REFSTR` columns for multiple object classes, the columns can be added to the command in comma-separated format:

```
REMOVECOLUMNS("ObjectClassName.REFSTR","ObjectClassName.REFSTR")
```

Whitespaces are not allowed in the command.

Defining Indicators as Show properties in the XML Element ShowProperty

In the XML definition of Show properties described in the section Defining Show and Sort Properties in an XML Element above, roles are defined in a `ShowProperty` XML element of the type `Indicator` with the following XML attributes:

```
<ShowProperty Type="Indicator" ClassName="ObjectClassName"
Name="IndicatorTypeName" ShowName="ColumnCaption" />
```

Attribute	Allowed Values	Default	Description

`Type`	`Property`
	`Role`
	`Indicator`
		MANDATORY	Defines the type of Show property. The XML attributes described in this table are for the type `Indicator` only.
			Show properties of the type `Indicator` define the display of indicators without adding `JOIN`s to the Alfabet query.

Attribute	Allowed Values	Default	Description
`ClassName`	Name of object class	**MANDATORY**	The name of the object class for which the indicator shall be displayed.
`ClassAlias`	Alias name of object class		When multiple `JOIN`s to the same object class are required in an Alfabet query, the object class is assigned a different alias name in the `JOIN` to distinguish between the objects of that object class found by one or the other `JOIN`. If the indicator is specified for an object class that has an alias name in the Alfabet query, the alias name must be specified with this attribute.
`Name`	Evaluation Type/Indicator Type		The name of the evaluation type and the name of the indicator type of the indicator separated with a slash. The value of the `Name` XML attribute is used to identify the indicator and as part of the column header of the output report if no XML attribute `ShowName` is specified.
`ShowName`	String	Value of the XML attribute `Name`	Optionally the caption of the column header can be defined with the XML attribute `ShowName`. If `ShowName` is not specified, the value defined for the `Name` XML attribute is displayed in the column header.
`ShowAsIcon`	`true` `false`	`true`	Select `false` to display the semantic value of the indicator in the Alfabet query output. Select `true` to display the indicator values as an icon in the Alfabet query output. **NOTE**: The icon gallery must be assigned to the relevant indicator type to display the indicators as icons. If the icon gallery is not assigned to the indicator types (in the **Evaluations and Portfolios** functionality of Alfabet), the semantic value for the indicator is displayed even if `ShowAsIcon` is set to `True`.

If the object class that the indicator is assigned to is not the base class, the following additional specifications are required in the Alfabet query:

- The specification of the `REFSTR` property of the object class the indicator is assigned to as Show property.
- The specification of an instruction that hides the `REFSTR` property from the report. Instructions are written in the section `Instructions` in the Alfabet query text. If you want to hide multiple columns, you can write the instructions into the same section.

Thus, the complete specification of Show conditions is:

```
Instructions
REMOVECOLUMNS("ObjectClassName.REFSTR")
EndOfInstructions
```

```
QUERY_XML<QueryDef>
    <ShowProperty Type="Property" ClassName="ObjectClassName" Name="REFSTR"
    />
    <ShowProperty Type="Indicator" ClassName="ObjectClassName"
    Name="EvaluationType/IndicatorType" ShowName="ColumnCaption"
    Reference="ReferenceString" />
</QueryDef>
```

If you want to hide `REFSTR` columns for multiple object classes, the columns can be added to the command in comma-separated format:

```
REMOVECOLUMNS("ObjectClassName.REFSTR","ObjectClassName.REFSTR")
```

Whitespaces are not allowed in the command.

Calculating Values in Alfabet Query Results

You can assign aggregation functions to Show properties of the type `Property`. Aggregation functions **cannot** be assigned to Show properties of the type `Role` or `Indicator`.

You can use the following functions in the Show properties of Alfabet queries:

Function	Description
`MIN`	Return the minimum of a set of values (Only works with numeric values - `Real` or `Integer`)
`MAX`	Return the maximum of a set of values (Only works with numeric values - `Real` or `Integer`)
`SUM`	Return the sum of a set of values (Only works with numeric values - `Real` or `Integer`)
`AVG`	Return the average of a set of values (Only works with numeric values -`Real` or `Integer`)
`COUNT`	Return the number of references

The result will be grouped by all properties not aggregated.

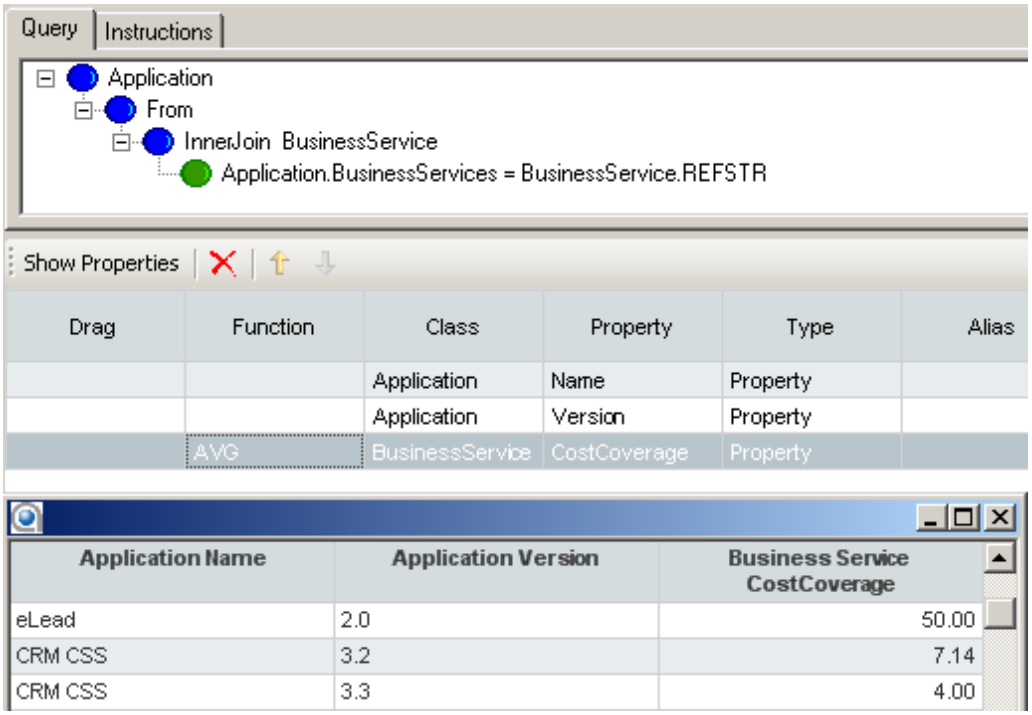
For example, an Alfabet query shall show the average of cost coverage values of all business services assigned to an application. If you define the Show properties for the Alfabet query to show the name and version of the application and the cost coverage values of the assigned business services, you will get the following report (the Alfabet query and the report are displayed in the following figures):

Show Properties

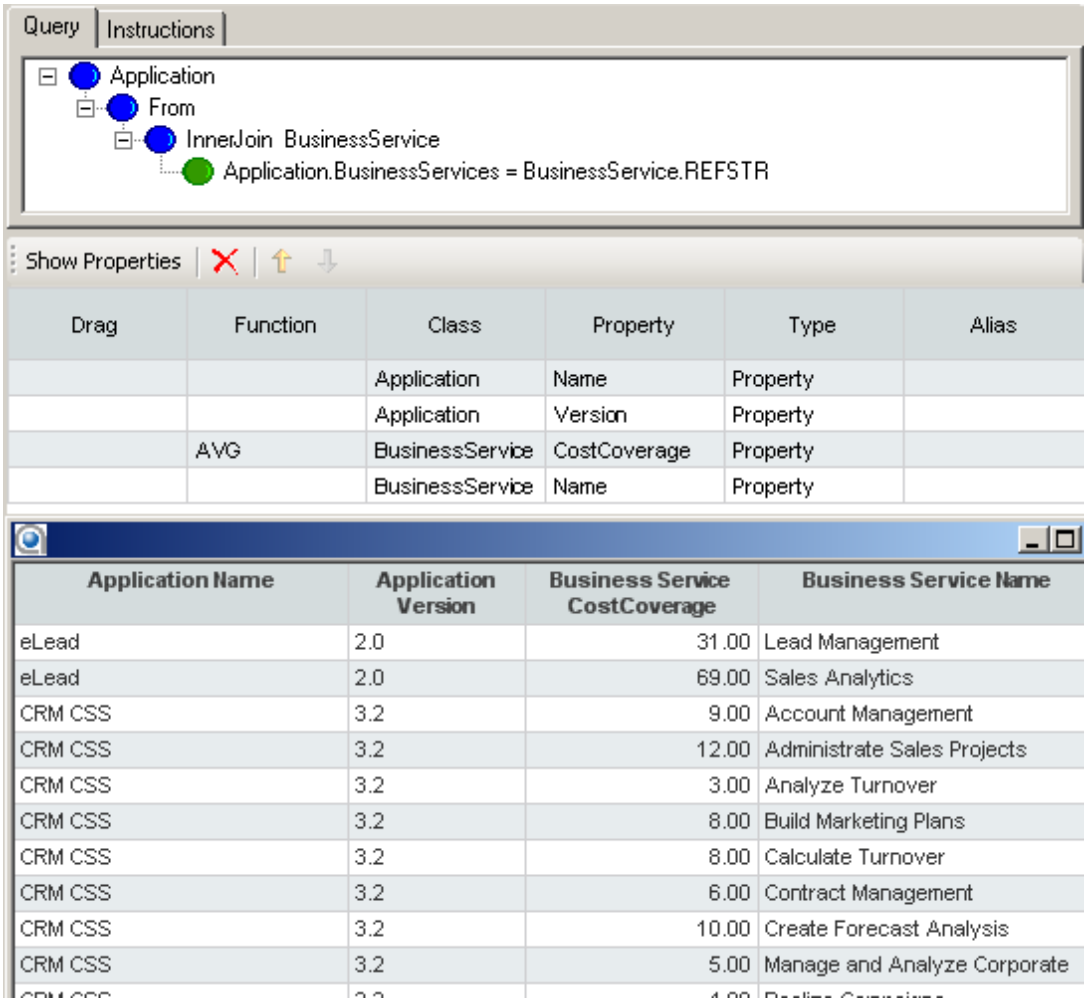
Drag	Function	Class	Property	Type
		Application	Name	Property
		Application	Version	Property
		BusinessService	CostCoverage	Property

Application Name	Application Version	Business Service CostCoverage
eLead	2.0	31.00
eLead	2.0	69.00
CRM CSS	3.2	6.00
CRM CSS	3.2	9.00
CRM CSS	3.2	12.00
CRM CSS	3.2	3.00
CRM CSS	3.2	8.00
CRM CSS	3.2	8.00
CRM CSS	3.2	10.00
CRM CSS	3.2	5.00
CRM CSS	3.2	4.00

To display the average cost coverage value per application, you must define in the Show properties that the function `AVG` is applied to the Show property `BusinessService.CostCoverage`. The report now displays one row for each application that displays the name and version of the application and the average cost coverage of the business services:



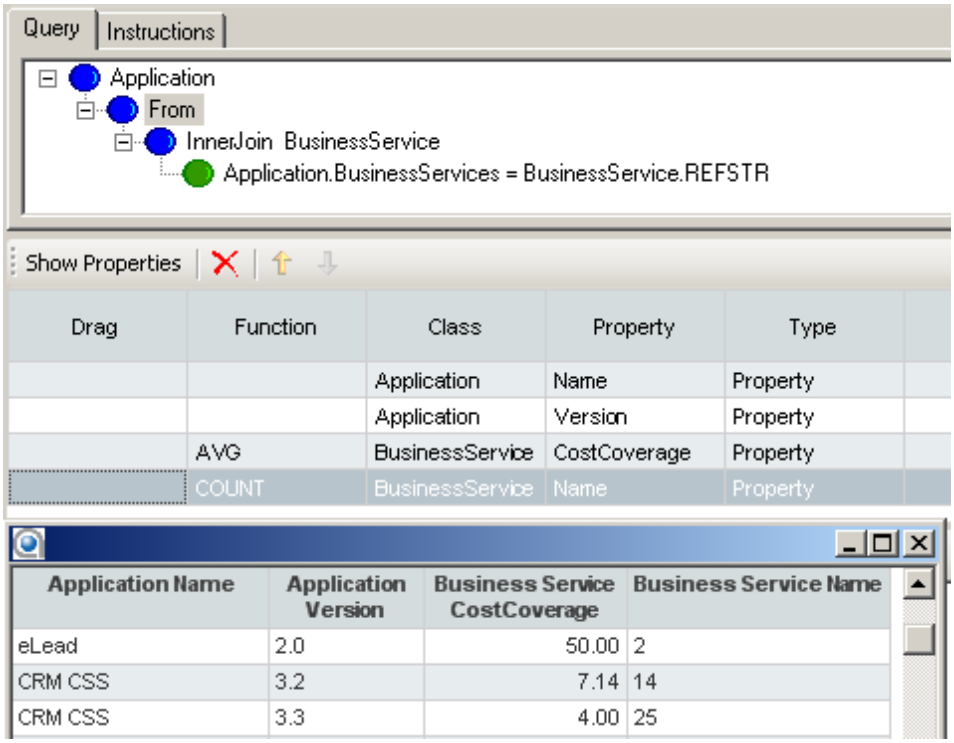
To see the average of the defined cost coverage values, you must make sure that no other properties of the business services are defined in the Show properties. If, For example, the report shows the name of the business service as well as the cost coverage values, a separate result row is displayed for each business service of the application to include the business service name in the report. Although the `AVG` function was assigned on the business service cost coverage, the function cannot be executed:



Drag	Function	Class	Property	Type	Alias
		Application	Name	Property	
		Application	Version	Property	
	AVG	BusinessService	CostCoverage	Property	
		BusinessService	Name	Property	

Application Name	Application Version	Business Service CostCoverage	Business Service Name
eLead	2.0	31.00	Lead Management
eLead	2.0	69.00	Sales Analytics
CRM CSS	3.2	9.00	Account Management
CRM CSS	3.2	12.00	Administrate Sales Projects
CRM CSS	3.2	3.00	Analyze Turnover
CRM CSS	3.2	8.00	Build Marketing Plans
CRM CSS	3.2	8.00	Calculate Turnover
CRM CSS	3.2	6.00	Contract Management
CRM CSS	3.2	10.00	Create Forecast Analysis
CRM CSS	3.2	5.00	Manage and Analyze Corporate

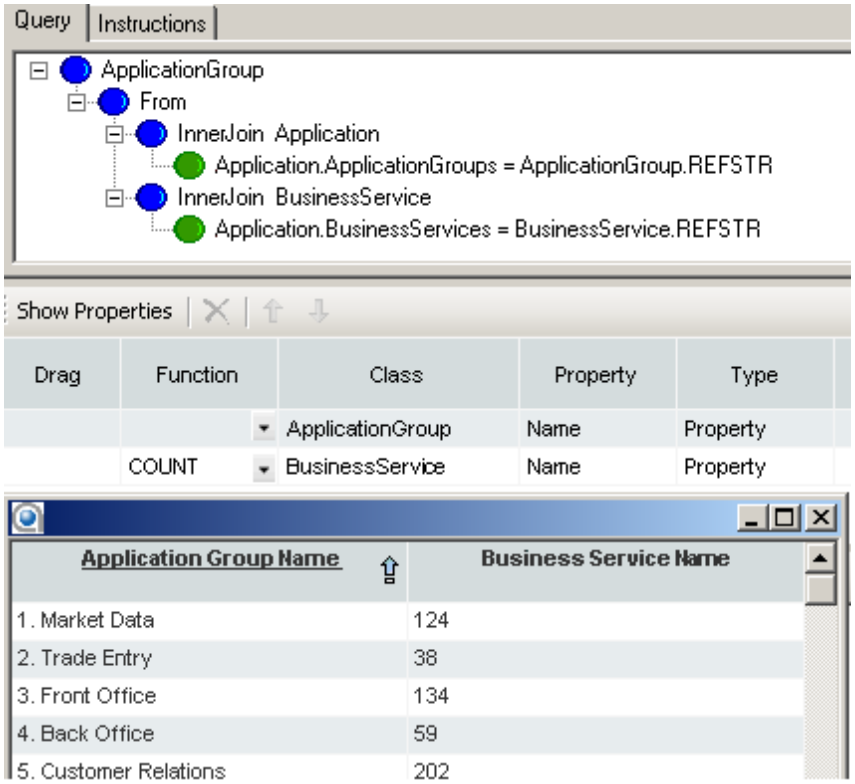
To see a report that not only shows the average cost coverage, but also the number of business services for which the average was calculated, you must include the business service name as Show property, but assign the `COUNT` function to it:



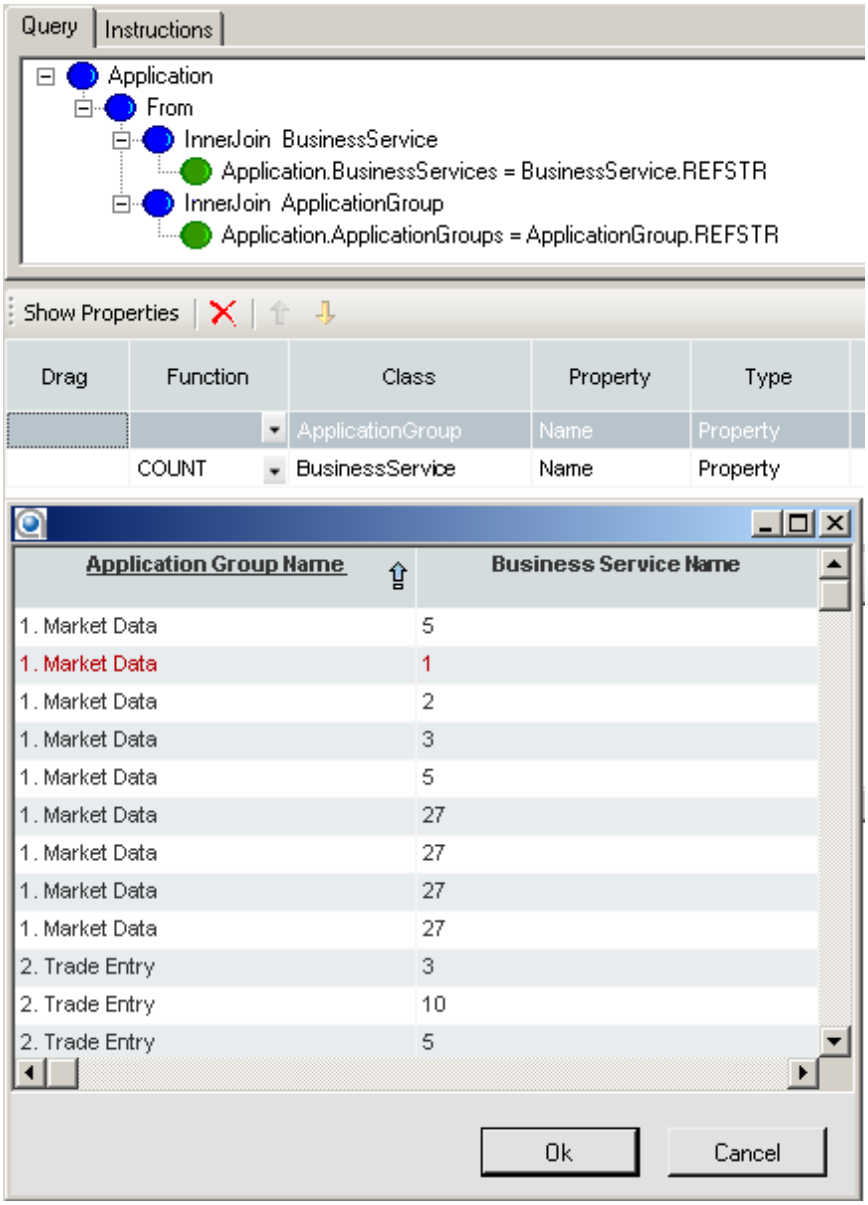
You have to take the following into account when using aggregation functions in queries with multiple `JOIN`s:

- Grouping is always performed on the `FIND` class. There is at least one row in the report for each object of the `FIND` class.
- The show properties must be limited to properties of the base class and the aggregated property.

To display the number of business services provided by all applications in an application group, the class `ApplicationGroup` must be specified as the `FIND` class of the report because values are to be aggregated per application group. One `JOIN` is defined to specify the relation between the application groups and the applications, and one `JOIN` is defined to specify the relation between the applications and the provided services. Show properties are limited to the application group name and a `SUM` over the business service name. The report now displays one row for each application group that displays the name of the application group and the number of business services provided by the applications in the application group:



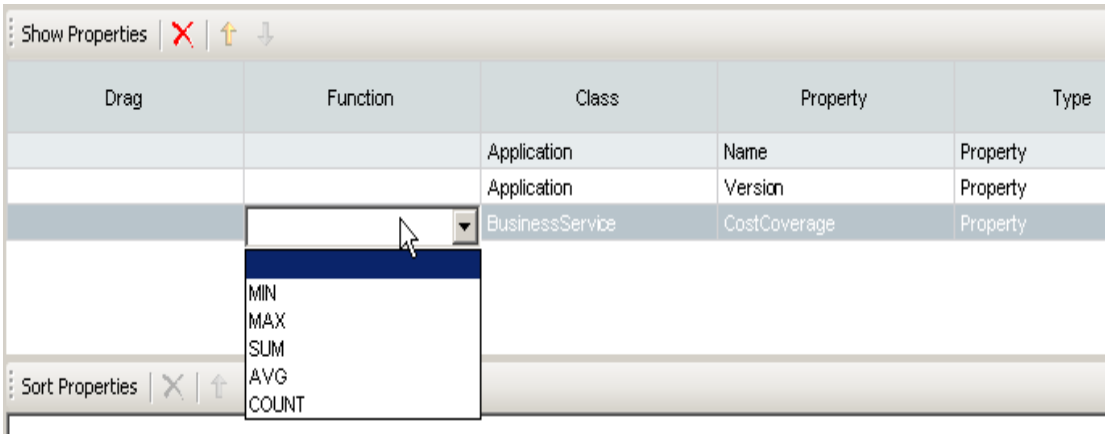
If you specify `Application` as `FIND` class and `JOIN` both application groups and business services to the `FIND` class, the results will not be as expected. Although only the name of the application group and the number of business services are displayed, the report contains one row for each application in an application group and the aggregated sum of business services in each row is the number of business services per application. In the example, the report is sorted by application group name to highlight this effect.



The same output will result from an Alfabet query for that `ApplicationGroup` is correctly defined as the `FIND` class, but object class properties of the object class `Application` are included in the Show properties. Aggregation is only performed on rows that are identical in all properties displayed in addition to the aggregated property. The values for application name and version are different for each application in an application group. An aggregation is performed on the level of applications instead of application groups.

To assign a function to a Show property in the **Alfabet Query Builder**:

1) In the **Show Properties** section, click the **Function** cell of the Show property to which you want to assign a function and select the function in the drop-down menu.



To assign a function to a Show property in the Alfabet query language, add the XML attribute `Function=" FunctionName "` to the `ShowProperty` XML element of the Show property that you want to assign the function to:

```
<ShowProperty ClassName="BusinessFunction" Name="CostCoverage"
Function="AVG"/>
```

In the alternative specification of Show properties in `SHOW` clauses, the function is specified in the `SHOW` clause with the prefix `AQL_`:

General syntax:

```
SHOW AQL_FUNCTION(ObjectClassName.PropertyName)
```

Example:

```
SHOW Application.Name Application.Version
AQL_AVG(BusinessService.CostCoverage)
```

The query syntax `AQL_<PROPERTY>` is reserved for Alfabet queries and may not be used as a name for custom properties.

Defining Native SQL Queries

Some queries defined to configure Alfabet can be defined in native SQL instead of using the Alfabet query language. For more information about the context in which native SQL can be used, see the table in the section Defining Queries.

You should have a general knowledge of native SQL. For general information about how to built a native SQL query consult the relevant publications on SQL. This section is limited to specific information that is only relevant for the use of native SQL in configurations in Alfabet:

- O/R Mapping Information Relevant for SQL-Based Access
- General Rules for the Specification of Native SQL for Alfabet
  - Allowed Query Types
  - Definition of the SELECT Clause

- Definition of Conditions
- Using Alfabet Parameters
  - Using the Alfabet Parameter CURRENT_MANDATE in Native SQL
- Using Native SQL in Combination with Alfabet Instructions
- Displaying Translated Object Data In the Current Language of the User Interface
- Defining Native SQL in XML Elements

- Special Rules for the Specification of Native SQL in the Context of Alfabet Configurations

O/R Mapping Information Relevant for SQL-Based Access

The name of the database table is specified by the **Tech Name** attribute of the object class. The names of the columns in the table are specified by the **Tech Name** attributes of the object class properties of the respective object class. For most standard Alfabet object classes and properties, the **Tech Name** is identical to the **Name** attribute of the object class or property. All **Tech Name** attributes are stored in upper case letters in Alfabet (<TECHNAME>).

If the technical name derived from the object class name conflicts with keywords reserved for the relational database management system (`RDBMS`) of the Oracle or Microsoft SQL Server, the **Tech Name** will be written with a prefix "T_" for tables of object classes and a prefix "A_" for columns representing attributes.

Reserved keywords are different for Oracle® and Microsoft® SQL® relational database management systems. Therefore, the migration of a Alfabet database between these environments may fail due to conflicts between the **Tech Name** attribute and the reserved keywords of the new relational database management system. Before the migration process is executed, the **Tech Name** specifications must be checked for keywords reserved for the new relational database management system and altered, if necessary.

For custom attributes defined by your company with the tool Alfabet Expand, the **Tech Name** attribute must be explicitly defined. Otherwise database migration procedures will not work. For more information about defining the **Tech Name** attribute, see the section Configuring Custom Properties for Protected or Public Object Classes in the reference manual *Configuring Alfabet with Alfabet Expand*.

When the **Support Data Translation** attribute is set to `True` for a language definition in Alfabet, the `Name` and `Description` properties of the objects in the database can be translated to the language culture. When a property is translatable, the translation is written to the database table column "<property tech name>_<language code>"

	REFSTR	INSTGUID	ID	NAME	NAME_1031	DES
▶	76-2518-0	117F79F6CC694...	APP-2518	Business EAI Pla...	*NULL*	*NULL*
	76-2525-0	C88B1BFE80A24...	APP-2525	Groupware Servi...	*NULL*	*NULL*
	76-2538-0	9447219E743F4...	APP-2538	Mafo-Portal	*NULL*	*NULL*

FIGURE: Section of a database table for applications with column headers specified with the TECHNAME property

The `REFSTR` property is a unique internal object ID that explicitly identifies each object in the database and is used for references between objects in the database.

The REFSTR property shall not be used in queries to identify single objects. Instead, it is recommended that you use unique key attributes such as an object's name and version. If you archive a database and restore the archive in another database, the REFSTR property of single objects may change. This is not affecting references between objects. References are automatically adapted to the new REFSTR scheme.

Data for the Alfabet property types Text (For example, object descriptions, attributes of the type StringArray) and Date are stored differently in different database servers:

Database	Data type: Text	Data type: Date
Oracle 9/10/11	NCLOB	TIMESTAMP
Microsoft SQL 2005/2008	nvarchar(max)	datetime

These data types may require special handling or possibly may not be queried from a certain reporting tool.

Object class properties of the type ReferenceArray are handled in two different ways dependent of the setting of the attribute **Reference Support** of the object class property:

- If **Reference Support** is set to True, the relations specified by the property are stored in the RELATIONS table. No database column is available for the property in the table of the object itself. The RELATIONS table specifies the relation in the following database columns:
  - FROMREF: The REFSTR value of the object that is referencing another object.
  - PROPERTY: The property of the object specified with FROMREF that defines the relation between the objects.
  - TOREF: The REFSTR value of the referenced object
- If **Reference Support** is set to False, the relations are stored directly in the database table of the object as a string. The REFSTR of all objects referenced by the property are listed whitespace separated.

General Rules for the Specification of Native SQL for Alfabet

For each configuration in Alfabet based on a query you can define a native SQL query instead of an Alfabet query in the respective text editor or input field. All queries starting with ALFABET_QUERY_500 are processed as Alfabet query, all other queries are processed as native SQL queries. There is no header definition required for native SQL.

```
SELECT app.NAME FROM APPLICATION app WHERE app.NAME LIKE 'CRM%'
```

The text editors in Alfabet Expand that allow the definition of a native SQL query have a button **Check**. You can use this button to check the correctness of Alfabet parameter definitions in the native SQL query. The **Check** functionality does not check the general syntax of the native SQL

query. The usage of Alfabet parameters in native SQL is described in the section Using Alfabet Parameters.

The following rules for the definition of native SQL are only relevant when defining the native SQL query in the context of Alfabet:

- Allowed Query Types
- Definition of the SELECT Clause
- Definition of Conditions
- Using Alfabet Parameters
  - Using the Alfabet Parameter CURRENT_MANDATE in Native SQL
- Using Native SQL in Combination with Alfabet Instructions
- Displaying Translated Object Data In the Current Language of the User Interface
- Defining Native SQL in XML Elements

Allowed Query Types

A native SQL query must follow the rules listed below when used in Alfabet configurations:

- Native SQL queries must be defined as ANSI-SQL-92 and no specific driver commands should be used.

  The embedded SQL parser is run in database-specific modes in order to take database-specific SQL syntax into account. The SQL parser will be automatically run in Oracle mode if the Alfabet database is installed on an Oracle® database server and in SQL Server mode if the Alfabet database is installed on a Microsoft® SQL Server®.

- XML extensions provided by the database server are not supported.
- Native SQL queries can be defined for either the selection of data from the Alfabet database for display on the Alfabet interface or for the selection of objects for via a valid configuration. Therefore, only SQL queries with a `SELECT` statement are allowed in the context of Alfabet configurations.

SQL statements that alter the data in the Alfabet database, For example, `DELETE`, `INSERT` or `UPDATE`, are not allowed in the context of Alfabet configurations with the exception of the SQL statements in ADIF schemes. In addition, `UPDATE` statements are allowed in workflow step actions and and wizard step actions.

- SQL queries must start with a `SELECT` or a `WITH` statement to be considered in Alfabet configurations.

  If you use `WITH` statements to built a temporary table within native SQL statements, you should make sure that the table name and all column names of the temporary table are written in lowercase letters only. Uppercase letters can lead to errors with some database server types or configurations.

It is possible to add a comment as first line of a query. All lines that are empty or that are starting with /* or with - are ignored by the check for correct definition of the native SQL query.

- Only one `SELECT` statement can be defined in a native SQL query in the context of Alfabet configurations.
- To use the function `ROW_NUMBER()` in SQL queries defined in the context of Alfabet configurations you must use `CAST` to convert the values to the type `INTEGER`.

  For example, instead of

  ```
  ROW_NUMBER() OVER (ORDER BY value DESC)
  ```

  you have to use

  ```
  CAST(ROW_NUMBER() OVER (ORDER BY value DESC) AS INTEGER)
  ```

- Native SQL queries might not be parsed successfully if a `HAVING` statement is used. If the `HAVING` statement cannot be parsed correctly, it is recommended that you use sub-queries instead of a `HAVING` statement to restrict the results.

  The following query is not correctly parsed:

  ```
  SELECT ou.REFSTR, ou.NAME, ou.STEREOTYPE,
  (SELECT '(' + CAST(COUNT(*) AS VARCHAR(5)) + ')' FROM
  ICTOBJECT icto WHERE icto.OWNER = ou.REFSTR HAVING COUNT(*) >
  0)
  FROM ORGAUNIT ou
  ORDER BY ou.NAME
  ```

  The following query is correctly parsed. It returns the same dataset without using the `HAVING` statement in the query:

  ```
  SELECT ou.REFSTR, ou.NAME, ou.STEREOTYPE,
  (SELECT '(' + CAST(value AS VARCHAR(5)) + ')'
  FROM (SELECT COUNT(*) AS value FROM ICTOBJECT icto WHERE
  icto.OWNER = ou.REFSTR) x
  WHERE x.value > 0)
  FROM ORGAUNIT ou
  ORDER BY ou.NAME
  ```

- `FOR XML PATH` cannot be used in SQL queries in the context of Alfabet configurations.
- Values for object class properties of the data type `REAL` are stored as database data type `FLOAT` in the Alfabet database. Independent from the database storage type, real values can be added for display in configured reports based on native SQL queries using the data types `real`, `float(53)` and `float(24)`.

Definition of the SELECT Clause

The SELECT clauses are used to build a result table that is then used as a basis for the following technical processes. Each property defined in the SELECT clause is one column in the resulting report table. The Alfabet software reads the result table to evaluate the data required to execute the process for which the query was defined. Therefore, the caption and order of the columns in the report is crucial for the execution of the functionality in which the query is involved. The required order and caption of report columns is described in the context of the documentation of the relevant functionality.

In Alfabet, the evaluation of SELECT clauses differs from the interpretation by SQL parsers. When defining the native SQL query, you must take into account that your result table is subject to the following changes:

- The first column of the result set is not displayed in the query results. It must specify the REFSTR of the object class selected for further processing by Alfabet components.

  If you configure a customer configured report of the type NativeSql and you do not want users to navigate to objects from a report, you can specify NULL as first column instead of the REFSTR of an object class. The first column is then ignored and navigation to objects from the report is disabled.

  NOTE: All but the basic functionality to display the query results in a table is disabled when the REFSTR is not specified in the first column of the SELECT clause. In other words, features like expandable report tables and the display of results in standard Alfabet report formats cannot be used.

- Names of database columns and database tables in the Alfabet database must be written in upper case letters in native SQL queries while names of temporary tables resulting from WITH statements must be written in lower case letters. The database table and column names are defined by the attribute **Tech Name** of the object class or object class property. The value of attribute is not necessarily identical with the value of the **Name** attribute of the object class or object class property.

- When no alias is specified for a column header in the SELECT clause, the property name is used as a column header. If two properties have the same name, the column headers in native SQL have the same name too. For example, if you display the NAME of applications and the NAME of local components, both column headers are named "NAME". When specifying native SQL in the context of Alfabet, two column headers with the same name are not allowed. It is recommended that you specify an alias name for the columns. If you do not specify an alias, the first column is given the name of the property and the following column headers are named <property name><number>, which will result in NAME1 for the second column header in the example.

- If the Alfabet database is located on an Oracle database server, the following Oracle specific requirements apply:

  - Numeric values are treated as integers regardless of the data type of the data in the database if no precision (the total number of digits both left and right of the decimal point) and scale (the number of digits on the right of the decimal point) are defined via a CAST statement. For example, to return a decimal number with a precision of 10 and a scale of two, the following CAST statement is required:

    ```
    CAST(ClassTechName.PropertyTechNameAS DECIMAL(10,2)) AS A_VALUE
    ```

- Column headers of the query result set are all converted to all upper-case letters if not written into inverted commas. In Alfabet, column headers of the query result set are often used for further processing and must meet specific output formats. Although in most cases the Alfabet components

adapt to this database condition, it is recommended that you either write alias names in inverted commas or only use upper-case letters in your alias specifications.

Definition of Conditions

Please note the following about the definition of `WHERE` conditions in native SQL in the context of Alfabet configurations:

- It is recommended to use the prefix `N` in `WHERE` conditions performing a string comparison. The `N` prefix ensures that the string is not converted into the character set as specified through the collation of the database. This is of special relevance for databases with a collation defining a character set not corresponding to Latin-1.

  For example,

  ```
  WHERE APPLICATION.STEREOTYPE=N'Technical Application'
  ```

- Please note that properties of the data type boolean can have three values:
  - `0` = the value is set to false
  - `1` = the value is set to true
  - `Null` = the value is not set

For boolean properties that are not configured to be mandatory, `WHERE` conditions must be formulated to take all three settings into account.

- Alfabet parameters can be used in `WHERE` conditions to base a comparison on a return value from a filter field or from the current environment, For example, the object the user is currently working with. For more information see Using Alfabet Parameters.

Using Alfabet Parameters

The Alfabet query language allows the specification of parameters for the following use cases:

- A set of specified parameters is available that refer to the current conditions in the Alfabet interface (For example, the object the user is currently working with or the user executing the configured report). Specified environment parameters can be used in `JOIN`s and `WHERE` clauses and `SELECT` statements for building temporary tables. For information about Alfabet parameters that refer to the current working environment, see Referring to the Current Alfabet Context in a WHERE Condition.

  The parameter `@BASE` corresponds to the `REFSTR` property of the current object and the parameter `@CURRENT_USER` refers to the `REFSTR` property of the current user. Therefore, parameters cannot be used to find single properties of the current object or user. Constructs like `@BASE.NAME`, to get the name of the current object, are not valid. On the other hand, the parameter can be used as a target for a reference without specifying the object class of the current object in the Alfabet query. For example, when a query shall display all applications in the domain the user is currently working with, the native SQL query is defined without adding the class `Domain` as:

  ```
  SELECT app.REFSTR, app.NAME
  ```

```
FROM APPLICATION app
WHERE app.DOMAIN = @BASE
```

The parameter is substituted at runtime with the `REFSTR` of the current application group. For example,:

```
SELECT app.REFSTR, app.NAME
FROM APPLICATION app
WHERE app.DOMAIN = '95-07-0'
```

- If the query output is a configured report, you can allow the user to specify the conditions for the report output by defining `WHERE` conditions with Alfabet parameters. If the condition value of the `WHERE` condition is an Alfabet parameter, that is any string starting with a @, a filter is created for the report that allows the user to define the value for the `WHERE` condition. The technical name of the filter is the string defined as Alfabet parameter. The kind of filters resulting from combinations of data types and operators differs between native SQL and the Alfabet query language. An specific overview of how to generate filter fields with native SQL is given in the section Defining Filters for Configured Reports and Selectors.

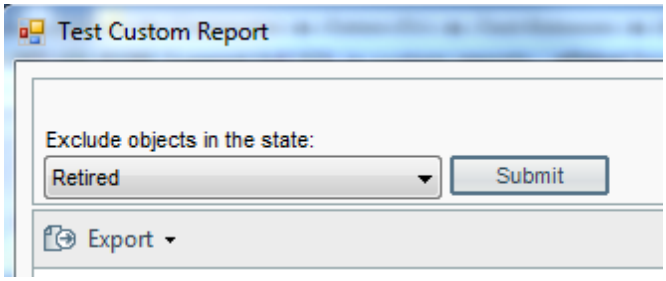
  After filter fields have been created, you should check that the automatically evaluated **Value Type** setting derived from the query data is matching the required setting of the filter field specified in the section Defining Filters for Configured Reports and Selectors. If the automatic evaluation failed, the filter field will not work.

- If the query output is a configured report with different layers referencing each other, the Alfabet parameter `@BASE` is used to refer to the object specified by the query in the parent layer. This is the case for most graphic representations in configured reports of the type `Custom`. For example, a layered diagram may show domains in one layer and applications assigned to the domains in the second layer. The parameter `@BASE` corresponds to the `REFSTR` of an object. Therefore, the native SQL query defining the parent layer must be defined with the `REFSTR` property of the object as the first column. As the first column is not displayed in the results, the definition of the `REFSTR` as first statement in the `SELECT` clause has no effect on the graphic output.

- For configured reports based on native SQL queries, the setting for **Show Retired Objects** in the users personal settings is ignored. This setting allows the user to decide whether objects that are in the object state `Retired` are displayed in report results. You can allow the user to decide about the display of retired objects per native SQL based report by creating a filter that allows to display all objects that are not in a defined object state. For example,:

  ```
  SELECT app.REFSTR, app.NAME, app.VERSION, app.STARTDATE
  FROM APPLICATION app
  WHERE app.OBJECTSTATE != @ExcludeState
  ```

This query generates a combo-box that allow the user to select an object state. Selection of an object state limits the display of objects in the report to objects that are not in the selected state. The caption of the filter field be changed to reflect that fact:



You can use the Alfabet parameters in the definition of `JOIN`s and `WHERE` clauses and `SELECT` statements for building temporary tables when defining a native SQL query for Alfabet. On execution of the native SQL query, an internal SQL parser will resolve the Alfabet parameter and generate a pure native SQL query resulting in the desired output.

Alfabet parameters are written as follows:

```
@ParameterName
```

This differs from the syntax in Alfabet query language, where parameters can also be written with a colon followed by the Alfabet parameter name.

For example,:

```
SELECT ag.REFSTR, ag.NAME
FROM APPLICATIONGROUP ag
WHERE ag.BELONGSTO = @BASE
```

finds all application groups subordinate to the application group the user is currently working with.

```
SELECT app.REFSTR, app.NAME, app.VERSION, app.STARTDATE
FROM APPLICATION app
WHERE app.NAME = @Name
```

The query creates a report table with a filter field that has the technical name **Name** and allows the user to specify search conditions for the name of the applications that shall be displayed in the report.

When resolving the Alfabet parameter on execution of the query, the SQL parser checks whether the value type of the return value is correct. This check restricts the definition of the native SQL query. For example, you may not use any function that leads to a change of the Alfabet parameter value type or want to compare the Alfabet parameter return value with a value from a temporary table in your native SQL query. You can disable the check by starting the parameter name with `NSQL_`:

```
@NSQL_ParameterName
```

For example,:

```
SELECT app.REFSTR, app.NAME
FROM APPLICATION app
WHERE EXTRACT(YEAR FROM STARTDATE) = @NSQL_year
```

finds all applications with a start date laying within the year that is defined in a filter field. Without the NSQL prefix, the SQL parser would throw an error because a data value type DateTime is expected as a compare value for STARTDATE.

Please note the following:

- When a filter field is generated based on an Alfabet parameter setting in a query of a configured report or a custom selector, the value type check is required to generate the correct type of filter field. If the NSQL_ prefix is used, no check of value type is performed which may result in a wrong type of filter field to be generated. The filter field must then be edited manually to correct the type.
- If Alfabet query language parameters are used in the SELECT statements for building temporary tables, the data type cannot be checked. A CAST statement is required at least for parameters of type DateTime to define the data type.

If no value is returned for a parameter, the following applies:

- In WHERE clauses, the WHERE condition containing the parameter is removed from the query.
- In EXIST statements and IsNULL or IN conditions, the removal of the part containing the parameter can lead to unexpected results. It is Therefore, recommended to add an alternative condition for each WHERE statement containing a parameter that will provide the correct result if the parameter has been removed.

For example, the following query returns true in case a 1=1 condition is added or false if a 1=2 condition is added:

```
SELECT dem.REFSTR, dem.ID, dem.NAME, dem.STATUS,
dem.CLASSIFICATION

FROM DEMAND dem

WHERE EXISTS(SELECT *

    FROM SCF_SplitString(dem.CLASSIFICATION,
    CHAR(13)+CHAR(10)) part

    WHERE part.value IN (@NSQL_ClassFilterOR) AND 1=1)

OR (SELECT COUNT(*)

       FROM SCF_Enum('DemandClassification') part

       WHERE part.VALUE IN (@NSQL_ClassFilterAND) OR 1=2)

    =

    (SELECT COUNT(DISTINCT value)

       FROM SCF_SplitString(dem.CLASSIFICATION,
       CHAR(13)+CHAR(10)) part

       WHERE part.value IN (@NSQL_ClassFilterAND) OR 1=2)
```

The text editors in Alfabet Expand that allow native SQL queries to be defined have a button **Check**. You can use this button to check the correctness of Alfabet parameter definitions in the

native SQL query. The **Check** functionality does not check the general syntax of the native SQL query.

The following information is available:

- Using the Alfabet Parameter CURRENT_MANDATE in Native SQL

Using the Alfabet Parameter CURRENT_MANDATE in Native SQL

The Alfabet parameter `CURRENT_MANDATE` returns the mandate mask resulting from the current mandate settings the user is logged in with. When using the Alfabet parameter in native SQL query language, you must take into account the way mandate masks are defined and compared in Alfabet.

The assignment of objects to mandates is stored in the database column `MANDATEMASK` in the database tables for all object classes that can have mandates in the Alfabet database. The mandate mask is an integer that represents a bit string calculated based on the number and kind of mandates assigned to an object.

When a company specifies a new mandate, an object of the class `ALFA_MANDATE` is created. Each mandate has an `ID` property. The `ID` is automatically assigned to the new mandate. The `ID` is a running number starting with 1 that defines the position of the mandate in the bit string of the mandate mask.

The mandate mask consists of one bit for each mandate. When the object is assigned to a mandate, the bit on the position of the mandate in the mask is set to 1. If the object is not assigned to a mandate, the bit on the position of the mandate is set to 0. The first bit in the bit string (the position 0) is set to 1 if the object is not assigned to any mandate. For objects assigned to a mandate, the first bit in the bit string is set to 0.

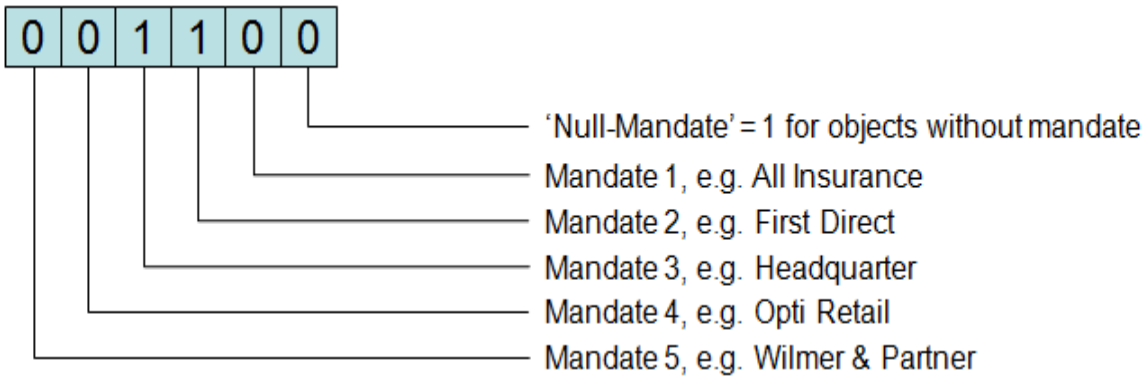


FIGURE: Example of a mandate mask in a configuration with 5 mandates. The object is assigned to mandate 2 and 3.

To evaluate whether an object is visible to a user, the mandate mask of the object is compared bit-wise with a mandate mask generated from the mandate settings of the current user.

When the mandate-related access permissions for an object are evaluated, the mandate mask of the current object is compared with the mandate mask of the current mandate that the user is logged in with. This mandate mask consists of one bit for each mandate. The bit on the position of the current mandate and the first bit in the bit string is set to 1.

The mandate mask generated to evaluate the current access permissions of the user is not identical to the mandate mask of the user stored in the property `MANDATEMASK` of the object class `Person`. The mandate mask stored with the property `MANDATEMASK` defines the access permissions for other users to the data about the user stored in the Alfabet database. The current user

mandate mask generated to evaluate access permissions is not stored in the database but generated during evaluation of access permissions as a parameter describing the current environment.

During evaluation of access permissions, the current user mandate mask and the object mandate mask are compared bitwise. If the bit on a position is 1 for both object and user, the resulting bit on the position is 1. If either the user or the object or both has a bit value of 0, the bit on the position is set to 0.

The result is a bit string representing an integer. If the bit string contains at least one bit set to 1, the resulting integer is higher than 0 and the object is visible to the user.

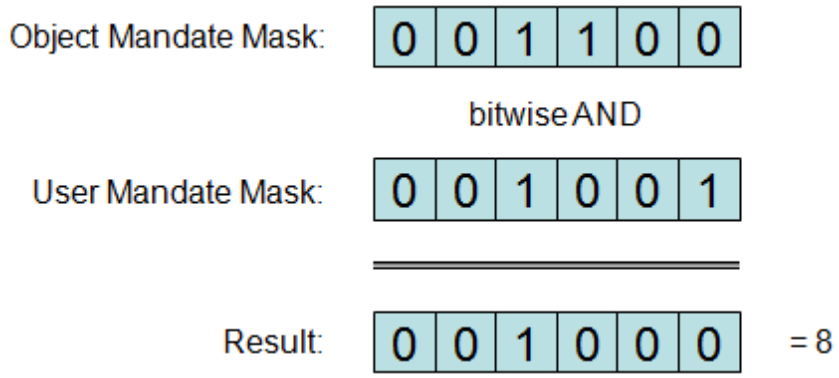

FIGURE: Calculation of the permission to an object based on the mandate masks of the current user mandate and the object

The Alfabet parameter `CURRENT_MANDATE` returns the current user mandate mask. You can use the parameter in native SQL to compare the bit strings of the current user mandate mask with the `MANDATEMASK` of the current object. For example, to show a list of all applications the current user can access with his/her current mandate settings, the query can be defined as:

```
SELECT app.REFSTR, app.NAME + ' ' + app.VERSION AS 'With your current
mandate, you have access to these application objects:'

FROM APPLICATION app, PERSON user

WHERE usr.REFSTR = @CURRENT_USER

AND (bitand(app.MANDATEMASK,@CURRENT_MANDATE)<>0)
```

To list all applications a user can access with any of the mandates assigned to him/her, the Alfabet parameter `CURRENT_MANDATE` is not suitable. Instead, the native SQL query must compare the `MANDATEMASK` property of the objects with the mandate settings of the user that are defined by a reference array with the property `MANDATES` of the object class `PERSON`. To show a list of all applications that the current user can access with any of the mandates assigned to him/her, the native SQL query can be defined as:

```
SELECT app.REFSTR, app.NAME + ' ' + app.VERSION AS 'According to all
your mandates combined, you have access to these application
objects:'

FROM APPLICATION app, PERSON user

WHERE usr.REFSTR = @CURRENT_USER

AND 0 <>app.MANDATEMASK &

    (
```

```
SELECT ISNULL(SUM(POWER(2,m.ID)),0)+1
FROM ALFA_MANDATE m
WHERE (usr.MANDATE_MASTER=1
    OR EXISTS(SELECT *
    FROM RELATIONS
    WHERE FROMREF=usr.REFSTR
    AND PROPERTY = 'MANDATES'
    AND TOREF=m.REFSTR))
)
```

Using Native SQL in Combination with Alfabet Instructions

This feature is only relevant for configured reports of the type `Custom` that are based on a template or configured reports of the type `NativeSQL`. These configured reports allow the definition of Alfabet instructions in combination with native SQL queries for the following purposes:

- To build a configured report with an expandable table. The grouping of results and the display of results as expandable table parts is based on instructions for column handling. For more information about building expandable table reports, see the section Grouping Query Results in Expandable Reports in the chapter Defining Queries.
- To specify the output format, For example, for date and time information.
- To specify the coloring of a table cell.
- To change the name or header caption of a table column.

These Alfabet instructions must be defined in Alfabet query language even if the query itself is written in native SQL. Therefore, Alfabet provides a separate tab for the definition of instructions in the text editor of the native SQL report and a separate field in the row and column definition tabs of the Alfabet report assistance of template-based matrix reports.

Alfabet instructions defined within an Alfabet query are built on basis of the Show properties of the Alfabet query. If the query is written in native SQL, the instructions refer to the definitions in the `SELECT` clause.

When defining native SQL queries in the context of the configuration of Alfabet, the first column of a result set is not displayed in the query results. (For more information, see the section Definition of the SELECT Clause). This applies to the result set after execution of the Alfabet instructions. The following order of execution of a native SQL query must be taken into account when defining the native SQL query:

- Alfabet -specific parameters in the Alfabet query are translated to corresponding native SQL code and a result set is created. (For information on parameters, see the section Using Alfabet Parameters.)
- Alfabet instructions are executed on the result set. This may influence the availability and display of columns in the result table.
- The first column in the result table after execution of instructions is not displayed.

For information about how to write instructions and the effect of instructions on the result table of configured reports, see the section Using Instructions to Format the Results of an Alfabet or Native SQL Query.

Displaying Translated Object Data In the Current Language of the User Interface

Some predefined protected properties and custom properties of the type `String` and `Text` can be translated to the secondary languages for which data translation is enabled in the cultures.

For more information about object data translation, see the section Configuring the Translation of Object Data in the chapter Localization and Multi-Language Support for the Alfabet Interface.

For configured reports of the type `Query` the translated object data is automatically displayed in the report in the language currently displayed in the user interface. For native SQL queries the change to the current language must be explicitly configured within the native SQL query. This applies to configured reports and all other configurations of the display of values on the Alfabet user interface based on native SQL, like For example, value controls in object cockpits.

The following configuration is required:

- The code `/*CULTURE_CODE*/` must be added after the object class property specification in the native SQL query.
- In `SELECT` statements, an alias must be defined for the column name of the dataset column containing the translated values.
- The object class property value is displayed automatically in the language currently selected for display of the Alfabet user interface.

If no data translation is configured for the current language for rendering the interface, the culture code setting will be ignored and the original language is used for display of results.

If the current languare for rendering the interface is configured to provide data translation, but no translation is provided, the respective cell in the result dataset is empty. To fall back to the original language if no translation is provided, the query should be defined with a condition that checks whether the translation is empty and displays the original language if applicable. For example,: `ISNULL(APPLICATION.NAME/*CULTURE_CODE*/, APPLICATION.NAME) AS NAME` as column definition in the `SELECT` statement. This is also relevant for specification of conditions refering to filter fields that may return values in either original or current language.

The following query defines a dataset that displays the name and description of applications in the current language with a fallback to the original language. A `WHERE` condition refering to a filter field is also added:

```
SELECT app.REFSTR, ISNULL(app.NAME/*CULTURE_CODE*/, app.NAME) AS
NAME, ISNULL(app.DESCRIPTION/*CULTURE_CODE*/, app.DESCRIPTION) AS
DESCRIPTION

FROM APPLICATION app

WHERE ISNULL(app.NAME/*CULTURE_CODE*/, app.NAME) LIKE @QUERY
```

Defining Native SQL in XML Elements

The configuration of some functionalities for Alfabet requires the definition of queries in XML objects. For example, this applies to the definition of treemap and layered diagram reports, the full-text search index and the rule-based access permissions.

The native SQL is then defined as value of an attribute of the relevant XML element.

```
<Query
   Class="Application"
   Query="SELECT app.NAME FROM APPLICATION app WHERE app.NAME LIKE
   'CRM%'"/>
```

You have to take the following into account to specify a native SQL query in an XML element.

- When the Alfabet query contains special characters (For example, a greater then (>) or lesser then (<) symbol) in the `WHERE` clause, you have to replace it with the HTML code for angle brackets:
  - > for >
  - < for <
  - " for "
  - [for [
  -] for]

Special Rules for the Specification of Native SQL in the Context of Alfabet Configurations

Depending on the configuration, you must take the following into account when specifying a native SQL query:

Feature	Query Defined In	Special Requirements
Configured reports of the type `NativeSQL`	text editor available via the attribute **Query as Text**	Alfabet instructions and parameters for the creation of filter fields can be used with the query. Alfabet parameters for referring to the current working environment can be used in the query. `WITH` statements are allowed to build complex queries. For information about the definition of configured reports of the type `NativeSQL`, see Creating a Tabular Configured Report of the Type NativeSQL.
Template-based configured reports of the type `Custom`	text input fields of the report assistant for query definition. Instructions must be defined in a separate text input field.	Alfabet instructions and parameters for the creation of filter fields can be used with the query. Alfabet parameters for referring to the current working environment can be used in the query.

Feature	Query Defined In	Special Requirements
		`WITH` statements may be used to build complex queries. For information about the definition of template based configured reports of the type `Custom`, see Creating a Graphic Report and Creating Configured Reports With Editing Capabilities.
Workflow configuration	text editor opening with the respective attribute **Query as Text**	A `SELECT` query with the `REFSTR` of the base object class defined as first `SELECT` argument must be defined. Alfabet parameters for referring to the current working environment can be used in the query. For information about the configuration of workflows, see Configuring Workflows.
Wizard Configuration	text editor opening with the respective attribute **Query as Text**	A `SELECT` query with the `REFSTR` of the base object class defined as first `SELECT` argument must be defined. Alfabet parameters for referring to the current working environment can be used in the query. For information about the configuration of wizards, see Configuring Wizards.
Access permission rules	XML object ***RightsManager***, attribute `Query` of the element ***RightsRule***	A `SELECT` query with the `REFSTR` of the base object class defined as first `SELECT` argument must be defined. Alfabet parameters for referring to the current working environment can be used in the query. The special requirements for Defining Native SQL in XML Elements apply. For more information about access permission rules, see Configuring Permission Rules for Access to Objects.
Computation rules	**Queries** tab of the editor **Computation Rule** via the user interface.	A `SELECT` query with one argument only that defines a property of the value type double or integer. The result of the query must correspond to a configured report with one column and one row. Native SQL queries must start with a `SELECT` statement to be executed in computation rules.

Feature	Query Defined In	Special Requirements
		Alfabet parameters for referring to the current working environment can be used in the query. For information about computation rules, see the chapter *Specifying Computation Rules for Indicator Types* in the reference manual *Configuring Evaluation and Reference Data in Alfabet*.
Color Rules	**Queries** tab of the editor **Color Rule** via the user interface. In the editor, queries must be defined within an XML object.	A `SELECT` query with the `REFSTR` of the base object class defined as first `SELECT` argument must be defined. The special requirements for Defining Native SQL in XML Elements apply. For information about color rules, see the chapter *Configuring Color Rules for Map Views and Diagram Views* in the reference manual *Configuring Evaluation and Reference Data in Alfabet*.
Consistency Monitors	**Query** tab of the editor **Consistency Monitor** via the user interface.	A `SELECT` query with the `REFSTR` of the base object class defined as first `SELECT` argument must be defined. The query must find all objects with the inconsistent attributes. The `SELECT` clause defines the object data that is displayed on the **Inconsistent Objects** page view.

Defining Filters for Configured Reports and Selectors

You can allow users to select the output of a report or search selector at runtime by means of filters that you configure. The process for the definition of filters is similar for reports and selectors. The following information focuses on the definition of filters for reports, but the same procedure can be applied to selectors. For more information about the configuration of reports, see the chapter Configuring Reports and for more information about the configuration of search selectors, see the section Configuring a Custom Selector for Search Functionalities.

The definition of filters for configured reports of the type `Query` differ from the general method described in this section and is described separately in the context of the documentation on how to create the report in the section Defining Filters for an Alfabet Query Based Configured Report.

The following steps are required to define filters for a configured report or selector:

- Defining a WHERE Clause that Causes the Generation of a Filter Field in the Report
- Defining Filter Fields in the **Custom Report View** of the configured report or the header panel of the page in the custom selector.
- Test the functionality of the filter fields in the configured report or custom selector.

The following information is available:

Defining a WHERE Clause that Causes the Generation of a Filter Field in the Report

To set a filter for a report or selector, you must configure a `WHERE` clause for the property you want the user to define in the filter field. The `WHERE` clause must be defined as follows:

- When defining the value for the condition, enter @ followed by a technical name of the filter field. The value is not used to search in the property, but rather only to assign a technical name to the filter field.

  An example `WHERE` clause for the generation of a filter field in a native SQL query:

  ```
  WHERE APPLICATION.NAME LIKE @ApplicationName
  ```

  and in Alfabet query language:

  ```
  WHERE Application.Name LIKE @ApplicationName
  ```

- Select a condition operator that allows the specification of a value. For example, `IS NULL` cannot be used for a filter because it does not require the specification of a value whereas, For example, the condition `LIKE` allow the specification of filter fields.

Depending on the data type of the property and condition that you have configured, different type of filter fields may be defined. The filter field types are described in detail in the section Defining Filter Fields.

Note the following when defining filter field name parameters in `WHERE` clauses:

- Queries with filter field name parameters can be defined for all queries in a report, including color rules and indicator rules.
- A filter field value can be used in multiple `WHERE` clauses by defining the same parameter name.
- When a filter field is not filled, the query processing mechanisms of the Alfabet components delete the condition with the filter parameter from the `WHERE` statement before executing the query. For example, the following `WHERE` statement of a native SQL query

```
WHERE APPLICATION.NAME CONTAINS @PARAM
AND APPLICATION.STATUS = 'Plan'
```

is shortened to the following statement before executing the query if the filter field with the name `@PARAM` is not filled:

```
WHERE APPLICATION.STATUS = 'Plan'
```

- In standard Alfabet views and configured reports based on Alfabet queries entries in filter fields are interpreted case insensitive. Filter values passed on to a native SQL query are interpreted case sensitive. To enhance usability it is recommended that the `WHERE` condition of the native SQL query that contains the parameter substituted by the filter field value is designed to enable a case insensitive comparison. This can be achieved by using the UPPER() or LOWER() function:

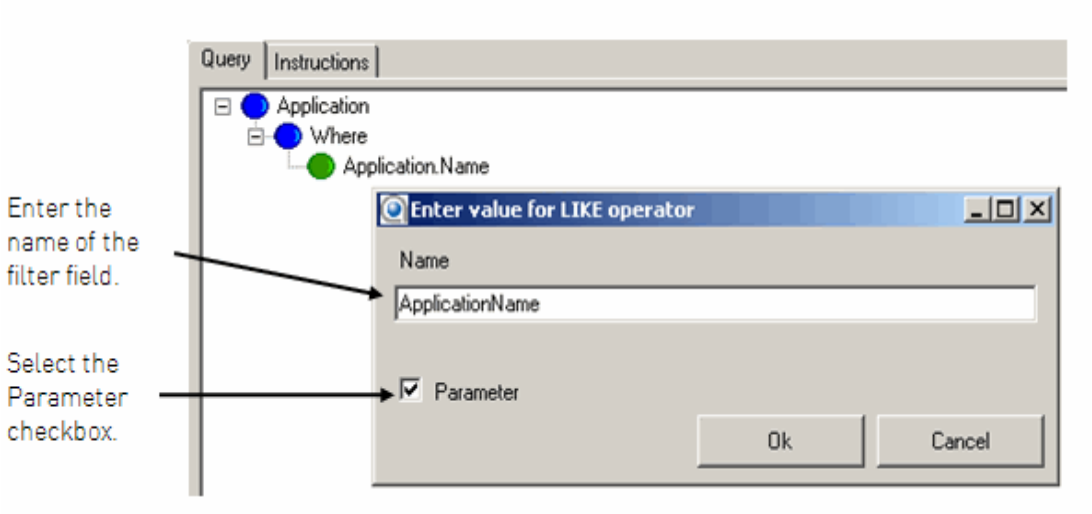
```
WHERE UPPER[APPLICATION.NAME LIKE UPPER(@ApplicationName)
```

- The search behaviour in edit fields is controlled by the setting of the ***AutoWildCard*** attribute of the XML object ***SearchManager***. When ***AutowildCard*** is set to `true`, a wildcard is added automatically to search strings entered by the user. Therefore, the = condition cannot be used for the definition of edit fields because the condition does not allow wildcards in the argument. It is also recommended to inform users with a static text in the filter section whether wildcards are automatically added to strings.

For more information about the ***AutoWildCard*** setting in the XML object ***SearchManager***, see the section Configuring the Wildcard for Standard and Custom Search Functionalities.

Note the following for the definition of the `WHERE` clause in Alfabet query language:

- When defining the value for the condition in the **Alfabet Query Builder**, select the checkbox **Parameter** in the dialog box, shown below. In the **Name** field, enter a technical name of the filter field. The value in the **Name** field is not used to search in the property, but rather only to assign a technical name to the filter field.



After clicking **OK**, you will see the `Where` clause in the **Alfabet Query Builder** with a colon written before the value.

- When defining the value for the condition in the Alfabet query syntax, you can enter a colon instead of an @ followed by the name of the resulting filter field:

```
WHERE
    Application.Name LIKE:ApplicationName
```

Defining Filter Fields

When the query that a custom selector or a configured report is based on includes one or multiple `WHERE` clauses with a parameter defining a filter name, a filter field must be added for each `WHERE` clause in the **Custom Report View** of the configured report or the header panel of the page in the custom selector.

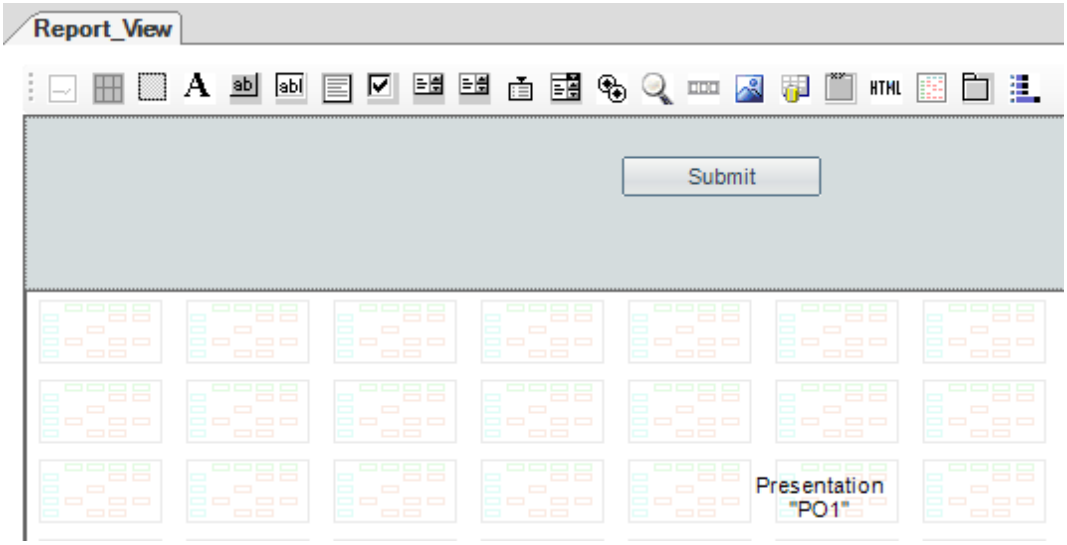
There are two mechanisms for adding filter fields:

- In general, filter fields are added manually to the filter panel. This method can be applied to both configured reports and custom selectors. The filter fields can be defined before or after writing the query for the configured report or custom selector page.
- For configured reports of the type `NativeSQL`, filter fields are generated automatically if the **Custom Report View** of the configured report is created after the query for the report has been defined. This special case is described separately in the section Configuring a Native SQL Query for a Configured Report in the chapter Configuring Reports.

Do the following to manually add a filter field to the report:

1) In the query of the configured report or custom selector, add a condition with a parameter as described in Defining a WHERE Clause that Causes the Generation of a Filter Field in the Report.

2) In the explorer, double-click the **Custom Report View** of the configured report or the presentation object of the class entry of the custom selector. The view editor opens with a toolbar for interface control creation on top. The interface controls are representing different types of filter fields. Beneath the toolbar, the view is displayed with a filter panel on top and a presentation object beneath the filter panel:



Please note that the filter panel can be moved from top to the left or right of the presentation object. the required configuration is described in the section Changing the Position of the Filter Panel.

3) In the toolbar, click the icon of the interface control type that you want to add. When you move the cursor over an icon, a tooltip gives information about the interface control type represented by the icon.

4) Drag the mouse on the filter panel in the report editor to create a text box in the location and width of your choice.

5) In the attribute window of the new filter field, change the name of the filter field to the parameter specified in the query of the report.

For the filter of the following native SQL query:

```
SELECT app.REFSTR, app.NAME, app.VERSION
FROM APPLICATION app
WHERE app.NAME LIKE @ApplicationName
```

the technical name of the filter field must be

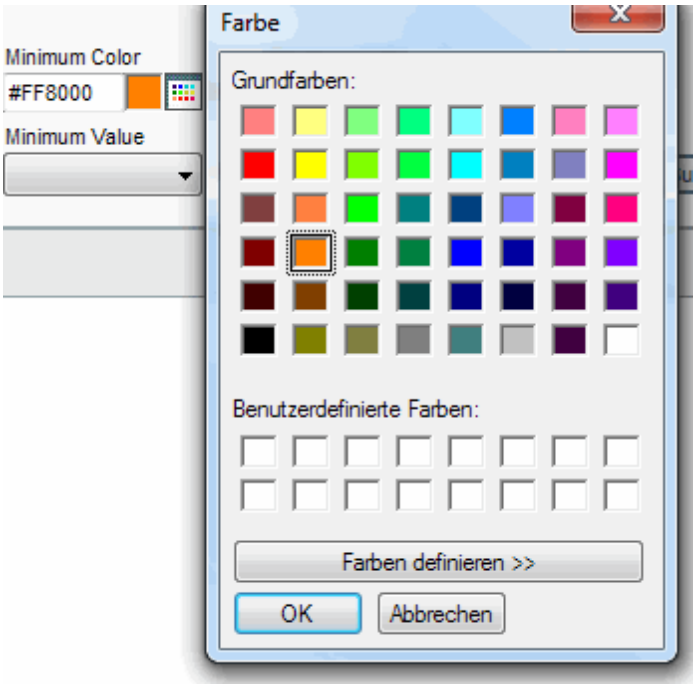
```
@ApplicationName
```

6) If applicable, specify all other attributes that are required for the type of control. The required settings for the addition of each control type are described below.

7) In the toolbar, click the **Save** button to save your changes.

The toolbar includes all interface controls that can be used in configuration objects of Alfabet Expand. This also includes interface controls that are not suitable for use in filters. Only interface control types included in the following list can be used in filter panels:

Menu Option	Generated Element	For more information see:
Filter fields for the definition of values returned to the underlying query		
Edit	The Edit field allows to search for data matching a string entered by the user.  If an Edit field is defined for a property of the data type `Date`, it includes a date picker:  If an edit field is defined for a property of the data type `Color`, it includes a color selector:	Configuring Edit Fields Configuring Date Pickers Configuring Color Pickers

Menu Option	Generated Element	For more information see:
		


Edit Search	The Edit Search field allows to search for an object via a selector or by entering the name or part of the name of the object. 	Configuring Edit Search Fields
Check Box	Check Boxes allow to select whether a boolean value is true. 	Configuring Check Boxes
Checked List Box	Checked List Boxes allow multiple values to be selected from a set of values. 	Configuring Radio Button Groups, Combo-Boxes, Checked Combo-Boxes, List Boxes or Checked List Boxes

Menu Option	Generated Element	For more information see:
Checked Combo Box	Checked Combo Boxes allow multiple values to be selected from a set of values. 	Configuring Radio Button Groups, Combo-Boxes, Checked Combo-Boxes, List Boxes or Checked List Boxes
Combo Box	Combo Boxes allow one value to be selected from a set of values. Combo Boxes are by default not set and allow deselection of values by selection of an empty value. 	Configuring Radio Button Groups, Combo-Boxes, Checked Combo-Boxes, List Boxes or Checked List Boxes
Radio Button Group	Radio Button Groups allow one value to be selected from a set of values. In radio button groups a value must be selected and when a user first opens the report, one of the values is preselected by default. 	Configuring Radio Button Groups, Combo-Boxes, Checked Combo-Boxes, List Boxes or Checked List Boxes

Design elements to enhance usability. These controls are not related to the underlying query

Menu Option	Generated Element	For more information see:
Static Text	A static text displayed on the filter, For example, to add an explanation on the filter settings.	Adding Static Information to the Filter Panel
Button	A button triggering an action. Both filter panels for configured reports and custom selectors have a preconfigured button **Submit** to apply the filter settings to the search result. On a filter, no other buttons are allowed. The button control can be used to re-create the **Submit** button if it has been deleted by mistake.	Configuring the Submit Button
Icon	An icon from the icon gallery displayed on the filter for design reasons or as an image with underlying link to another Alfabet view. 	Adding an Icon With or Without a Link to Another Alfabet View to the Filter Panel
Group Box	A Group Box groups filter fields optically to enhance usability. 	Changing the Sequence of the Focus on Filter Fields
HTML Control	Used to add HTML text, URL, or a link that opends a document located in the **Internal Document Selector**. 	Adding Static Information to the Filter Panel

Menu Option	Generated Element	For more information see:
Slider Control	Slider Controls allow multiple numeric values to be selected independently from each other or summing up to a defined value. Each value is selected by moving a slider on a scale. 	Configuring Slider Controls

The following sections describe the basic configuration settings of the filter field controls related to the query:

- Configuring Edit Fields
- Configuring Date Pickers
- Configuring Color Pickers
- Configuring Edit Search Fields
- Configuring Check Boxes
- Configuring Radio Button Groups, Combo-Boxes, Checked Combo-Boxes, List Boxes or Checked List Boxes
  - Attribute Settings for Selection of Objects Found via a Query
  - Attribute Settings for Selection of a String Value
  - Attribute Settings for Selection of a Value Defined in a Configuration Object
- Configuring Slider Controls

Functionality available for all filter fields can additionally be configured by setting the respective attributes of the filter fields. These options are described separately in the sections:

- Configuring Filter Layout
- Defining Mandatory Filter Fields
- Excluding Filters From Storage in Bookmarks
- Automatically Adding Wildcards to Search Strings
- Configuring Cascading Filters
- Configuring Reusability of Filter Settings Across Reports

Configuring Edit Fields

Available for Data Types: String, `Text`, `Date`, `DateTime`, `Integer`, `Real`

Dependent on the operator used in the `WHERE` condition in the query, the edit field allows search with or without wild cards. For example, using the =, != or <> operators results in a text field that requires the specification of the whole property value without wild cards.

To define an edit field for a filter:

1) In the explorer, double-click the **Custom Report View** of the configured report or the presentation object of the class entry of the custom selector. The view editor opens with a toolbar for interface control creation on top.

2) In the toolbar, click the **Edit**  icon.

3) Drag the mouse on the filter panel in the report editor to create a text box in the location and width of your choice.

4) In the attribute window of the new filter field, set the following attributes:

   - **Name**: Change the name of the filter field to the parameter specified in the query of the report.
   - **Caption**: Enter a caption for the filter field. The caption is displayed on top of the field.
   - **Hint**: Optionally define a tooltip that is displayed for the filter field when the user moves the cursor over the field caption.
   - **Value Type**: Select the data type of the property that you compare with the filter value.
   - **Allow Wildcards**: The setting of wildcards in filter fields depends on the configuration of the `AutoWildCard` element in the XML object ***SearchManager***. The search function can be configured to automatically add a wildcard before and after the search string entered in an edit field and Therefore, search for any string containing the search criteria. Alternatively, the search function can be configured to use the search string as explicitly entered in the field. In other words, the user entering the string in the edit field must add a wildcard to the string in the field if he/she wants to search for a string containing but not equal to the defined search string. If wild cards are automatically set and the edit field requires that the whole string entered into the filed is equal to a property value, the attribute **Allow Wildcards** must be set to `False`. Otherwise the automatically set wild cards will be added to the string before comparing it to the property value and inhibit search for the string.
   - **Enable Look-Ahead Typing**: If the **Value Type** attribute of the filter field is set to `String`, you can set this attribute to `True` to enable an auto-fill capability for the filter field. When the user types in the filter field, the look-ahead functionality will search for a matching string that has previously been used to search in the current configured report or custom selector. A list of matching objects will be offered in a drop-down menu and the user can select the relevant option. The list of matching objects will be updated with each additional letter typed in to the search field. The search can be triggered to find only matching search strings previously entered by the current user or by all users in the user community.

     The XML attribute `SearchOnlyCurrentUserStrings` in the XML object ***Solution-Options*** should be set to "`true`" if the stored search strings of the current user shall be used for the search context or set to "`false`" if the stored search strings of all users in the user community shall be used for the search context. The default value is set to "`true`".

5) In the toolbar, click the **Save**  button to save your changes.

Configuring Date Pickers

Available for Data Types: `Date`

To define a date picker for a filter:

1) In the explorer, double-click the **Custom Report View** of the configured report or the presentation object of the class entry of the custom selector. The view editor opens with a toolbar for interface control creation on top.
2) In the toolbar, click the **Edit**  icon.
3) Drag the mouse on the filter panel in the report editor to create a text box in the location and width of your choice.
4) In the attribute window of the new filter field, set the following attributes:
   - **Name**: Change the Name of the filter field to the parameter specified in the query of the report.
   - **Caption**: Enter a caption for the filter field. The caption is displayed on top of the field.
   - **Hint**: Optionally define a tooltip that is displayed for the filter field when the user moves the cursor over the field caption.
   - **Value Type**: Select `Date`.
5) In the toolbar, click the **Save**  button to save your changes.

Date pickers can also be configured for filters that are compared to properties of the data type `DateTime` if the operator is <, >, >= or <=. The interface control must then be configured to return the data type `Date`. If you compare the date time property with a date, the date is amended with a time of 00:00:00, which means that setting a filter that defines that the value must be higher than 24/11/2010, the value 24/11/2010 15:51:98 is regarded as higher as the selected filter setting.

Configuring Color Pickers

Available for Data Types: `String` representing a color.

Color pickers returns the color code name or the hexadecimal notation for the selected color.

A color selector may For example, be used in a graphic report with a color rule specification to allow the user to select which color shall be used to display objects matching a defined condition. In that case, the filter field is not used to limit the search results to a subset of the available objects but to alter the appearance of the graphic display of the report.

To define a color picker for a filter:

1) In the explorer, double-click the **Custom Report View** of the configured report or the presentation object of the class entry of the custom selector. The view editor opens with a toolbar for interface control creation on top.
2) In the toolbar, click the **Edit**  icon.

3) Drag the mouse on the filter panel in the report editor to create a text box in the location and width of your choice.

4) In the attribute window of the new filter field, set the following attributes:

   - **Name**: Change the Name of the filter field to the parameter specified in the query of the report.
   - **Caption**: Enter a caption for the filter field. The caption is displayed on top of the field.
   - **Hint**: Optionally define a tooltip that is displayed for the filter field when the user moves the cursor over the field caption.
   - **Value Type**: Select `String`.
   - **Sub Type**: Select `Color`.

5) In the toolbar, click the **Save** button to save your changes.

Configuring Edit Search Fields

Available for Data Types: `Reference`, `ReferenceArray`

To define an edit search field for a filter:

1) In the explorer, double-click the **Custom Report View** of the configured report or the presentation object of the class entry of the custom selector. The view editor opens with a toolbar for filter field creation on top.

2) In the toolbar, click the **Edit Search** icon.

3) Drag the mouse on the filter panel in the report editor to create a text box in the location and width of your choice.

4) In the attribute window of the new filter field, set the following attributes:

   - **Name**: Change the **Name** of the filter field to the parameter specified in the query of the report.
   - **Caption**: Enter a caption for the filter field. The caption is displayed on top of the field.
   - **Hint**: Optionally define a tooltip that is displayed for the filter field when the user moves the cursor over the field caption.
   - **Value Type**: Select the data type of the property that you compare with the filter value.
   - **Parameters**: Enter

     `ClassName``|`*`PropertyName`*`|OPERATOR`

where `ClassName` and `PropertyName` define the name of the object class and object class property the filter value is compared to.

For example, to define an **Edit Search** field that allows to select a person that shall be defined as responsible user for an application, the **Parameters** attribute must be set to:

`Application|ResponsibleUser|OPERATOR`

5) In the toolbar, click the **Save** button to save your changes.

Configuring Check Boxes

Available for Data Types: `Boolean`

In the Alfabet database, Boolean values can be `True`, `False` or `NULL`, where `NULL` is the value stored for a boolean property that is not set to `True` by the user and for which no default value is defined. If you specify a check box to filter for a boolean value, selecting the checkbox will find all objects for that the property is set to `True`. Deselecting the checkbox will find all objects for which the property is set to `False`. Objects for which the property is not defined (set to `NULL`), will never be displayed in the report. To avoid such misleading search results in filters, a default value shall be defined for each Boolean property in Alfabet.

To define an edit search field for a filter:

1) In the explorer, double-click the **Custom Report View** of the configured report or the presentation object of the class entry of the custom selector. The view editor opens with a toolbar for interface control creation on top.
2) In the toolbar, click the **Check Box** icon.
3) Drag the mouse on the filter panel in the report editor to create a box in the location and width of your choice.
4) In the attribute window of the new filter field, set the following attributes:
   - **Name**: Change the **Name** of the filter field to the parameter specified in the query of the report.
   - **Caption**: Enter a caption for the filter field. The caption is displayed on the right side of the check box.
   - **Hint**: Optionally define a tooltip that is displayed for the filter field when the user moves the cursor over the field caption.
   - **Value Type**: Select `Boolean`.
5) In the toolbar, click the **Save** button to save your changes.

Configuring Radio Button Groups, Combo-Boxes, Checked Combo-Boxes, List Boxes or Checked List Boxes

Available for Data Types: `Reference`, `ReferenceArray`, `String`, `StringArray`

In Alfabet multiple different types of filter fields are available that allow to select one or multiple values from listed pre-defined options:

- In combo boxes and radio button groups, a single value can be selected from the listed values. When a user opens the report for the first time, no value is pre-selected.
- In checked list boxes and checked combo boxes, multiple values can be selected from the listed values. When a user opens the report for the first time, no values are pre-selected.

The values available for selection by the user can be defined by one of the following mechanisms:

- A query can be defined in the filter field that finds objects to be selected. The selector displays the Show properties defined in the Alfabet query or the properties defined in the `SELECT` statement of the native SQL query and returns the `REFSTR` of the object represented by each selection.
- A list of strings can be provided that are selectable by the user. The selector field returns the selected string value.
- The selector can be configured to return predefined values from an enumeration or values defined in an XML object or mandates defined for your company.

The selectable single values must not contain commas. If a property shall be selectable via a multi select filter field and the property shall contain a comma separated list of values, the property should be of the type StringArray or the commas must be replaced with other separator when defining the filter field content.

To define an edit search field for a filter:

1) In the explorer, double-click the **Custom Report View** of the configured report or the presentation object of the class entry of the custom selector. The view editor opens with a toolbar for interface control creation on top.
2) In the toolbar, click the icon of the box that you want to define:
   -  for a radio button group
   -  for a checked list box
   -  for a combo box
   -  for a checked combo box
3) Drag the mouse on the filter panel in the report editor to create a box in the location and width of your choice.
4) In the attribute window of the new filter field, set the following attributes:
   - **Name**: Change the **Name** of the filter field to the parameter specified in the query of the report.
   - **Caption**: Enter a caption for the filter field. The caption is displayed on the right side of the check box.
   - **Hint**: Optionally define a tooltip that is displayed for the filter field when the user moves the cursor over the field caption.
5) In the attribute window, define the content of the combo box. The content depends on the type of data that shall be found in the selection:
   - To find the target of a property of the type `Reference` or `ReferenceArray`, a query can be defined in the filter field that finds objects to be selected. The selector displays the Show

properties defined in the Alfabet query or the properties defined in the `SELECT` statement of the native SQL query and returns the `REFSTR` of the object represented by each selection. For more information, see Attribute Settings for Selection of Objects Found via a Query.

- A list of strings can be provided that are selectable by the user. The selector field returns the selected string value. For more information, see Attribute Settings for Selection of a String Value.
- The selector can be configured to return predefined values from an enumeration or values defined in an XML object or mandates defined for your company. This configuration applies when the selection shall return one of the following:
  - The object's object state.
  - The object's release status.
  - The mandate assignment of the object.
  - A lifecycle status of the object.
  - The object's stereotype.
  - A value selectable from an enumeration.

For more information see Attribute Settings for Selection of a Value Defined in a Configuration Object.

6) In the toolbar, click the **Save** button to save your changes.

Attribute Settings for Selection of Objects Found via a Query

The following settings are required in the attribute section of the filter field to define the content on basis of a query:

- **Value Type**: For a combo box or radio button group, select `Reference`. For a checked combo box, select `ReferenceArray`.
- **Sub Type**: Select `SqlEnum`
- **Range**: Define an Alfabet query or a native SQL query to specify the content of the combo-box.

  The query should not return more than twenty values to ensure usability of the filter field.

For example, a filter shall allow to limit display of information flows to information flows with a defined connection type. Connection types for information flows are user defined objects in the Alfabet database that the information flow links to via the property Connection Type that is of the data type `Reference`.

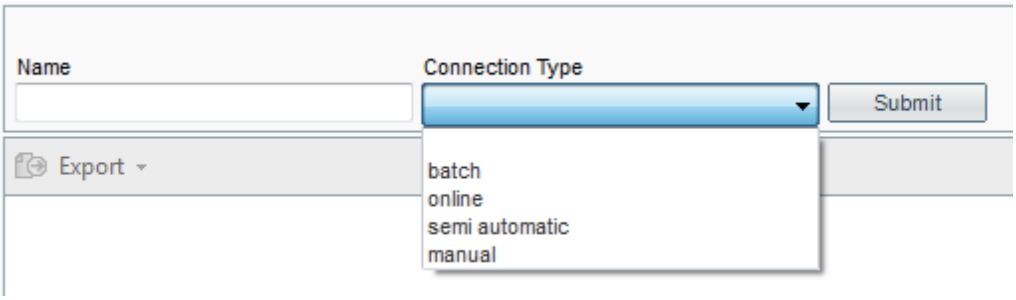
In the first configuration example, the filter shall include a combo box that allows one connection type to be selected.

To display the available connection types in the combo box, you must specify a query for the **Connection Type** combo box in the **Range** attribute of the filter field. The native SQL query

must find connection types and defines the property `NAME` of the connection type in the `SELECT` statement:

```
SELECT REFSTR, NAME
FROM CONNECTIONTYPE
```

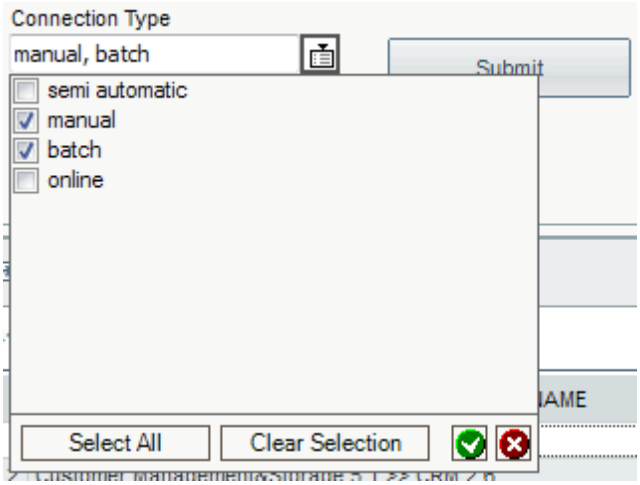
The checked combo box will then allow the user to select between the available connection types:



The combo box will return the `REFSTR` of the selected connection type. Therefore, the native SQL query the report is based on includes a `WHERE` clause that defines that the `REFSTR` stored in the property connection type of the information flow must be identical to the returned filter value:

```
SELECT inf.REFSTR, inf.NAME, con.NAME
FROM INFORMATIONFLOW inf, CONNECTIONTYPE con
WHERE inf.CONNECTIONTYPE=con.REFSTR
   AND inf.CONNECTIONTYPE = @type
```

In the second configuration example, the filter shall include a checked combo-box that allows multiple connection types to be selected:



The query used for the combo box above is also used for the checked combo box to fill the checked combo box with the names of the selectable connection types. Please note that although the property connection type of the information flow is of the data type Reference, the **Value Type** attribute of the checked combo box must be set to `ReferenceArray`. The **Value Type** attribute of the checked combo box specifies, which data type is returned by the filter field. When the user selects multiple values from the box, the returned value is a Reference Array.

In the query the report is based on, this has to be taken into account. The `WHERE` clause must be defined to find the connection type of the current information flow in the set of connection types returned by the filter field:

```
SELECT inf.REFSTR, inf.NAME, con.NAME
FROM INFORMATIONFLOW inf, CONNECTIONTYPE con
WHERE inf.CONNECTIONTYPE=con.REFSTR
   AND inf.CONNECTIONTYPE IN (@type)
```

Attribute Settings for Selection of a String Value

The following settings are required in the attribute section of the filter field to define a selectable list of strings:

- **Value Type**: Select `String`.
- **Sub Type**: Select `StringEnum`
- Range: Define each value separated by a line break, that means each value in a separate line:

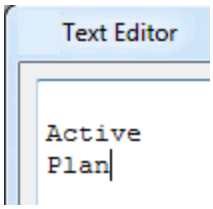
```
String1
String2
```

Limit the definition to no more than twenty values to ensure usability of the filter field.

If the user shall be allowed to deselect the filter setting, an empty line can be included.

Empty selections are not allowed for radio button groups and if defined for a radio button group, they are ignored.

For example, a configured report about applications shall include a filter field that allows the user to limit display to applications in a defined object state. The applications in the object state Retired are not relevant for the user and shall Therefore, not be selectable in the filter. In the filter a checked list box is defined with a **Value Type** `String` and a **Sub Type** `StringEnum`. In the attribute **Range**, the string values of the selectable object states are defined as well as an empty selection that allows the user to see all applications regardless of the object state:



In the checked list box, the user can select between "not set", "Active" and "Plan":

In the underlying query the value for the object state for each application is compared to the value returned by the filter field. The checked list box allows the selection of multiple values and the `WHERE` condition in the query checks whether the object state value of the application is within the range of values returned from the filter setting:

```
SELECT REFSTR, NAME, VERSION, OBJECTSTATE
FROM APPLICATION
WHERE OBJECTSTATE IN (@state)
```

Attribute Settings for Selection of a Value Defined in a Configuration Object

Operators are available to automatically fetch the values that are defined in XML objects or enumerations.

The following settings are required in the attribute section of the filter field to define the content on basis of content defined in an enumeration or an XML object.

1) In the attribute window, set the following attributes:

- **Value Type**: Select `String`
- **Parameter**: Enter the call of the operator that you want to use:
  - For enumerations: <name of object class>|<name of property based on enum>|`OPERATOR`
  - For lifecycle statuses: `TimeStatus|Status|OPERATOR`
  - For mandates: `Mandate|OPERATOR`
  - For stereotypes: <name of object class>|`Stereotype|OPERATOR`
  - For release statuses: <name of object class>|`Status|OPERATOR`
  - For object states:<name of object class>|`ObjectState|OPERATOR`
- **Custom Attribute**:
  - For enumerations: This attribute is not evaluated. No entry is required.
  - For lifecycle statuses: enter the name of the object class for that the lifecycle definitions shall be displayed.
  - For mandates: This attribute is not evaluated. No entry is required.
  - For stereotypes: This attribute is not evaluated. No entry is required.
  - For release statuses: To display the available release status definitions for a project stereotype in a combo box or a drop-down list, enter the name of the project

stereotype in the attribute field **Custom Attribute**. The release status for projects is configured individually for each project stereotype. For other release status definitions, this attribute is not evaluated. No entry is required.

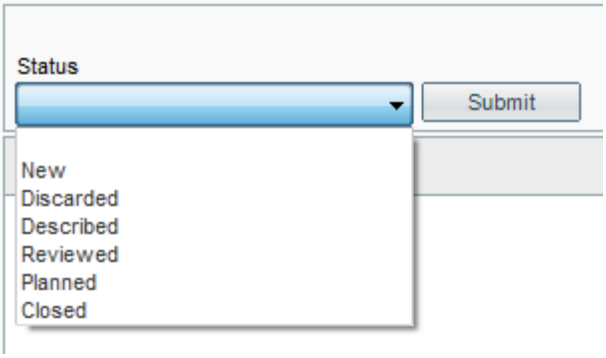
- For object states: This attribute is not evaluated. No entry is required.

A report shall allow users to view information about projects of the project stereotype `Program` with a specific release status. The query for the report defines the search condition for the stereotype as a fixed value and the search condition for the release status as a filter:

```
SELECT proj.REFSTR, proj.NAME, proj.STATUS
FROM PROJECT proj
WHERE proj.STEREOTYPE = 'Program'
   AND proj.STATUS LIKE @Status
```

To display release statuses in the combo-box, you must specify which release status definition you want displayed. In the example, the report lists projects of the project stereotype `Program`. Therefore, Program must be entered as **Custom Attribute** property.

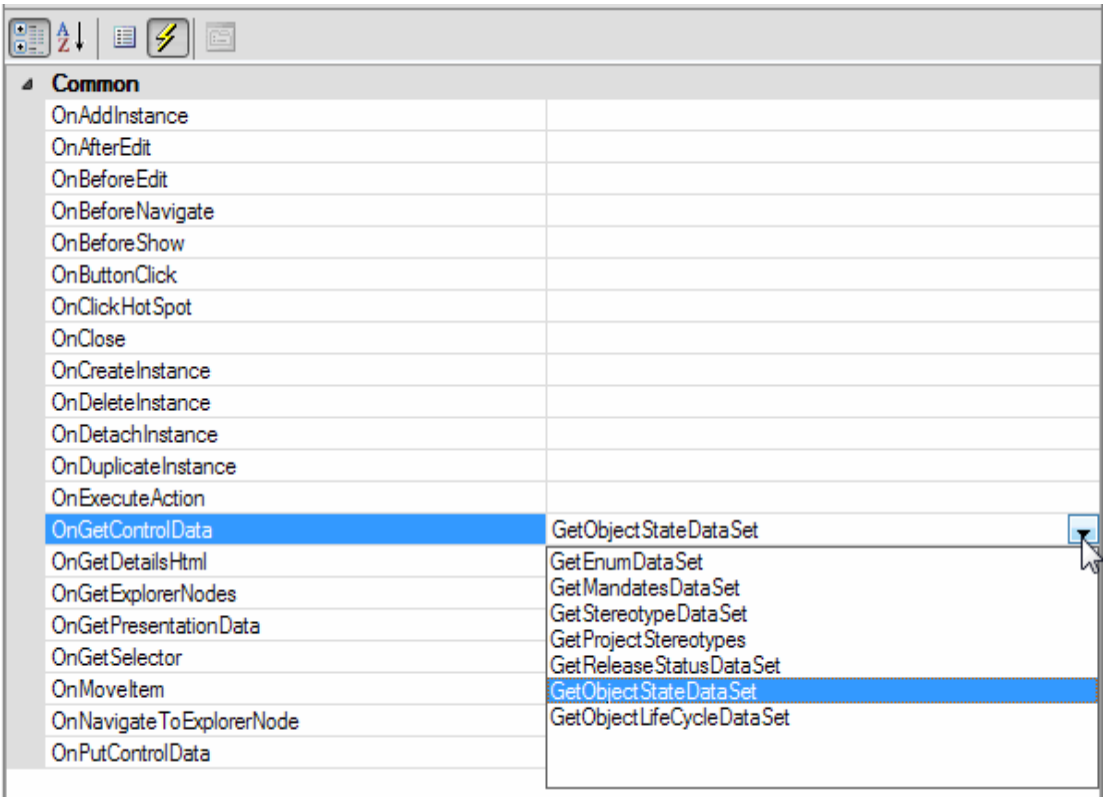
The checked combo box will then allow the user to select between the available release statuses of the project stereotype `Program`:



2) In the toolbar on top of the attribute window, click the  button. The content of the attribute window changes to display available operations.

To return to the attribute view, click the  button in the toolbar.

3) In the ***OnGetControlData*** field, select an operator from the drop-down list:



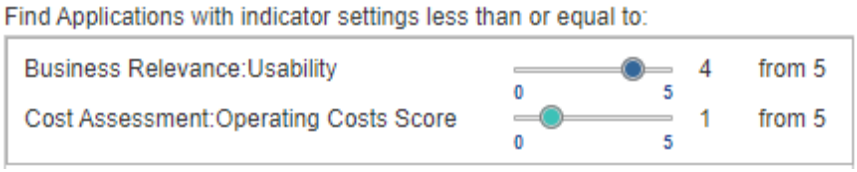
- For enumerations: `GetEnumDataSet`
- For lifecycle statuses: `GetObjectLifeCycleDataSet`
- For mandates: `GetMandatesDataSet`
- For stereotypes: `GetStereotypeDataSet` or `GetProjectStereotypes` if the object class is Project
- For release statuses: `GetReleaseStatusDataSet`
- For object states:`GetObjectStateDataSet`

4) In the toolbar of Alfabet Expand, click the **Save** button to save your changes.

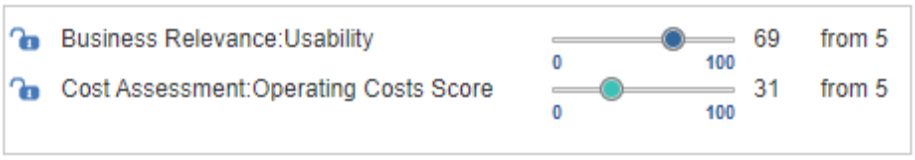
Configuring Slider Controls

Available for Data Types: `Integer`, `Real`

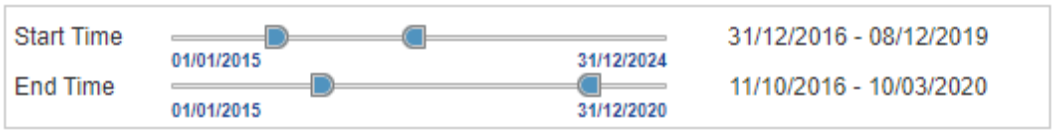
Slider controls combine the selection of multiple numeric or date values in one field. For each selectable value, a slider line is displayed with a slider that can be set to the currently selected value. A caption informing about the kind of value to be selected is displayed in front of each slider line and optionally the unit for the slider line values can be displayed at the end of the slider line. Information about the start and end values of the slider bar are automatically added as text beneath the start and end point of the slider. Optionally, the slider handlers can be colored differently in each bar:



Slider bars can be set independent from each other or the slider control can be configured to force the settings in all slider bars to sum up to a specified value or to be less than or equal to a specified value. If the slider bar settings must be less or equal to a specific value and the maximum value is reached, the user can only move a slider to a higher value if he/she has reduced the value for another slider bar first. If the slider bar settings must match a defined sum, moving one slider will automatically move all other sliders to matching values. In that case, a lock is displayed on the left of the slider caption:



Sliders can be configured to allow a range of values to be selected. In each slider line, two sliders are displayed, one for the selection of the start value of the range and one for the selection of the end value of the range.



In the query of the configured report, the values set for each slider bar can be used as parameters in `WHERE` clauses. The parameter must be identical to the name of the slider control followed by two underscores and the number of the slider bar, starting with zero for the first slider bar, For example, `@SliderControl__0`.

For sliders that allow a range of values to be selected, the parameter name must have an f for the "from value" and a t for the "to value" added in front of the slider bar number, For example, `@SliderControl__f0` and `@SliderControl__t0` for the from and to value in the first slider bar.

The content of the slider control is defined in both an XML element and in a query, which can be defined either in native SQL or in Alfabet query language.

The following parts of the slider control are only defined in the XML definition and are static, that means they are identical for each slider bar:

- The width of the slider control reserved for the captions of the slider bars.
- Whether slider bars are independent of each other or sum up to a defined value.
- Whether each slider bar allows a single value or a range from and to defined values to be selected.
- Whether dates or numeric data shall be selected in the slider.
- A message with instructions for the user that will pop up if the slider definition depends on the setting in a master filter field and the master filter field is not set.

The following parts of the slider control can be defined either in the XML definition as static values or in the query:

- The range and step definition of the slider bars.
- The text at the right of each slider bar.

The following parts of the slider control are defined exclusively in the query:

- The number of slider bars is identical to the number of results found by the query.
- The caption of the slider bar is defined in the query.
- The primary location of the slider on the slider bar is defined in the query.

To define a slider control for a filter:

1) In the explorer, double-click the **Custom Report View** of the configured report or the presentation object of the class entry of the custom selector. The view editor opens with a toolbar for interface control creation on top.
2) In the toolbar, click the **Slider**  icon.
3) Drag the mouse on the filter panel in the report editor to create a box in the location and width of your choice.
4) In the attribute window of the new filter field, set the following attributes:
   - **Name**: Change the **Name** of the filter field to the parameter specified in the query of the report.
   - **Caption**: Enter a caption for the filter field. The caption is displayed on top of the field.
   - **Hint**: Optionally define a tooltip that is displayed for the filter field when the user moves the cursor over the field caption.
5) Click the **Range As Native SQL Query** or **Range As Alfabet Query** attribute and click the **Browse**  button at the right of the field to open the text editor or the Alfabet query builder respectively.
6) Define a query that returns one row for each slider bar, with the following columns in the result dataset:
   - If the query is a native SQL query, the first column in the dataset is ignored.
   - The string that shall be displayed as caption on the left of the slider bar must be returned. The column name must be `Name`, or, if another column name is returned, this column name must be specified in the **XML Definition** attribute.
   - The numeric or date value of the start position of the slider on the slider bar must be returned. The column name must be `Value`, or, if another column name is returned, this column name must be specified in the **XML Definition** attribute.

     For numeric values, the value must be a multiple of the defined step value. If you have defined a step of 10, you cannot define a value of 25, but of 20 or 30 only.

   - Optionally, the maximum and minimum value of the slider bar can be returned in two columns of the report. The column names must be `MinValue` and `MaxValue`. Alternatively, a fixed value can be defined for the slider bar range in the **XML Definition** attribute.

Please note the following:

- If the minimum and maximum value of the slider bar are both defined in the query and in the **XML Definition** attribute, the query definition supersedes the XML definition.
- If the slider is configured to select numerical values, and the minimum and maximum value are defined in the query, the step for setting the slider handle must also be defined in the query.

- Optionally, the step for setting the slider can be returned. The column name must be `Step`, or, if another column name is returned, this column name must be specified in the **XML Definition** attribute.

  For sliders configured to select dates, the step is always 1 and cannot be defined via the query or the **XML Definition** attribute.

  For sliders configured to select numeric values, the step definition is optional. It can be omitted in both the query and the **XML Definition** attribute. The default step is 1.

- Optionally, the unit to be displayed behind the slider bar can be returned as text string. The column name must be `Unit`, or, if another column name is returned, this column name must be specified in the **XML Definition** attribute. This feature is currently only available if the XML attribute `Mode` in the **XML Definition** attribute is set to `None` which means that the slider values are numerical values set independent from each other.
- Optionally, the color of the slider marking the current value in a slider bar can be returned in HTML compatible color code. The column name must be `Color`, or, if another column name is returned, this column name must be specified in the **XML Definition** attribute.

Alfabet parameter `@BASE` can be used in the query to refer to the current object the report or selector is opened for. For more information about Alfabet parameters, see Comparing Property Values with Other Property Values.

The following native SQL query defines two slider bars, using the default column names for all defined values:

```
SELECT NULL AS REFSTR, 'Business Relevance:Usability' AS
'Name', 3.0 AS 'Value' 1 AS 'MinValue', 5 AS 'MaxValue', 1 AS
Step, '#336699' AS 'Color'

UNION ALL

SELECT NULL AS REFSTR, 'Cost Assessment:Operating Costs
Score' AS 'Name', 4.0 AS 'Value', 1 AS 'MinValue', 5 AS
'MaxValue', 1 AS Step, '#3CC1B7' AS 'Color'
```

The following query defines two slider bars for a range of dates to be selected in each slider bar:

```
SELECT NULL AS 'REFSTR', 'Start Time' AS Name, cast('2015-01-
01' AS date) AS MinValue, cast('2024-12-31' AS date) AS
MaxValue, cast('2016-12-31' AS date) AS FromValue,
cast('2017-12-31' AS date) AS ToValue

UNION ALL
```

```
SELECT NULL AS 'REFSTR', 'End Time' AS Name, cast('2015-01-
01' AS date) AS MinValue, cast('2020-12-31' AS date) AS
MaxValue, cast('2018-01-01' AS date) AS FromValue,
cast('2020-12-31' AS date) AS ToValue
```

7) Click the **XML Definition** attribute and click the **Browse** button at the right of the field to open the text editor. A template with the XML code for the slider definition is displayed.

8) Set the following for the XML attributes in the XML elements of the **XML Definition** code, as needed:

`Slider` XML element:

- `Mode`:Enter one of the following modes:
  - `None`: The slider allows numeric values to be selected. All slider lines are independent from each other. This is the default value. This setting allows a slider to be defined with two slider handlers for setting a range from a defined value to a defined value.
  - `SumLessEqual`: The slider allows numeric values to be selected. The slider settings on all slider bars must be less than or equal to the value defined with the attribute `CompareValue`. If the maximum value is reached, a slider can only be moved to a higher value if another slider is set to a smaller value beforehand.
  - `SumEqual`: The slider allows numeric values to be selected. The sum of the slider settings on all slider bars must match the value defined with the attribute `CompareValue`. If one slider is moved, the sliders on the other bars are adapted automatically to keep the overall value.
  - `Date`: The slider allows dates to be selected. All slider lines are independent from each other.
- `CompareValue`: If the `Mode` is set to `SumLessEqual` or `SumEqual`, enter the sum that the slider settings shall match or be less than or equal to.
- `EmptyMessage`: If the rendering of the slider control depends on the setting in a master filter field, you can define a message to inform the user what he/she shall do to view the slider control. The message will be automatically displayed if the master filter field is empty.
- `NameColumn`: The text displayed to the left of each slider bar is defined in a query with the attribute **Range As Native SQL Query** or **Range As Alfabet Query** . Enter the name of the column in the result data set of the query that returns the text. The default column name is `Name`.
- `RangeType`: This XML attribute must be set to `true` if a range of values shall be selected per slider bar. It must be set to `false` or left out in the XML definition to configure a slider with a single value selection per slider line.
- `MinValueColumn`: If the minimum value of the slider bar is defined via the query in the **Range As Native SQL Query** or **Range As Alfabet Query** attribute. Enter the name of the column in the result data set of the query that returns the minimum value. The default column name is `MinValue`. The slider range can alternatively be defined statically via the XML element Range in this XML definition. A definition in the query overrides a definition in the XML element.
- `MaxValueColumn`: If the maximum value of the slider bar is defined via the query in the **Range As Native SQL Query** or **Range As Alfabet Query** attribute. Enter the name of the column in the result data set of the query that returns the maximum value. The default

column name is `MaxValue`. The slider range can alternatively be defined statically via the XML element `Range` in this XML definition. A definition in the query overrides a definition in the XML element.

- `StepColumn`: If the steps on the slider bar are defined via the query in the **Range As Native SQL Query** or **Range As Alfabet Query** attribute, enter the name of the column in the result data set of the query that returns the step of the slider handle on the slider bar. The default column name is `Step`. The step can alternatively be defined statically via the XML element `Range` in this XML definition. A definition in the query overrides a definition in the XML element.
- `UnitColumn`: If the unit that shall be displayed on the right side of the slider bar is defined via the query in the **Range As Native SQL Query** or **Range As Alfabet Query** attribute, enter the name of the column in the result data set of the query that returns the unit text. The default column name is `Unit`. The unit text can alternatively be defined statically via the XML element `ItemValueText` in this XML definition. A definition in the query overrides a definition in the XML element.
- `ValueColumn`: For a single value selection per slider bar, the initial placement of the slider handle on each slider bar is defined in a query in the **Range As Native SQL Query** or **Range As Alfabet Query** attribute. Enter the name of the column in the result data set of the query that returns the value on the slider bar that the slider handle is set to on first opening of the configured report. The default column name is `Value`.
- `FromValueColumn`: For selection of a range of values per slider bar, the initial placement of the slider handle for the start of the range on each slider bar is defined in a query in the **Range As Native SQL Query** or **Range As Alfabet Query** attribute. Enter the name of the column in the result data set of the query that returns the value on the slider bar that the slider handle for the minimum value selection is set to on first opening of the configured report. The default column name is `FromValue`.
- `ToValueColumn`: For selection of a range of values per slider bar, the initial placement of the slider handle for the end of the range on each slider bar is defined in a query in the **Range As Native SQL Query** or **Range As Alfabet Query** attribute. Enter the name of the column in the result data set of the query that returns the value on the slider bar that the slider handle for the maximum value selection is set to on first opening of the configured report. The default column name is `ToValue`
- `ColorColumn`: If the color of the slider handles can be defined via the query in the **Range As Native SQL Query** or **Range As Alfabet Query** attribute. Enter the name of the column in the result data set of the query that returns the text. The default column name is `Color`

`Range` XML element:

This XML element is optional. A definition in the query in the **Range As Native SQL Query** or **Range As Alfabet Query** attribute supersedes the XML definition.

- `MinValue`: Enter the minimum value for the slider bars. All slider bars have the same range. By default all sliders start with zero.
- `MaxValue`: Enter the maximum value for the slider bars. All slider bars have the same range. By default all sliders end with 100.
- `Step`: Enter the step for the settings of the slider on the slider bars. All slider bars have the same step definition. The default step width is 1.

`ItemName` XML element:

- `NameWidthInPercents`: Enter the percentage of the space in the slider control that will be used for display of the slider bar name in front of the slider bar. For sliders with the `Mode` set to `SumEqual`, a lock symbol is displayed in front of the name. In this case the space defined with `NameWidthInPercents` is used for both lock symbol and name. Enter the percentage of space as an integer between 0 and 100. The default value is 50, which means 50% of the slider width is used for the slider bar name.

`ItemValueText` XML element:

This XML element is optional. A definition in the query in the **Range As Native SQL Query** or **Range As Alfabet Query** attribute supersedes the XML definition.

- `Value`: Enter the text that shall be displayed behind the slider bars to inform the user about the units used in the slider. By default this XML attribute is empty and no text is displayed.

9) In the toolbar of Alfabet Expand, click the **Save** button to save your changes.

Re-Using Filter Fields Using the Copy and Paste Functionalities

Copy and paste functionalities are available to re-use filter fields. A filter field can be copied to another location in the same filter panel or to another filter panel. If the filter field is copied to the same filter panel, the Name attribute is changed, but all other attribute settings are kept. Copying a filter field into the same filter panel can be useful if two fields in the filter differ in a subset of the attribute settings and shall have the same design. One filter filed can be completely designed, copied into the same filter panel and the attributes defining the content of the filter field and the mapping to the report content can then be changed.

To copy and paste a filter field:

1) In the explorer, right-click the **Custom Report View** of the configured report containing the filter field that you want to copy and click **Design View**. The report view opens in the middle pane of Alfabet Expand and in the menu bar, the menus **Edit** and **Format** are displayed.
2) Click the filter field that you want to copy, click on the **Edit** menu and select **Copy**, if you want to copy the filter field or **Cut**, if you want to move the filter field to another location.
3) In the explorer, right-click the **Custom Report View** of the configured report to which you want to copy the filter field and click **Design View**. The report view opens in the middle pane of Alfabet Expand and in the menu bar, the menus **Edit** and **Format** are displayed.
4) In the menu bar, click the **Edit** menu and select **Paste**.
5) In the filter panel, click the location that you want to add the filter field to. The filter field is included into the filter panel.
6) In the toolbar of Alfabet Expand, click the **Save** button to save your changes.

In addition to the copy, cut and paste options the **Edit** menu allows to delete a selected filter field. Filter fields removed from a filter panel via the **Delete** option of the **Edit** menu are not available for paste actions.

Configuring Filter Layout

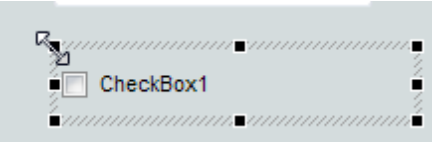
After having added filter fields to a filter panel, you can further design the filter to enhance usability. The following options are available:

- Changing the Size of a Single Filter Field
- Changing the Location of a Single Filter Field
- Aligning the Size and Position of Filter Fields
- Grouping Filters on the Filter Panel
- Adding Static Information to the Filter Panel
  - Adding Plain Text to the Filter Panel
  - Adding an HTML text to the Filter Panel
- Adding an Icon With or Without a Link to Another Alfabet View to the Filter Panel
- Configuring the Submit Button
- Changing the Sequence of the Focus on Filter Fields
- Configuring the Complete Filter Area to be Collapsible
- Configuring Part of the Filter Area to be Collapsible
- Allowing the User to Clear the Filter Area
- Changing the Position of the Filter Panel

Changing the Size of a Single Filter Field

There are two methods to change the size of a filter field on the panel:

- Click a filter field and pull the handles to resize it.



- Click the filter field in the panel to open the attribute window and change the following attributes in the section **Coordinates**:
  - **Height**: Define the height of the filter field.
  - **Width**: Define the width of the filter field.

After changing the size, click the **Save** button in the toolbar to save your changes.

You can combine both methods for easy and correct sizing of filter fields on the panel. After having resized the fields using the handles to define the basic layout of the filter panel, correct the size of the filter fields

in relation to each other using the attributes in the section **Coordinates**. For example, you can define an equal **Width** for filter fields that are placed below each other or an equal **Height** for filter fields displayed in the same row.

The attributes **Height** and **Width** cannot be defined for filter fields in configured reports of the type `Query`.

Changing the Location of a Single Filter Field

There are two methods to change the location of a filter field on the panel:

- Drag-and-drop the filter field to the correct location and click the **Save** button in the toolbar to save your changes.
- Click the filter field in the panel to open the attribute window and change the following attributes in the section **Coordinates**:
  - **Left**: Define the distance from the left of the panel
  - **Top**: Define the distance from the top of the panel

    If filter fields are placed in a group box, the values for **Left** and **Top** are marking the distance to the border of the group box instead to the border of the filter panel.

After changing the field location, click the **Save** button in the toolbar to save your changes.

You can combine both methods for easy and correct placement of filter fields on the panel. After having used drag-and-drop to define the basic layout of the filter panel, correct the location of the filter fields in relation to each other using the attributes in the section **Coordinates**. Filter fields that are placed below each other should have the same value for the attribute **Left**. Filter fields that are placed next to each other in the same row should have the same value for the attribute **Top**.

The attributes **Left** and **Top** cannot be defined for filter fields in configured reports of the type `Query`.

Aligning the Size and Position of Filter Fields

When you click an element in a filter panel, you can see a menu **Format** in the menu bar of Alfabet Expand. Via the options in the **Format** menu the design of multiple filter fields in the filter panel can be aligned to each other with regard to the position of the filter field in the filter panel and the filter size:

Aligning the Position of Multiple Filter Fields

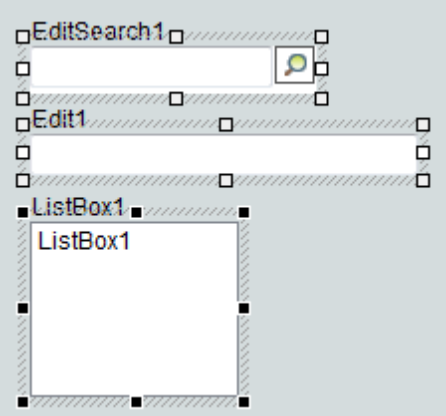
You can align multiple filter fields with one another to have an equal position for one of the borders of the field. For example, if you select multiple fields that are located next to each other in the same row, you can align the position of the top border to ensure that all fields are on the same horizontal axis.

1) In the filter panel, place one of the filter fields in the correct position.

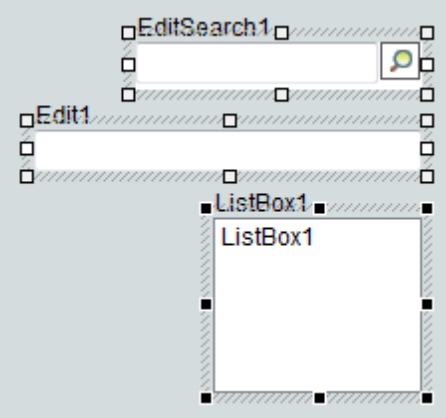
2) Select all filter fields that you want to align with each other holding CTR + SHIFT while clicking on the fields. The last field that you select is the field that determines the position.

3) In the toolbar, select:

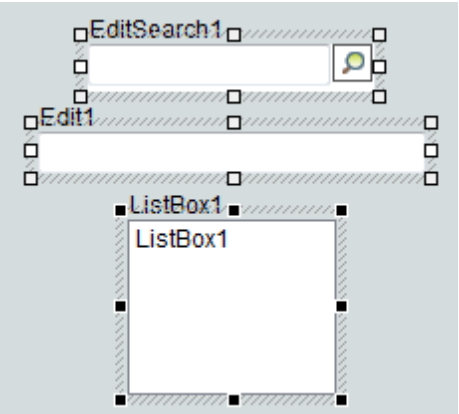
- **Format** > **Align Left** to align the position of the left border of all selected filter fields with the position of the last selected filter field.



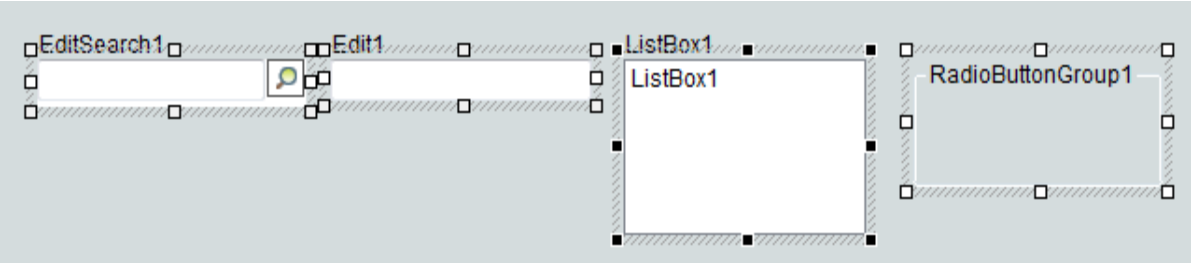
- **Format** > **Align Right** to align the position of the right border of all selected filter fields with the position of the last selected filter field.



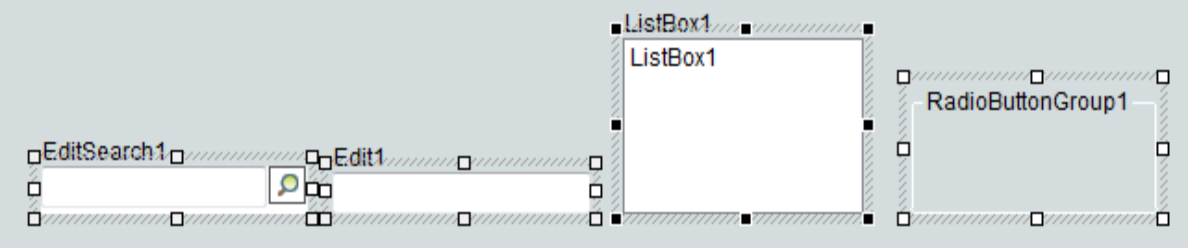
- **Format** > **Align Center** to align the horizontal middle position of all selected filter fields with the horizontal middle position of the last selected filter field.



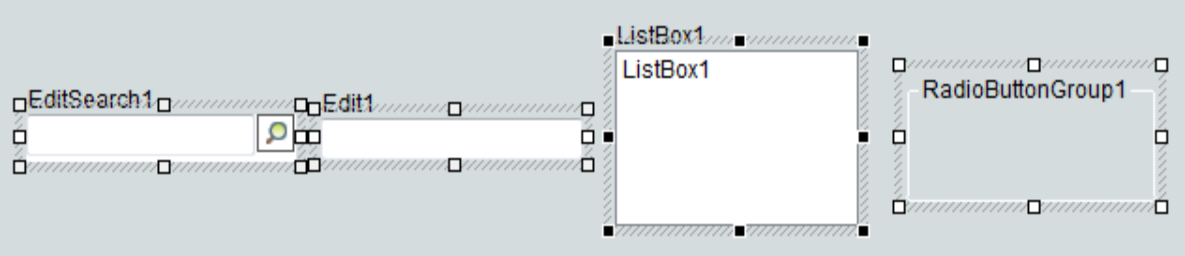
- **Format** > **Align Top** to align the position of the top border of all selected filter fields with the position of the last selected filter field.



- **Format** > **Align Bottom** to align the position of the bottom border of all selected filter fields with the position of the last selected filter field.



- **Format** > **Align Middle** to align the vertical middle position of all selected filter fields with the vertical middle position of the last selected filter field.



4) In the toolbar, click the **Save** button to save your changes.

Aligning the Size of All Filter Fields

The width or height or one or multiple selected filter fields can be aligned to the width or height of a selected filter field.

1) In the filter panel, select all filter fields that you want to resize holding CTR + SHIFT while clicking on the fields. The last field that you select is the field that determines the resulting width or height of all fields.

2) In the toolbar, select:

- **Format** > **Make Widths Equal** to adapt the widths of all selected fields to the width of the last selected field.

- **Format** > **Make Heights Equal** to adapt the heights of all selected fields to the height of the last selected field.

3) In the toolbar, click the **Save**  button to save your changes.

Aligning Spacing between Filter Fields

If multiple filter fields are placed in a horizontal row or a vertical column you can define an equal spacing between all fields in a single row or in a single column. The position of the first and the last field is maintained and the fields in between are distributed equally in between.

1) In the filter panel, select all filter fields that you want to distribute equally along a vertical or horizontal axis. Please note that only fields from a single column or row shall be selected.
2) In the toolbar, select:
   - **Format** > **Make Vertical Spacing Equal** to distribute the fields equally along the vertical axis.
   - **Format** > **Make Horizontal Spacing Equal** to distribute the fields equally along the horizontal axis.
3) In the toolbar, click the **Save**  button to save your changes.

Applying the Default Spacing between Filter Fields

When filters are created automatically, a default spacing is applied that takes font size for filter headings into account. You can apply the default spacing to your filter fields after having added design elements and fields:

1) Click anywhere in the filter panel.
2) In the toolbar, select **Format** > **Set Default Spacing**.
3) In the toolbar, click the **Save**  button to save your changes.

The default spacing is applied to all elements in the filter.

Aligning the Filter Fields Along a Grid

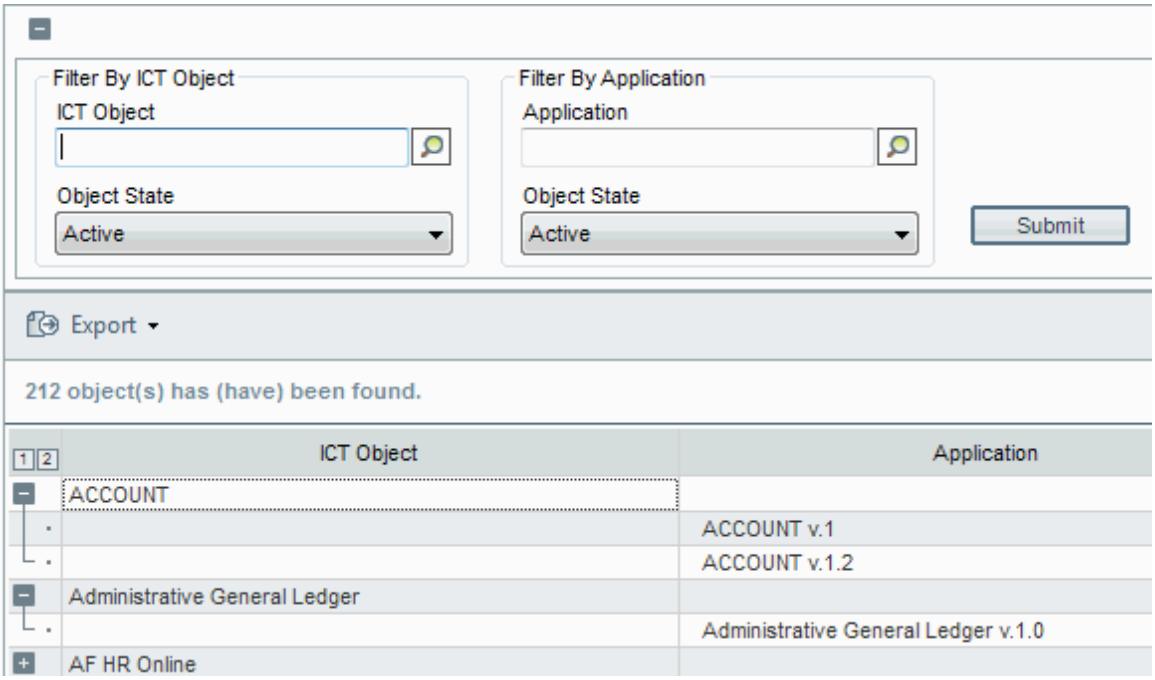
The filter fields can be aligned along a grid that is invisibly drawn on the filter panel. This method allows to align the position to the filter fields horizontally and vertically.

The top left corner of the filter fields are aligned with the respective crossing point of the grid lines left and above the filter field.

1) Select the filter fields that you want to align with along the grid by holding CTR + SHIFT while clicking the fields.
2) In the toolbar, select **Format** > **Snap to Grid**. The selected filter fields are positioned with the upper left corner matching the nearest crossing point of grid lines.
3) If the results are not as expected, you can alter the spacing between grid lines by selecting **Format** > **Grid Size...** in the toolbar and setting the spacing between grid lines in the window that opens. The default value is 2. It is recommended to select a number between 2 and 10 for a start and check the resulting effect on the filter first before moving on to higher numbers. If the spacing between grid lines is too high, the filter fields might be placed outside the filter panel.
4) In the toolbar, click the **Save**  button to save your changes.

Grouping Filters on the Filter Panel

You can optically group fields into group boxes:



To group filter fields:

1) In the toolbar, click the **Group Box** icon.
2) Drag the mouse on the filter panel in the report editor to create a text box in the location and width of your choice.

   The group box must be placed next to the filter fields that shall be part of the group. If you place the group box on top of the filter fields, the filter fields are not placed within the box but under the box and are not visible any longer.

3) In the attribute window of the new filter field, set the following attributes:
   - **Caption**: Enter a caption for the group box. The caption is displayed within the upper border of the field.
4) Place the filter fields that shall be part of the group into the group box using drag and drop.
5) In the toolbar, click the **Save** button to save your changes.

After having filled the group box, you can alter the size and location of both boxes and fields within the box using the mechanisms described in the sections Changing the Size of a Single Filter Field and Changing the Location of a Single Filter Field.

For filter fields that are placed in a group box, the values for the attributes **Left** and **Top** of the filter field are marking the distance to the border of the group box instead to the border of the filter panel.

Adding Static Information to the Filter Panel

You can add text to the filter panel, display current values stored in the Alfabet database for informational purposes or link from the filter panel to information available via a URL For example, to provide information about how to work with the filter or to provide information about the output of the configured report or selector. The following methods to add information to a filter panel are available:

- Adding Plain Text to the Filter Panel
- Adding an HTML text to the Filter Panel

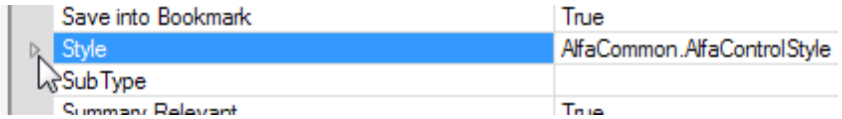
Adding Plain Text to the Filter Panel

To add a static text field to a filter panel:

1) In the toolbar, click the **Static Text** icon.
2) Drag the mouse on the filter panel in the report editor to create a text box in the location and width of your choice.
3) In the attribute window of the new filter field, set the following attributes:
   - **Caption**: Enter the text that shall be displayed in the text box.
4) In the toolbar, click the **Save** button to save your changes.

Optionally you can alter the style of the text by defining borders and a background color and by altering the text style and color:

1) Click the static text field in the filter panel.
2) In the attribute window, expand the **Style** attribute by clicking on the triangle in front of the attribute.

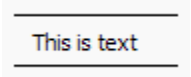


3) To alter a style, alter the style sub-attributes.

Please note that an attribute with a triangle in front of the attribute name cannot be set in the attribute itself. Instead, click the triangle to see a lower level of sub-attributes that can be used to define single dimensions of the attribute.

- **To define a border:**

Borders can be defined separately for each side of the text field. For example, you can set a border on top and bottom of the text only:



To define a border for one side of the box, expand one of the style attributes **Border Left**, **Border Right**, **Border Bottom** or **Border Top** and define both sub-attributes:

- **Border**: Define the width of the border as integer. If you define 0, no border is displayed. Setting the attribute to 1 results in display of a thin border. To define a wide margin, enter an integer higher than 1.
- **Color**: Click in the attribute field. A button appears on the right of the attribute field. Click the button to open a color picker and select a color. By default the color of the border is transparent.

- **To define a background color:**

To define a background color, click in the **Back Color** attribute field. A button appears on the right of the attribute field. Click the button to open a color picker and select a color. By default the background color is transparent.

The background color is applied to the whole text box when the filter is displayed on the Alfabet user interface, but in the editor in Alfabet Expand, the background color is only applied directly to the text.

- **To define the text style:**

To define the text style, expand the **Font** attribute and define the following sub-attributes:

- To alter the font style, click in the **(Name)** attribute field. A button appears on the right of the attribute field. Click the button and select a text style from the drop-down list.
- To alter the text color, click in the **Color** attribute field. A button appears on the right of the attribute field. Click the button and select a color from the color selector.
- To display text in bold, italic, underline or strike the text, set the corresponding attribute **Bold**, **Italic**, **Underline** or **Strikeout** to `True`.
- To alter the text size, change the real number in the **Size** attribute.

- **To define the text location in the text field:**

To define the location of the text in the text field, do one of the following:

- Expand the attribute **Font** and define the horizontal alignment of the text in the text box with the attribute **Horizontal Alignment** and the vertical alignment of the text in the text box with the attribute **Vertical Alignment**.
- Expand the attribute **Margin** and define the distance between the text and the border of the text box. If you want the same distance between the text and the border to be applied for all directions, you can define the value in the attribute **All**. Alternatively, you can define different values for the margin on top, bottom, left and right of the text by setting the attributes **Bottom**, **Top**, **Left** and **Right** to the individual values. The attribute **All** is then automatically set to -1.

4) In the toolbar, click the **Save**  button to save your changes.

Adding an HTML text to the Filter Panel

An **HTML Control** interface element can be added to a filter panel to display text with HTML formatting (font and color). A link to an URL providing additional information can also be added to the HTML text.

Embedded images may not be included in the HTML code.

To add HTML text to a customer editor:

1) In the toolbar, click the **HTML Control**  icon.
2) Drag the mouse on the filter panel in the report editor to create a text box in the location and width of your choice.
3) In the attribute window of the new filter field, set the following attributes:

- **Sub Type**: Select `EmbeddedHTML`.

  The HTML interface element has additional options in the drop-down list for the specification of the **Sub Type** attribute. These other options are currently not activated.

- **HTML Source**: Enter the HTML content that shall be displayed in the field. Note the following requirements for the definition of the HTML code:

  - The HTML must be compliant with XHTML, XML-conform HTML, compliant with HTML 5, and use standard HTML tags. The HTML header implements standard HTML elements.
  - The code must start with an `<xhtml>` tag and end with `</xhtml>`. Standard HTML elements must be written in lower-case letters in order to be correctly parsed: `<xhtml>`, `<html>`, `<head>`, `<body>`, and `<culture_>`. The definition of `<head>`, `<body>`, and `<culture_>` is optional.
  - The formatting of the HTML can either be written explicitly in the `<body>` element or can be specified via a stylesheet that is stored in the **Internal Document Selector** . In this case, the HTML must refer to the target CSS file in a `<link>` element. The CSS file should contain all necessary styles to display the content of the HTML. Please note that the CSS file may not be stored in the root folder of the **IDOC** explorer. The CSS file stored in the **Internal Document Selector** must be located in a document folder that is subordinate to the root folder of the **IDOC** explorer. To upload a file to the **Internal Document Selector**, see the section *Uploading Documents and Managing User Permissions to Document Folders in the Internal Document Selector* in the reference manual *User and Solution Administration*. For example,:

```
<xhtml>
    <culture_1033>
        <html>
        <body
        style="margin:4px;background:#3d4b60;overflow:hidden;">
            <link type="text/css" rel="stylesheet"
            href="IDOC:\CSS\my_style_file.css"></link>
            <p>This is the content for the header of the wizard
            step.</p>
```

```
            ...
        </body>
        </html>
    </culture_1033>
</xhtml>
```

- All CSS formatting instructions must end with `!important` to ensure that they are processed by the Alfabet application. For example,:

```
<xhtml>
    <culture_1033>
        <html>
        <body style="margin:4px !important;background:#3d4b60
        !important;overflow:hidden !important;">
            <style type="text/css">
                p.header
                {
                    font-family:verdana !important;
                    font-size:18px !important;
                    color:#ff0000 !important;
                    text-align: Left !important;
                }
            </style>
            <p class="header">This is the content for the header of
            the wizard step.</p>
            ...
        </body>
        </html>
    </culture_1033>
</xhtml>
```

- If translation to a secondary language is required, you must provide the translation in the HTML specification. Please note that HTML texts cannot be translated via the **Translation Editor** available in Alfabet Expand. Please consider the following:
  - If the HTML description is required in additional languages, each language text must be defined within language elements (For example, `<culture_1031>` for English, `<culture_1033>` for German, etc.)
  - The element `<culture_xxx>` must be specified as a child of the root element `<xhtml>`. The element `<html>` must be specified as a child of the element `<culture_xxx>`. The element `<html>` contains the HTML specification in the relevant language. For example, to provide information in English and German:

```
<xhtml>
    <culture_1033>
        <html>
```

```
                    <body>
                        <h3>Glossary: Application</h3>
                        <p>An application is a fully-functional integrated
                        IT product that provides functionality to end
                        users and/or to other applications. As such, an
                        application supports the business to accomplish
                        its mission. Applications operate on a platform
                        made up of hardware and software components
                        necessary to run the application.</p>
                    </body>
                </html>
            </culture_1033>
            </culture_1031>
                <html>
                    <body>
                        <h3>Glossar: Applikation</h3>
                        <p>Eine Applikation ist ein voll funktionsfähiges,
                        integriertes IT-Produkt, das Funktionalitäten für
                        Endanwender und/oder für andere Applikationen
                        bietet. Eine Applikation unterstützt das
                        Unternehmen bei der Zielerreichung. Applikationen
                        werden auf einer Plattform betrieben, die aus den
                        für die Ausführung der Applikation erforderlichen
                        Hardware- und Software-Komponenten besteht.</p>
                    </body>
                </html>
            </culture_1031>
        </xhtml>
```

4) In the toolbar, click the **Save** button to save your changes.

Instead of writing the text directly into the HTML control, you can alternatively store it as an HTML document and upload it to the **Internal Document Selector** in Alfabet. In the HTML control, you can link to the document in the **Internal Document Selector** and the text will be uploaded from the HTML document. This method is useful if you want to re-use the same text in various HTML controls.

For information about adding documents to the **Internal Document Selector** available in the **Internal Documents** functionality in Alfabet, see the section *Uploading Documents and Managing User Permissions to Document Folders in the Internal Document Selector* in the reference manual *User and Solution Administration*.

To add an HTML control reading content from an HTML file in the **Internal Document Selector**:

1) In the toolbar, click the **HTML Control** icon.
2) Drag the mouse on the filter panel in the report editor to create a text box in the location and width of your choice.
3) In the attribute window of the new filter field, set the following attributes:
   - **Sub Type**: Select `IDocument`.

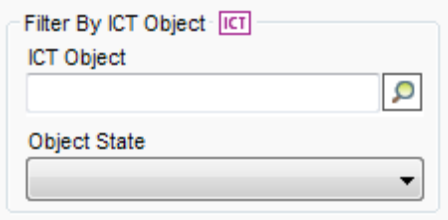
- **HTML Source**: Specify the full path to the HTML document in the **Internal Document Selector** . The path starts with `IDOC:\` followed by the folder structure within the **Internal Document Selector** defined with backslashes between folder names and file name. For example,:

  ```
  IDOC:\Documents\FilterHelp\General.html
  ```

4) In the toolbar, click the **Save** button to save your changes.

Adding an Icon With or Without a Link to Another Alfabet View to the Filter Panel

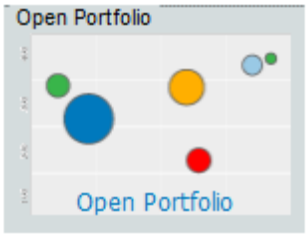
Icons can be added to the filter panel to enhance the design. Optionally, a link can be added to the image. When the user clicks the image with the underlying link, the configured target view in Alfabet opens. The link target can be either a standard graphic view or a configured report. For example, if a group box groups filter fields that allow to select properties of a defined object class, the icon used for the object class in explorers on the Alfabet user interface can be added next to the text in the group box:



Any icon that you want to add to the filter panel first must be imported to the icon gallery. For more information, see the section Adding and Maintaining Icons for the Alfabet Interface in the chapter Configuring the Visualization of the Alfabet Interface.

Icon fields can have a caption. The caption is displayed beneath the image in the Alfabet user interface, but when you design the view in Alfabet Expand you will see the caption within the image:

Icon field in Alfabet Expand:



Icon field displayed in the Alfabet user interface:

Open Portfolio

To add an icon to the filter panel:

1) In the toolbar, click the **Icon** icon.
2) Drag the mouse on the filter panel in the report editor to create a box in the location and width of your choice.
3) In the attribute window of the new filter field, set the following attributes:

   - **Sub Type**: Select the relevant option based on the size of the icon that you want to add:

- `Icon`: To add an icon that is 22x22 pixel in size.
- `IconLarge`: To add an icon that is 30x30 pixel in size.
- `IconFree`: To add an icon that has an arbitrary size.

- **Icon**: Click into the attribute field and then click the button on the right of the field to select an icon from the drop-down list.

4) To adjust the icon interface control to the general size of the icon, expand the **Coordinates** section of the property grid and enter pixel values in the **Height** and **Width** fields. For example, if you plan to add an icon that is 22x22 pixel in size, you could enter values 22 or larger in the **Height** and **Width** field to make handling the element easier while designing the custom editor.

5) In the **Caption** attribute, alter the default caption or delete it, if you do not want a text to be displayed beneath the icon.

6) In the toolbar, click the **Save** button to save your changes.

Optionally, you can configure the image to provide a link to a standard page view or configured report:

Please note the following about links from icons in filter panels:

- No base object is provided for the link. Make sure that a target standard page view is designed to provide meaningful results without a base object specification. For configured reports, filter settings of the current report can be provided to the link target using storage of filter results in the object class `UserGlobalData`. For more information, see Configuring Reusability of Filter Settings Across Reports.
- If a caption is displayed beneath the image, the font style of the caption is identical to the font style of all filter captions. If a link is provided with the icon, the caption style is the link font style defined for the user interface in the current GUI scheme. For more information about GUI schemes for defining the design of the Alfabet user interface, see Configuring GUI Scheme Definitions for the Alfabet Interface.

1) Click the icon field in the filter panel.

2) In the attribute window, click the **Source** attribute and click the **Browse** button at the end of the field. A new window opens.

3) Set the following attributes:

- **Source Type**: Select **Configured Reports** if the link shall open a configured report or **Page Views** if the link shall open a standard Alfabet page view.
- **Source Object**: Select a configured report or standard Alfabet page view from the drop-down list. The list is automatically adapting to the choice made in the field **Source Type**.

4) Click **OK** to close the window.

5) In the toolbar, click the **Save** button to save your changes.

Configuring the Submit Button

Both filter panels for configured reports and custom selectors have a preconfigured button **Submit** to apply the filter settings to the search result. On a filter, no other buttons are allowed.

You can adapt the text of the button according to your demands:

1) Click the button in the filter panel to open the attribute window of the button.
2) In the attribute window, edit the following attributes, if applicable:
   - **Caption**: Enter the text that shall be displayed in the button.
   - **Hint**: Define a tooltip that is displayed for the button when the user moves the cursor over the button.

The size and the position of the button can also be altered as described in the sections Changing the Size of a Single Filter Field and Changing the Location of a Single Filter Field.

The coloring and text style of the button is designed via the GUI scheme configuration for the user profile. The two different button styles **Primary Button Skin** and **Secondary Button Skin** can be configured in the GUI scheme to highlight the central buttons in a view with multiple buttons via a different design. The **Submit** button in filters is assigned the **Primary Button Skin**.

For more information about GUI scheme configuration, see Configuring GUI Scheme Definitions for the Alfabet Interface.

Usually, the styling of buttons is determined by the **Default Button** attribute of the button. If it is set to `True`, the **Primary Button Skin** style is used and if it is set to `False`, the **Secondary Button Skin** style is used. Please note that this setting is ignored for **Submit** buttons. **Submit** buttons are always displayed with the **Primary Button Skin** style.

The **Button** control can be used to re-create the **Submit** button if it has been deleted by mistake:

1) In the toolbar, click the **Button**  icon.
2) Drag the mouse on the filter panel in the report editor to create a box in the location and width of your choice.
3) In the attribute window of the new button, set the following attributes:
   - **Caption**: Enter the text that shall be displayed in the button.
   - **Hint**: Define a tooltip that is displayed for the button when the user moves the cursor over the button.
   - **Submit**: Select `True`.
4) In the toolbar on top of the attribute window, click the  button. The content of the attribute window changes to display available operations.

    To return to the attribute view, click the  button in the toolbar.
5) In the ***OnButtonClick*** field, select `OnClickSubmit` from the drop-down list.
6) In the toolbar, click the **Save**  button to save your changes.

Changing the Sequence of the Focus on Filter Fields

The user can use the TAB key to move the focus to another widget field, but by default, there is no order within the widget fields that is followed for each widget. You can define the sequence for moving the focus via the tab key:

1) Click anywhere in the filter panel.
2) In the toolbar, select **Format** > **Define Tab Order**. A blue box with a number is displayed in each filter field.
3) Click the blue boxes in the order that they should be sequenced.
4) In the toolbar, click the **Save** button to save your changes.
5) In the toolbar, select **Format** > **Define Tab Order** to remove the blue boxes from the panel.

Alternatively, the tab index of individual fields can be set via the attributes of the filter field. Please note that this alternative method is not available for filter fields in configured reports of the type `Query`.

1) Click the filter field that you want to set the tab order for to open the attribute window.
2) In the attribute window, set the following attribute:
   - **Tab Index**: Set the tab index of the field the user shall start browsing through the filter fields to 0. Set the **Tab Index** of the next filter field to 1. Increment the Tab Index by one for each sub-sequent filter field. The focus will move from the lowest number to the highest number following the order of numbers subsequently.
3) In the toolbar, click the **Save** button to save your changes.

Configuring the Complete Filter Area to be Collapsible

The complete filter area can be configured to be collapsible. The **Collapse Filter** option available in the **Options** menu on the top right side of the filter area allows users to close the filter area of the configured report or selector in order to increase the amount of space available to display the search results / report.

To configure the filter panel to be collapsible:

1) Open the attribute window of the filter panel:
   - For selectors: Click in the header panel of the graphic view to open its attribute window.
   - For reports: Click the parameter panel of the custom report view to open its attribute window.
2) In the **Collapsible** field, select `True` to implement the **Collapse Filter** button.

> The **Collapse Filter** option is automatically added to the **Options** menu when the **Clear Search Patterns** option is implemented. The setting of the **Collapsible** attribute to `True` is only required if the **Clear Search Patterns** option is not implemented, that means that the attribute **Has Clear Button** of the filter panel is set to `False`. The

Options menu is only available when either the **Clear Search Patterns** or the **Collapse Filter** option is implemented.

3) In the toolbar, click the **Save** button to save your changes.

Configuring Part of the Filter Area to be Collapsible

If some of the filter fields for a configured report should be set to meaningfully execute the configured report while others are only for advanced filtering, the filter panel can be split into a part that is always displayed and a part that will only be displayed if the user clicks a link. The user can collapse and expand the advanced filter fields according to demand.

To configure part of the filter to be collapsible, two panels must be added to the existing filter panel:

1) In the toolbar of the view editor, click the **Panel** icon.
2) Drag the mouse on the filter panel in the view editor to create a panel covering the top area of the filter panel in the size required for all filter fields that shall be always visible and the button to submit the filter values.
3) If filter fields and buttons have already been added to the filter panel prior to configuring part of the filter panel to be collapsible, move the filter fields and buttons that shall be always visible to the new panel.

   If you add a panel, it will be added on top of existing filter fields. To add the fields to the panel, change the location of the new panel in the mail filter panel area until you can see the filter fields, move them to the new panel and move the new panel back to the final location. for information about resizing and moving filter elements, see Changing the Size of a Single Filter Field and Changing the Location of a Single Filter Field.

   If the main filter area is left or right aligned and the **Options** menu shall be visible, the filter fields must be placed with enough spacing from top of the panel to allow the **Options** menu to be displayed.

4) Click into the new filter panel to open the attribute window of the new filter panel.
5) Set the **Dock** attribute to `Top`.
6) In the toolbar of the view editor, click the **Panel** icon.
7) Drag the mouse on the filter panel in the view editor to create a panel covering the lower area of the filter panel in the size required for all filter fields that shall be collapsible.
8) If filter fields and buttons have already been added to the filter panel prior to configuring part of the filter panel to be collapsible, move the filter fields that shall be hidden to the new panel.
9) Click into the filter panel that shall be collapsible to open the attribute window.
10) Set the **Dock** attribute to `Fill`.
11) Set the **Advanced Details Filter Panel** attribute to `True`.

    This attribute is only visible if the **Dock** attribute is set to `Fill`.

12) In the toolbar, click the **Save** button to save your changes.

Allowing the User to Clear the Filter Area

The filter panel can be configured to display a **Clear Search Patterns** option in the **Options** menu on the right side of the filter area. The **Clear Search Patterns** option allows users to clear all filter settings with a single click:

When the **Clear Search Pattern** option is activated, the setting of the **Collapsible** attribute of the filter panel is ignored and the **Collapse Filter** option is automatically added to the filter panel. It allows users to close the filter area of the selector in order to increase the amount of space available to display the search results/report. The **Options** menu is only available when either the **Clear Search Patterns** or the **Collapse Filter** option is implemented.

To include the **Clear Search Patterns** option in the **Options** menu of the filter panel of a configured report or custom selector:

1) Open the attribute window of the filter panel:
   - For custom selectors: Click in the header panel of the graphic view to open its attribute window.
   - For configured reports: Click the parameter panel of the custom report view to open its attribute window.
2) In the **Has Clear Button** field, select `True` to implement the **Clear Search Patterns** option.
3) In the toolbar, click the **Save** button to save your changes.

You can optionally configure individual filter fields to be excluded from the **Clear Search Patterns** action. To prevent a specified filter field to be cleared:

1) Click the filter field that you want to exclude from the **Clear Search Patterns** action to open its attribute window.
2) In the **Allow Clear Value** field, select **False** to prevent the field's value set by a user from being cleared when the user clicks the **Clear Search Patterns** option.

Changing the Position of the Filter Panel

By default, filter panels are added on top of a view for configured reports or selectors. The filter panel can optionally be moved to the left or right of the view:

1) In the view for a configured report or custom selector, click the filter panel.
2) In the attribute section of the filter panel, set the **Dock** attribute to `None`.
3) Click the ***Presentation*** object in the view.
4) In the attribute section of the ***Presentation*** object, set the **Dock** attribute to `None`.

5) Click the filter panel and pull the handles to change the size and position to include both the area the final filter field should cover and the position of existing buttons and filter fields.

6) If applicable, move existing filter fields and buttons to the correct position in the new filter field area.

> For information about moving filter elements, see Changing the Location of a Single Filter Field.

7) Click the filter panel and pull the handles to change the size and position the filter panel should have in the final view design.

8) In the attribute section of the filter panel, set the **Dock** attribute to `Left` for a filter panel positioned on the left of the view or to `Right` for a filter panel positioned on the right of the view.

9) Click the ***Presentation*** object in the view.

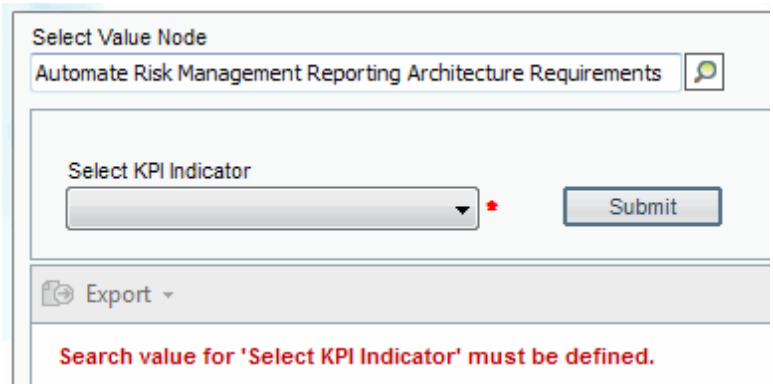
10) In the menu of Alfabet Expand, select **Edit** > **Cut**.

11) In the menu of Alfabet Expand, select **Edit** > **Paste** and click into the view area the ***Presentation*** object should be displayed in.

12) In the attribute section of the ***Presentation*** object, set the **Dock** attribute to `Fill`.

Defining Mandatory Filter Fields

Filter fields that were added manually to a report can be set to mandatory. The filter field is then marked with an asterisk. When the user clicks the **Submit** button without setting the filter field, a warning is displayed:



Please note the following:

- This feature is not available for automatically generated filter fields.
- Filters cannot be set to mandatory in console reports. The subordinate reports do not evaluate the filter field settings of the console report but read the stored filter data from a table in the Alfabet database.

To set a filter field to mandatory

1) Click the filter field that you want to edit.

2) In the attribute window, set the attribute **Presence** to `Always`.

3) In the toolbar, click the **Save**  button to save your changes.

Excluding Filters From Storage in Bookmarks

When a bookmark is set for a report, all filter settings are stored by default in the bookmark. When a user opens the report via the bookmark, the report opens with the filter settings that were selected when the bookmark was created. The filter field is displayed with the preset values in the filter fields.

A filter field can be excluded from being saved in bookmarks. A filter field that is excluded from the bookmark is not automatically filled with the settings stored in the bookmark. Instead, it is filled with the filter settings derived from the user context - in other words, with the values the user has entered in the field when he/she last executed the report. If no values have been stored in the user's personal settings, the field will be left empty when the user opens the report via the bookmark.

The user can change the settings of all filter fields to alter the predefined values for both filter fields included in bookmarks and excluded from bookmarks.

To exclude a filter field from storage in bookmarks:

1) Click the filter field that you want to edit.
2) In the attribute window, set the attribute **Save into Bookmark** to `False`.
3) In the toolbar, click the **Save**  button to save your changes.

For filter fields in Console Reports that are configured to store the user settings in an object of the object class `UserGlobalData`, the values currently stored for the properties of the `UserGlobalData` object are all stored in the bookmark independent from the setting for **Save into Bookmark**. For those filter fields, the values selected when creating the bookmark are reset when opening the bookmark even if **Save into Bookmark** is set to `False`. In addition, the values for all properties of the `UserGlobalData` object are overwritten with the data stored in the bookmark. That means that filter settings that have in the meantime been changed for other reports are also overwritten.

Excluding Filters from the Filter Summary in Exports

By default, a button **Export** is displayed in the toolbar of configured reports. Via the **Export** button the results currently displayed in the configured report can be exported for use outside of Alfabet. The available output formats depend on the type of configured report. When a configured report is exported via the **Export** functionality in Alfabet, the filter settings used to generate the exported report output can be included in the export.

For information on how to export configured reports, see the section *Exporting Data* in the reference manual *Getting Started with Alfabet*.

A filter field or the whole filter panel can be excluded from being displayed in the export.

To exclude a filter field from the exported filter summary:

1) Click the filter field that you want to edit.
2) In the attribute window, set the attribute **Summary Relevant** to `False`.
3) In the toolbar, click the **Save** button to save your changes.

To exclude all filter fields from the exported filter summary:

1) Click into the filter panel area.
2) In the attribute window, set the attribute **Summary Relevant** to `False`.
3) In the toolbar, click the **Save** button to save your changes.

Automatically Adding Wildcards to Search Strings

The setting of wildcards in filter fields depends on the configuration of the `AutoWildCard` element in the XML object ***SearchManager***. The search function can be configured to automatically add a wildcard before and after the search string entered in an edit field and Therefore, search for any string containing the search criteria. Alternatively, the search function can be configured to use the search string as explicitly entered in the field . In other words, the user entering the string in the edit field must add a wildcard to the string in the field if he/she wants to search for a string containing but not equal to the defined search string.

For more information about the configuration of the XML object ***SearchManager***, see Configuring the Wildcard for Standard and Custom Search Functionalities

If the XML object ***SearchManager*** is configured so that wildcards are automatically implemented, you can configure individual filter fields in a configured report or custom selector to be excluded from wildcard setting. Depending on the underlying query, the setting of wildcards might be undesirable if, For example, when comparing the entry in the filter field with a string using an equal to operator.

For example, a `WHERE` condition is defined that uses an equal to operator to compare the return value:

```
WHERE @Fieldvalue = 'Content'
```

When the user enters "`Content`" in the filter field and **Allow Wildcards** is set to `True`, the return string is "`%Content%`", which is not equal to "`Content`" and Therefore, the condition in the `WHERE` clause above is not fulfilled. You must either select a `LIKE` operator or include the wildcards in the compare value and define that the return value from the field must equal "`%Content%`". Alternatively, you can set **Allow Wildcards** to `False` for the filter field.

To exclude a filter field from automatic wildcard settings:

1) Click the filter field that you want to edit.
2) In the attribute window, set the attribute **Allow Wildcards** to `False`.
3) In the toolbar, click the **Save** button to save your changes.

Configuring Cascading Filters

In complex filters it can be useful to define the choice available to fill one control dependent on a selection already performed in another filter field. For example, a report that shows indicators for selected applications allows to select an application group in one filter field to show the indicators for all applications in the selected group and to select a single application in a second filter field to show the indicators of the selected application. The report can be configured to show For example, a drop-down list of available applications in the filter field for selection of the application. The content of the drop-down list depends on the settings performed for the selection of the application group. When the user has selected an application group, the drop-down list content is limited to the applications assigned to the selected application group.

When two filter fields are configured to be cascading, one must be defined as the master control that contains the content that the subordinate control depends on. Both master and subordinate control require a special configuration:

- The master control must be configured to submit changes when the user leaves the control after selecting/entering a search condition.
- The subordinate control must be configure to trigger a refresh of the field content on submit of changes of a defined master control.
- The query defined to find the objects displayed for selection in the subordinate filter field must define a dependency with the data from the master control.

Please note the following when defining cascading filters:

- The value type of the master control must be one of the following:
  - `Reference`
  - `ReferenceArray`
  - `String`
  - `Date`
  - `DateTime`
  - `Integer`
  - `Real`
- The following types of filter fields are not suitable for use as master control:
  - Check box
  - List box
  - Checked list box
  - Radio button group
  - Slider control
  - Value control

Edit fields can only be used as master controls if they are populated with a date.

- You can define more than one level of cascading filter fields. A filter field can depend on a master control and at the same time be the master control for another filter field.
- A filter can depend on multiple master controls. The query defined to find the objects displayed for selection in the subordinate filter field must then define dependencies with the data of all master controls.
- A filter field can be configured to depend on the base object of the report or selector instead of a master control. In that case, the query defining the filter field content must include the dependency to the current base object of the report.
- When defining cascading filters, make sure that no circular references occur between master and subordinate filter fields.

To configure an existing control as master control:

1) Click the filter field that you want to configure as master .
2) In the attribute window, edit the following attributes:
   - **Submit**: Select `True` to submit the current value when the user leaves the control after selecting/entering a search condition.
3) In the toolbar, click the **Save** button to save your changes.

To configure a control as subordinate control:

1) Click the filter field that you want to edit.
2) In the attribute window, edit the following attributes:
   - **Refresh on Submit**: Select `True` to re-evaluated the selection in the filter field each time the filter is submitted.
   - **Master Controls**: Click into the field and then click on the Browse button at the end of the field. A new window opens that lists all available controls. Select the checkbox of one or multiple controls to select them as master control fields. Click **OK** to save your selection.

If the control shall depend on the base object of the report or selector, the **Masters** attribute must remain undefined.

3) In the query defining the content of the filter field, define a dependency with the data from the master control. To refer to the content of the master control, the name of the master control must be used as parameter in a condition. The parameter returns the `REFSTR` of the object currently selected in the master control. To refer to the current base object of the report or selector, use the parameter `BASE`.

   The following example shows a native SQL query defined for a filter subordinate to the filter field `@APP` that allows to select an application:

```
SELECT COMP.REFSTR, COMP.NAME, COMP.VERSION FROM COMPONENT
COMP

INNER JOIN LOCALCOMPONENT AS LCOMP

   ON LCOMP.COMPONENT = COMP.REFSTR AND LCOMP.OWNER = @APP

/* Alfabet Instructions */
```

```
JoinColumns("COMP.NAME,COMP.VERSION", "COMP.NAME", " v.");
```

The following example shows an Alfabet query defined for a filter field that is filled with values dependent on the current base object. All applications in the application group the user is currently working with are listed in the selection:

```
ALFABET_QUERY_500

FIND Application

   WHERE Application.ApplicationGroups CONTAINS:BASE

Instructions

JoinColumns("Application.Name,Application.Version","Applicatio
n.Name", " v.");

EndOfInstructions

QUERY_XML

<QueryDef>

   <ShowProperty Type="Property" ClassName="Application"
   Name="Name" />

   <ShowProperty Type="Property" ClassName="Application"
   Name="Version" />

</QueryDef>
```

4) In the toolbar, click the **Save** button to save your changes.

In the following example, a tabular report shall display components that are assigned as local components to applications. Two filter fields of the type checked combo box for the selection of multiple values shall be available as a cascading filter. The user can first select one or multiple application groups to restrict the report results to local components of applications assigned to one of the selected application groups. A second checked combo box shall allow to further restrict display to a subset of the applications in the selected application groups. The content of the combo box for the selection of applications depends on the selection in the combo box for application groups.

	Application Name	Application Version	Component Name	Component
1	ACCOUNT	1	HP ProLiant Server BL Series	all
2	ACCOUNT	1	IBM DB2	9.x
3	ACCOUNT	1	Microsoft Excel	2003
4	ACCOUNT	1	Microsoft Windows	XP
5	ACCOUNT	1	Microsoft Windows Enterprise Server	2003 32bit
6	ACCOUNT	1.2	HP ProLiant Server SL Series	all
7	ACCOUNT	1.2	IBM DB2	9.x
8	ACCOUNT	1.2	Microsoft Excel	2010
9	ACCOUNT	1.2	Microsoft Windows	7

The definition of the report is described here both for an Alfabet query based report and for a native SQL based report in parallel.

Definition of the query for the report:

The query contains two parameters in the `WHERE` conditions, one that allows the user to restrict the report to data for selected application groups and one to restrict the report to data for selected applications in that application groups.

The report can be based on the following Alfabet query:

```
ALFABET_QUERY_500

FIND DISTINCT Component

InnerJoin LocalComponent ON LocalComponent.Component =
Component.REFSTR

InnerJoin Application ON LocalComponent.Owner = Application.REFSTR

InnerJoin ApplicationGroup ON Application.ApplicationGroups =
ApplicationGroup.REFSTR

WHERE

    (AND

       ApplicationGroup.REFSTR CONTAINSOR @APPG_REF

       Application.REFSTR CONTAINSOR @APP_REF

    )

QUERY_XML

<QueryDef>

<ShowProperty Type="Property" ClassName="Application" Name="Name" />

<ShowProperty Type="Property" ClassName="Application" Name="Version"
/>

<ShowProperty Type="Property" ClassName="Component" Name="Name" />
```

```
<ShowProperty Type="Property" ClassName="Component" Name="Version"
/>

<SortProperty Type="Property" ClassName="Application" Name="Name" />

<SortProperty Type="Property" ClassName="Application" Name="Version"
/>

<SortProperty Type="Property" ClassName="Component" Name="Name" />

<SortProperty Type="Property" ClassName="Component" Name="Version"
/>

</QueryDef>
```

In the `WHERE` clauses with the parameter the `CONTAINSOR` operator is used which means that the property is compared to a number of values from which one must apply. Therefore, when generating the custom report view, two filter fields of the type checked combo box for the selection of multiple values are created automatically.

The report can be based on the following native SQL query:

```
SELECT DISTINCT com.REFSTR, app.NAME As 'Application.Name',
app.VERSION As 'Application Version', com.NAME As 'Component Name',
com.VERSION As 'Component Version'

FROM COMPONENT com

INNER JOIN LOCALCOMPONENT lcom

   ON lcom.COMPONENT = com.REFSTR

INNER JOIN APPLICATION app

   ON lcom.OWNER = app.REFSTR

INNER JOIN RELATIONS rel

   ON rel.FROMREF = app.REFSTR

INNER JOIN APPLICATIONGROUP appg

   ON rel.TOREF = appg.REFSTR

WHERE rel.PROPERTY = 'ApplicationGroups'

   AND appg.REFSTR IN (@APPG_REF)

   AND app.REFSTR IN (@APP_REF)

ORDER BY app.NAME, app.VERSION, com.NAME, com.VERSION;
```

When generating the custom report view, combo boxes are automatically generated as filter fields. These are substituted by the corresponding checked combo boxes manually with the filter field attributes defined as described in the section Configuring Radio Button Groups, Combo-Boxes, Checked Combo-Boxes, List Boxes or Checked List Boxes. The following description of filter field configuration is limited to the query definition and the settings required for configuring the filter fields as cascading filter.

Definition of the master control:

The combo box for the selection of the application group is defined as master control, with the attribute **Submit** set to `True`.

The query defined for the combo box content searches for application groups. If a high number of application groups is defined, it is recommended to restrict the content of the combo box to a subset relevant for the user opening the report. In the example, a simple restriction to application groups with a name starting with '`Co%`' is added to the query.

In Alfabet query language, the following query is used:

```
ALFABET_QUERY_500

FIND ApplicationGroup

WHERE ApplicationGroup.Name LIKE 'Co%'

QUERY_XML

<QueryDef>

<ShowProperty Type="Property" ClassName="ApplicationGroup"
Name="Name" />

<SortProperty Type="Property" ClassName="ApplicationGroup"
Name="Name" />

</QueryDef>
```

In native SQL, the following query is used:

```
SELECT appg.REFSTR, appg.NAME

FROM APPLICATIONGROUP appg

WHERE appg.NAME LIKE 'Co%'

ORDER BY appg.NAME
```

Definition of the subordinate control:

The combo box for the selection of the applications is defined as subordinate control of the combo box for the selection of the application groups. The **Refresh on Submit** attributeis set to `True` and the **Master Controls** attribute defines the filter field `@APPG_REF` as master.

The query defined for the combo box content searches for all applications that are assigned to one of the selected first level application groups. An application can be assigned to multiple application groups. The assignment to application groups is stored via the property `ApplicationGroups` as a reference array, that means that the relations are stored in the relation table. In the Alfabet query language, it is nevertheless possible to define a simple `WHERE` clause that directly compares each assignment of an application group via the `ApplicationGroups` property with the values selected in the master control using a `CONTAINSOR` operator. The condition returns true if the application is assigned to at least one of the selected application groups:

```
ALFABET_QUERY_500

FIND Application

WHERE Application.ApplicationGroups CONTAINSOR @APPG_REF

QUERY_XML

<QueryDef>

<ShowProperty Type="Property" ClassName="Application" Name="Name" />

<ShowProperty Type="Property" ClassName="Application" Name="Version"
/>

<SortProperty Type="Property" ClassName="Application" Name="Name" />

<SortProperty Type="Property" ClassName="Application" Name="Version"
/>

</QueryDef>
```

In native SQL, the query must define the condition via a `JOIN` with the relations table, comparing the property `TOREF` of the relation with the values returned from the master control:

```
SELECT app.REFSTR, app.NAME, app.VERSION
FROM APPLICATION app
INNER JOIN RELATIONS rel
   ON rel.FROMREF = app.REFSTR
WHERE rel.PROPERTY = 'ApplicationGroups'
   AND rel.TOREF IN (@APPG_REF)
ORDER BY app.NAME, app.VERSION
```

Configuring Reusability of Filter Settings Across Reports

In Alfabet, filter settings done by the user in the report can be stored and re-used via the following mechanisms:

- For all filters in Alfabet, independent of whether they are standard or customer defined, the filter settings of the user are stored and when the user re-opens the report or selector at a later time, the report or selector opens with the stored filter settings.

Note the following regarding this mechanism:

  - The mechanism stores the filter settings in the context of the current user, the current user profile and the current report. When the same user logs in with different user profiles, the same report can open with different preset filter settings. Also, if a user was searching for an application with a defined name in one report, all other reports that include a filter searching for applications by name do not take over the filter setting.
  - Each time the user alters the filter settings, the stored settings are overwritten with the new settings and these are used when the user re-opens the report the next time.
  - The filter settings are stored either on submitting the report or on navigation to an object from the report. When a user alters the filter settings, but prior to re-submitting the new settings, decides to navigate to an object from the report, the altered settings are nevertheless stored and used to open the report when the user navigates back to the report.

It is recommended not to execute configured reports with filter fields storing the filter settings into the `UserGlobalData` object class offline. On rendering of the offline executed report results, the values stored in the `UserGlobalData` object class will be overwritten with the filter values defined on triggering the report execution of the current report results. The opening of offline executed report results in a new tab might change a filter setting depending on the same object of the `UserGlobalData` object class for a report opened in parallel in the original tab for working with Alfabet without further notice.

For more information about offline execution of long running configured reports, see Configuring Offline Execution for Long Running Tabular Reports with Filters.

- Filter settings made by a user in one configured report can be stored in the Alfabet database and referenced in `WHERE` conditions of queries in other reports to open one report dependent on the search performed in another report. A typical use case for this configuration is the design of a configured console report. A console report is a multi part report that allows to display results for multiple configured reports in one view. A filter can be defined for the console report. If filter fields of the filter in the console report are configured to be stored in the database, the reports displayed as

sub-ordinate reports can be configured to take over the filter settings from the database and open with the same context.

For example, a console report displays multiple reports about applications. In the filter, the user defines that only applications with a start date after a defined date are relevant. The sub-ordinate reports take over the filter settings and only display results for applications with a start date in the relevant period.

Please note the following:

- This mechanism is not available for filters defined in custom selectors or in configured reports of the type `Query`.
- Filters cannot be set to mandatory in console reports. The subordinate reports do not evaluate the filter field settings of the console report but read the stored filter data from a table in the Alfabet database.

The reuse of filter settings across reports requires a configuration of the meta-model and the filter in the configured report. It is based on the class `UserGlobalData`, that stores filter settings per filter field and user. The object class has one protected object property, `USERREF` that establishes a link to the object class Person.

An object of the object class `UserGlobalData` is automatically created the first time a new user logs in to Alfabet and the `USERREF` property is set to the `REFSTR` of the object of the object class Person that stores the data of that user.

To store filter settings in the class `UserGlobalData`, the solution designer must define the following:

- A custom property must be added to the object class `UserGlobalData` for each filter field for that the settings shall be applied to other reports.
- The configured report that includes the filter fields must be configured to find the instance of the object class `UserGlobalData` that is assigned to the current user.
- The filter fields of the filter for that the settings shall be re-used must be configured to store the settings performed by the user into the respective custom attribute of the `UserGlobalData` object of the user performing the setting on submit of the filter settings.

  The configuration of filter fields to store settings in `UserGlobalData` is not possible in configured reports of the type `Query` and custom selectors.

  If filter fields in a filter are defined to store values in `UserGlobalData`, all filter settings are submitted to the respective objects of the object class `UserGlobalData` even if only one or none of the filter settings has been changed.

- Reports that shall show results dependent on the settings from another report stored in the `UserGlobalData` objects must be configured to refer to values of the custom properties of the `UserGlobalData` object of the current user.

The following sections provide a detailed step by step instruction on how to define filter setting reusability:

- Configuring the Object Class UserGlobalData to Store Filter Settings
- Configuring the Configured Report to Store Filter Settings in UserGlobalData
- Configuring Filter Fields for Storage of Settings in UserGlobalData Properties

- Configuring Queries in Reports Referring To Global Filter Settings

Configuring the Object Class UserGlobalData to Store Filter Settings

The **Audit** attribute must be set to `False` for the object class `UserGlobalData`. Activation of auditing for the object class `UserGlobalData` significantly lowers performance.

To configure the object class `UserGlobalData` to store a filter setting:

1) In the **Meta Model** tab of Alfabet Expand, expand the **Classes** folder.
2) Right-click the object class `UserGlobalData` in the explorer and select **Add New Property**. The **Create New Property** editor opens. Define the following fields:
   - In the **Property Name** field, enter a unique name for the custom property. This value is used in the configuration of configured reports and custom selectors to refer to the current setting of a filter.

     A validation mechanism checks for correct syntax when defining a technical name. The technical name of a configuration object may not begin with an empty space nor include any of the following special characters: **\ / * ? " > < | ':**

     Furthermore, please note that names may not begin with an empty space nor include special characters. For a list of the special characters that are not allowed, see the section Defining Attributes for Configuration Objects in the chapter Getting Started with Alfabet Expand.

     Furthermore, if the technical name of a configuration object is changed, the name will be correctly updated in other configuration objects referencing the changed object during design time. Please note that the name of a changed configuration object will not be updated in guide pages nor if the guide pages reference a configuration object listed in the **Show Usage** functionality. If you plan to change the name of a configuration object, the reference in the guide page should be changed prior to changing the configuration object name.

   - In the **Tech Name** field, enter a unique technical name for the custom property that will be used in the database table. Click **OK** to save the definition.

     Please keep the following in mind:

     - The technical name may not begin with an empty space nor include special characters. For a list of the special characters that are not allowed, see the section Defining Attributes for Configuration Objects in the chapter Getting Started with Alfabet Expand.
     - The technical name should only contain standard `ASCII` characters.
     - The technical name should consist of upper-case letters only.
     - The maximum length of a technical name may not exceed 30 characters.
     - The technical name may not coincide with any of the reserved key words of the relational database management system.

A validation mechanism checks for correct syntax when defining a technical name. Please note that if the technical name of a configuration object is changed, the name will be correctly updated in other configuration objects referencing the changed object during design time. However, the name of a changed configuration object will not be updated in guide pages nor if the guide pages reference a configuration object listed in the **Show Usage** functionality. If you plan to change the name of a configuration object, the reference in the guide page should be changed prior to changing the configuration object name.

3) Click the custom property in the tree. You will see the attribute window in which you can define the custom property's attributes.

4) The custom property stores values added to a filter field. Filter fields allow to select values for a defined object class property from the Alfabet meta model. The data type of that object class property must be identical to the data type defined for the custom property of `UserGlobalData` storing the value. Therefore, set the following attributes to the values also defined for the object class property your filter field will target:

   - **Property Type**
   - **Type Info**
   - **Reference Support**

5) In the toolbar, click the **Save**  button to save the new custom property.

Configuring the Configured Report to Store Filter Settings in UserGlobalData

A configured report that shall store filter settings made in the filter setting of the configured report into the properties of the object class UserGlobalData must be configured to find the object of the class UserGlobalData referencing the user performing the filter settings as base class:

1) In the explorer of the ***Reports*** tab in Alfabet Expand, click the configured report for that you want to define reusable filter settings.

2) In the attribute window of the configured report, make sure that the **Apply to Class** attribute is not set.

3) In the **Base Object Query** attribute field, click the **Browse**  button. A text editor opens.

4) In the editor, enter a query finding the `UserGlobalData` object referencing the current user working with the configured report.

   You can use the following query in Alfabet query language:

   ```
   ALFABET_QUERY_500
   FIND UserGlobalData
   WHERE UserGlobalData.USERREF = @CURRENT_USER
   ```

   or in native SQL:

   ```
   SELECT REFSTR
   FROM USERGLOBALDATA
   WHERE USERREF = @CURRENT_USER
   ```

Configuring Filter Fields for Storage of Settings in UserGlobalData Properties

In addition to the settings required for the basic configuration of a filter field for a defined data type, the following configuration must be performed for each filter field for that the settings shall be stored in a custom property of the object class `UserGlobalData`:

1) In the explorer of the ***Reports*** tab in Alfabet Expand, click the custom report view for that the filter shall be defined.
2) In the attribute window of the custom report view, select `UserGlobalData` from the drop-down list in the **Class Name** field.
3) Double-click the custom report view to open the view.
4) In the editor area, click the filter control that you want to edit.
5) In the attribute window of the filter control, select the custom property of the object class `UserGlobalData` that is configured to store the filter value from the drop-down list in the attribute **Property**.
6) In the toolbar, click the **Save**  button to save your changes.

Configuring Queries in Reports Referring To Global Filter Settings

Note the following for the definition of the queries directly defined in the report containing the filters that are configured to store data in the object class `UserGlobalData`:

- The object class `UserGlobalData` must be defined as base class of the report with the attribute **Apply To Class** of the report. Therefore, the queries in the underlying report cannot refer to the object with that the user is currently working with the parameter `BASE`.
- The `WHERE` conditions in the query can refer to the filter fields by using the filter field name as parameter in the query independent from the storage of data into the `UserGlobalData` object class.

When filter settings of a report are stored in the object class `UserGlobalData`, all configured reports can refer to the filter settings by defining a JOIN to the `UserGlobalData` element of the current user and comparing the respective object data with the value stored in the `UserGlobalData` object.

The **Test Report** functionality in the context menu of the explorer cannot be used if a filter stores data in the object class UserGlobalData and the report reads the filter settings from the properties of UserGlobalData. Changing the filter settings in the test window will not update the reports that read data from `UserGlobalData`, because the test functionality will not change data in the Alfabet database. To test the report, set the **State** of the report to `Active`, open the Alfabet user interface and open the report via the **Reports** functionality. If the results are not as expected, set the **State** of the report back to `Plan` and edit the report until the output of the report meets your expectations.

Using Instructions to Format the Results of an Alfabet or Native SQL Query

Instructions are available in the Alfabet query language in order to allow solution designers to alter the display of datasets resulting from Alfabet queries or native SQL queries. Instructions can be used in the Alfabet query language and can be combined with native SQL.

The instructions must be defined in Alfabet query language even if the query itself is written in native SQL. If instructions may be combined with native SQL, a tab for the definition of instructions will be available in text editors and the report assistant. If a tab is not available to define instructions, then it is not permissible to define instructions with native SQL for the respective configuration.

Specifying an Alfabet Instruction in an Alfabet or Native SQL Query

When writing an Alfabet query directly in a text editor, all instructions are written in a section that starts with `Instructions` and ends with `EndOfInstructions`:

```
Instructions
any of the instructions specified below;
any of the instructions specified below;
EndOfInstructions
```

When writing a native SQL query directly in a text editor, the instructions must be separated from the native SQL query with the comment `/* Alfabet Instructions */`:

```
/* Alfabet Instructions */
any of the instructions specified below;
any of the instructions specified below;
```

However, in the **Alfabet Query Builder** and in the tabs for instructions definition in combination with native SQL, the instructions are defined without the delimiters `Instructions` and `EndOfInstructions`.

Please consider the following when defining instructions:

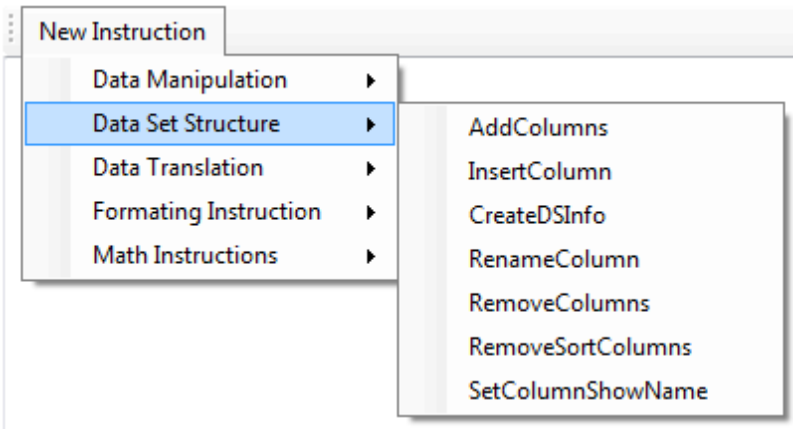
- To define instructions, the Show properties of the Alfabet query must be defined as an XML element. When using the **Alfabet Query Builder**, this is automatically done.
- It is not allowed to use whitespaces in the instruction outside of string specification of the delimiter.
- It is not allowed to use line breaks within the instruction.
- Each instruction must end with a semi-colon.
- You can specify multiple instructions in the same `Instructions` section.
- When defining instructions, you must specify column names to identify the columns that the instruction applies to. For information about the column names resulting from Alfabet query and native SQL query definitions, see the section Defining Column Names and Captions. Alternatively, instructions can refer to columns by their index number. For more information see Referencing Columns in Instructions by Index Number.
- Instructions are executed in the order that they are specified. This can be crucial for the instruction definition (For example, if an instruction refers to a column that has been renamed by an instruction that is executed earlier). An exception to this rule is the coloring of cells in the report via `ColorAssignment` and `RowColorAssignment` instructions. The `ColorAssignment` instruction supersedes the `RowColorAssignment` independent from the order of specification. If you define the `GroupBy_Ex` instruction in combination with instructions that are assigned to rows in a report, For example, to define link assignment or coloring of cells or rows, the `GroupBy_Ex` instruction must be defined first and the instruction for formatting of the rows must defined after the `GroupBy_Ex` instruction.

When defining native SQL queries in the context of the Alfabet configuration, the first column of a result set is not displayed in the query results. This applies to the result set after execution of the Alfabet instructions. The following sequence of execution of a native SQL query must be taken into account when defining the native SQL query:

1) Alfabet -specific parameters in the Alfabet query are translated to corresponding native SQL code and a result set is created.
2) Alfabet instructions are executed on the result set. This may influence the availability and display of columns in the result table.
3) The first column in the result table after the execution of instructions is not displayed.

To specify instructions in the **Alfabet Query Builder** or the **Instructions** tab of the SQL query editor of Alfabet Expand:

1) Go to the **Instructions** tab.
2) Click the **New Instruction** button, select the sub-menu containing the instruction and select the instruction from the drop-down list.



3) Either an example instruction will be written in the text editor or an editor will open. If the example is written in the text editor, change the example as needed. If an editor opens, enter the required values in the editor controls. For further information about the individual instructions that are available, see the relevant table row:

Instruction	Description	Described in Section...
Data Manipulation		
`GroupBy`	Allows an expandable report table by grouping results to be built.	Grouping Query Results in Expandable Reports
`JoinColumns`	Displays multiple Show properties in one row of the report.	Aggregating Multiple Query Results in One Column of a Configured Report
`CreateRefImage`	This instruction is for use in configured Data Table reports only. It adds the ability to navigate to the object	Configuring Cells in a Data Table Report to

Instruction	Description	Described in Section...
	profile of an object represented by a cell to all cells of a defined column in the configured report.	Provide Navigation to an Object Profile
RemoveEmptyRows	Removes empty rows from the report table. This instruction is only required if the report is an expandable report table built with the GROUPBY_EX instructions and if the root level of the report shows objects with no subordinate search results.	Grouping Query Results in Expandable Reports
SetClassCaption	Displays the class caption of the object class of the displayed objects in a defined column of the report. The REFSTR of the objects must be included in the query result dataset to execute the SetClassCaption instruction.	Displaying the Class Name and/or Class Caption of an Object Class That Is Not the Base Class
GetClassSettingInfo	Displays the name of the object class icon and the foreground and background color defined for an object class in the relevant class settings in defined columns of the report.	Inserting Columns with Information About the Class Icon And Class Colors
SetClassCaptionByRow	Displays the class caption of the base object class in the report in a defined column of the report.	Displaying the Class Name and/or Class Caption of the Base Object Class
SetClassNameByRow	Displays the class caption of the base object class in the report in a defined column of the report.	Displaying the Class Name and/or Class Caption of the Base Object Class
SetClassName	Displays the class name of the object class of the displayed objects in a defined column of the report. The REFSTR of the objects must be included into the query result dataset to execute the SetClassName instruction.	Displaying the Class Name and/or Class Caption of an Object Class That Is Not the Base Class
SetRowCategories	Creates categories based on values in a column of the result data set. The categories can be used to configure buttons in the toolbar of the report to be active for objects belonging to defined categories only.	Limiting Toolbar Button Functionality To a Subset of Objects in a Configured Report
SetRowReference	Defines an object class that was added to the result data set via a JOIN to be processed as the base object class of the result data set. For example, the **Navigate** button directs the user to the object profile of the	Changing the Navigation Behavior of the Base

Instruction	Description	Described in Section...
	selected class instead of the object profile of the `FIND` object class.	Object Class in a Configured Report
`SetStereotypeCaption`	Displays the caption of the object class stereotype of the displayed objects in a defined column of the report. Alternatively, the stereotype icon can be displayed next to or instead of the caption. The dataset resulting from the query must include the information about the stereotype name to execute the `SetStereotypeCaption` instruction.	Displaying the Stereotype Caption and/or Icon of Objects Displayed in the Report
`SetStereotypeIndex`	Defines the column in a dataset that lists the stereotype of an object. This instruction is exclusively used in custom selectors to create selectors that display only objects of a defined stereotype. When the search results are displayed in the explorer, the information provided in the column defined in the instruction is used to filter results by stereotype.	Enabling a Stereotype-Specific Search in Custom Selectors
`SortBy`	Defines the sorting of rows in the report overwriting the sort behavior determined by the database. This instruction is required to sort values in a column that is the result of a `JoinColumns` instruction and the column displays objects from multiple object classes.	Aggregating Multiple Query Results in One Column of a Configured Report
`ReplaceServerVariable`	Replaces the content of a defined column with the value of a server variable defined in the server alias of the Alfabet Web Application. For more information about the definition of server variables, see Using Server Variables in Web Link and Database Server-Related Specifications.	Adding the Value of a Server Variable to the Dataset
`ReplaceValues`	Replaces defined strings in the cells of a column in the dataset with replacement values defined per original string in the instruction. Only complete return values of the type string or text are replaced.	Replacing Values Returned in the Query with a Defined String
`RetrieveIDOCPath`	Triggers export of attachments specified in the result dataset to a temporary runtime folder. The path information is written into the result dataset.	Exporting Attachments to a Runtime Folder During Report Execution
`JoinURLLink`	If a configured report contains a link to an URL, this instruction can be used to display any text instead of the target URL specification as link text.	Masking a Link Target in A Configured Report With a Text

Instruction	Description	Described in Section...
Data Set Structure		
`AddColumns`	Adds multiple columns to the dataset. The instruction must be combined with a `SetColumnShowName` instruction or a `CreateDSInfo` command to display the columns in the report output.	Adding Multiple Columns with the AddColumns Instruction
`InsertColumn`	Inserts a single column to the dataset. The instruction must be combined with a `SetColumnShowName` instruction or a `CreateDSInfo` command to display the columns in the report output.	Adding A Single Column With the InsertColumn Instruction
`CreateDSInfo`	Redefines the complete dataset displayed to the user on the Alfabet interface when opening the report. The number and order of columns, and the column captions in the report are re-configured.	Changing the Order and Number of Columns Displayed in a Report
`RenameColumn`	Changes the column name.	Defining Column Names and Captions
`RemoveColumns`	Removes defined Show properties from the report. Some instructions require the setting of defined Show properties for technical reasons. The `RemoveColumns` command is designed to hide these technical show properties from the result table.	Hiding a Column in a Configured Report
`RemoveSortColumns`	Prevents sorting by the user for columns in the report. This instruction can only be used for reports based on an Alfabet query that display a grouped data set.	Preventing Users from Sorting According to Subordinate Objects in the section Aggregating Multiple Query Results in One Column of a Configured Report
`SetColumnShowName`	Changes the column caption after execution of instructions. This instruction is designed for use in native SQL queries. It is not required in Alfabet queries.	Defining Column Names and Captions

Instruction	Description	Described in Section...
`SetFreezeHeader`	Freezes one or multiple columns in a tabular dataset of a configured report. These columns will then stay visible during horizontal scrolling.	Freezing Columns in Tabular Datasets
Data Translation		
`TranslateEnums`	Enumeration, object state, and status values are translatable in Alfabet, but the translated values are not used per default in configured reports. The instruction triggers the translation of enumerations, object states, and statuses for defined columns of the configured report. The values are then displayed in the translation for the culture selected by the user viewing the configured report.	Translating Enumerations, Object States, Release Statuses, and Indicator Values in a Configured Report
`TranslateIndicators`	Indicator range values are translatable in Alfabet, but the translated values are not used in configured reports by default. The instruction triggers translation of indicator range values for defined columns of the configured report. The values are then displayed in the translation for the culture selected by the user viewing the configured report.	Translating Enumerations, Object States, Release Statuses, and Indicator Values in a Configured Report
`TranslateTimeStatus`	lifecycle status values are translatable in Alfabet, but the translated values are not used in configured reports by default. The instruction triggers translation of lifecycle status values for defined columns of the configured report. The values are then displayed in the translation for the culture selected by the user viewing the configured report.	Translating Enumerations, Object States, Release Statuses, and Indicator Values in a Configured Report
`SetTranslatedValue`	For object class properties for which data translation is enabled in Alfabet, translated values are automatically displayed in reports based on an Alfabet query in the language currently used to display the user interface. For native SQL queries the change to the current language must be included in the report with the instruction `SetTranslatedValue`.	Display Translated Values for Object Class Properties Subject to Data Translation in Configured Reports Based on Native SQL
Formating Instruction		
`CellColorAssignment`	Defines the coloring of the cells in a result table for cells matching a defined search condition.	Defining Coloring for Cells or Rows Containing Specific Data

Instruction	Description	Described in Section...
`Convert2Boolean`	Displays `String`, `Integer` and `Real` values as `Boolean` in the report.	Displaying String, Integer or Real Values as Boolean Values
`ConvertBoolean2String`	Displays defined strings instead of `True` or `False` for `Boolean` values in the report.	Changing the Output Format for Boolean Values
`Convert2Posix`	Displays `Date` and `DateTime` values in POSIX format.	Specification of Dates
`LinkAssignment`	Adds a link to a view in Alfabet to each cell of a defined column of the report. The link target can be an object profile, an object cockpit, a graphic view or a configured report.	Opening the Same Page View, Object Profile, Object Cockpit, or Configured Report for all Search Results
`EditLinkAssignment`	Adds a link to an editor or wizard to each cell of a defined column of the report. The editor can be opened at a defined tab and the wizard can be opened at a defined wizard step.	Opening the Same Wizard or Editor for all Search Results
`DynamicLinkAssignment`	Adds a link to a view, editor or wizard to each cell of a defined column of the report. The information which view, editor or wizard shall open is dynamically defined via the query the instruction is defined for.	Opening Diffent Views, Wizards, or Editors for Search Results
`PictureAssignment`	Defines a substitution or amendment of the return value in a cell with an icon from the icon gallery when the cell matches a defined search condition. The icon can be 22x22, 30x30, or an icon in the the free size icon gallery.	Displaying Graphics for Cells Containing Specific Data
`RowColorAssignment`	Defines the coloring of the rows in a result table for the cell in a defined column matching a defined search condition.	Defining Coloring for Cells or Rows Containing Specific Data
`SetColumnDateSubType`	Defines whether information of the data type `DateTime` is displayed as date only or date and time without defining an output format. The output format is then defined by the language settings of the user interface.	Changing the Output Format for Date and Time Information

Instruction	Description	Described in Section...
SetColumnFormat	Sets the output format for date and time information to a defined format. This format is used independent from the language settings of the user interface.	Changing the Output Format for Date and Time Information
SetColumnsAlignment	Displays content of cells in defined columns in the result table with a different alignment as the default. The cell content can be defined as left, right, or center aligned.	Changing the Alignment of Cell Content
FontStyleAssignment	Defines the formatting of the text in the cells in a result table for cells matching a defined search condition. Text can be formatted as italic, bold or underlined.	Defining Text Formatting for Cells Containing Specific Data
FontStyleColorAssignment	Defines the formatting of the text as well as the coloring of the cells in a result table for cells matching a defined search condition. Text can be formatted as italic, bold or underlined.	Defining Text Formatting for Cells Containing Specific Data
SetDynamicWebLink	Provides the ability to open a dynamic web link for an object selected in the configured report via a button interaction.	Adding Dynamic Web Links to a Configured Report
SetObjectIcon	Display the icons assigned to objects in a cell of a tabular configured report.	Displaying the Object Icon
Math Instructions		
CreateColumnSum	For a defined column of the data type Integer or Real all values in the query output are counted up. The resulting sum is displayed in an additional row added at the bottom of the data set. Optionally, a caption for the additional row can be defined for display in one of the other columns of the data set.	Displaying the Sum of All Values in a Table Column
CreateRowSum	Calculates the sum per row of multiple values of the type Real or Integer displayed in selected columns of the dataset. A new column must be added to the dataset for display of the result.	Displaying the Sum of Multiple Values in a Table Row

Instruction	Description	Described in Section...
`NTile_Weighted`	This instruction groups the results in the dataset according to the ascending order of values in a defined column of the data type `Integer` or `Real`. The number of groups can be defined in the instruction. The groups are represented by numbers, with 1 being the group with the lowest values. Each group is assigned the same number of results. If the number of results cannot be divided equally among the groups, the first group(s) have a higher count. A new column of the data type Integer or Real must be added to the data set to display the results.	Displaying the Sum of All Values in a Table Column

Defining Column Names and Captions

The name of the database column is used to identify the column results in technical processes. This is relevant, For example, for the following:

- to specify the column within an instruction.
- to enable the **Alfabet Report Assistant** (used for the creation of chart reports) to identify the columns used to display the X-axis or Y-axis of the report.

The caption of the database column is the information that is displayed as column header in the tabular output of the query.

When you define a simple Alfabet query or a native SQL query, the name of a database column and the caption displayed in the report are identical. This chapter provides information about the standard column names and captions resulting from query definitions and the methods available to alter the names with instructions.

Please note the following about the definition of column names and captions:

- The special characters # and: as well as commas (,) are not allowed in column names.
- Tabular reports in Alfabet have a fixed row high for the header cells. If the column caption is longer than the width of the header cell, a line break is added when the width of the header cell is reached, but only the first line of text is displayed in the header cell.
- The strings on the Alfabet user interface can be translated and the user interface can be rendered in other language cultures than the original English (USA) language culture. When query results are displayed on the Alfabet user interface in a translated version, column captions are only displayed translated if one of the following applies:
  - The string of the column caption is available in the standard vocabulary, For example, because it is identical to an object class property caption.
  - the string of the column caption has been added manually to the vocabulary by writing it into the XML object ***VocXML***. For more information about the translation of column captions in query results see Translating Configured Reports.

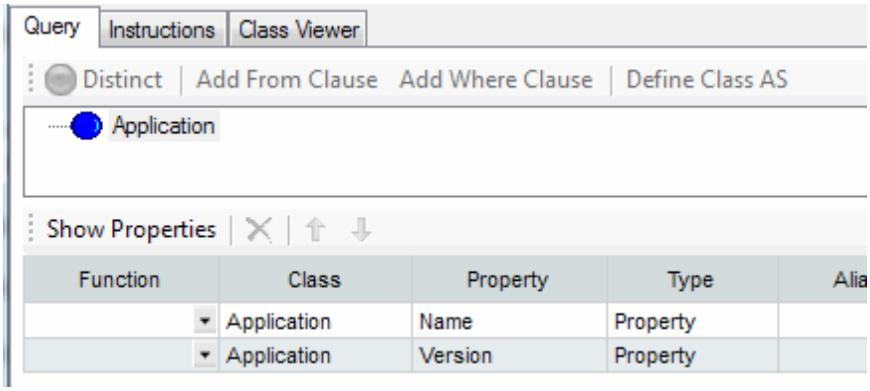
The following information is available:

- Defining Column Names and Captions in Alfabet Queries
- Defining Column Names and Captions in Native SQL Queries
- Defining Column Names and Captions with Instructions
- Referencing Columns in Instructions by Index Number

Defining Column Names and Captions in Alfabet Queries

In the Alfabet query language, the columns of the resulting data set are defined via the Show properties. The standard name of a column resulting from an Alfabet query is "ClassName.PropertyName" and the standard caption is "ClassName PropertyName".

A simple Alfabet query displays the name and the version of applications:



In the **Alfabet Query Builder**, you can see the object class name in the **Show Property** section in the column **Class** and the value of the property name in the column **Property**. In the Show properties of the resulting Alfabet query, the object class name is defined with the attribute ***ClassName*** and the object property name with the attribute ***Name***.

```
ALFABET_QUERY_500
FIND
Application
QUERY_XML
<QueryDef>
<ShowProperty Type="Property" ClassName="Application" Name="Name" />
<ShowProperty Type="Property" ClassName="Application" Name="Version"
/>
</QueryDef>
```

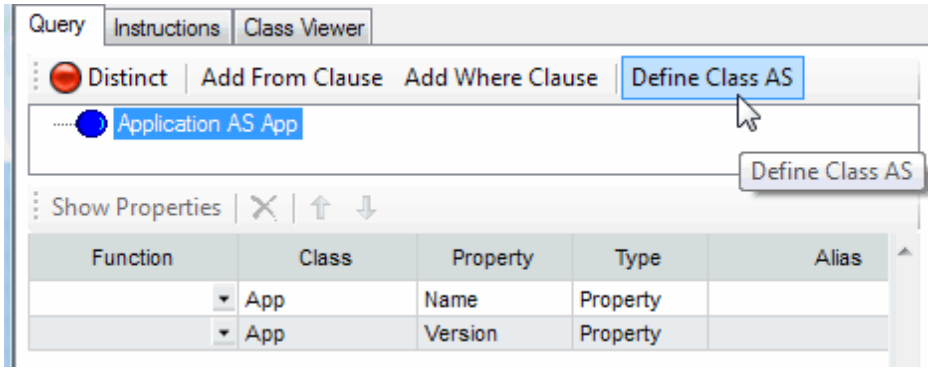
The resulting column names and captions are:

Column Name	Column Caption
Application.Name	Application Name
Application.Version	Application Version

The column caption is concatenated from the caption of the object class and the caption of the object class property. Usually these strings are available in all language cultures and are automatically displayed in the language used to render the user interface when displaying the query results. Please note however that the class name and the property name are translated separately and not as a combined string which may lead to differen translation results in some languages.

You can set an alias for the class name in the Alfabet query both for the `FIND` class and for classes added to the class via a `JOIN`. This alias changes the name, but not the caption of the column.

The alias `App` is defined for the object class `Application` in the Alfabet query:



In the **Alfabet Query Builder**, you can see the value of the object class alias in the **Show Property** section in the column **Class** and the value of the property name in the column **Property**. In the Show properties of the resulting Alfabet query, the object class alias is defined with the attribute ***ClassAlias*** and the property name with the attribute ***Name***.

```
ALFABET_QUERY_500

FIND

Application AS App

QUERY_XML

<QueryDef>

<ShowProperty Type="Property" ClassName="Application"
ClassAlias="App" Name="Name" />

<ShowProperty Type="Property" ClassName="Application"
ClassAlias="App" Name="Version" />

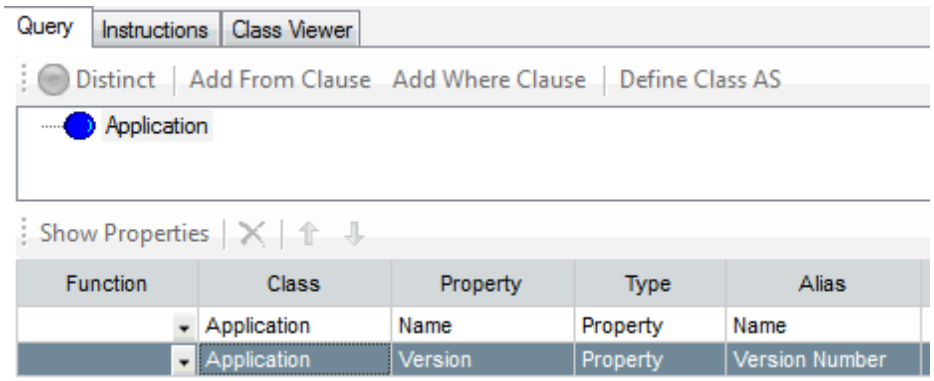
</QueryDef>
```

The resulting column names and captions are:

Column Name	Column Caption
App.Name	Application Name
App.Version	Application Version

You can set an alias for a column in the Show properties. This alias does not change the name, but only the caption of the database column.

An alias is defined for the columns in the Show properties of the Alfabet query defined to find applications:



In the **Alfabet Query Builder**, the alias is defined in the **Show Property** section in the column **Alias**. In the Show properties of the resulting Alfabet query, the object class alias is defined with the attribute ***Alias***.

```
ALFABET_QUERY_500
FIND
Application
QUERY_XML
<QueryDef>
<ShowProperty Type="Property" ClassName="Application" Name="Name"
ShowName="Name" />
<ShowProperty Type="Property" ClassName="Application" Name="Version"
ShowName="Version Number" />
</QueryDef>
```

The resulting column names and captions are:

Column Name	Column Caption
Application.Name	Name

Application.Version	Version Number

Defining Column Names and Captions in Native SQL Queries

When you define a native SQL query, the column names and captions are derived from the `SELECT` clause. Column names and captions are identical.

When no alias is specified for a column header in the `SELECT` clause, the property name is used as a column header.

In native SQL queries, names of database columns and database tables in the Alfabet database must be written in upper-case letters.

The following native SQL query finds applications and returns the properties `Name` and `Version`:

```
SELECT APPLICATION.REFSTR, APPLICATION.NAME, APPLICATION.VERSION
FROM APPLICATION
```

The resulting column names and captions are:

Column Name	Column Caption
NAME	NAME
VERSION	VERSION

If two properties have the same name, the column headers in native SQL have the same name too. When specifying native SQL in the context of Alfabet, two column headers with the same name are not allowed. It is recommended that you specify an alias name for the columns. If you do not specify an alias, the first column is given the name of the property and the following column headers are named <property name><number>.

A native SQL query finds applications and returns the name and version of the application and the name of the ICT object the application is assigned to:

```
SELECT APPLICATION.REFSTR, APPLICATION.NAME, APPLICATION.VERSION,
ICTOBJECT.NAME
FROM APPLICATION, ICTOBJECT
WHERE APPLICATION.ICTOBJECT = ICTOBJECT.REFSTR
```

The resulting column names and captions are:

Column Name	Column Caption
NAME	NAME
VERSION	VERSION
NAME1	NAME1

Setting an alias in the SELECT clause not only changes the caption but also changes the name of the database column.

Aliases are defined for the native SQL query of the example above to avoid identical column names:

```
SELECT APPLICATION.REFSTR, APPLICATION.NAME AS 'Application Name',
APPLICATION.VERSION AS 'Application Version', ICTOBJECT.NAME AS 'ICT
Object Name'
FROM APPLICATION, ICTOBJECT
WHERE APPLICATION.ICTOBJECT = ICTOBJECT.REFSTR
```

The resulting column names and captions are:

Column Name	Column Caption
Application Name	Application Name
Application Version	Application Version
ICT Object Name	ICT Object Name

Defining Column Names and Captions with Instructions

For some Alfabet configurations, it is required or desirable to alter either the name of the column (which is not possible in the Show properties of an Alfabet query), or only the caption of the column (which is not possible in the SELECT clause of a native SQL query).

The Alfabet query language provides instructions that allow you to change only the name of the database column or only the caption of columns in a dataset.

The column name can be defined by adding the following instruction to the Alfabet query:

```
RENAMECOLUMN("ColumnName","NewColumnName");
```

Use the following parameter(s):

Code Parameter	Description
ColumnName	The name of the column that shall be renamed.
NewColumnName	The new name of the column.

The column caption can be defined by the following instruction:

```
SETCOLUMNSHOWNAME("ColumnName","ColumnCaption");
```

Use the following parameter(s):

Code Parameter	Description
ColumnName	The name of the column for that a new caption shall be defined.
ColumnCaption	The new caption of the column.

Referencing Columns in Instructions by Index Number

When writing instructions, the columns the instruction references are defined via their name in the instruction. Alternatively, instructions allow column definition via the position of the column in the column index. This mechanism is For example, required to write instructions for queries based on a stored procedure building dynamic datasets. For example, a return data set can include one column for each application currently defined in the Alfabet database.

The first column in the data set is position 1 and can be referenced within the instruction as `#1`. The next columns are numbered consecutively. For data sets created via a native SQL query, the first, invisible column defining the `REFSTR` of the current object is not included into the index.

Within the instruction, the index specification can either define one column or a range of columns by index when a single column specification is required. The instruction is then executed for each column in the range.

To define a range, the first and the last column of the range must be defined with a colon in between after the opening # sign:

```
#1:8
```

Alternatively, a range starting with a defined column and ending with the end of the dataset can be defined with the reserved keyword `end` defining the end of the range:

```
#1:end
```

Freezing Columns in Tabular Datasets

The first column or columns in a configured report displaying a tabular dataset can be defined as frozen to remain visible during horizontal scrolling.

Please note the following:

- The first columns in a dataset are the columns on the left of the dataset for most cultures. If you render the Alfabet user interface in Arabic language, the first columns are the columns on the right of the dataset.
- The freezing logic is applied to the final, visible dataset. If your configured report contains For example, instructions that are hiding columns, these columns are not to be taken into account when defining the number of frozen columns.

The following instruction freezes columns in a tabular dataset:

```
SetFreezeHeader(NumberOfFrozenColumns);
```

Use the following parameter(s):

Code Parameter	Description
`NumberOfFrozenColumns`	Define the number of columns that shall be frozen as an integer.

Aggregating Multiple Query Results in One Column of a Configured Report

In a configured report, each defined Show property of an Alfabet query or `SELECT` statement in the `SELECT` clause of a native SQL query will correspond to one column in the report table per default. By adding an instruction, you can define the Alfabet query to display multiple properties in one column. For example, the name and version of an application can be displayed in one column instead of two.

The following instruction aggregates two columns in one column:

```
JOINCOLUMNS("OldColumn1,Oldcolumn2","NewColumn","Delimiter");
```

Use the following parameter(s):

Code Parameter	Description
`OldCol-umn1,OldCol-umn2`	The names of the two columns that are aggregated. For information about the names of the columns resulting from Alfabet queries and native SQL queries, see Defining Column Names and Captions. The specifications of the two columns is delimited with a comma. White spaces are not allowed in the specification. You can specify more than two columns in a comma-separated format.

Code Parameter	Description
NewColumn	Define which of the two columns that are aggregated should be used to display the results. The specification of the new column must be identical to one of the column specifications of the old column.
Delimiter	The delimiter can be any string, including whitespaces. It will be written between the two values in the combined column in the report.

When joining columns, you should consider defining an alias for the column header to reflect both values in the column name. Otherwise, the default column header which specifies only one of the properties will be displayed.

A report shows application groups and the applications assigned to the application group. The name and version of the application shall be displayed in one column in the report. The code for the definition of the Show properties in the Alfabet query is:

```
Instructions

JOINCOLUMNS("Application.Name,Application.Version","Application.Name
"," v. ");

EndOfInstructions

QUERY_XML

<QueryDef>

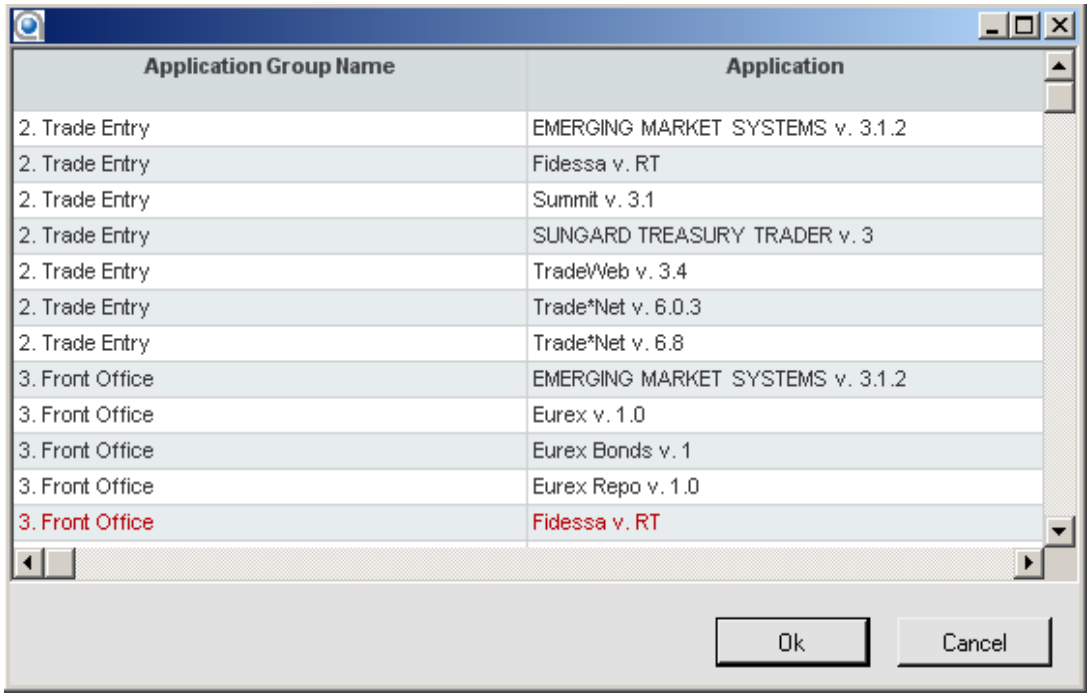
   <ShowProperty Type="Property" ClassName="ApplicationGroup"
   Name="Name" />

   <ShowProperty Type="Property" ClassName="Application" Name="Name"
   ShowName="Application"/>

   <ShowProperty Type="Property" ClassName="Application"
   Name="Version" />

</QueryDef>
```

In the resulting report, the name and version of the applications is displayed in one column separated with `v.` The column header is `Application` because this is the header defined for the column `Application.Name`.



You can also use the `JoinColumns` instruction to narrow the display of a report having multiple columns where only one of the columns contain a result in a row. In other words, if one column displays a result, the other column will be empty in this row.

If the columns that are joined display results from different object classes, you cannot sort the results in the joined column using the Sort properties of the Alfabet query. Instead, a `SortBy` instruction must be added to the instruction section that triggers the sorting of values derived from various tables of the Alfabet database:

```
SortBy("ColumnName,ColumnName");
```

Use the following parameter(s):

Code Parameter	Description
`ColumnName`	The name of the column that shall be sorted. For information about the names of the columns resulting from Alfabet queries and native SQL queries, see Defining Column Names and Captions. You can define multiple column names comma-separated to sort multiple columns of the report. Columns are sorted in the order defined in the instruction.

For example, the configured report should display all architecture elements assigned to projects as well as the user that is the authorized user responsible for the architecture element. One row in the report will display each architecture element. A project can include objects from different object classes as architecture elements. The Alfabet query must be written as follows:

```
ALFABET_QUERY_500

FIND

ProjectArch

InnerJoin Project ON ProjectArch.Project = Project.REFSTR

LeftJoin Application ON ProjectArch.Object = Application.REFSTR

LeftJoin ICTObject ON ProjectArch.Object = ICTObject.REFSTR

LeftJoin Domain ON ProjectArch.Object = Domain.REFSTR

LeftJoin OrgaUnit ON ProjectArch.Object = OrgaUnit.REFSTR

LeftJoin BusinessProcess ON ProjectArch.Object =
BusinessProcess.REFSTR

LeftJoin BusinessFunction ON ProjectArch.Object =
BusinessFunction.REFSTR

LeftJoin Person ON (Or Person.REFSTR = Application.ResponsibleUser
Person.REFSTR = BusinessFunction.ResponsibleUser Person.REFSTR =
Domain.ResponsibleUser Person.REFSTR = BusinessProcess.ResponsibleUser
Person.REFSTR = ICTObject.ResponsibleUser Person.REFSTR =
OrgaUnit.ResponsibleUser)

Instructions

JoinColumns("Application.Name,Application.Version","Application.Name",
" v. ");

EndOfInstructions

QUERY_XML

<QueryDef>

<ShowProperty Type="Property" ClassName="Project" Name="Name" />

<ShowProperty Type="Property" ClassName="Application" Name="Name" />

<ShowProperty Type="Property" ClassName="Application" Name="Version"
/>

<ShowProperty Type="Property" ClassName="ICTObject" Name="Name" />

<ShowProperty Type="Property" ClassName="Domain" Name="Name" />

<ShowProperty Type="Property" ClassName="OrgaUnit" Name="Name" />

<ShowProperty Type="Property" ClassName="BusinessProcess" Name="Name"
/>

<ShowProperty Type="Property" ClassName="BusinessFunction" Name="Name"
/>

<ShowProperty Type="Property" ClassName="Person" Name="Name" />

<SortProperty Type="Property" ClassName="Project" Name="Name" />

</QueryDef>
```

The Alfabet query results in a report displaying architecture elements with one column per affected architecture object class:

	Project Name	Application Name	ICT Object Name	Domain Name	Organization Na...	Business Process Name	Business Function Na...	Person Name
47	Consolidate Trading Applic...					Bond Trading		Ngombe
48	Consolidate Trading Applic...					Custody Services		Ngombe
49	Consolidate Trading Applic...					Equity Trading		Ngombe
50	Consolidate Trading Applic...					Foreign Exchange Dealings		Ngombe
51	Consolidate Trading Applic...					Money Market Business		Ngombe
52	Consolidate Trading Applic...					Security Trading		Picard
53	Consolidate Trading Applic...				FD Trading			Customer
54	Consolidate Trading Applic...				OR Trading			Customer
55	Consolidate Trading Applic...				Wilmer & Partner			Picard
56	Consolidate Trading Applic...			The Enterprise				Customer

Adding a second `JoinColumns` instruction results in a report with three columns only. One for the project, one for the architecture element, and one for the authorized user of the architecture element. To enhance the usability of the report, you can add a `SetColumnShowName` instruction to rename the column caption to a neutral name (such as `Architecture Element`instead of `Application Name`, etc.) and a `SortBy` instruction to sort the result set by architecture element.

To do so, add the following instructions to the `Instruction` section of the Alfabet query defined above:

```
JoinColumns("Application.Name,ICTObject.Name,BusinessProcess.Name,Domain.Name,OrgaUnit.Name,BusinessFunction.Name","Domain.Name", "");

SetColumnShowName("Domain.Name","Architecture Element");

SortBy("Domain.Name");
```

The following columns are displayed in the configured report:

	Project Name	Architecture Element	Person Name
16	Consolidate HR Systems	AF HR Online US v. 2.2 Var.	Customer
17	CRM Analytics Center	AF HR Online US v. 2.2 Var.	Customer
18	Streamline CRM Applications	AF HR Online US v. 2.2 Var.	Customer
19	Consolidate HR Systems	AF HR Online v. 2.2	Customer
20	Consolidate HR Systems	AF HR Online v. 3.0	Customer
21	Replace AF HR Online by SAP HR HQ	AF HR Online v. 3.0	Customer
22	Enable Internet-based Trading with TradeNet	AI Reinsurances	Ngombe
23	Implement salesforce Greenfield strategy	AI Sales & Marketing	Alfabet
24	Rollout salesforce 9.2	AI Sales & Marketing	Alfabet
25	Rollout salesforce 9.3	AI Sales & Marketing	Alfabet
26	Integrate CRM with SAP	Analyze Turnover	Mustermann
27	Best in Breed Solution	Balance Analysis DB v. 1.2.2	Administrator
28	Central CRM Application	Balance Analysis DB v. 1.2.2	Administrator
29	CRM Architectural Study	Balance Analysis DB v. 1.2.2	Administrator
30	Implement Confidentiality and Integrity Mitiga...	Balance Analysis DB v. 1.2.2	Administrator
31	Streamline CRM Applications	Balance Analysis DB v. 1.2.2	Administrator
32	Make Bloomberg future compatible	BLOOMBERG	Administrator
33	Setup Bloomberg access	BLOOMBERG	Administrator
34	Upgrade Bloomberg	BLOOMBERG	Administrator

Hiding a Column in a Configured Report

By default, each property defined in the Show properties of an Alfabet query or the `SELECT` clause of a native SQL query (with the exception of the first statement in the `SELECT` clause) corresponds to one column in the report table. For some configurations (For example, when building a report with collapsed tables), it is

required to add properties for technical reasons only. In most cases the REFSTR property of an object class must be added to the report. This information is not relevant for the user viewing the report. You can hide a column in the report by adding the following instruction:

```
REMOVECOLUMNS("ColumnName");
```

Use the following parameter(s):

Code Parameter	Description
ColumnName	The name of the column that is hidden. For information about the names of the columns resulting from Alfabet queries and native SQL queries, see Defining Column Names and Captions. You can hide multiple columns with one command by specifying multiple column names delimited with a comma. White spaces are not allowed in the specification.

Grouping Query Results in Expandable Reports

By default, tabular reports about two related object classes display one row for each combination of the two object classes found by the Alfabet query or native SQL query. You can add an instruction to the query to group the results and display one object class as subordinate to the other object class in an expandable table section. The advantage of grouping is that the users will have a better overview of the results in the table. Users will see a report that displays one row for each object found for the superordinate object class, each with a + symbol in front. The objects of the subordinate object class are displayed each in a separate row beneath the selected object when the + symbol is clicked and the table section expanded.

For example, for a configured report that displays applications and their local components and shows the names and end dates of the objects in the resulting dataset, the normal result table would include one row for each combination of application and local component, with one column for each of the properties.

Application Name	Application End Date	Local Component Name	Local Component End Date
Groupware Services	2/18/2012	DB 2 Universal Database	9/29/2024
Mafo-Portal	7/3/2015	DB 2 Universal Database	9/29/2024
SAP@OptiRetail	1/24/2010	DB 2 Universal Database	9/29/2024
SAP@OptiRetail	1/24/2010	SAP PM	9/29/2024
SAP@OptiRetail	1/24/2010	MS Windows XP	9/29/2024
SAP@OptiRetail	1/24/2010	ORBIX	9/29/2024
SAP@OptiRetail	1/24/2010	MS Internet Explorer	9/29/2024

SAP@OptiRetail	1/24/2010	LDAP	9/29/2024
SAP@OptiRetail	1/24/2010	Ubuntu Linux	9/29/2024
SAP@OptiRetail	1/24/2010	ORBIX	9/29/2024
SAP@OptiRetail	1/24/2010	Ubuntu Linux	9/29/2024
SAP@OptiRetail	1/24/2010	IBM Power Systems	9/29/2024

With the grouping instruction, the outlook of the report can be changed to display local components subordinate to applications. When the user opens the report, he/she can see one row for each application with a + symbol in front to expand the table section, displaying the application's name and end date. When the user clicks the + symbol, one row for each local component will be displayed beneath the row with the parent application, displaying the component's name and end date.

1 2	Application Name	Application End Date	Local Component Name	Local Component End Date

Instructions are executed after the Alfabet query or native SQL query has been executed. Therefore, the information that is required to specify the relation between two object classes must not only be defined in the query, but also be reflected in the dataset resulting from the query. The instruction reads the technical data required to group the classes from the plain report table prior to instruction execution.

Relations between object classes are based on the following properties:

- Objects of the subordinate class are identified by their `REFSTR` property.

  For example, a configured report displays demands and their classification as well as the applications that are assigned to the demand as architecture objects. In this case, the class `Demand` is the superordinate object class. The data in the report can be grouped by demand `REFSTR`. The column with the `REFSTR` information is hidden from the report output via a `RemoveColumns` instruction. The classification information is the same in all rows for a demand and can Therefore, also be displayed in a grouped version of the report:

Demand Name	Demand Classification	Application	Application Version
CRM Consolidation	Strategic	CRM CSS	3.3

Enhance Reliability of Tra	Operational	Bysis GL	2.0
Enhance Reliability of Tra	Operational	GL Trade	2.3

  Although the grouping instruction is configured to work with the `REFSTR` property to find objects of the superordinate class, you may also define that grouping shall be performed based on an identical property value for the superordinate class. This is an exception to the normal specification of the report and no guarantee is given that the grouping can be performed on any property.

  If you define grouping based on a property that is equal for multiple objects, all subordinate objects of all superordinate objects belonging to the group are displayed in one group. The columns in the table providing information about the superordinate level must then be limited to information that is identical per group.

  Grouping by a property that is equal for multiple objects is best configured via an Alfabet query. Native SQL queries can only be used if defined in a special way. The grouping by property is described in the section Grouping By Category Instead of By Object.

- Objects of the subordinate class are identified by their `REFSTR` property.

To group two object classes in a report, the column names in the resulting dataset must match a specific scheme. They must be defined as

ClassName.PropertyName

If a class alias is defined in the query for the object class, the definition must be:

ClassAlias.PropertyName

For native SQL queries, the column names resulting from the Show property definition automatically match this criterion. A RenameColumn instruction must not be used.

For native SQL queries an alias must be defined for the properties in the SELECT clause that defines the column names as matching to the scheme.

For example, the Name property of the object class Demand must be specified in the SELECT statement as:

```
SELECT DEMAND.REFSTR, DEMAND.NAME As 'Demand.Name'
FROM DEMAND
```

If an alias specification is used for a class in the native SQL query, the alias instead of the class name must be used as class name in the column header. For example,:

```
SELECT dem.REFSTR, dem.NAME As 'dem.Name'
FROM DEMAND dem
```

To group two object classes in a report:

1) Add the REFSTR property of the subordinate object class and the REFSTR property of the superordinate object class to the Show properties of the Alfabet query or the SELECT clause of the native SQL query.

   In native SQL queries, you must add the REFSTR property of the superordinate class two times to the SELECT statement. Evaluation of native SQL requires that the REFSTR of the main object class found by the native SQL query is defined as first property in the SELECT statement. In the resulting report set, the first column containing the REFSTR is removed prior to executing instructions.

   To hide properties that are used for technical reasons only from display in the query results, use the REMOVECOLUMNS instruction described in the section Hiding a Column in a Configured Report.

2) For native SQL only: Define alias specification for the column headers in the SELECT clause. Each column header must follow the following syntax: <ClassName>.<PropertyName> or, if an alias is specified for the class in the FROM statement, <AliasName>.<PropertyName>.

3) Define Sort properties in the Alfabet query or ORDER BY clauses in the native SQL query that result in rows sorted by the grouping property of the superordinate class. In other words, all rows in the report with the same grouping property of the superordinate class must follow each other.

4) Go to the **Instructions** tab of the **Alfabet Query Builder** and write the following instruction:

   GROUPBY_EX("*SuperordinateObject*","*SubordinateObject*","*SuperordinateClass*",*Level*);

Use the following parameter(s):

Code Parameter	Description
SuperordinateObject	The name of the column that displays the REFSTR property of the superordinate object class used to identify the objects of the superordinate class in the report. For information about the names of the columns resulting from Alfabet queries and native SQL queries, see *Defining Column Name And Caption*.
SubordinateObject	The name of the column that displays the REFSTR property of the subordinate object class used to identify the objects of the subordinate class in the report.
Superordinate Class	The object class that is displayed in the superordinate level. The class must be specified as If an alias specification is used for a class in the Alfabet query or native SQL query, the alias instead of the class name must be specified as superordinate class and used as class name in the column header specifications. ClassName All columns with headers starting with the specified class alias are displayed in the rows for the superordinate object.
Level	You can define multiple GROUPBY_EX instructions for one Alfabet query or native SQL query. The level defines the ranking of grouping commands. It is specified by a natural number. The first grouping has a level of 0, the next grouping below that has a level of 1.

The instruction is interpreted as follows:

- The class that is first defined in the GROUPBY_EX command with the level number 0 is the class that is displayed on the root level. All columns with headers starting with the specified class alias are displayed in the rows for the superordinate object. This is independent from the position of the columns displaying the attributes in the report.
- The columns with properties of the subordinate class are displayed in the second level result rows independent from their position in the report.
- The properties of any object classes that are joint to the subordinate object class are also displayed in the second level row, as long as no further grouping is specified.

You can combine the GROUPBY_EX instruction with other instructions:

Please note that the order of defining instructions is relevant. If you define the GroupBy_Ex instruction in combination with instructions that are assigned to rows in a report, For example, to define link assignment or coloring of cells or rows, the GroupBy_Ex instruction must be defined first and the instruction for formatting of the rows must defined after the GroupBy_Ex instruction.

- Use the REMOVECOLUMNS instructions to hide the columns added for technical reasons, like the REFSTR property of objects, from the results displayed to the user. For more information about the RemoveColumns instruction, see Hiding a Column in a Configured Report.

- Use the REMOVEEMPTYROWS instruction if your report is based on a left join between the grouped object classes. When objects of the superordinate class are displayed for which no objects are found, the objects of the superordinate class are nevertheless displayed with a + symbol to expand the table section, even though there are no subordinate rows displayed when you click the + symbol. You can remove the + symbol before rows that do not have subordinate object results by adding the REMOVEEMPTYROWS command as follows:

```
REMOVEEMPTYROWS();
```

- Use the REMOVESOERTCOLUMNS instruction to prevent that the user can sort the data in a column.
- Use the JOINCOLUMNS instruction to enhance readability of the configured report.
  - For example, a report includes two object classes that are displayed one subordinate to the other. For both objects, the end dates are displayed. These values are normally displayed in two columns in the report, one showing the end dates of one object class and the other the end dates of the second object class. Grouping the results make it possible to display all end dates of all objects on both hierarchy levels in one row.
  - For example, if you group the display of the names of the superordinate and subordinate objects in the first column, the report will appear to display both classes in one row. Values for subordinate objects will be indented.

For the report in the previous example where local components are grouped under applications and the start and end dates of both applications and local components are displayed, the basic configuration includes one grouping instruction to group local components under applications. An instruction to remove the columns for the REFSTR properties is also included.

The report can be created with the following Alfabet query:

```
ALFABET_QUERY_500

FIND Application

   InnerJoin LocalComponent ON LocalComponent.Owner =
   Application.REFSTR

Instructions

GROUPBY_EX("Application.REFSTR","LocalComponent.REFSTR","Application
",0);

REMOVECOLUMNS("Application.REFSTR,LocalComponent.REFSTR");

EndOfInstructions

QUERY_XML

<QueryDef>

   <ShowProperty Type="Property" ClassName="Application" Name="Name"
   />

   <ShowProperty Type="Property" ClassName="Application"
   Name="EndDate" />

   <ShowProperty Type="Property" ClassName="LocalComponent"
   Name="Name" />

   <ShowProperty Type="Property" ClassName="LocalComponent"
   Name="EndDate" />
```

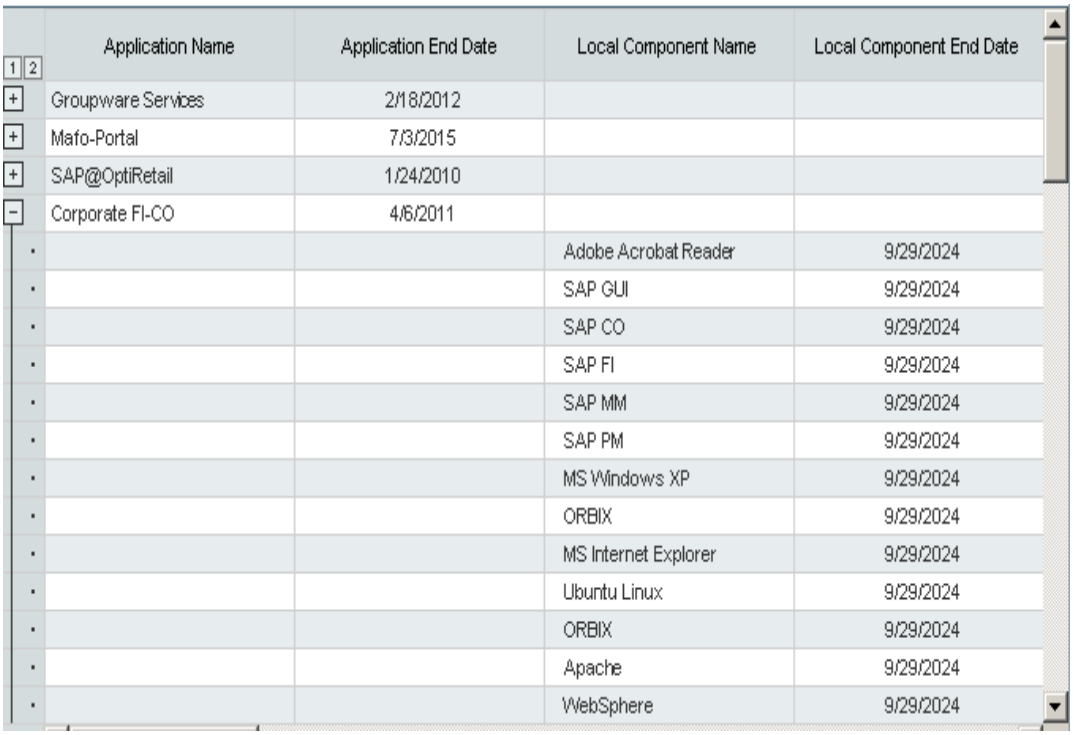
```
    <ShowProperty Type="Property" ClassName="LocalComponent"
    Name="REFSTR" />

    <ShowProperty Type="Property" ClassName="Application"
    Name="REFSTR" />

    <SortProperty Type="Property" ClassName="Application" Name="Name"
    />

</QueryDef>
```

In the resulting report, results for objects of each class are displayed in separate rows and separate columns. The results for local components can be collapsed in the table.



Application Name	Application End Date	Local Component Name	Local Component End Date
Groupware Services	2/18/2012		
Mafo-Portal	7/3/2015		
SAP@OptiRetail	1/24/2010		
Corporate FI-CO	4/6/2011		
		Adobe Acrobat Reader	9/29/2024
		SAP GUI	9/29/2024
		SAP CO	9/29/2024
		SAP FI	9/29/2024
		SAP MM	9/29/2024
		SAP PM	9/29/2024
		MS Windows XP	9/29/2024
		ORBIX	9/29/2024
		MS Internet Explorer	9/29/2024
		Ubuntu Linux	9/29/2024
		ORBIX	9/29/2024
		Apache	9/29/2024
		WebSphere	9/29/2024

To display the object names in the same column, a `JOINCOLUMN` instruction must be added to the Alfabet query's `Instructions` section. It is also recommended that you rename the column header for the resulting combined column:

```
ALFABET_QUERY_500

FIND Application

    InnerJoin LocalComponent ON LocalComponent.Owner =
    Application.REFSTR

Instructions

GROUPBY_EX("Application.REFSTR","LocalComponent.REFSTR","Application
",0);

REMOVECOLUMNS("Application.REFSTR,LocalComponent.REFSTR");

JOINCOLUMNS("Application.Name,LocalComponent.Name","Application.Name
","");

EndOfInstructions

QUERY_XML

<QueryDef>
```

```
    <ShowProperty Type="Property" ClassName="Application" Name="Name"
    ShowName="Application / local Component"/>

    <ShowProperty Type="Property" ClassName="Application"
    Name="EndDate" />

    <ShowProperty Type="Property" ClassName="LocalComponent"
    Name="Name" />

    <ShowProperty Type="Property" ClassName="LocalComponent"
    Name="EndDate" />

    <ShowProperty Type="Property" ClassName="LocalComponent"
    Name="REFSTR" />

    <ShowProperty Type="Property" ClassName="Application"
    Name="REFSTR" />

    <SortProperty Type="Property" ClassName="Application" Name="Name"
    />

    <SortProperty Type="Property" ClassName="LocalComponent"
    Name="Name" />

</QueryDef>
```

In the resulting report, results for objects of each class are displayed in separate rows and in the same column with regard to the `Name` property. The results for local components can be collapsed in the table.

1 2	Application / local Component	Application End Date	Local Component End Da
+	Groupware Services	2/18/2012	
−	Mafo-Portal	7/3/2015	
•	DB 2 Universal Database		9/29/2024
+	SAP@OptiRetail	1/24/2010	
+	Corporate FI-CO	4/6/2011	
+	eLead	10/11/2010	
+	CRM CSS	2/4/2013	

The same report results from the following native SQL query:

```
SELECT app.REFSTR, app.REFSTR as 'app.REFSTR', app.NAME AS
'app.Name', app.ENDDATE as 'app.EndDate', LOCALCOMPONENT.REFSTR as
'LocalComponent.REFSTR', LOCALCOMPONENT.NAME as
'LocalComponent.Name', LOCALCOMPONENT.ENDDATE As
'LocalComponent.EndDate'

FROM APPLICATION app

LEFT JOIN LOCALCOMPONENT

ON app.REFSTR =LOCALCOMPONENT.OWNER

ORDER BY app.REFSTR
```

Grouping is performed on basis of the `REFSTR` of the class Application. Therefore, the `REFSTR` property is added two times to the `SELECT` statement of the native SQL query.

In the native SQL query, the alias `app` is defined in the `FROM` clause for the object class Application. When defining the instructions, the columns containing information about the superordinate object class must be defined as `app.`<PropertyName>.

It is also recommended that you rename the column header for the resulting combined column.

The following instructions must be defined for the native SQL query to create the grouped report displayed above:

```
GROUPBY_EX("app.REFSTR","LocalComponent.REFSTR","app",0);

REMOVECOLUMNS("app.REFSTR,LocalComponent.REFSTR");

JOINCOLUMNS("app.Name,LocalComponent.Name","app.Name","");

SETCOLUMNSHOWNAME("app.Name","Application / local Component");

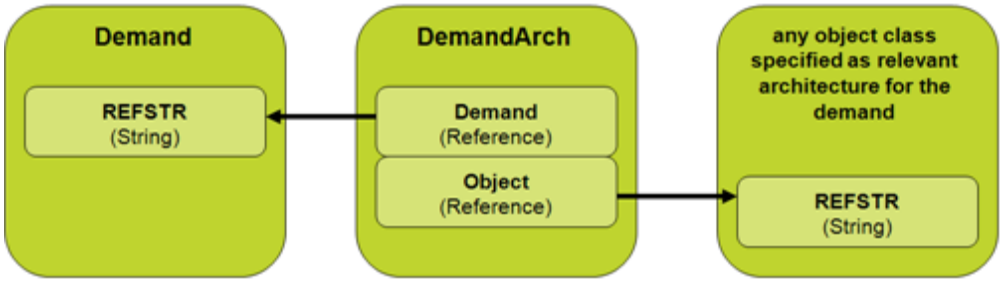
SETCOLUMNSHOWNAME("app.EndDate","Application End Date");

SETCOLUMNSHOWNAME("LocalComponent.EndDate","Local Component End
Date");
```

Grouping Indirectly Related Object Classes

It is possible to group object classes that are indirectly related via a third object class. If the object class establishing the relation is used for grouping, but properties of that class are not included in the report results, the report looks as if the two indirectly related object classes are grouped.

For example, if you want to display all applications that are architecture elements relevant for demands, you can group applications under demands although they are only indirectly connected via the `DemandArch` object:



In the query, two `JOIN`s are required to display applications assigned to the demands.

In an Alfabet query:

```
ALFABET_QUERY_500

FIND Demand

   LeftJoin DemandArch ON DemandArch.Demand = Demand.REFSTR

   InnerJoin Application ON DemandArch.Object = Application.REFSTR

QUERY_XML

<QueryDef>

   <ShowProperty Type="Property" ClassName="Demand" Name="Name" />

   <ShowProperty Type="Property" ClassName="Application" Name="Name"
   ShowName="Application" />

   <ShowProperty Type="Property" ClassName="Application"
   Name="Version" />
```

```
    <SortProperty Type="Property" ClassName="Demand" Name="Name" />
</QueryDef>
```

In a native SQL query:

```
SELECT DEMAND.REFSTR, DEMAND.REFSTR as 'Demand.REFSTR', DEMAND.NAME
As 'Demand.Name', APPLICATION.REFSTR As 'Application.REFSTR',
APPLICATION.NAME As 'Application.Name', APPLICATION.VERSION As
'Application.Version'
FROM DEMAND
LEFT JOIN DEMAND_ARCH ON DEMAND_ARCH.DEMAND = DEMAND.REFSTR
INNER jOIN APPLICATION ON DEMAND_ARCH.OBJECT = APPLICATION.REFSTR
ORDER BY DEMAND.REFSTR;
```

Properties of the `DemandArch` object are not shown in the query results. Nevertheless, a grouping can be done that groups the class `DemandArch` as subordinate to the class `Demand`. The object class `Application` is joined to the object class `DemandArch`, and the properties for applications displayed in report columns are Therefore, displayed on the subordinate level:

1 2	Demand Name	Application
+	Revise Charting Capability	
−	Re-implement Monthly Consolidation Report	
.		eBank v. 1.2
+	Implement Sobolev algorithm	
−	Rework CRM for regional support	
.		CRM Opti Retail v. 3.0 Var.
.		CRM CSS v. 3.2
.		CRM Opti Retail v. 2.0
.		CRM v. 2.6
.		CRM AI v. 2.0
+	Roll-out SAP to the regions	
+	Update trading system to new version	
+	Retire Russia CL and CL Trade	

For this report, the Alfabet query was changed as follows:

```
ALFABET_QUERY_500
FIND Demand
   LeftJoin DemandArch ON DemandArch.Demand = Demand.REFSTR
   InnerJoin Application ON DemandArch.Object = Application.REFSTR
Instructions
JOINCOLUMNS("Application.Name,Application.Version","Application.Name
"," v. ");
GROUPBY_EX("Demand.REFSTR","Application.REFSTR","Demand",0);
REMOVECOLUMNS("Demand.REFSTR, Application.REFSTR");
EndOfInstructions
QUERY_XML
```

```
<QueryDef>
   <ShowProperty Type="Property" ClassName="Demand" Name="Name" />
   <ShowProperty Type="Property" ClassName="Application" Name="Name"
   ShowName="Application" />
   <ShowProperty Type="Property" ClassName="Application"
   Name="Version" />
   <ShowProperty Type="Property" ClassName="Application"
   Name="REFSTR" />
   <ShowProperty Type="Property" ClassName="Demand" Name="REFSTR" />
   <SortProperty Type="Property" ClassName="Demand" Name="Name" />
</QueryDef>
```

For this report, the following instructions must be combined with the native SQL query above:

```
JOINCOLUMNS("Application.Name,Application.Version","Application.Name
"," v. ");
GROUPBY_EX("Demand.REFSTR","Application.REFSTR","Demand",0);
REMOVECOLUMNS("Demand.REFSTR,Application.REFSTR");
SETCOLUMNSHOWNAME("Demand.Name","Demand Name");
SETCOLUMNSHOWNAME("Application.Name","Application");
```

Grouping By Category Instead of By Object

In the examples above, grouping was performed by specifying the superordinate class based on the `REFSTR` attribute of the object class. This ensures that the first level results are grouped to one group per object. But grouping does not have to be performed per object. You can use any other column in the tabular report to sort the results in the upper level. This allows grouping of sub-level items according to the value for a defined property of the superordinate class independent of the assignment of subordinate objects to superordinate objects.

The grouping by other than the `REFSTR` property of the superordinate object class is an exception that is not part of the guaranteed functionality of the `GroupBy_Ex` instruction. It may not work for some grouping scenarios.

The following example explains the possibilities and limits of grouping by non-unique property values for superordinate objects.

In the example, applications are displayed as subordinate to the demands to which they are assigned as architecture objects. Each demand was classified via the definition of the property `Classification`. If you add the `Classification` property to the Show properties of the Alfabet query or the `SELECT` clause of the native SQL query, and define the Sort properties of the Alfabet query or the `ORDER BY` clause of the native SQL query to sort demands by classification values, you can see in the result output that multiple demands share the same classification.

Demand Name	Demand Classification	Application
Development CRM Briefing Center Analytics	Application Mgmt.	
		CRM Opti Retail v. 3.0
Implement Sobolev algorithm	Application Mgmt.	
		eBank v. 1.2
Improve Commercial Order Management	Application Mgmt.	
		ARIS v. 6.2.1
Integration CRM CSS and Trade*Net	Application Mgmt.	
		CRM CSS v. 3.2
		Trade*Net v. 6.0.3
Rework CRM for regional support	Application Mgmt.	
		CRM Opti Retail v. 3.0 Var.
		CRM AI v. 2.0
		CRM CSS v. 3.2
		CRM Opti Retail v. 2.0
		CRM v. 2.6
Development Portfolio Management Tool	Application Mgmt.,Strategic	
Integrate Risk Management in Trade*Net	Application Mgmt.,Strategic	
Parcel Deliverables Optionization	Application Mgmt.,Strategic	
Rollout / Implementation of CRM onDemand	Application Mgmt.,Strategic	

If you want to see all applications that are relevant for the architecture assigned to any demand of a defined demand classification group, you can use the `Classification` property in the `GroupBy_Ex` command. The name of the demand must be excluded from the report because it is not identical for all rows within a group.

In an Alfabet query:

```
ALFABET_QUERY_500
FIND Demand
   LeftJoin DemandArch ON DemandArch.Demand = Demand.REFSTR
   InnerJoin Application ON DemandArch.Object = Application.REFSTR
Instructions
JOINCOLUMNS("Application.Name,Application.Version","Application.Name"," v.
");
GROUPBY_EX("Demand. Classification ","Application.REFSTR","Demand",0);
REMOVECOLUMNS("Application.REFSTR");
EndOfInstructions
QUERY_XML
<QueryDef>
   <ShowProperty Type="Property" ClassName="Demand" Name="Classification" />
   <ShowProperty Type="Property" ClassName="Application" Name="Name"
   ShowName="Application" />
   <ShowProperty Type="Property" ClassName="Application" Name="Version" />
   <ShowProperty Type="Property" ClassName="Application" Name="REFSTR" />
```

```
    <SortProperty Type="Property" ClassName="Demand" Name=" Classification "
    />
</QueryDef>
```

In native SQL, grouping strictly depends on the objects of the class in the FROM statement. If this class is an Alfabet object class, groups containing multiple objects are not allowed in the superordinate level. To solve this problem, the SQL query must be defined with a `FROM` clause not pointing to an object class in the database, but to an alias that is derived from a `WITH` statement collecting the required data from the Alfabet database. For the `SELECT` statement of the alias class, the required first argument returning a `REFSTR` is defined as `NULL`, because the alias class has no `REFSTR` property:

```
WITHAliasClassAs

(SELECTDEMAND.CLASSIFICATION As 'Name', APPLICATION.REFSTR As 'Application',
APPLICATION.NAME As 'AppName', APPLICATION.VERSION As 'AppVersion'

FROM DEMAND

LEFT JOIN DEMAND_ARCH ON DEMAND_ARCH.DEMAND = DEMAND.REFSTR

INNER JOIN APPLICATION ON DEMAND_ARCH.OBJECT = APPLICATION.REFSTR

)

SELECTNULL As 'REFSTR',Name As "AliasClass.Name ", Application As
'Application.REFSTR', AppName As 'Application.Name', AppVersion As
'Application.Version'

FROMAliasClass

ORDER BY AliasClass.Name ;
```

with the following instructions:

```
JOINCOLUMNS("Application.Name,Application.Version","Application.Name"," v.
");

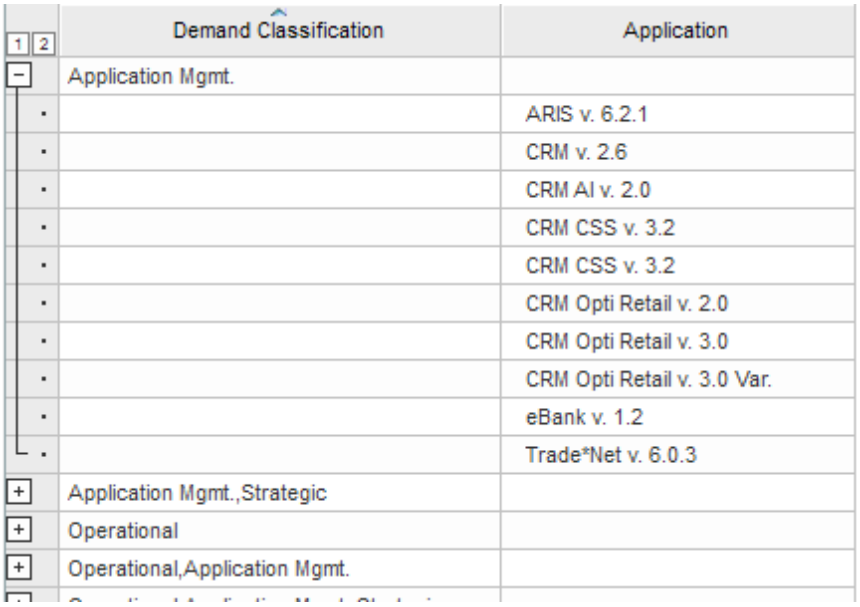
GROUPBY(" AliasClass.Name ","Application.REFSTR","AliasClass",0);

REMOVECOLUMNS("Application.REFSTR");

SETCOLUMNSHOWNAME("Demand.Name","Demand Name");

SETCOLUMNSHOWNAME("Application.Name","Application");

SETCOLUMNSHOWNAME("AliasClass.Name","Demand Classification");
```



Demand Classification	Application

Preventing Users from Sorting According to Subordinate Objects

By default, users can click any header cell of a tabular report to sort the results in the report alphanumerically according to the information displayed in the selected column. Clicking the header again changes the sort order from ascending to descending. This is independent of the definition of Sort properties in Alfabet queries or `ORDER BY` clauses in native SQL queries that define presorting for the first display of data in the report.

If the user sorts results alphanumerically by a property of a subordinate object class, correct alphanumeric sorting is inhibited by the grouping by superordinate object. The sorting is done as follows:

- Within a group, the subordinate objects are sorted alphanumerically.
- The order of superordinate objects is also changed. The superordinate objects are sorted according to the alphanumeric order of the selected sort property of the first subordinate object in their group.

You can prevent sorting by the user by adding the following instruction to the report:

The report must be based on an Alfabet query to use the instruction. Sorting in reports based on native SQL queries cannot be prevented.

```
RemoveSortColumns("ColumnName,ColumnName");
```

Use the following parameter(s):

Code Parameter	Description
`ColumnName`	The name of the column in the tabular output of the report that shall not be sortable. For information about the names of the columns resulting from Alfabet queries and native SQL queries, see *Defining Column Name And Caption*.

Code Parameter	Description
	If multiple columns shall not be sorted, the columns can be defined comma separated.

Changing the Order and Number of Columns Displayed in a Report

The instruction `CreateDSInfo` can be used to restructure per batch the output of a query. The following tasks can be performed within a single instruction:

- Changing the order of columns from the result dataset displayed in the report.
- Removing columns from display in the report.
- Adding multiple columns added via `InsertColumn` commands or an `AddColumns` instruction to the dataset.
- Changing all column captions in a single instruction.

The main use cases for the `CreateDSInfo` instruction are:

- Columns have been added to the dataset via `InsertColumn` or `AddColumns` instructions and the columns shall be displayed before or in the middle of the data set resulting from the query. By default, inserted columns are displayed at the end of the tabular report. For more information, see Inserting One or Multiple Columns to a Report.
- A report requires a high number of `SetColumnShowName` and `RemoveColumn` commands, For example, to display a complex grouped dataset. Instead, a `CreateDSInfo` command can be used to define the resulting data set in a single command. An example is given in this section.

Use the following instruction to restructure the output of your query:

```
CreateDSInfo("ColumnName,ColumnName","ColumnCaption,ColumnCaption");
```

Use the following parameter(s):

Code Parameter	Description
`ColumnName`	The comma-separated list of the columns that shall be displayed in the result dataset. Each column is identified by the column name. For information about the names of the columns resulting from Alfabet queries and native SQL queries, see *Defining Column Name And Caption*. The order of specification in the comma-separated list of column names defines the order of the display of the columns in the resulting dataset.

Code Parameter	Description
`ColumnCaption`	The comma-separated list of captions to be displayed for the columns in the dataset. For each column specified in the comma-separated list of column names, a caption must be specified in the same order than the column definition.

Note the following about the use of the `CreateDSInfo` instruction:

- If you define a `CreateDSInfo` instruction for a native SQL query, you must include the first `SELECT` argument defining the `REFSTR` of the base object of the report in the result data set. This column is hidden in the report output, but removal of the first column from the data set is performed after the execution of the instruction (on the dataset resulting from the `CreateDSInfo` instruction).
- The `CreateDSInfo` instruction re-creates the complete result dataset. Even if only a subset of the result columns need re-configuration, you must include the complete result dataset that you want to display to the user ins the `CreateDSInfo` command.
- If you want to use a `PictureAssignment` instruction in combination with the `CreateDSInfo` instruction, the `CreateDSInfo` instruction must be defined prior to the `PictureAssignment` instruction.

For example, a report shall show all applications that are assigned to demands with defined classifications in a grouped dataset.

	Demand Classification	Application
−	Application Mgmt.	
		ARIS v. 6.2.1
		CRM v. 2.6
		CRM AI v. 2.0
		CRM CSS v. 3.2
		CRM CSS v. 3.2
		CRM Opti Retail v. 2.0
		CRM Opti Retail v. 3.0
		CRM Opti Retail v. 3.0 Var.
		eBank v. 1.2
		Trade*Net v. 6.0.3
+	Application Mgmt.,Strategic	
+	Operational	
+	Operational,Application Mgmt.	

The report is based on a native SQL query:

```
SELECT DEMAND.REFSTR, DEMAND.CLASSIFICATION As
'Demand.Classification', APPLICATION.REFSTR As 'Application.REFSTR',
```

```
APPLICATION.NAME As 'Application.Name', APPLICATION.VERSION As
'Application.Version'

FROM DEMAND

LEFT JOIN DEMAND_ARCH ON DEMAND_ARCH.DEMAND = DEMAND.REFSTR

INNER jOIN APPLICATION ON DEMAND_ARCH.OBJECT = APPLICATION.REFSTR

ORDER BY DEMAND.CLASSIFICATION;
```

with the following instructions:

```
JOINCOLUMNS("Application.Name,Application.Version","Application.Name"
," v. ");

GROUPBY("Demand.Classification","Application.REFSTR","Demand",0);

REMOVECOLUMNS("Application.REFSTR");

SETCOLUMNSHOWNAME("Application.Name","Application");

SETCOLUMNSHOWNAME("Demand.Classification","Demand Classification");
```

Alternatively, you can define the instructions with a `CreateDSInfo` instruction instead of using one `RemoveColumns` instruction and two `SetColumnShowName` instructions.

```
JOINCOLUMNS("Application.Name,Application.Version","Application.Name"
," v. ");

GROUPBY("Demand.Classification","Application.REFSTR","Demand",0);

CREATEDSINFO("DEMAND.REFSTR,Demand.Classification,Application.Name","
DEMAND.REFSTR,Demand Classification,Application");
```

Inserting One or Multiple Columns to a Report

The columns displayed in the tabular output of a query are defined with the Show properties of the Alfabet query or the `SELECT` statement of the native SQL query. Instructions not only allow to hide, change, or merge columns defined via the query, but also to add columns to the result dataset.

When the results of a query are displayed in the Alfabet interface, the processing of the query is done in multiple steps. The query results are gathered in an internal dataset in the background and the final report is generated from the internal dataset in a second step.

The specification of additional columns requires the definition of multiple instructions that do the following:

- Add the column to the internal dataset resulting from the query.
- Define the content to be filled in the column.
- Define the display of the column in the result dataset.

You must do the following to add new columns to the dataset:

1) Add the column to the query result dataset that is formed during query execution prior to displaying the results on the Alfabet interface:
   - Use `AddColumns` to add multiple columns to the end of the query result dataset. The columns are added to the internal dataset of query results at the end of the

dataset in the order of specification in the instruction. For information about the required syntax, see Adding Multiple Columns with the AddColumns Instruction.

- Use `InsertColumn` to add one column at a defined position of the internal query result dataset. For information about the required syntax, see Adding A Single Column With the InsertColumn Instruction.

2) Define the column caption and the position of the column in the dataset displayed in the report with one of the following instructions:

- `SetColumnShowName`: This instruction defines a caption for a new column. For each added column that shall be displayed in the results, a `SetColumnShowName` instruction must be added to the instructions section.

New columns added via an `AddColumns` instruction are displayed at the end of the tabular report, regardless of their position in the internal dataset. The order of display is exclusively defined by the order of `SetColumnShowName` definitions in the instructions. The first column for which a caption is defined is displayed first.

For more information about the `SetColumnShowName` instruction, see Defining Column Names and Captions with Instructions.

- `CreateDSInfo`: This instruction redefines the complete dataset. If `CreateDSInfo` is used, the columns resulting from the original query without instructions must also be redefined in the instruction to be displayed in the dataset. The `CreateDSInfo` instruction allows new columns to be displayed before or between columns resulting from the original query dataset.

For more information about the `CreateDSInfo` instruction, see Changing the Order and Number of Columns Displayed in a Report.

3) Define the content for the new column using instructions. For example,:

- Insert information about which object class or object class stereotype the objects in the report belong to. For more information, see Inserting a Column With Object Class Information in the Configured Report.

Complete examples regarding the definition of new columns are provided in the section Inserting a Column With Object Class Information in the Configured Report.

Adding A Single Column With the InsertColumn Instruction

To add a single column to the internal query result dataset at a defined position, add the following instruction to your query:

```
InsertColumn("Position","ColumnName");
```

Use the following parameter(s):

Code Parameter	Description
Position	The position of the new column in the internal query result dataset. The position is the number of the column after which the additional column is added. For example, if the position is set to 3, the column is added after the third column of the dataset. If the position is set to "0", the column is added before the first row of the report.  If the additional column is defined for a native SQL query-based report, the position must not be set to "0". The first column of a native SQL query report must define the REFSTR of the objects in the report for technical reasons and is excluded from display in the tabular report. The evaluation of the REFSTR and exclusion of the column is done after execution of instructions. Therefore, inserting the new column as first column of the report will cause the REFSTR information in the native SQL query to be displayed in the report and the mechanisms that depend on the REFSTR evaluation, like navigation to an object from the report, will not work.
ColumnName	The name of the column that shall be added to the internal dataset of query results that is generated in the background as a basis of report generation. The name is not identical to the column caption that is displayed in the result dataset of the report. The column caption must be defined separately with either a CreateDSInfo or SetColumnShowName instruction. Otherwise the column exists but is not displayed in the dataset displayed in the report.

Adding Multiple Columns with the AddColumns Instruction

To add multiple columns to the internal query result dataset, add the following instruction to your query:

```
AddColumns("ColumnName,ColumnName");
```

Use the following parameter(s):

Code Parameter	Description
ColumnName	The comma-separated list of the columns that shall be added to the internal dataset of query results that is generated in the background as a basis of report generation. A name must be defined for each column. The name is not identical to the column caption that is displayed in the result dataset of the report. The column caption must be defined separately with either a CreateDSInfo or SetColumnShowName instruction. Otherwise, the column will exist but is not displayed in the dataset displayed in the report.

Inserting a Column With Object Class Information in the Configured Report

If a report displays information about objects from different object classes within one column, For example, when the JoinColumns instruction is used in the report, the information about which object belongs to

which object class cannot be derived via the query because the object class name and caption are not a property of the object.

If a report displays information about objects from different object class stereotypes, the stereotype name can be included in the report because the property `Stereotype` of the object stores the stereotype name as string. The caption of the stereotype is defined via an XML object and cannot be derived by the query.

In the above mentioned use cases, you can add an additional column to the report using an `InsertColumn` or `AddColumns` command and additional instructions to display the class or stereotype information in the additional column.

You must do the following to add new columns displaying class or stereotype information to the dataset:

1) Add the column to the query result dataset that is formed during query execution prior to displaying the results on the Alfabet interface:

   - Use `AddColumns` to add multiple columns to the end of the query result dataset. The columns are added to the internal dataset of query results at the end of the dataset in the order of specification in the instruction. For information about the required syntax, see Adding Multiple Columns with the AddColumns Instruction.
   - Use `InsertColumn` to add one column at a defined position of the internal query result dataset. For information about the required syntax, see Adding A Single Column With the InsertColumn Instruction.

2) Define the column caption and the position of the column in the dataset displayed in the report with one of the following instructions:

   - `SetColumnShowName`: This instruction defines a caption for a new column. For each added column that shall be displayed in the results, a `SetColumnShowName` instruction must be added to the `Instructions` section. New columns are displayed at the end of the tabular report, regardless of their position in the internal dataset. The order of display is exclusively defined by the order of `SetColumnShowName` definitions in the instructions. The first column for that a caption is defined is displayed first.

For more information about the `SetColumnShowName` instruction, see Defining Column Names and Captions with Instructions.

   - `CreateDSInfo`: This instruction redefines the complete dataset. If `CreateDSInfo` is used, the columns resulting from the original query without instructions must also be redefined in the instruction to be displayed in the dataset. The `CreateDSInfo` instruction allows new columns before or between columns resulting from the original query dataset to be displayed.

For more information about the `CreateDSInfo` instruction, see Changing the Order and Number of Columns Displayed in a Report.

3) Define the content for the new column using instructions. The instructions to fill the column with data are described in this section. A complete configuration example is given for each instruction.

The class caption and stereotype caption are displayed in the translation for the language culture selected by the user viewing the report if a translation is provided via the mechanisms described in the section Localization and Multi-Language Support for the Alfabet Interface.

Displaying the Class Name and/or Class Caption of the Base Object Class

Use the instruction `SetClassNameByRow` to display the object class name of the base object of each row:

```
SetClassNameByRow("ColumnName");
```

Use the instruction `SetClassCaptionByRow` to display the object class caption of the base object for each row:

```
SetClassCaptionByRow("ColumnName");
```

Use the following parameter(s):

Code Parameter	Description
`ColumnName`	The name of the column inserted with an `InsertColumn` or `AddColumns` instruction to display the class name or caption.

For example, a report shall display all architecture elements assigned to projects and the user that is the authorized user responsible for the architecture element. One row in the report displays architecture elements. A project can include objects from different object classes as architecture elements. The column Architecture Element is defined via a `JoinColumns` instruction and displays objects from different object classes. The architecture elements are defined as base objects of the report to enable navigation to the objects with a `SetRowReference` instruction.

Two new columns are added to the result dataset with the `AddColumns` instruction to display the object class icon and caption for the base object of the result row. To display the caption of the object classes in one of the new columns, a `SetClassCaptionByRow` is used. To display the icon of the object class, the second new column is configured to display the object class name with a `SetClassName` instruction and `PictureAssignment` instructions are used to trigger display of the different names as icons.

A `CreateDSInfo` instruction is used to place the new columns between the `Project` and `Architecture Element` columns and to remove the `REFSTR` of the objects that was added to execute the `SetRowReference` instruction from the dataset displayed in the report.

The following Alfabet query would be implemented. Please note that the Alfabet query does not join all object classes that can be assigned to a project as architecture elements to enhance readability of the example. If you want to use the example as a template for a report, you should ensure that all object classes that might be assigned to one of your projects is included.

```
ALFABET_QUERY_500

FIND ProjectArch

InnerJoin Project ON ProjectArch.Project = Project.REFSTR
```

```
LeftJoin Application ON ProjectArch.Object = Application.REFSTR

LeftJoin ICTObject ON ProjectArch.Object = ICTObject.REFSTR

Consolidate HR Systems		Business Process	Human Resources Management	Ngombe

Displaying the Class Name and/or Class Caption of an Object Class That Is Not the Base Class

If you want to add information about the object class that objects in the report belong to, the `REFSTR` of the objects must be added to the report data set. The information about the `REFSTR` is required to identify the object and evaluate which class the object belongs to.

The REFSTR, which added to the query results for technical reasons only, can be hidden from display in the tabular report by using a RemoveColumns instruction or by redefining the dataset with a CreateDSInfo instruction that does not include the REFSTR information.

Use the instruction SetClassName to display the object class name of the objects that are not the base object of the report:

```
SetClassName("SourceColumnName","TargetColumnName");
```

Use the instruction SetClassCaptionByRow to display the object class caption of objects that are not the base objects of the report:

```
SetClassCaption("SourceColumnName","TargetColumnName");
```

Use the following parameter(s):

Code Parameter	Description
SourceColumn-Name	The name of the column for the REFSTR of the objects for that the class information shall be added to the report. For information about the names of the columns resulting from Alfabet queries and native SQL queries, see Defining Column Names and Captions.
TargetColumn-Name	The name of the column inserted with an InsertColumn or AddColumns instruction to display the class name or caption.

For example, a report shall display all architecture elements assigned to projects and the user that is the authorized user responsible for the architecture element. There is one column in the report displaying architecture elements. A project can include objects from different object classes as architecture elements. The column Architecture Element is defined via a JoinColumns instruction and displays objects from different object classes. The architecture elements are not the base objects of the report. The base object class is the object class Project.

The REFSTR of the architecture elements is added to the report via the Show properties and joined into one column using a JoinColumns instruction.

Two new columns are added to the result dataset with the AddColumns instruction. A SetClassCaption instruction is used to display the caption of the class in one of the new columns. To display the icon of the object class, the second new column is configured to display the object class name with a SetClassName instruction and PictureAssignment instructions are used to trigger display of the different names as icons.

A CreateDSInfo instruction is used to hide the REFSTR information and to place the new columns between the Project and Architecture Element column.

The following Alfabet query would be implemented. Please note that the example of the Alfabet query does not join all object classes that can be assigned to a project as architecture elements to enhance readability. If you want to use the example as a template for a report, you should ensure that all object classes that might be assigned to one of your projects are included.

```
ALFABET_QUERY_500

FIND ProjectArch
```

```
InnerJoin Project ON ProjectArch.Project = Project.REFSTR

Consolidate HR Systems		Business Process	Human Resources Management	Ngombe

Displaying the Stereotype Caption and/or Icon of Objects Displayed in the Report

Stereotypes are defined in an XML stored in the attribute `Stereotype` of the respective object class. The stereotypes included in the definition can then be selected for each object. In the database table for the object class, the name of the stereotype assigned to an object is stored as a string in the column of the property `Stereotype` for the object class.

Object classes have both attributes and properties. Attributes are part of the meta-model definition. Most of the attributes of an object class are not editable but some can be changed in Alfabet Expand.

Properties define the columns of the database table for the object class. When you create an object of an object class on the Alfabet user interface, you define the values of the properties of the object class for that object.

Via a query, you can read the information about the stereotype name from the database table of the object class. But usually, the stereotype caption is displayed to the users in the Alfabet user interface and Therefore, it would be more convenient to display the stereotype caption in the configured report as well.

The instruction converting the stereotype name into the stereotype caption extracts the information about the object and the stereotype name of the object from the dataset resulting from the query. The dataset must provide the following information:

- The `REFSTR` of the object for that the stereotype information shall be displayed.
- The name of the stereotype assigned to the object.

The stereotype caption can be written into a new column that has been added to the report using an `AddColumns` or `InsertColumn` instruction. Alternatively, you can overwrite the stereotype name information. The additional column displaying the `REFSTR` of the object can be removed using a `RemoveColumns` instruction.

For more information about adding columns to a report dataset, see Inserting One or Multiple Columns to a Report.

For more information about removing columns from the report dataset, see Hiding a Column in a Configured Report.

Instead of or in addition to the stereotype caption, the icon defined for the stereotype via the class settings can be displayed in the configured report.

Use the following instruction to display the stereotype caption instead of the stereotype name in the data set displayed for a configured report:

```
SetStereotypeCaption("ReferenceColumn","StereotypeColumn","TargetColumn",RenderMode);
```

Use the following parameter(s):

Code Parameter	Description
`ReferenceColumn`	The name of the column containing the values of the `REFSTR` property of the objects for which the stereotype caption shall be displayed. For information about the names of the columns resulting from Alfabet queries and native SQL queries, see Defining Column Names and Captions.
`StereotypeColumn`	The name of the column containing the values of the `Stereotype` property of the objects for which the stereotype caption shall be displayed.

Code Parameter	Description
`TargetColumn`	The name of the column to which the stereotype caption shall be written. The target column can be added to the result dataset using an `AddColumns` or `InsertColumn` instruction. For more information, see Inserting One or Multiple Columns to a Report.
`RenderMode`	This parameter defines whether the stereotype caption or the icon defined for the stereotype are displayed. The following values can be set for `RenderMode`: • `Icon`: Only the icon is displayed. • `TextIcon`: Both the stereotype caption and the icon are displayed with the caption first. • `IconText`: Both the stereotype caption and the icon are displayed with the icon first. If `RenderMode` is not defined, only the stereotype caption will be displayed. If only an icon is displayed, a legend will be added to the report that explains which stereotype is represented by which icon.

For example, the following native SQL query results in a list of projects and displays the name and the stereotype of the projects:

```
SELECT proj.REFSTR, proj.NAME,proj.STEREOTYPE
FROM PROJECT proj
```

	NAME	STEREOTYPE
1	Consolidate Trading Applications	Program
2	Retire GL Applications	Project
3	Upgrade GenLManager	Project
4	Reshape Core Trading Applications	Project
5	Enhance TradeNet	Project
6	Implement Unified Trade Solution	Project
7	UTS phase 1	ProjectStep
8	UTS phase 2	ProjectStep
9	UTS phase 3	ProjectStep
10	Streamline CRM Applications	Program
11	Migrate CRM Opti Retail to CRM CSS	Project

To display the stereotype caption next to the stereotype name, the following instructions can be added to the query:

- An `InsertColumn` instruction that inserts a new column to the dataset. Please note that the column must be added to the dataset after the first column returning the `REFSTR` if the instruction is used in combination with native SQL.

- A `SetColumnShowName` instruction to trigger display of the new column in the result dataset and to define a caption for the column.

The column inserted via the `InsertColumn` instruction is displayed at the end of the dataset. New columns are always displayed at the end of the dataset regardless of the position defined in the `InsertColumn` instruction. If you want to display the column at any other position, use the `CreateDSInfo` instruction to re-define the complete dataset instead of triggering column display with the `SetColumnShowName` instruction.

- A `SetStereotypeCaption` instruction to display the stereotype caption in the new column.

The object reference is read from the first column of the report that is hidden in datasets resulting from native SQL. Therefore, it is not required to hide the information via a `RemoveColumns` instruction.

The following instructions are added to the example query:

```
InsertColumn("1","StereotypeCaption");
SetColumnShowName("StereotypeCaption","Stereotype Caption");
SetStereotypeCaption("REFSTR","STEREOTYPE", "StereotypeCaption");
```

resulting in the following report:

	NAME	STEREOTYPE	Stereotype Caption
1	Consolidate Trading Applications	Program	Program
2	Retire GL Applications	Project	Project
3	Upgrade GenLManager	Project	Project
4	Reshape Core Trading Applications	Project	Project
5	Enhance TradeNet	Project	Project
6	Implement Unified Trade Solution	Project	Project
7	UTS phase 1	ProjectStep	Project Step
8	UTS phase 2	ProjectStep	Project Step
9	UTS phase 3	ProjectStep	Project Step
10	Streamline CRM Applications	Program	Program
11	Migrate CRM Opti Retail to CRM CSS	Project	Project

Alternatively, you can display the stereotype caption instead of the stereotype name by doing one of the following:

- Add a `RemoveColumn` instruction to the instruction configuration displayed above that removes the column displaying the stereotype name from the result dataset:

  ```
  RemoveColumns("STEREOTYPE");
  ```

- Instead of defining the set of instructions displayed above, define one `SetStereotypeCaption` instruction that has an identical `StereotypeColumn` and `TargetColumn` definition, Therefore, overwriting the information about the stereotype name with the information about the stereotype caption in the result dataset:

  ```
  SetStereotypeCaption("REFSTR","STEREOTYPE", "STEREOTYPE");
  ```

Inserting Columns with Information About the Class Icon And Class Colors

The instruction `GetClassSettingInfo` allows information about the object class icon and coloring defined in the class settings of an object class to be returned in a configured report.

This information can For example, be used to color a configured graphic report that includes graphic representations of objects of multiple different classes. For user profiles, individual class settings with different colors and icons representing an object class can be defined. If the coloring and icon setting is derived from the class settings, the coloring and icons displayed for the graphics will automatically correspond to the coloring and icon that is used in general for the respective object class for the user profile the user is currently logged in with when opening the report.

The `GetClassSettingInfo` instruction requires the following preconditions to be met in the dataset of the query it is applied on:

- The dataset must contain a column that returns the object class name of the object class the current object belongs to. For information about how to add the object class name to the dataset, see Inserting a Column With Object Class Information in the Configured Report.
- Optionally, the stereotype can be taken into account. The dataset must then contain a column that returns the name of the stereotype of the object. The stereotype is stored in the object class property `Stereotype` of the object.
- For each information returned, an empty target column of the data type string must be included into the dataset. The instruction can return the icon name, foreground color and background color defined in the class settings. Whether all or only a subset of the information is returned, can be defined in the instruction. for information about how to add empty columns to the dataset, see .Inserting One or Multiple Columns to a Report.

After having configured the query to return the required dataset, the following instruction can be added to return foreground color, background color and icon defined in the class settings:

```
GetClassSettingInfo(ClassNameCol,StereotypeNameCol,TargetIconNameCol,TargetF
oreColorCol,TargetBackColorCol);
```

Use the following parameters:

Code Parameter	Description
`ClassNameCol`	The name of the column returning the object class name. For information about the names of the columns resulting from Alfabet queries and native SQL queries, see Defining Column Names and Captions. For information about how to add the object class name to the dataset, see Inserting a Column With Object Class Information in the Configured Report.
`Stereo-typeNameCol`	The name of the column returning the object class stereotype name. This definition is optional.

Code Parameter	Description
`TargetIcon-NameCol`	The name of the empty column in the result dataset that shall contain the information about the name of the icon of the object class. The data type of the empty column must be String. For information about how to add an empty column to the dataset, see Inserting One or Multiple Columns to a Report.
`TargetForeCol-orCol`	The name of the empty column in the result dataset that shall contain the information about the foreground color of the object class. The data type of the empty column must be String. For information about how to add an empty column to the dataset, see Inserting One or Multiple Columns to a Report.
`TargetBackCol-orCol`	The name of the empty column in the result dataset that shall contain the information about the background color of the object class. The data type of the empty column must be String. For information about how to add an empty column to the dataset, see Inserting One or Multiple Columns to a Report.

Most of the information that can be added to the instruction is optional. Please note that the columns are identified by their position in the comma separated list. If you do not want to define a column, provide no text in the position of the comma separated list.

For example, the instruction:

```
GetClassSettingInfo(ClassName,ClassStereotype,Target1,Target2,)
```

will return the object class icon name in the column `Target1` and the foreground color in the column `Target 2`, whereas the instruction

```
GetClassSettingInfo(ClassName,ClassStereotype,Target1,Target2)
```

will return the object class fore color in the column `Target1` and the background color in the column `Target2`.

The following Alfabet query returns a dataset that includes the information about the icon, foreground color and background color of the object classes that the objects in the as-is architecture of a selected project belong to. The query could be used in a graphic report to define coloring and icon display via the query that finds the object to be displayed in the graphic:

```
ALFABET_QUERY_500
FIND ProjectArch
InnerJoin Project ON ProjectArch.Project = Project.REFSTR
LeftJoin Application ON ProjectArch.Object = Application.REFSTR
LeftJoin ICTObject ON ProjectArch.Object = ICTObject.REFSTR

Displaying the Object Icon

The instruction `SetObjectIcon` allows object icons to be displayed instead of or in combination with string values. The instruction returns the object icon for the object found in the current row of the query dataset. The following rule apply for the setting of the object icon:

- If an icon is assigned to the object via the standard property Icon, this icon is displayed.
- If no icon is assigned to the object and the object is based on a stereotype, the icon defined for the object class stereotype in the class settings of the object class stereotype is displayed.

- If no icon is assigned to the object and the object is not based on a stereotype, the icon defined in the class settings of the object class is displayed.

To display the object icon of the row reference object, add the following instruction to your query:

```
SetObjectIcon(ColumnName,IconPosition);
```

Use the following parameter(s):

Code Parameter	Description
`ColumnName`	The column containing the value that should be replaced by or amended with the object icon. The returned data type must be string. For information about the names of the columns resulting from Alfabet queries and native SQL queries, see Defining Column Names and Captions.
`IconPosition`	The icon can either be displayed instead of the string or in combination with the string. Allowed values for the icon position are: • `Icon`: The icon is displayed instead of the string. • `TextIcon`: The string is displayed in front of the icon. • `IconText`: The icon is displayed in front of the string. This parameter is optional. If it is not specified, the icon is displayed instead of the string.

Displaying Graphics for Cells Containing Specific Data

The instruction `PictureAssignment` allows values to be displayed via icons rather than or in combination with text or numeric values. For example, indicator values can be represented by icons. Or, if a report contains a column displaying the object class caption of the object found by the query with the instruction `InsertClassCaptionColumn`, the object class icon can be displayed rather than the object class caption.

In the legend of the report, the pictures are displayed with the column caption and the condition for picture assignment or with a text defined in the instruction.

To display an icon instead of or together with text or numbers in a column, add the following instruction to your query:

```
PictureAssignment(ColumnName,ConditionString,"Argument",IconPosition:IconNam
e,"LegendText", "IconAltText",Alignment);
```

Use the following parameter(s):

Code Parameter	Description
`ColumnName`	The column containing the value that constitutes the icon. For the `PictureAssignment` instruction, this is the column for which the cell icon is specified. For information about the names of the columns resulting from Alfabet queries and native SQL queries, see Defining Column Names and Captions.
`ConditionString`, "*Argument*"	The condition that the cell content must match to display the icon is defined by a condition string like `EqualTo` or `Contains`, and an argument. The specification of the argument is mandatory. The content of the argument depends on the condition string. All allowed filter condition strings and the argument specification required for the condition string are listed in the context of instructions for color assignments in the section Filter Condition Strings for Instructions. The argument must be written in quotation marks.
`IconPosition`	If the icon should be included into the cell in combination with the text or numeric value, this parameter defines whether the icon is located before or after the text. Allowed values are: • `TextIcon`: The text is displayed in front of the icon. • `IconText`: The icon is displayed in front of the text. This parameter is optional. If it is not specified, the icon is displayed instead of the text or numeric value. If the parameter is not specified, the `IconName` must be specified without the colon in front.
`IconName`	Name of an icon available in the icon gallery of Alfabet. For more information about the icon gallery see the section Adding and Maintaining Icons for the Alfabet Interface. If you define the instruction in the **Alfabet Query Builder**, you can select the icon from a drop-down list of available icons.
`LegendText`	The text that shall be displayed for the icon in the legend of the report. This parameter is optional. If no legend text is defined, the icons will be displayed with the column caption and the condition for picture assignment.
`IconAltText`	The text that will be displayed instead of the icon if the icon is not available. The text will also be read as description for the icon if a screen reader software is used. If the **Legend Item Text** shall not be defined but the **Icon Alt Text** shall be defined, you must enter an empty **Legend Item Text** to the instruction.
`Alignment`	The alignment of the icon in the cell. This parameter is only evaluated if `IconPosition` is set to `Icon` which means that only the icon is displayed without text. Allowed values are `Left`, `Center`, and `Right`. By default, the icon is center aligned.

Note the following when defining `PictureAssignment` instructions:

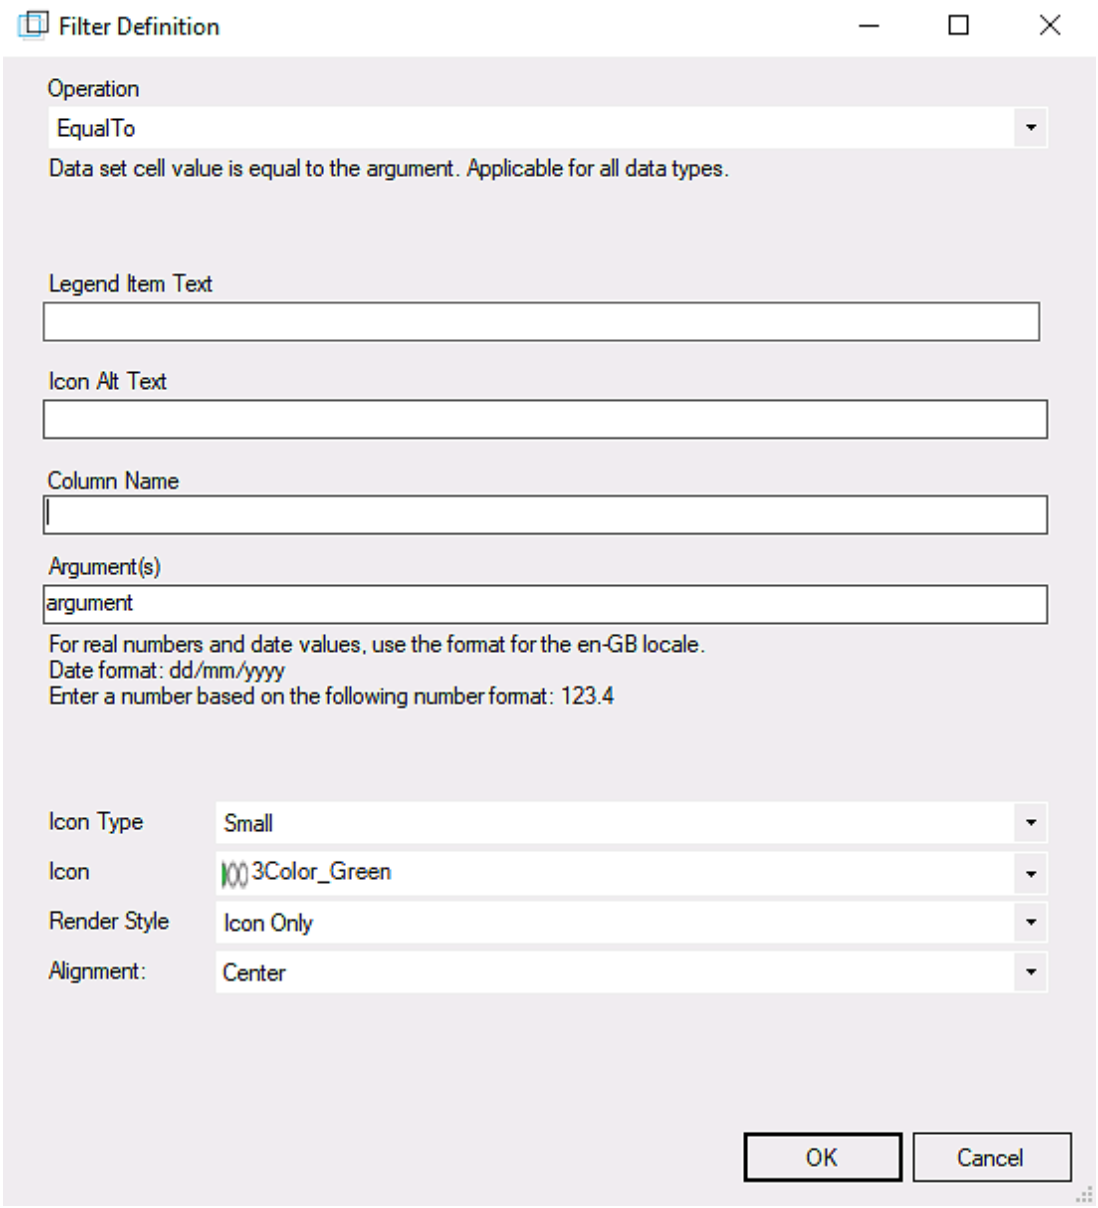
- If you do not specify optional parameters in the middle of the list of parameters, you must add a double comma between the previous and the next argument to maintain the order of parameters in the instruction.
- `PictureAssignment` instructions are executed in the order of their specification. If you define two `PictureAssignment` instructions that shall display a different icon in the same cell (For example, a specification that all numbers less than 3 are substituted with a red icon and another one that defines that all numbers greater than 2 are substituted with a red icon), the second instruction will overwrite the first one for the cells that correspond to both instructions.
- `PictureAssignment` instructions are not evaluated when testing an Alfabet query with the **Test Query**  button in the **Alfabet Query Builder** interface. Close the **Alfabet Query Builder** and use the **Test Report** functionality of the context menu of the configured report to see the result of your instruction configuration.
- If you combine `PictureAssignment` instructions with a `GroupBy_Ex` instruction, the grouping will split the results in one row into two rows, one containing the data for the superordinate object and one containing the data for the subordinate data. The empty cells in each resulting row are set to `NULL`, but color instructions are maintained and executed when the report is rendered in the client interface.

If you define a `PictureAssignment` instruction with an `IsNull` operator, the picture is displayed in the empty cells in all rows. For example, if the `PictureAssignment` instruction is defined to display an icon in a cell when a property of the subordinate class is set to `Null`, the respective empty cells in the rows containing the information about the superordinate class also display the icon. To avoid this problem, the query of the report shall return a value like "Not set" when the property of the subordinate class is set to `Null` and the picture assignment can than be applied to the string value instead of using an `IsNull` operator.

- If you combine `PictureAssignment` instructions with a `JoinColumns` instruction, the content of the source cells is concatenated and placed into the target cell. The picture assignment defined for the target cell is maintained and applied to the concatenated content when rendering the report.
- If you change the column caption with a `SetColumnShowName` instruction, the change is reflected in the legend of the picture assignment.

In the **Alfabet Query Builder**, `PictureAssignment` instructions can be defined via an editor:

1) In the **Instructions** tab of the **Alfabet Query Builder**, click the **New Instruction** button and select **Formatting Instructions** > `PictureAssignment` from the sub-menu. An editor opens.



2) Define the condition for icon display in the **Filter Definition** editor:

- **Column Name**: Enter the name of the column for which values shall be substituted with icons. The column name is specified by a combination of the attributes `ClassAlias` and `Name` in the ***ShowProperty*** XML element defining the column, delimited with a period.
- **Operation**: The condition that the cell content must match to display the icon is defined by a condition string like `EqualTo` or `Contains`, and an argument. Select the condition from the drop-down list. An overview of the conditions available for the instruction is given in the table above.
- **Argument(s)**: Define the argument(s) for the condition that the cell content must match to display the icon. The specification of arguments depend on the selection in the field **Operation**. An overview of the operations and argument specifications required by the argument are given in the table above.
- **Icon Type**: Select from the drop-down list whether the icon that you want to display belongs to the `Small`, `Large` or `Free` icon type.

- **Icon**: Select the icon displayed in all cells matching the defined condition. The drop-down list displays all icons of the icon type defined with the parameter **Icon Type**.
- **Render Style**: Select one of the following:
  - Icon Only: The icon will be displayed instead of the text.
  - Text Followed by Icon: Both text and icon will be displayed and the text is written in front of the icon.
  - Icon Followed by Text: Both text and icon will be displayd and the icon is displayed in front of the text.
- **Legend Item Text**: Define a text that will be displayed in the legend to explain the meaning of the icon. In the legend, the column caption and the defined text is displayed for the selected icon. If no legend text is defined, the icons will be displayed with the column caption and the condition for picture assignment.
- **Icon Alt Text**: Define a text that will be displayed instead of the icon if the icon is not available. The text will also be read as description for the icon if a screen reader software is used.
- **Alignment**: Select whether the icon should be center, left or right aligned in the cell of the dataset. This parameter is only evaluated if the **Render Style** parameter is set to `Icon Only`.

3) Click **OK** to save your settings. The resulting instruction is written into the text field of the **Instructions** tab.

Adding Graphic Icons from the Icon Gallery to a Tabular Report

An icon from any of the icon galleries can be displayed in cells of a configured tabular reports instead of or in addition to a string. The icon and all related information must be returned by the query of the configured report as specified below and the following instruction must be added to the query definition:

```
DynamicPictureAssignment(ColumnName,IconColumn,LegendItemTextColumn,RenderStyleColumn,AlignmentColumn,AltTextColumn);
```

Use the following parameters:

Code Parameter	Description
`ColumnName`	The name of the column in the result dataset the icon shall be displayed in either in addition to the cell content or in front of the cell content. This parameter is mandatory.
`IconColumn`	The name of the column in the result dataset returning the specification of the icon that shall be displayed. The icon must have been uploaded to the icon gallery. The icon must be defined as: `IconGalleryName:IconName`

Code Parameter	Description
	`IconGalleryName` must be `Small` (22x22), `Large`, or `Free`. The icon name is the name of the icon without extension as displayed in the icon gallery view. This parameter is mandatory.
`LegendItemTextColumn`	The name of the column in the result dataset returning the text to be displayed in the legend for the defined icon. The legend will show one entry for each differing combination of legend text and icon. The parameter is optional. If it is not defined, no legend will be displayed.
`RenderStyleColumn`	The name of the column in the result dataset returning whether the icon shall be displayed instead of or in addition to the cell content. This parameter is optional. The return value can be one of the following: • `Icon`: The icon will be displayed instead of the text. This is the default value. • `IconText`: the icon will be displayed in front of the text. • `TextIcon`: The icon will be displayed after the text.
`AlignmentColumn`	The name of the column in the result dataset returning the alignment of the icon or the icon and text in the cell it is displayed in. By default, the cell content is left aligned. Allowed return values are `Left`, `Center`, and `Right`.
`AltTextColumn`	The name of the column in the result dataset returning a text that will be displayed instead of the icon if the icon is not available. The text will also be read as description for the icon if a screen reader software is used.

Please note the following about the definition of the instruction:

- If you do not specify optional parameters in the middle of the list of parameters, you must add a double comma between the previous and the next argument to maintain the order of parameters in the instruction.
- Columns added to the report dataset to provide the picture rendering definition can be removed from the visible dataset via a `RemoveColumns` instruction.
- `PictureAssignment` and `DynamicPictureAssignement` instructions are executed in the order of their specification. If you define two instructions that shall display a different icon in the same cell, the second instruction will overwrite the first one for the cells that correspond to both instructions.
- If you combine `DynamicPictureAssignment` instructions with a `GroupBy_Ex` instruction, the grouping will split the results in one row into two rows, one containing the data for the superordinate object and one containing the data for the subordinate data. The empty cells in each resulting row are set to `NULL`, but picture instructions are maintained and executed when the report is rendered in the client interface.

- If you combine a `DynamicPictureAssignment` instruction with a `JoinColumns` instruction, the content of the source cells is concatenated and placed into the target cell. The picture assignment defined for the target cell is maintained and applied to the concatenated content when rendering the report.

Defining Coloring for Cells or Rows Containing Specific Data

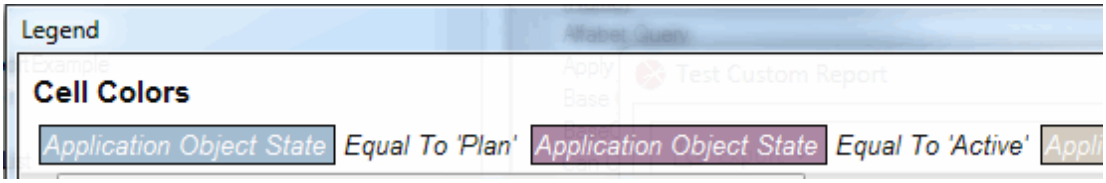
You can define colors to fill cells or entire rows in tabular reports based on a query. Colors are displayed in all cells or rows in the configured report that are found by a condition. A legend is displayed for the report that gives information about the color setting.

For example, a report is configured to display applications. The object state of the application shall be highlighted by cell coloring. There are two ways to highlight the object state:

- The color of the cells in the column containing the information about the object state depends on the application's current object state:

Application Name	Application Version	Application Object State
Business EAI Platform	2.2	Active
Groupware Services	2.2	Active
Mafo-Portal	2.6	Active
PS Global	2.5	Active
ALLFiance PISA	2.9	Retired
SAP@OptiRetail	2.0	Active
SAP@AI	4.0	Active
BookIT	2.9	Retired
Corporate FI-CO	2.2	Active
SAP International	2.8	Active
compas	2.2	Active
Electronic Personal Files	2.5	Active
Opti-SAP HR	2.X	Active
IT-Reporting Tool (SAP B	2.X	Retired
Prodi	2.7	Active
eLead	2.0	Active
KSK	2.0	Retired
CRM CSS	3.2	Active
CRM CSS	3.3	Plan
Compass	1.0	Active
SAP	4.6 c	Active

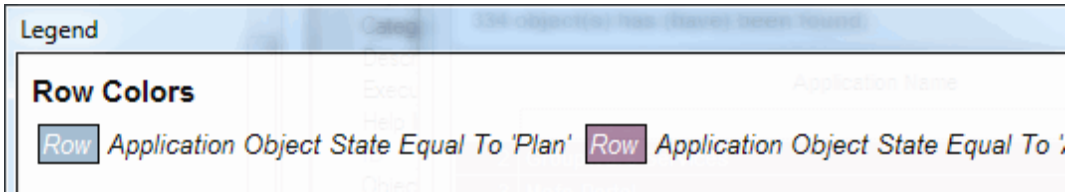
The legend displays all colors with the operator and argument leading to the specific coloring. The caption of the column is displayed in the colored field. If you do not like this information to be displayed in the legend, you can define a legend text in the instruction that will overwrite the default text.



- The color of the rows in the report depends on the application's current object state:

Application Name	Application Version	Application Object State
Business EAI Platform	2.2	Active
Groupware Services	2.2	Active
Mafo-Portal	2.6	Active
PS Global	2.5	Active
ALLFiance PISA	2.9	Retired
SAP@OptiRetail	2.0	Active
SAP@AI	4.0	Active
BookIT	2.9	Retired
Corporate FI-CO	2.2	Active
SAP International	2.8	Active
compas	2.2	Active
Electronic Personal Files	2.5	Active
Opti-SAP HR	2.X	Active
IT-Reporting Tool (SAP B	2.X	Retired
Prodi	2.7	Active
eLead	2.0	Active
KSK	2.0	Retired
CRM CSS	3.2	Active
CRM CSS	3.3	Plan
Compass	1.0	Active
SAP	4.6 c	Active

The legend displays all colors with the column caption, the operator and the argument leading to the specific coloring. In the colored field, Row is displayed to indicate that the color resulting from the data in one column is responsible for coloring of a complete row. If you do not like this information to be displayed in the legend, you can define a legend text in the instruction that will overwrite the default text.



The cell coloring based on a condition can be defined by adding one of the following instructions to the query:

- To color cells in one column based on the cell's content:

```
ColorAssignment(ColumnName,ConditionString,"Argument",TextColor,CellColor
,"LegendText");
```

- To color rows based on the content of the row's cell in a defined column:

```
RowColorAssignment(ColumnName,ConditionString,"Argument",TextColor,CellCo
lor,"LegendText");
```

Use the following parameter(s):

Code Parameter	Description
`ColumnName`	The column containing the value that constitutes the coloring. For the `ColorAssignment` instruction, this is the column for which the cell color is specified. For information about the names of the columns resulting from Alfabet queries and native SQL queries, see Defining Column Names and Captions.
`ConditionString`, "*Argument*"	The condition that the cell content must match to apply the coloring is defined by a condition string like `EqualTo` or `Contains`, and an argument. The specification of the argument is mandatory. The content of the argument depends on the condition string. All allowed filter condition strings and the argument specification required for the condition string are listed in the section Filter Condition Strings for Instructions. The argument must be written in quotation marks.
`TextColor`	HTML compliant definition of the color of the text in the cell matching the defined condition. For example, the color white can be defined as `White` or `#FFFFFF`.
`CellColor`	HTML compliant definition of the color of the background the cell matching the defined condition. For example, the color white can be defined as `White` or `#FFFFFF`.
`LegendText`	The text that shall be displayed for the color in the legend of the report. This parameter is optional. If no legend text is displayed, the color will be displayed with the column caption and the condition for picture assignment.

Note the following when defining `ColorAssignment` and `RowColorAssignment` instructions:

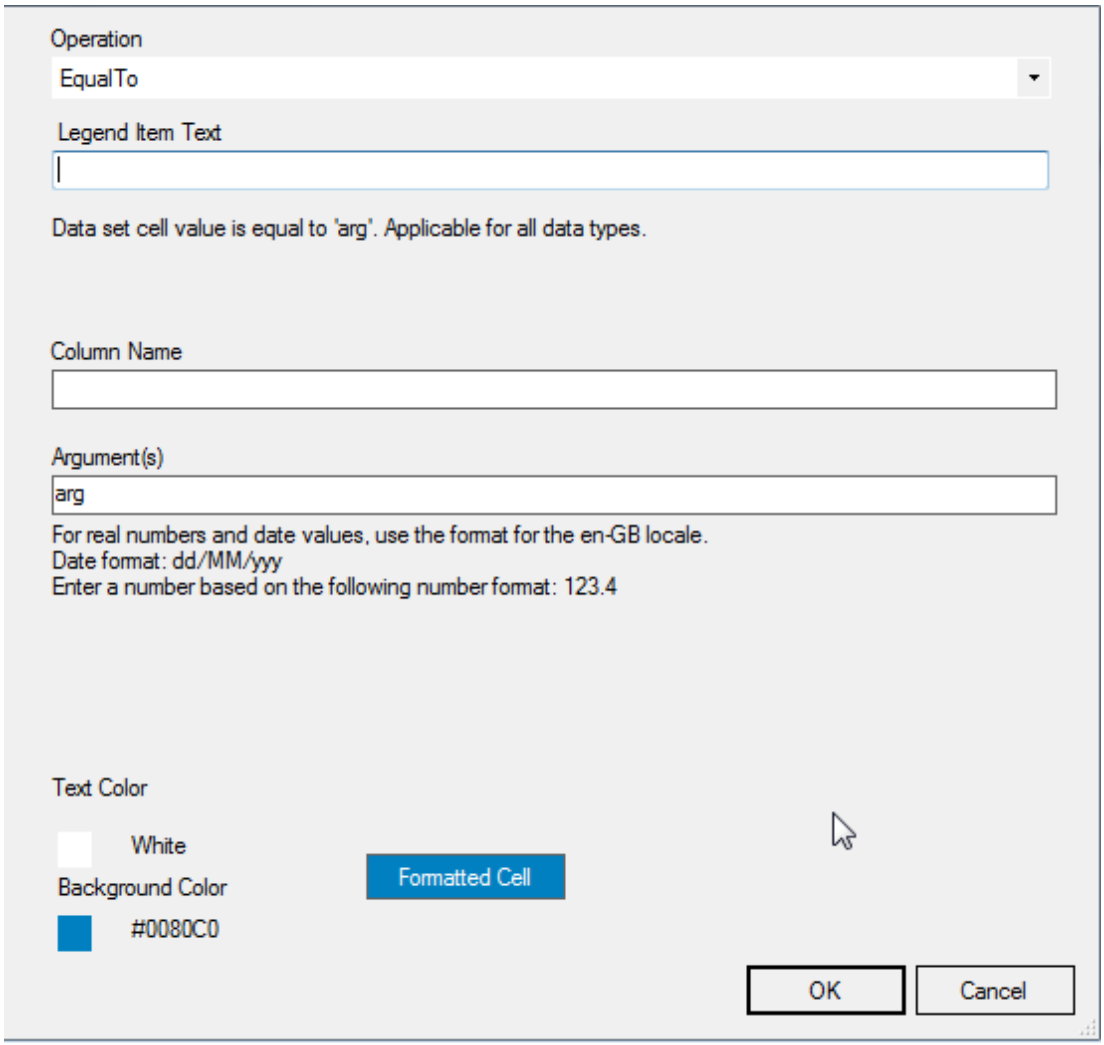
- `ColorAssignment` instructions supersede `RowColorAssignment` instructions independent from the order of definition.
- An additional instruction `FontStyleColorAssignment` is available to change both the coloring of a cell and the formatting of the text in the cell. For more information about this instruction see Defining Text Formatting for Cells Containing Specific Data.
- If you define two `ColorAssignment` instructions that shall color the same cell in different manners (For example, a specification that all numbers less than 3 are colored in blue and another one that defines that all numbers greater than 2 are colored in green), the second instruction overwrites the first one for the cells that correspond to both instructions.
- If you combine color assignments with a `GroupBy_Ex` instruction, the grouping will split the results in one row into two rows, one containing the data for the superordinate object and one containing the data for the subordinate object. The empty cells in each resulting row are set to `NULL`, but color instructions are maintained and executed when the report is rendered in the client interface.

If you define a color assignment instruction with an `IsNull` operator, the color assignment colors the empty cells in all rows with the defined color. For example, if the color assignment is defined to color cells when a property of the subordinate class is set to `Null`, the respective empty cells in the rows containing the information about the superordinate class are also colored. To avoid this problem, the query of the report shall return a value like "Not set" when the property of the subordinate class is set to `Null` and the coloring can than be applied to the string value instead of using an `IsNull` operator.

- If you combine color assignments with a `JoinColumns` instruction, the content of the source cells is concatenated and placed into the target cell. The color rule defined for the target cell is maintained and applied to the concatenated content when rendering the report.
- If you change the column caption with a `SetColumnShowName` instruction, the change is reflected in the legend of the color rules.

In the **Alfabet Query Builder**, color assignments can be defined via an editor:

1) In the **Instructions** tab of the **Alfabet Query Builder**, click the **New Instruction** button and select either **Formatting Instructions** > `ColorAssignment` or **Formatting Instructions** > `RowColorAssignment` in the sub-menu. An editor opens.



2) Define the condition for cell coloring in the **Filter Definition** editor:
   - **Column Name**: Enter the name of the column containing the value that constitutes the coloring. For the `ColorAssignment` instruction, this is also the column that will be colored. The column name is specified by a combination of the attributes `ClassAlias` and `Name` from the ***ShowProperty*** XML element defining the column, delimited with a period.
   - **Operation**: The condition that the cell content must match to apply the coloring is defined by a condition string like `EqualTo` or `Contains`, and an argument. Select the condition from the

drop-down list. An overview of the conditions available for the instruction is given in the table above.

- **Argument(s)**: Define the argument(s) for the condition that the cell content must match to apply the coloring. The specification of arguments depend on the selection in the filed **Operation**. An overview of the operations and argument specifications required by the argument are given in the table above.

3) Define the cell color and the text color that shall be used for cells or rows with a content matching the defined condition:

- **Text Color** / **Background Color**: Click on the colored rectangle to change the text color or cell background color respectively. A color selector opens. You can select one of the colors displayed in the selector by clicking the color field or define a new color by clicking the **Define Custom Color** button. The new color can either be selected from the colors displayed in the top area or defined as RGB color value. Click the **Add as New Color** button to add the color to the set of colors in the standard selector.

After color selection click **OK** to apply your selection. The selected color is displayed in the **Filter Definition** editor and the preview on the right of the color selection fields displays the resulting color format.

4) Optionally, define a text to be displayed for the color in the legend in the field **Legend ItemText**. If you do not define a text, the column name containing the data and the condition causing the coloring will be displayed in the legend with the color.

5) Click **OK** to save your settings. The resulting instruction is written into the text field of the **Instructions** tab.

Filter Condition Strings for Instructions

The following conditions can be specified for instructions that assign color to cells and rows of the report. The same conditions are also applicable to instructions defining cells that shall display a graphic icon. See Displaying Graphics for Cells Containing Specific Data for more information about instructions defining graphic cell content.

Condition	Description and Example
`Contains`	Data set cell value has the argument as part of the string. Applicable for columns of type `String` only. `ColorAssignment(Application.Name,Contains,"Trade",White,#336699);`
`DoesNotContain`	Data set cell value does not have the argument as part of the string. Applicable for columns of type `String` only. `ColorAssignment(Application.Name,DoesNotContain,"Trade",White, #336699);`
`StartsWith`	Data set cell value starts with the argument. Applicable for columns of type `String` only.

Condition	Description and Example
	`ColorAssignment(Application.Name,StartsWith,"Trade",White, #336699);`
`EndsWith`	Data set cell value ends with the argument. Applicable for columns of type `String` only. `ColorAssignment(Application.Name,EndsWith,"Trade",White, #336699);`
`EqualTo`	Data set cell value is equal to the argument Applicable for all column types. `ColorAssignment(Application.ObjectState,EqualTo,"Active",White, #336699);`
`NotEqualTo`	Data set cell value is not equal to the argument. Applicable for all column types. `ColorAssignment(Application.ObjectState,NotEqualTo,"Active",White, Red);`
`GreaterThan`	Data set cell value is greater than the argument. Applicable for column types `Real`, `Integer`, or `Date`. `ColorAssignment(Application.StartDate,GreaterThan,"13.02.2008",White, #336699);`
`GreaterThanOrEqualTo`	Data set cell value is greater than or equal to 'arg'. Applicable for column types `Real`, `Integer`, or `Date`. `ColorAssignment(Application.StartDate,GreaterThanOrEqualTo, "13/02/2008",White,#336699);`
`LessThan`	Data set cell value is less than the argument. Applicable for column types `Real`, `Integer`, or `Date`. `ColorAssignment(Application.StartDate,LessThan,"2008/02/13",White, #336699);`
`LessThanOrEqualTo`	Data set cell value is less than or equal to `'arg'`. Applicable for column types `Real`, `Integer`, or `Date`. `ColorAssignment(Application.StartDate,LessThanOrEqualTo, "2008/02/13",White,#336699);`
`Between`	The argument must contain two values separated by a comma. Data set cell value is greater than or equal to the value before the comma and less than or equal to the value after the comma. Applicable for column types `Real`, `Integer`, or `Date`. `ColorAssignment(Application.StartDate,Between, "2008/02/12,2008/09/12",White,#336699);`

Condition	Description and Example
`IsNull`	Data set cell value is not defined. Applicable for all column types. **NOTE**: `ColorAssignment` and `PictureAssignment` instructions require an argument definition to be processed. Although searching for undefined values does not require an argument, you must specify an argument, containing For example, a whitespace, for technical reasons. `ColorAssignment(Application.PreviousVersion,IsNull," ",White, #336699);`
`IsNotNull`	Data set cell value is defined. Applicable for all column types. **NOTE**: `ColorAssignment` instructions require an argument definition to be processed. Although searching for undefined values does not require an argument, you must specify an argument, containing For example, a whitespace, for technical reasons. `ColorAssignment(Application.Variant,IsNotNull," ",White, #336699);`
`In`	Data set cell value is equal to one of the values specified as comma separated list in the argument. Applicable for all column types. `ColorAssignment(Application.Version,In,"2.2,3.2,4.0",White, #336699);`
`NotIn`	Data set cell value is equal to one of the values specified as comma separated list in the argument. Applicable for all column types. `ColorAssignment(Application.Version,NotIn,"2.2,2.5,2.8",White , #336699);`

Defining Cell Coloring With Colors Defined in the Report's Query

The background and text color of cells in a tabular configured report can be defined via the query the configured report it is based on. The color definitions returned in the query will then be applied to a defined column of the dataset.

Define the following Instructions to apply colors defined in the query results to the cells in the result dataset:

```
DynamicColorAssignment(ColumnName,BackColorColumn,ForeColorColumn,LegendItem
TextColumn);
```

Use the following parameter(s):

Code Parameter	Description
`ColumnName`	The name of the column in the result dataset the coloring shall be applied to. This parameter is optional. If it is not specified, all columns are colored. Please note that the columns defined in the parameters of the instruction are excluded from coloring.
`BackColorColumn`	The name of the column in the result dataset returning the color in HTML compliant color coding (like #0FFFFFF for white coloring) that shall be applied to the background of the cells. This parameter is mandatory.
`ForeColorColumn`	The name of the column in the result dataset returning the color in HTML compliant color coding that shall be applied to the text in the cells. This parameter is optional.
`LegendItemTextColumn`	The name of the column in the result dataset returning the text to be displayed in the legend for the defined coloring. The legend will show one entry for each differing combination of text and color setting. The parameter is optional. If it is not defined, no legend will be displayed.

Please note the following about the definition of the instruction:

- If you do not specify optional parameters in the middle of the list of parameters, you must add a double comma between the previous and the next argument to maintain the order of parameters in the instruction.
- Columns added to the report dataset to provide the coloring definition can be removed from the visible dataset via a `RemoveColumns` instruction.
- `ColorAssignment` and `DynamicColorAssignment` instructions are executed in the order of their specification. If you define two instructions that shall display a different icon in the same cell, the second instruction will overwrite the first one for the cells that correspond to both instructions.
- If you combine `DynamicColorAssignment` instructions with a `GroupBy_Ex` instruction, the grouping will split the results in one row into two rows, one containing the data for the superordinate object and one containing the data for the subordinate data. The empty cells in each resulting row are set to `NULL`, but color instructions are maintained and executed when the report is rendered in the client interface.
- If you combine `DynamicColorAssignment` instructions with a `JoinColumns` instruction, the content of the source cells is concatenated and placed into the target cell. The picture assignment defined for the target cell is maintained and applied to the concatenated content when rendering the report.

Defining Text Formatting for Cells Containing Specific Data

You can define formatting of text as bold, undeline or italic in tabular reports based on a condition. The text format is changed in all cells of a defined column of the configured report that match the condition. A

legend is displayed for the report that gives information about the text formatting. There are two instructions for text formatting. One is for the definition of text formatting only. The other allows text formatting and coloring of the cell text and background to be configured in a single instruction.

For example, a report is configured to display applications. The object state of the application shall be highlighted by text formatting and cell coloring. For active applications, the text shall be written in bold and for retired applications, the text should be written in italic and at the same time the cells shall be displayed with a red background:

Application Name	Application Version	Application Object S
AF HR Online	3.0	**Active**
AF HR Online EU	2.2 Var.	**Active**
AF HR Online US	2.2 Var.	**Active**
AF WorkPortal	1.0	Plan
AI-Miner	1	Plan
Alfabet @ Cloud	9.8	Plan
ALLFinance PISA	2.9	*Retired*
Anno-Fact	1.0	**Active**
Anno-Fact	2.0	Plan
Announcements for Federal Reserve	1.0	**Active**

The legend displays the cell's text formatting and colors with the operator and argument leading to the specific coloring. The caption of the column is displayed in the cell.

If you do not like the information about the condition to be displayed in the legend, you can define a legend text in the instruction that will overwrite the default text.

The cell text formatting and optional coloring can be defined by adding one of the following instructions to the query:

- To format text of cells in a column based on the cell's content:

  ```
  FontStyleAssignment(ColumnName,ConditionString,"Argument",TextFormat,"LegendText");
  ```

- To format text of cells and color the text and background of cells in a column based on the cell's content:

  ```
  FontStyleColorAssignment(ColumnName,ConditionString,"Argument",TextFormat,TextColor,CellColor,"LegendText");
  ```

Use the following parameter(s):

Code Parameter	Description
`ColumnName`	The column containing the value that constitutes the formatting of text and coloring. For information about the names of the columns resulting from Alfabet queries and native SQL queries, see Defining Column Names and Captions.
`Condi-tionString`, " *Argument* "	The condition that the cell content must match to apply the formatting and coloring is defined by a condition string like `EqualTo` or `Contains`, and an argument. The specification of the argument is mandatory. The content of the argument depends on the condition string. All allowed filter condition strings and the argument specification required for the condition string are listed in the section Filter Condition Strings for Instructions. The argument must be written in quotation marks.
`TextFormat`	The formatting that shall be applied to the text. Allowed values are: • `bold` • `italic` • `underline` Multiple values can be defined comma separated. The text format has to be written in quotation marks if multiple values are selected.
`TextColor`	For `FontStyleColorAssignment` instructions only: HTML compliant definition of the color of the text in the cell matching the defined condition. For example, the color white can be defined as `White` or `#FFFFFF`.
`CellColor`	For `FontStyleColorAssignment` instructions only: HTML compliant definition of the color of the background the cell matching the defined condition. For example, the color white can be defined as `White` or `#FFFFFF`.
`LegendText`	The text that shall be displayed for the text formatting and color in the legend of the report. This parameter is optional. If no legend text is displayed, the color will be displayed with the column caption and the condition for picture assignment.

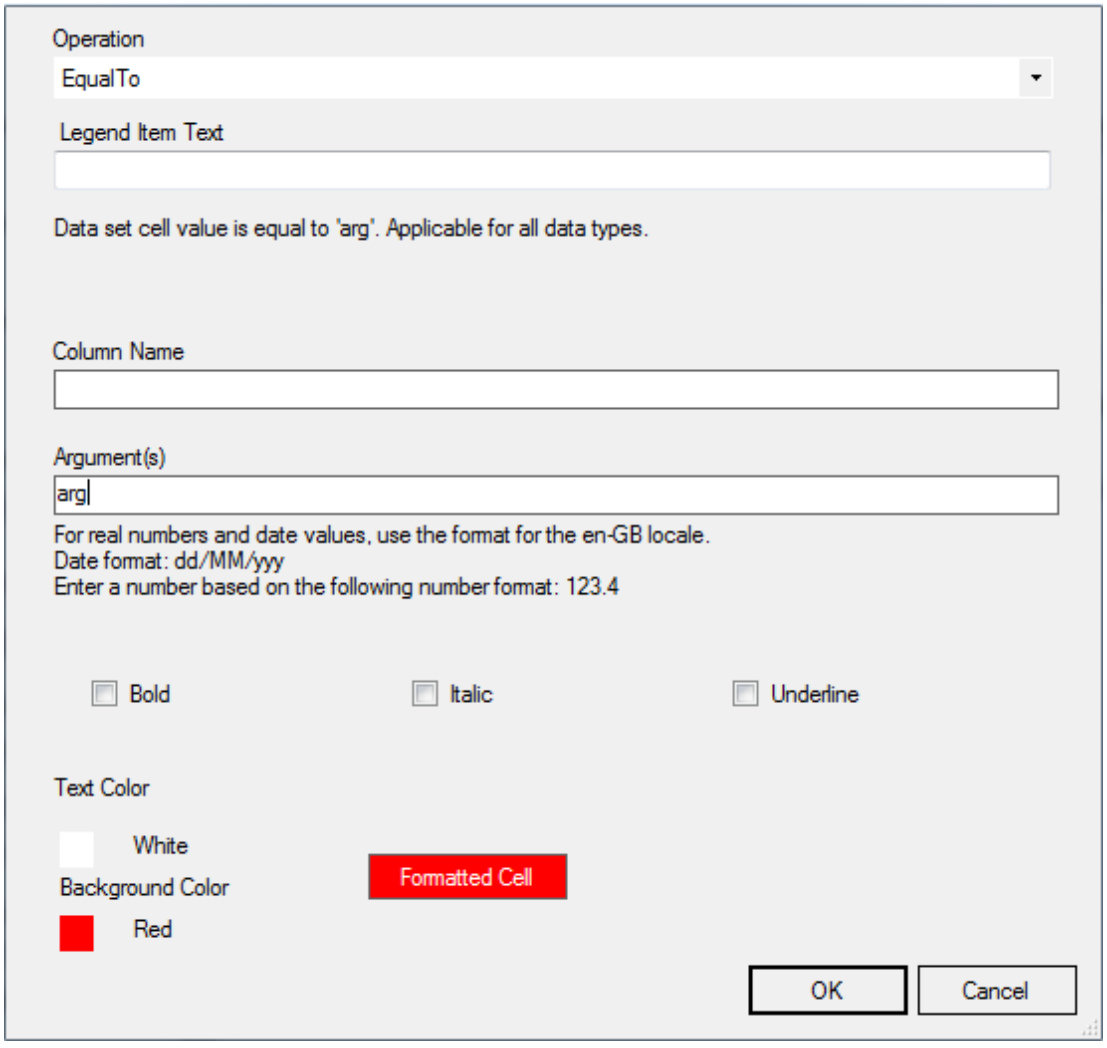
Note the following when defining `ColorAssignment` and `RowColorAssignment` instructions:

- If you define two instructions that shall format the same cell in different manners (For example, a specification that all numbers less than 3 are displayed in bold and another one that defines that all numbers greater than 2 are underlined), the second instruction overwrites the first one for the cells that correspond to both instructions.
- If you combine formatting instructions with a `GroupBy_Ex` instruction, the grouping will split the results in one row into two rows, one containing the data for the superordinate object and one containing the data for the subordinate data. The empty cells in each resulting row are set to `NULL`, but formatting instructions are maintained and executed when the report is rendered in the client interface.

- If you combine color assignments with a `JoinColumns` instruction, the content of the source cells is concatenated and placed into the target cell. The formatting defined for the target cell is maintained and applied to the concatenated content when rendering the report.
- If you change the column caption with a `SetColumnShowName` instruction, the change is reflected in the legend.

In the **Alfabet Query Builder**, formatting assignments can be defined via an editor:

1) In the **Instructions** tab of the **Alfabet Query Builder**, click the **New Instruction** button and select either **Formatting Instructions** > `FontStyleAssignment` or **Formatting Instructions** > `FontStyleColorAssignment` in the sub-menu. An editor opens.



2) Define the condition for cell formatting in the **Filter Definition** editor:

   - **Column Name**: Enter the name of the column containing the value that constitutes the coloring. For the `ColorAssignment` instruction, this is also the column that will be colored. The column name is specified by a combination of the attributes `ClassAlias` and `Name` from the ***ShowProperty*** XML element defining the column, delimited with a period.
   - **Operation**: The condition that the cell content must match to apply the coloring is defined by a condition string like `EqualTo` or `Contains`, and an argument. Select the condition from the

drop-down list. An overview of the conditions available for the instruction is given in the table in the section Filter Condition Strings for Instructions.

- **Argument(s)**: Define the argument(s) for the condition that the cell content must match to apply the coloring. The specification of arguments depend on the selection in the filed **Operation**. An overview of the operations and argument specifications required by the argument are given in the table above.

3) Define the formatting that shall be applied to the text by selecting one or multiple of the checkboxes **Bold**, **Italic**, and **Underline**.

4) For `FontStyleColorAssignement` only: Define the cell color and the text color that shall be used for cells or rows with a content matching the defined condition:

   - **Text Color** / **Background Color**: Click on the colored rectangle to change the text color or cell background color respectively. A color selector opens. You can select one of the colors displayed in the selector by clicking the color field or define a new color by clicking the **Define Custom Color** button. The new color can either be selected from the colors displayed in the top area or defined as RGB color value. Click the **Add as New Color** button to add the color to the set of colors in the standard selector.

After color selection click **OK** to apply your selection. The selected color is displayed in the **Filter Definition** editor and the preview on the right of the color selection fields displays the resulting color format.

5) Optionally, define a text to be displayed for the formatting in the legend in the field **Legend ItemText**. If you do not define a text, the condition causing the formatting will be displayed in the legend with the cell.

6) Click **OK** to save your settings. The resulting instruction is written into the text field of the **Instructions** tab.

Changing the Alignment of Cell Content

By default, integer and real values are right aligned in cells of a tabular report, icons are center aligned and all other data types are displayed left aligned. The default alignment of the cell content can be changed for all or a subset of columns returning a string value in a result data set. For all other data types, the alignment cannot be changed.

Use the one of the following instructions to change the default cell content alignment for a configured report:

- To change alignment of defined columns:

```
SetColumnsAlignment("Left:Column1,Column3","Right:Column5,Column6","Center:Column2,Column4");
```

- To change the alignment of cells in a defined column:

```
SetCellAlignment("Left:Column1,Column3","Right:Column5,Column6","Center:Column2,Column4");
```

Use the following parameter(s):

Code Parameter	Description
`Left: Column1,Column2`	The prefix `Left:` followed by a comma separated list of the names of columns that shall be displayed left aligned. The parameter must be written in quotation marks. The selected columns must return string values. For information about the names of the columns resulting from Alfabet queries and native SQL queries, see Defining Column Names and Captions.
`Right: Column1,Column2`	The prefix `Right:` followed by a comma separated list of the names of columns that shall be displayed right aligned. The parameter must be written in quotation marks.
`Center: Column1,Column2`	The prefix `Center:` followed by a comma separated list of the names of columns that shall be displayed center aligned. The parameter must be written in quotation marks.

Note the following when defining `SetCellAlignment` and `SetColumnsAlignment` instructions:

- `SetCellAlignment` instructions supersede `SetColumnsAlignment` instructions, independent of the order of definition.
- `SetColumnsAlignment` instructions only affect column rendering. If another instruction specific to cell rendering is applied on the same column (For example, if both `COLORASSIGNMENT` and `SetColumnsAlignment` are used on the same column), the formatting of the cell-level instruction will take precedence and `SetColumnsAlignment` will be ignored.
- The order of the parameters to be defined in these instructions is not relevant. If a parameter is not required, it can be left out.

Changing the Output Format for Boolean Values

Boolean values are stored as `true` or `false` in the Alfabet database.

Theses values can be changed to any other string in the report output using the following instruction:

```
ConvertBoolean2String(ColumnName,StringForTrue,StringForFalse,StringForUndefined);
```

Use the following parameter(s):

Code Parameter	Description
`ColumnName`	The column in the tabular output containing the boolean values that shall be changed to a string.

Code Parameter	Description
	For information about the names of the columns resulting from Alfabet queries and native SQL queries, see Defining Column Names and Captions.
`StringForTrue`	Define the string that shall be displayed if the boolean property is set to `true`.
`StringFor-False`	Define the string that shall be displayed if the boolean property is set to `false`.
`StringForUn-defined`	Define the string that shall be displayed if the boolean property is undefined, that means NULL in the database table. This parameter is optional.

For example, a report displays devices and the information, whether the device is a physical hardware device or a virtual host. The information, whether the device is physical or virtual is defined by the `IsPhysical` property of the object class `Device`. The `IsPhysical` property has the **Property Type** attribute set to `Boolean`.

A simple report showing the `Name` and the `IsPhysical` property looks as follows:

Device	Device Is Physical
New York Collaboration Server	x
Cisco Router X189	x
Switch, Baracuda N8000	x
Information Server	x
Transaction Server	x
Oracle Exadata OnPremise Machine	x
Sun Server - Fire Wall	
Sun OS DB Server	x
Windows 2000 Server	x
Backup Server	x
Web Server	x
cRM Server	x

The `ConvertBoolean2String` instruction can be used to alter the output to display the information '`physical host`' or '`virtual host`' instead of an x or an empty cell in the column for the **Is Physical** property:

Device	Host Type
New York Collaboration Server	physical host
Cisco Router X189	physical host
Switch, Baracuda N8000	physical host
Information Server	physical host
Transaction Server	physical host
Oracle Exadata OnPremise Machine	physical host
Sun Server - Fire Wall	virtual host
Sun OS DB Server	physical host
Windows 2000 Server	physical host
Backup Server	physical host
Web Server	physical host
cRM Server	physical host
e-Peopel	physical host

The report is based on the following Alfabet query:

```
ALFABET_QUERY_500

FIND Device

InnerJoin Location ON Device.Location = Location.REFSTR

Instructions

ConvertBoolean2String(Device.IsPhysical,physical
host,virtualhost,undefined);

EndOfInstructions

AUTODSINFO

QUERY_XML

<QueryDef>

   <ShowProperty Type="Property" ClassName="Device" Name="Name"
   ShowName="Device" />

   <ShowProperty Type="Property" ClassName="Device"
   Name="IsPhysical" ShowName="Host Type" />

</QueryDef>
```

The same output can be defined by the following SQL query:

```
SELECT DEVICE.REFSTR, DEVICE.NAME As 'Device', DEVICE.ISPHYSICAL As
'Host Type'

FROM DEVICE
```

in combination with the following instruction definition:

```
ConvertBoolean2String("Host Type","physical host","virtual host");
```

Displaying String, Integer or Real Values as Boolean Values

For object class properties of the **Data Type** `String`, `Integer` or `Real`, the values stored in the database can be displayed as boolean values in a report.

Conversion of values to boolean is done dependent on the property type:

- For properties of the type `Integer` or `Real`, all values that are not equal to zero (=0) are set to true. If the value equals zero, it is set to false. Undefined values are left undefined.
- For properties of the type `String`, the string that shall be set to true must be defined in the instruction. All other strings are set to false. Undefined values are left undefined.

In the resulting report output, an x is displayed in the table cells for that a `String`, `Integer` or `Real` is set to true. If the value is set to false or is undefined, the table cell is empty.

Integer or real values can be changed to boolean in the report output using the following instruction:

```
Convert2Boolean("ColumnName(s)");
```

String values can be changed to boolean in the report output using the following instruction:

```
Convert2Boolean("ColumnName(s)",StringForTrue);
```

Use the following parameter(s):

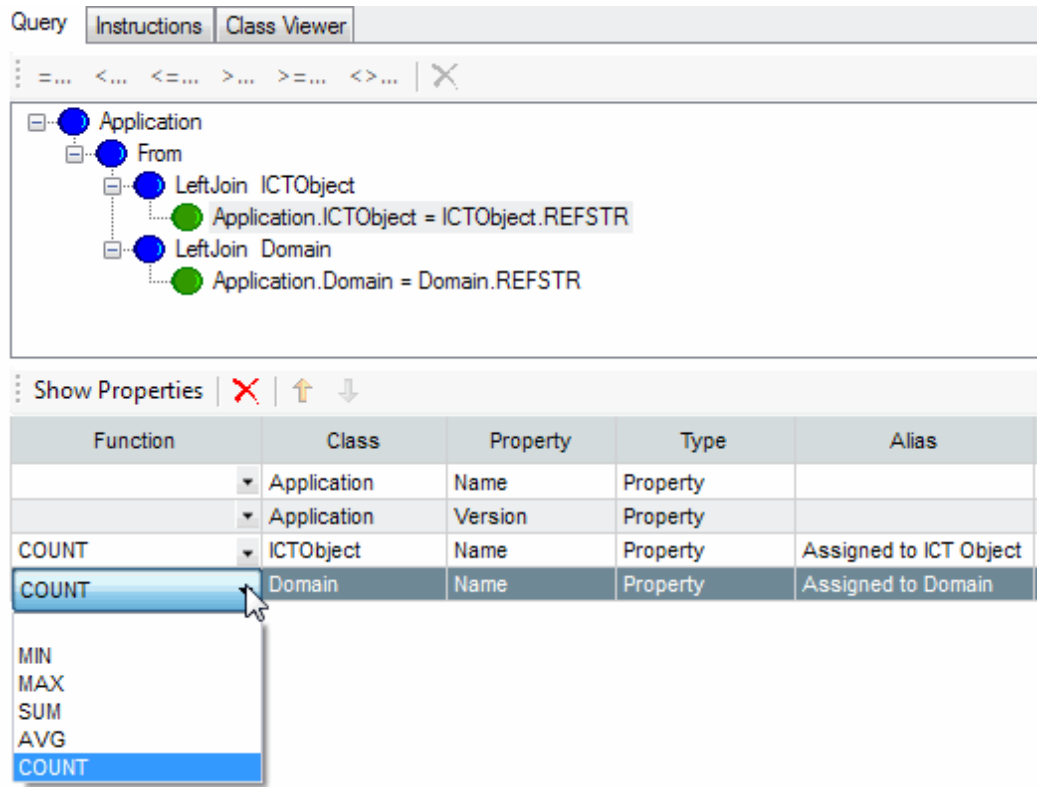
Code Parameter	Description
`ColumnName(s)`	The column in the tabular output containing the values of the **Data Type** `String`, `Integer` or `Real` that shall be displayed as boolean. If multiple columns contain values that shall be displayed as boolean, the columns can be defined comma separated. If multiple columns are defined, and a `StringForTrue` parameter is also defined, this parameter is applied to all columns with string values defined in the comma separated list. For all columns containing integer and real values, the `StringForTrue` parameter is ignored. For information about the names of the columns resulting from Alfabet queries and native SQL queries, see Defining Column Names and Captions.
`StringForTrue`	Define the string that shall be set to true.

For example, a report displays the assignment of applications to ICT objects and domains.

Application Name	ICT Object Name	Domain Name
Business EAI Platform v.2.2	Business EAI Platform	Deliver and Run IT Services
Groupware Services v.2.2	Groupware Services	
Mafo-Portal v.2.6	Mafo-Portal	Customer Management
PS Global v.2.5	SON	
ALLFiance PISA v.2.9	ALLFinance PISA	Short- and Mid-Term Financial Plan
SAP@OptiRetail v.2.0	SAP@OptiRetail	Finance and Controlling
SAP@AI v.4.0	SAP@AI	Finance and Controlling
BookIT v.2.9	BookIT	Stake Holder Management
Corporate FI-CO v.2.2	Corporate FI-CO	Internal Audit
SAP International v.2.8	SAP Template	
compas v.2.2	compas	Regulatory Compliance Manageme
Electronic Personal Files v.2.5		
Opti-SAP HR v.2.X	Opti-SAP HR	Human Resources
IT-Reporting Tool (SAP BW) v.2.X		Fraud and Incident Management
Prodi v.2.7	Prodi	
eLead v.2.0	eLead	
KSK v.2.0	KSK	
CRM CSS v.3.2	CRM CSS	Customer Management
CRM CSS v.3.3	CRM CSS	Customer Management

The report is generated to check whether all applications are assigned to both a domain and an ICT object. To provide a better overview, the assignment to ICT Objects and Domains shall be displayed as a boolean value.

For that purpose, the information about the assignment to an ICT Object or Domain is first converted into an integer by using the `COUNT` function. To enhance readability, an alias is defined for the column headers reflecting the change in the information displayed in the column:



This change results in the following output:

Application Name	Assigned to ICT Object	Assigned to Domain
Business EAI Platform v.2.2	1	1
Groupware Services v.2.2	1	0
Mafo-Portal v.2.6	1	1
PS Global v.2.5	1	0
ALLFiance PISA v.2.9	1	1
SAP@OptiRetail v.2.0	1	1
SAP@AI v.4.0	1	1
BookIT v.2.9	1	1
Corporate FI-CO v.2.2	1	1
SAP International v.2.8	1	0
compas v.2.2	1	1
Electronic Personal Files v.2.5	0	0
Opti-SAP HR v.2.X	1	1

The use of the `Convert2Boolean` instruction further enhances the readability of the information:

Application Name	Assigned to ICT Object	Assigned to Domain
Business EAI Platform v.2.2	x	x
Groupware Services v.2.2	x	
Mafo-Portal v.2.6	x	x
PS Global v.2.5	x	
ALLFiance PISA v.2.9	x	x
SAP@OptiRetail v.2.0	x	x
SAP@AI v.4.0	x	x
BookIT v.2.9	x	x
Corporate FI-CO v.2.2	x	x
SAP International v.2.8	x	
compas v.2.2	x	x
Electronic Personal Files v.2.		
Opti-SAP HR v.2.X	x	x
IT-Reporting Tool (SAP BW)		x
Prodi v.2.7	x	
eLead v.2.0	x	

The report is based on the following Alfabet query:

```
ALFABET_QUERY_500

FIND

Application

LeftJoin ICTObject ON Application.ICTObject = ICTObject.REFSTR

LeftJoin Domain ON Application.Domain = Domain.REFSTR

Instructions

JoinColumns("Application.Name,Application.Version","Application.Name
", " v.");

Convert2Boolean("ICTObject.Name,Domain.Name");

EndOfInstructions

AUTODSINFO

QUERY_XML
```

```
<QueryDef>
<ShowProperty Type="Property" ClassName="Application" Name="Name" />
<ShowProperty Type="Property" ClassName="Application" Name="Version"
/>
<ShowProperty Type="Property" ClassName="ICTObject" Name="Name"
ShowName="Assigned to ICT Object" Function="COUNT" />
<ShowProperty Type="Property" ClassName="Domain" Name="Name"
ShowName="Assigned to Domain" Function="COUNT" />
</QueryDef>
```

For example, a report displays the object state and status of applications.

	Application Name	Object State	Status
1	Business EAI Platform v.2.2	Retired	Approved
2	Groupware Services v.2.2	Active	Approved
3	Mafo-Portal v.2.6	Active	Approved
4	PS Global v.2.5	Retired	Approved
5	ALLFiance PISA v.2.9	Retired	Approved
6	SAP@OptiRetail v.2.0	Active	Approved
7	SAP@AI v.4.0	Retired	Closed
8	BookIT v.2.9	Retired	Approved
9	Corporate FI-CO v.2.2	Active	Draft
10	SAP International v.2.8	Retired	Approved

The report is generated to check whether all applications with the object state set to Retired have a status Closed assigned. To provide a better overview, the report is configured to display object state and status as boolean values. True is returned if the object state is set to Retired and if the status is set to Closed.

	Application Name	Is Retired	Is Closed
1	Business EAI Platform v.2.2	x	
2	Groupware Services v.2.2		
3	Mafo-Portal v.2.6		
4	PS Global v.2.5	x	
5	ALLFiance PISA v.2.9	x	
6	SAP@OptiRetail v.2.0		
7	SAP@AI v.4.0	x	x
8	BookIT v.2.9	x	
9	Corporate FI-CO v.2.2		
10	SAP International v.2.8	x	

Two `Convert2Boolean` instructions must be defined for the query, because two different strings must be displayed as true.

The report is based on the following native SQL query:

```
SELECT APPLICATION.REFSTR, APPLICATION.NAME AS 'Application Name',
APPLICATION.VERSION, APPLICATION.OBJECTSTATE AS 'Is
Retired',APPLICATION.STATUS AS 'Is Closed'
FROM APPLICATION
```

in combination with the following instruction definition:

```
JoinColumns("Application Name,VERSION","Application Name", " v.");
Convert2Boolean("Is Retired","Retired");
Convert2Boolean("Is Closed","Closed");
```

Changing the Output Format for Date and Time Information

Dates are stored as a timestamp with the date and time information in the Alfabet database tables. If only date information is specified by selecting a date via the calendar button in an editor, For example, the time information will be set to 00:00:00:000 (hh:mm:ss:ms).

The output format of date and time information depends on the culture definition for the client and the property displayed. If the timestamp of a property is irrelevant to the user, it will not be displayed in the results even though it is stored in the database.

Three instruction can be configured to display a non-standard date and/or time format in a tabular report.

Whether date only, date and time, or time only are displayed in the result dataset is defined using the following instruction:

```
SetColumnDateSubType("ColumnName",DateType);
```

The date and time format used depends on the culture definition of the client.

Use the following parameter(s):

Code Parameter	Description
`ColumnName`	The name of the column for which the output format is specified. For information about the names of the columns resulting from Alfabet queries and native SQL queries, see Defining Column Names and Captions.
`DateType`	The following values can be set: • `Date`: Only the date is displayed with the date pattern defined in the culture settings for the client. • `Time`: Only the time information is displayed with the time pattern defined in the culture settings for the client. • `DateTime`: Date and time information are displayed with the date and time patterns defined in the culture settings for the client separated by a white space.

The output format of date/time information can be changed using the following instruction:

```
SetColumnFormat("ColumnName","DateFormat");
```

The format defined with the instruction is used independent from the culture settings for the client.

Use the following parameter(s):

Code Parameter	Description
`ColumnName`	The name of the column for which the output format is specified. For information about the names of the columns resulting from Alfabet queries and native SQL queries, see Defining Column Names and Captions.
`DateFormat`	The date format that shall be used to display the results in the specified column. Allowed values are listed in the section Changing the Output Format for Date and Time Information.

The output format can be changed to POSIX using the following instruction:

```
Convert2Posix("ColumnName",ConversionMethod);
```

Use the following parameter(s):

Code Parameter	Description
`ColumnName`	The name of the column for which the output format is specified. For information about the names of the columns resulting from Alfabet queries and native SQL queries, see Defining Column Names and Captions.
`ConversionMethod`	The method for conversion to POSIX. Allowed values are: • `UTC`: Posix is calculated based on UTC time. • `undefined`: The conversion standard is used. This parameter is optional. The default is `undefined`.

Permissible Date and Time Formats in Alfabet

Please note that the dates in editor fields are always displayed as a numeric value, regardless of the date format. For example, whereas the date format dddd, dd MMMM yyyy will be displayed as Tuesday, 22 August 2006 in the object profile, it will be displayed as 22/08/2006 in the editor field.

Please consider the following syntax for the specification of date and time formats.

- To specify the 24-hour clock system, use "H" or "HH" for hours.
- To specify the 12-hour clock system, use "h" or "hh". Users will need to specify AM or PM.
- To specify a time format, use "M" for month and "m" for minute.

The following formats can be specified:

Date/Time/Separator Syntax	Date/Time/Separator Output
MM/dd/yyyy	08/22/2006
dddd, dd MMMM yyyy	Tuesday, 22 August 2006
dddd, dd MMMM yyyy HH:mm	Tuesday, 22 August 2006 06:30
dddd, dd MMMM yyyy hh:mm tt	Tuesday, 22 August 2006 06:30 AM
dddd, dd MMMM yyyy H:mm	Tuesday, 22 August 2006 6:30
dddd, dd MMMM yyyy h:mm tt	Tuesday, 22 August 2006 6:30 AM
dddd, dd MMMM yyyy HH:mm:ss	Tuesday, 22 August 2006 06:30:07
MM/dd/yyyy HH:mm	08/22/2006 06:30
MM/dd/yyyy hh:mm tt	08/22/2006 06:30 AM
MM/dd/yyyy H:mm	08/22/2006 6:30
MM/dd/yyyy h:mm tt	08/22/2006 6:30 AM
MM/dd/yyyy h:mm tt	08/22/2006 6:30 AM
MM/dd/yyyy h:mm tt	08/22/2006 6:30 AM
MM/dd/yyyy HH:mm:ss	08/22/2006 06:30:07

Date/Time/Separator Syntax	Date/Time/Separator Output
MMMM dd	August 22
MMMM dd	August 22
yyyy'-'MM'-'dd'T'HH':'mm':'ss.fffffffK	2006-08-22T06:30:07.7199222-04:00
yyyy'-'MM'-'dd'T'HH':'mm':'ss.fffffffK	2006-08-22T06:30:07.7199222-04:00
ddd, dd MMM yyyy HH':'mm':'ss 'GMT'	Tue, 22 Aug 2006 06:30:07 GMT
ddd, dd MMM yyyy HH':'mm':'ss 'GMT'	Tue, 22 Aug 2006 06:30:07 GMT
yyyy'-'MM'-'dd'T'HH':'mm':'ss	2006-08-22T06:30:07
HH:mm	06:30
hh:mm tt	06:30 AM
H:mm	6:30
h:mm tt	6:30 AM
HH:mm:ss	06:30:07
yyyy'-'MM'-'dd HH':'mm':'ss'Z'	2006-08-22 06:30:07Z
dddd, dd MMMM yyyy HH:mm:ss	Tuesday, 22 August 2006 06:30:07
yyyy MMMM	2006 August
yyyy MMMM	2006 August

Replacing Values Returned in the Query with a Defined String

For object class properties of the **Data Type** `String` or `Text`, the values stored in the database can be replaced with defined strings in the result dataset of a query. Only the complete return value can be replaced with this instruction. Substrings in a text or string cannot be replaced.

The following instruction replaces values returned in a defined column of the result dataset of the query:

```
ReplaceValues("ColumnName","value1,...,valueN","replacementvalue1,...,replacementvalueN");
```

Use the following parameters:

Code Parameter	Description
`ColumnName`	The name of the column for which the output format is specified. For information about the names of the columns resulting from Alfabet queries and native SQL queries, see Defining Column Names and Captions.
`value1,...,valueN`	A comma separated list of values that shall be replaced. If a cell in the column returns one of the defined values, the value in the cell is replaced.
`replacementvalue1,...,replacementvalueN`	A comma separated list of values that shall be added to the dataset instead of the originally returned values. The position in the comma separated list must be identical to the position of the value to be replaced in the comma separated list of original values.

For example, a configured report returns the name and version of applications in a selected application group and information about the object state of the applications to inform about the availability of the applications for the user:

Application Name	Application Version	Application Object Stat
AF HR Online EU	2.2 Var.	Active
AF HR Online US	2.2 Var.	Active
AF WorkPortal	1.0	Plan
ALLFinance PISA	2.9	Retired
ARBI	1.2.1	Active

Instead of the object state value **Plan**, the string **For future use** shall be displayed.

Instead of the object state value **Active**, the string **Available** shall be displayed.

The object state value **Retired** shall be displayed unchanged.

The ReplaceValues instruction is added to the Alfabet query of the configured report. The instruction replaces the values for the object states **Plan** and **Active**.

```
ALFABET_QUERY_500

FIND Application

InnerJoin ApplicationGroup ON Application.ApplicationGroups =
ApplicationGroup.REFSTR

Instructions

   ReplaceValues("Application.ObjectState","Plan,Active","For future
   use,Available");

EndOfInstructions

QUERY_XML

<QueryDef>

   <ShowProperty Type="Property" ClassName="Application" Name="Name"
   />

   <ShowProperty Type="Property" ClassName="Application"
   Name="Version" />

   <ShowProperty Type="Property" ClassName="Application"
   Name="ObjectState" />

   <ShowProperty Type="Property" ClassName="Application"
   Name="Status" />

</QueryDef>
```

The resulting report displays the replaced values in the Application Object State column:

Application Name	Application Version	Application Object State
AF HR Online EU	2.2 Var.	Available
AF HR Online US	2.2 Var.	Available
AF WorkPortal	1.0	For future use
ALLFinance PISA	2.9	Retired
ARBI	1.2.1	Available

Adding the Value of a Server Variable to the Dataset

The instruction `ReplaceServerVariable` replaces the content of a specified column of the data set returned by a query with the value of a server variable. Server variables are defined in the server alias configuration in the tab **Variables** and provide a means to include environment specific data into configurations. If a specification is different in a test and production environment, the environment specific value can be defined in the server alias as required and the same, unchanged report can be used in all environments, returning different values. The `ReplaceServerVariable` instruction requires the specification of a column in the result dataset of the query and of a server variable defined as `$ ServerVariableName`.

For information about the specification of server variables, see Using Server Variables in Web Link and Database Server-Related Specifications .

The content of all cells in the result dataset is overwritten with the value of the server variable defined in the server alias of the Alfabet Web Application.

The following instruction adds a server variable value to a result dataset:

```
ReplaceServerVariable(ColumnName,ServerVariableName);
```

Use the following parameters:

Code Parameter	Description
`ColumnName`	The name of the column that shall return the server variable value. For information about the names of the columns resulting from Alfabet queries and native SQL queries, see Defining Column Names and Captions.
`ServerVariableName`	The name of the server variable defined in the server alias configuration of the Alfabet Web Application with the prefix `$`. For example, the server variable defined in the server alias as `ExternalHelpServer` must be defined as `$ExternalHelpServer`.

Limiting Toolbar Button Functionality To a Subset of Objects in a Configured Report

Usually, the functionality of buttons in the toolbar of configured reports is applied to the base object of the selected row in the report. The base object is either the `FIND` object in an Alfabet query or the object defined by its `REFSTR` as the first argument of the `SELECT` clause in a native SQL query. For example, when the user selects a row in a tabular report and clicks the **Navigate** button, the object profile of the base object of the report opens.

The buttons in the toolbar can be configured to work with a subset of the base objects only. For example, when the report is about objects for which object class stereotypes are defined, you can limit the button functionality to objects of a defined stereotype. Or, when the report displays objects with different object states, you may want a button to work only for objects with a defined state.

The instruction `SetRowCategory` allows a toolbar button functionality to be defined as dependent on property values. The instruction points to a column in the query results. The values in the column are the categories that specify the subset of objects a button functionality is applied to:

```
SetRowCategory("ColumnName");
```

Use the following parameter(s):

Code Parameter	Description
`ColumnName`	The name of the column that shall be used for the definition of the object categories. Each column value is a different category. For information about the names of the columns resulting from Alfabet queries and native SQL queries, see Defining Column Names and Captions.

For example, a configured report displays applications with different object states:

Application Name	Application Version	Application Object State
Xetra	0.10	Retired
ACCOUNT	1	Active
Brokertec	1	Active
CAPRICE	1	Active
CashLine Web - Germany	1	Active
Cognotec	1	Active
Configuration	1	Plan
Course	1	Active

The configured report is based on the following Alfabet query:

```
ALFABET_QUERY_500

FIND Application

Instructions

   SetRowCategories("Application.ObjectState");

EndOfInstructions

QUERY_XML

<QueryDef>

   <ShowProperty Type="Property" ClassName="Application" Name="Name"
   />

   <ShowProperty Type="Property" ClassName="Application"
   Name="Version" />

   <ShowProperty Type="Property" ClassName="Application"
   Name="ObjectState" />

</QueryDef>
```

The user shall only be able to navigate to applications that are in the state `Active`. The `SetRowCategory` instruction added to the report Therefore, defines the column `Application.ObjectState` as relevant for the definition of categories. The resulting categories are all object states that can be defined for an application:

- `Plan`
- `Active`
- `Retired`

In the example above, you could limit the button functionality to objects with the object state `Plan` by setting the **Apply to Category** attribute of the button to "`Plan`". Or, you could limit the button functionality to objects with the object state `Plan` or `Active` by setting the **Apply to Category** attribute to "`Plan,Active`".

After object categories have been defined for a configured report via the `SetRowCategory` instruction, the button of the toolbar must be configured to be active for either one or multiple of the defined categories. This is done by defining the category in the button's attribute **Apply to Category**. The button can be defined to be active for objects that match multiple categories by defining a comma-separated category list.

The configuration of the button is exclusively performed by Software AG Support. If you want a button to be applied to objects of defined categories, you must define the categories in the underlying query of the report and provide Software AG Support with the information about which values shall be entered in the **Apply to Category** attribute of the button. Please note that Software AG Support must be informed about the required value of the attribute and which button shall be configured.

Note the following when defining categories:

- You can add multiple `SetRowCategory` instructions to a query. All values of all columns defined in a `SetRowCategory` instruction can be used as category. For example, you can define that the activity of a button depends on both the stereotype and the object state of an object.
- When multiple categories are listed in the **Apply to Category** attribute of a button, the button is active when at least one of the categories applies. For example, when both object class stereotype and object state of an object are defined as categories and the **Apply to Category** attribute of the button is set to "`Area,Active`", the button is active for all objects with either the stereotype `Area` or the object state `Active` or objects for that both conditions apply.
- To define that a button is active when an object applies to two categories, you must join the columns that contain the information about the two conditions into one column using the `JoinColumns` instruction and define the resulting combined column as category definition column.
- If a table is grouped via a `GroupBy_Ex` instruction, the category definition can be applied to all levels of the grouped dataset. The `GroupBy_Ex` instruction must be defined first. The columns returning the category for the different levels must then be joined into a single column with a `JoinColumns` instruction. The `SetRowCategories` instruction must be defined after the `GroupBy_Ex` and `JoinColumns` instructions.

Changing the Navigation Behavior of the Base Object Class in a Configured Report

Typically, the user will navigate to the object view of the base object class of the configured report when double-clicking an object in a row. It is also possible to configured a query so that the user can navigate to the object view of an object class that is not the base object.

The base object of a query is by default the `FIND` object of the Alfabet query or the object for which the `REFSTR` is defined as the first argument in the `SELECT` clause of the native SQL query. The navigate functionality of configured reports refers per default to the base object. This is independent of the information displayed in the tabular output of the report. Therefore, it is possible that a user might even be directed to an object class that is not visible in the report results.

You can use the SetRowReference instruction to define that the object defined in another row of the report is used as base object:

```
SetRowReference("ColumnName");
```

Use the following parameter(s):

Code Parameter	Description
ColumnName	The name of the column that shall be used as base object definition. The column value must be the REFSTR of the object. For information about the names of the columns resulting from Alfabet queries and native SQL queries, see Defining Column Names and Captions.

The SetRowReference instruction requires that the selected column returns the REFSTR of the objects from the object class that has been selected as new base class. Usually, the REFSTR of the objects should not be displayed in the configured report because it is useless information for the user. You can hide the column in the report output by using the RemoveColumns instruction described in the section Hiding a Column in a Configured Report.

For example, a configured report shall display all architecture elements assigned to projects and the user that is the authorized user responsible for the architecture element. There is one row in the report for each architecture element. A project can include objects from different object classes as architecture elements. The report is based on the following Alfabet query:

```
ALFABET_QUERY_500

FIND

ProjectArch

InnerJoin Project ON ProjectArch.Project = Project.REFSTR

LeftJoin Application ON Project

tArch.Object = Application.REFSTR

LeftJoin ICTObject ON ProjectArch.Object = ICTObject.REFSTR

LeftJoin Domain ON ProjectArch.Object = Domain.REFSTR

LeftJoin OrgaUnit ON ProjectArch.Object = OrgaUnit.REFSTR

LeftJoin BusinessProcess ON ProjectArch.Object =
BusinessProcess.REFSTR

LeftJoin BusinessFunction ON ProjectArch.Object =
BusinessFunction.REFSTR

LeftJoin Person ON (Or Person.REFSTR = Application.ResponsibleUser
Person.REFSTR = BusinessFunction.ResponsibleUser Person.REFSTR =
Domain.ResponsibleUser Person.REFSTR = BusinessProcess.ResponsibleUser
Person.REFSTR = ICTObject.ResponsibleUser Person.REFSTR =
OrgaUnit.ResponsibleUser)

Instructions

JoinColumns("Application.Name,Application.Version","Application.Name",
" v. ");
```

```
JoinColumns("Application.Name,ICTObject.Name,BusinessProcess.Name,Doma
in.Name,OrgaUnit.Name,BusinessFunction.Name","Domain.Name", "");

EndOfInstructions

QUERY_XML

<QueryDef>

<ShowProperty Type="Property" ClassName="Project" Name="Name" />

<ShowProperty Type="Property" ClassName="Application" Name="Name" />

<ShowProperty Type="Property" ClassName="Application" Name="Version"
/>

<ShowProperty Type="Property" ClassName="ICTObject" Name="Name" />

<ShowProperty Type="Property" ClassName="Domain" Name="Name" />

<ShowProperty Type="Property" ClassName="OrgaUnit" Name="Name" />

<ShowProperty Type="Property" ClassName="BusinessProcess" Name="Name"
/>

<ShowProperty Type="Property" ClassName="BusinessFunction" Name="Name"
/>

<ShowProperty Type="Property" ClassName="Person" Name="Name" />

<SortProperty Type="Property" ClassName="Project" Name="Name" />

<SortProperty Type="Property" ClassName="Person" Name="Name" />

</QueryDef>
```

The resulting report has a deactivated **Navigate** button, because the `FIND` class of the Alfabet query is the class `ProjectArch` that does not have an object view. Additionally, the `ProjectArch` object class is a pure representation of the link between the project and an architecture element. The user clicking the **Navigate** button should be directed to either the project or the architecture element.

	Project Name	Architecture Element	Person Name
1	Best in Breed Solution	PS Global v. 2.5	Administrator
2	Best in Breed Solution	Balance Analysis DB v. 1.2.2	Administrator
3	Best in Breed Solution	SAS Enterprise Guide v. 1.0	Administrator
4	Best in Breed Solution	OR Marketing Solution	Administrator
5	Best in Breed Solution	CRM AI	Administrator
6	Best in Breed Solution	CRM	Alfabet
7	Best in Breed Solution	CRM Opti Retail	Alfabet
8	Best in Breed Solution	OR Strategy, Marketing & Sales	Alfabet
9	Best in Breed Solution	SAP PLM v. 2.0	Alfabet
10	Best in Breed Solution	eLead v. 2.0	Alfabet
11	Best in Breed Solution	Corporate FI-CO v. 2.2	Customer

In the following example, the query is changed to allow navigation to the architecture element. There are architecture elements from 6 different object classes displayed in the `Architecture Element` column of the report. To navigate to the objects of either of these classes, a new column returning the `REFSTR` of the object class must be added to the Alfabet query for each of the joined object classes. The columns are then joined into one column using a `JoinColumns` instruction and

this column is used in the `SetRowReference` instruction to select the object as the base object of the result row. The column is then hidden from the configured report using a `RemoveColumns` instruction because the `REFSTR` of the objects is not relevant for the user viewing the report.

```
ALFABET_QUERY_500

FIND

ProjectArch

InnerJoin Project ON ProjectArch.Project = Project.REFSTR

LeftJoin Application ON Project

tArch.Object = Application.REFSTR

Providing a Link to Alfabet Views, Editors or Wizards from Cells in a Report

In a configured report displaying a table, cells in the data set can be configured to open either a page view, an object view or object cockpit, an editor, or a wizard when a user clicks the cell in the table. The text in a cell that opens the view, editor or wizard is formatted as a link and a tooltip can optionally be defined that is displayed to a user moving the mouse over the link.

The view, editor or wizard opens for the base object of the current row of the table. By default, this is the `FIND` class of an Alfabet query or the object found via the `REFSTR` defined as first argument of the `SELECT` statement of a native SQL query, but the base class can be changed for a table via a `SetRowReference` instruction.

There is no mechanism that controls whether the editor or wizard that is defined for the link in the cell is valid for the base object class of the configured report. If you define an editor or wizard for the wrong object class, you may cause damage to the storage of object data.

If the link target is an editor or wizard, the editor or wizard will open in a modal window. you can optionally configure the link to open a defined tab of the editor or a defined step of the wizard. Editors can only be opened with any other than the first tab opened if they are not embedded in a wizard. If you want a specific tab of the editor to open when opening an editor embedded in a wizard, you must configure the wizard to open the editor with that specific tab.

If the link target is an Alfabet view, the user will be redirected to the new view. The behavior is the same as for all navigation operations in Alfabet. Optionally filters can be defined for opening the view.

A link can either be defined statically to open the same view, wizard, or editor for all results or dynamically, opening a different type of view, editor or wizard for each row of the result dataset.

- Opening the Same Page View, Object Profile, Object Cockpit, or Configured Report for all Search Results
- Opening the Same Wizard or Editor for all Search Results

- Opening Diffent Views, Wizards, or Editors for Search Results

Opening the Same Page View, Object Profile, Object Cockpit, or Configured Report for all Search Results

Double-clicking on a cell in a configured report opens the object profile of the base object of the current row. In addition to this basic navigation, additional navigation can be configured for tabular reports by using the `LinkAssignment` instruction. A link can be assigned to the content of the cells in a defined column of the report. The link target can be an object profile, an object cockpit, a configured report or a standard Alfabet page view. The linked view opens either for the object that is the base object of the current row in the report containing the link or for an object defined via a `REFSTR` value in another column of the report. If the link target is a configured report, this object is the base object of the report referred to with the parameter `BASE`. The `LinkAssignment` instruction can contain definitions to populate values for other parameters defined for the configured report opened by the link.

The link is defined using the following instruction:

```
LinkAssignment("LinkColumnName",ViewType:ViewName:ViewDetail,"BaseObjectColumnName","ParameterColumnNames");
```

Use the following parameter(s):

Code Parameter	Description
`LinkColumnName`	The name of the column that shall contain the link. The content of the cell defined via the query of the report is displayed as link text. For information about the names of the columns resulting from Alfabet queries and native SQL queries, see Defining Column Names and Captions. Alternatively, the position of the column in the index of columns can be used to specify the column. For more information see Referencing Columns in Instructions by Index Number.
`ViewType`	The kind of view that opens when the user clicks the link. Allowed values are: • `ObjectView` to open an object profile or object cockpit. • `GraphicView` to open a standard page view. • `Report` to open a configured report.
`ViewName`	The name of the view that shall open. The name is the value for the **Name** attribute of the view. For object profiles and object views, the name of the object view configuration element that contains the object profile or object cockpit configuration must be defined.
`ViewDetail`	This parameter is only relevant for opening an object cockpit and defines the name of the object cockpit that shall open. If the `ViewType` is `ObjectView` and the

Code Parameter	Description
	`ViewDetail` parameter is not defined, the object profile configured for the object view is the target of the link.
`BaseObjectColumnName`	This parameter defines the object for that the link target view is opened for. Allowed values are: • The name of the column that contains the value of the `REFSTR` property of the object that shall be the base object for that the link target opens. Alternatively, the position of the column in the index of columns can be used to specify the column. For more information see Referencing Columns in Instructions by Index Number. • `ROW`: If the parameter is set to "`ROW`", the base object found for the row in the report containing the link is used as base object for the link target. If the link target is a configured report, the object can be referenced in the query of the report with the parameter `@BASE`.
`ParameterColumnNames`	This parameter is only relevant if the link target is a configured report. It defines the column names of the columns each containing the values for an Alfabet parameter used in the query of the configured report that opens. The name of the column must be identical to the name of the parameter without the prefix @ . Alternatively, the position of the column in the index of columns can be used to specify the column. For more information see Referencing Columns in Instructions by Index Number.

If the link target is a configured report, the query defined for the report can use Alfabet parameters that are substituted with values from the report containing the `LinkAssignment` instruction during runtime. Next to the parameters defined via the instruction, the name of the column containing the link can be used as parameter value.

The parameters in the link target report must be defined as `@<ParameterName>`. The alternative syntax:`ParameterName` cannot be targeted by a `LinkAssignment` instruction.

Please note that the Alfabet Query Builder creates parameters starting with a colon. This has to be changed manually using the attribute " **Query As Text** " of the configured report.

The following table lists the Alfabet parameters that can be used in the configured reports and the values from the report containing the `LinkAssignment` instruction that they represent:

Parameter of the query in the target report	Value from the report containing the link
`@BASE`	The REFSTR value of the object that the link target view is opened for. In the `LinkAssignment` instruction, the specification of the `BaseObjectColumnName` defines whether this is the base object of the row of the report containing the link or a REFSTR value read from a defined cell of the row.
`@COLUMN`	The name of the column containing the link. This column is defined with the `LinkColumnName` definition in the `LinkAssignment` instruction. Instead of the column name, the position of the column in the index of columns can be used to specify the column. (For more information see Referencing Columns in Instructions by Index Number.) In this case, the `@COLUMN` is still substituted with the name, and not the index position of the column containing the link. The definition of the column by index position also allows to define a range of columns for that the instruction will be processed. In that case, the value substituting the parameter `@COLUMN` is the name of the column containing the link that the user clicked on. An example is given below.
`@<Parameter-Name>`	The `LinkAssignment` instruction can contain a `ParameterColumnNames` definition, that specifies the names of one or multiple columns of the report containing the link. The values in this columns are substituting the parameters that are defined as the column name.

The following example shows a configured report that opens a configured report via a link defined with a `LinkAssignment` instruction. The main report shows application groups and the number of applications in the group that are in the object state Active, Plan, or Retired. The number of applications is calculated via a `COUNT` command. The column displaying the number of applications contains a link that opens a configured report displaying all applications in the application group in the respective object state:

	Application Group Name	Application Object State	Number of Applications
1	1. Market Data	Active	12
2	1. Market Data	Plan	4
3	2. Trade Entry	Active	6
4	3. Front Office	Active	9
5	3. Front Office	Plan	4
6	3. Front Office	Retired	1
7	4. Back Office	Active	13

The report is based on the following Alfabet query:

```
ALFABET_QUERY_500

FIND ApplicationGroup
```

```
InnerJoin Application ON Application.ApplicationGroups =
ApplicationGroup.REFSTR

Instructions

   RenameColumn("Application.ObjectState","OState");

   LinkAssignment("Application.REFSTR",
   "Report:LinkAssignmentTarget", ROW," OState ");

EndOfInstructions

QUERY_XML

<QueryDef>

   <ShowProperty Type="Property" ClassName="ApplicationGroup"
   Name="Name" />

   <ShowProperty Type="Property" ClassName="Application"
   Name="ObjectState" />

   <ShowProperty Type="Property" ClassName="Application"
   Name="REFSTR" Function="COUNT" />

   <SortProperty Type="Property" ClassName="ApplicationGroup"
   Name="Name" />

   <SortProperty Type="Property" ClassName="Application"
   Name="ObjectState" />

</QueryDef>
```

In the `LinkAssignment` instruction, the configured report `LinkAssignmentTarget` is defined as target of the link. The configured report `LinkAssignmentTarget` shows all applications in the respective application group and with the respective object state. It is based on the following Alfabet query:

```
ALFABET_QUERY_500

FIND Application

WHERE

   (AND

      Application.ApplicationGroups CONTAINS@BASE

      Application.ObjectState =@OState

   )

QUERY_XML

<QueryDef>

   <ShowProperty Type="Property" ClassName="Application" Name="Name"
   />

   <ShowProperty Type="Property" ClassName="Application"
   Name="Version" />

   <ShowProperty Type="Property" ClassName="Application"
   Name="CommitedRecoveryPoint" />

   <ShowProperty Type="Property" ClassName="Application"
   Name="CommitedRecoveryTime" />

</QueryDef>
```

The query contains two parameters that are populated with values from the configured report containing the `LinkAssignment` instruction: `@BASE` and `@OState`.

The `@BASE` refers to the `REFSTR` property of the base object of the row containing the link opening the report. In the `LinkAssignment` instruction, this is defined with the specification of the `BaseObjectColumnName` as `ROW`.

The `@OState` refers to the value of the column named `OState` for the row containing the link opening the report. In the `LinkAssignment` instruction, this is defined with the specification of `ParameterColumnNames` as `OState`.

The following report is a dynamically generated report that is based on a stored procedure. The columns of the report are dynamically generated. For each application of a selected application group a column is added to the report. The column name is identical to the name and version of the application. As a result, the overall number of columns and the names of the individual columns differ for each application group for that the report is opened. The rows of the report show costs for different cost types together with an indicator that evaluates whether the costs are critical.

Select Application Group

6. Risk Reporting

Year*

2014 Submit

Export

7 object(s) has (have) been found.

	Cost Type	ARBI 1.2.1	Credient 2.2.1 SP4	CRES 9.0.0
1	Software Subscriptions	55.00	60.00	45.00
2	Other Operational Costs	35.00	33.00	27.00
3	Hardware Replacement Costs			
4	Other Deployment Costs			
5	Internal Maintenance Costs	303.00	263.00	239.00
6	External Maintenance Costs	82.00	70.00	69.00
7	TOTAL	475.00	426.00	380.00

The report contains links in all cells of the dynamically generated columns. The `LinkAssignment` instruction added to the report refers to the column containing the link as a range of index numbers starting with the second column of the report, which is the first column that is created dynamically and including all columns until the last one:

```
LinkAssignment(#2:end, Report:Demands4SelectedApplication, ROW);
```

The target report for the links is a report that shows all demands that are pending for the selected application. The application name and version are given in the name of the column containing the link. Therefore, the Alfabet parameter `@COLUNMN` is used in the native SQL query of the report that opens when a user clicks the link:

```
SELECT dem.REFSTR, dem.ID, dem.NAME, dem.STATUS, dem.TARGETDATE,
dem.DESCRIPTION
```

```
FROM DEMAND dem, DEMAND_ARCH dema, APPLICATION app
WHERE dema.DEMAND=dem.REFSTR
AND dema.OBJECT=app.REFSTR
AND (app.NAME+' '+app.VERSION) LIKE @COLUMN
```

Opening the Same Wizard or Editor for all Search Results

Use the following instruction to set a link to an editor or wizard statically defined in the instruction definition:

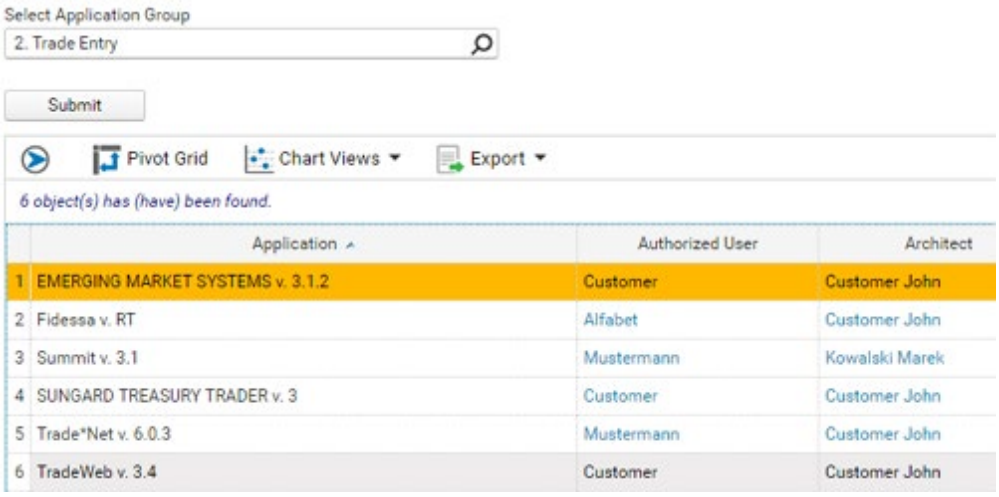
```
LinkAssignment_Edit("LinkColumnName",EditViewType:EditViewName,
"Step:WizardStepName","Page:EditorTabPosition", "TooltipText");
```

Use the following parameters:

Code Parameter	Description
`LinkColumnName`	The name of the column that shall contain the link. The content of the cell defined via the query of the report is displayed as link text. For information about the names of the columns resulting from Alfabet queries and native SQL queries, see Defining Column Names and Captions. Alternatively, the position of the column in the index of columns can be used to specify the column. For more information see Referencing Columns in Instructions by Index Number.
`EditViewType`	The kind of edit view that opens when the user clicks the link. Allowed values are: • `Editor` to open an editor. • `Wizard` to open a wizard.
`ViewName`	The name of the edit view that shall open. The name is the value for the **Name** attribute of the standard editor or wizard. For custom editors, the name of the standard editor of the object class that the custom editor is defined for must be specified. Custom editors are additional tabs amended to standard editors. They can be opened by defining a landing tab for opening the editor with the `EditorTabPosition` parameter.
`WizardStepName`	This parameter is only relevant for opening a wizard and defines the name of the wizard step at which the wizard shall open. When the `EditViewType` is `Editor`, an empty definition must be added to the instruction to maintain the order of parameters. An empty parameter can be defined by adding two commas between `EditViewType:EditViewName` and `Page:EditorTabPosition`.

Code Parameter	Description
`EditorTabPosition`	This parameter is only relevant for opening an editor and defines the position of the tab in the tab order of the editor at which the editor shall open. When the `EditViewType` is `Wizard` and a tooltip text shall be defined, an empty definition must be added to the instruction to maintain the order of parameters. An empty parameter can be defined by adding two commas between `Step:WizardStepName` and `TooltipText`.
`TooltipText`	A string that shall be displayed when the user moves the mouse over the link text. This parameter is optional.

For example, a configured report shall be created for checking and redefining application responsibilities. The report displays all applications in an application group and informs about the current authorized user setting and the assignment of the role 'Architect' for the application:



The configured report is based on an Alfabet query and the `FIND` class is `Application`:

```
ALFABET_QUERY_500

FIND Application

InnerJoin Person ON Application.ResponsibleUser = Person.REFSTR

WHERE Application.ApplicationGroups CONTAINS:BASE

Instructions

   JoinColumns("Application.Name,Application.Version","Application.N
   ame", " v. ");

EndOfInstructions

QUERY_XML

<QueryDef>
```

```
        <ShowProperty Type="Property" ClassName="Application" Name="Name"
        ShowName="Application" />

        <ShowProperty Type="Property" ClassName="Application"
        Name="Version" />

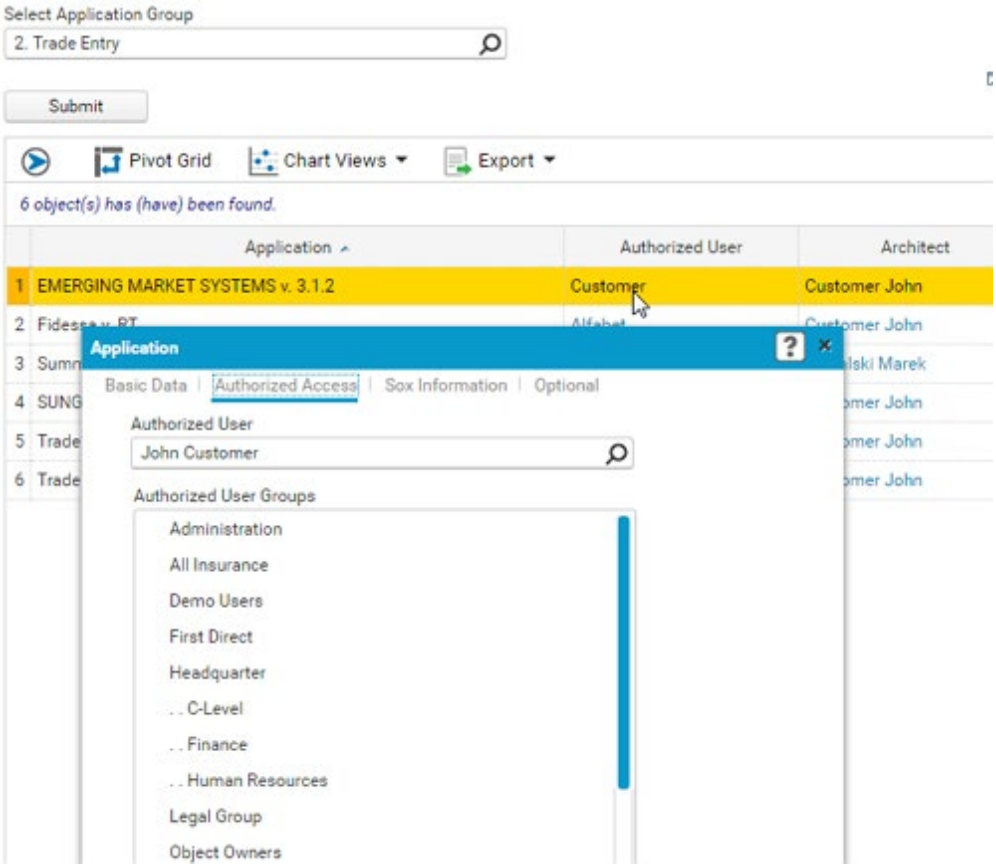
        <ShowProperty Type="Property" ClassName="Person" Name="Name"
        ShowName="Authorized User" />

        <ShowProperty Type="RoleType" ClassName="Application"
        Name="Architect" ShowName="Architect"
        ImageProps1="Name,FirstName" ImageProps2="Name" />

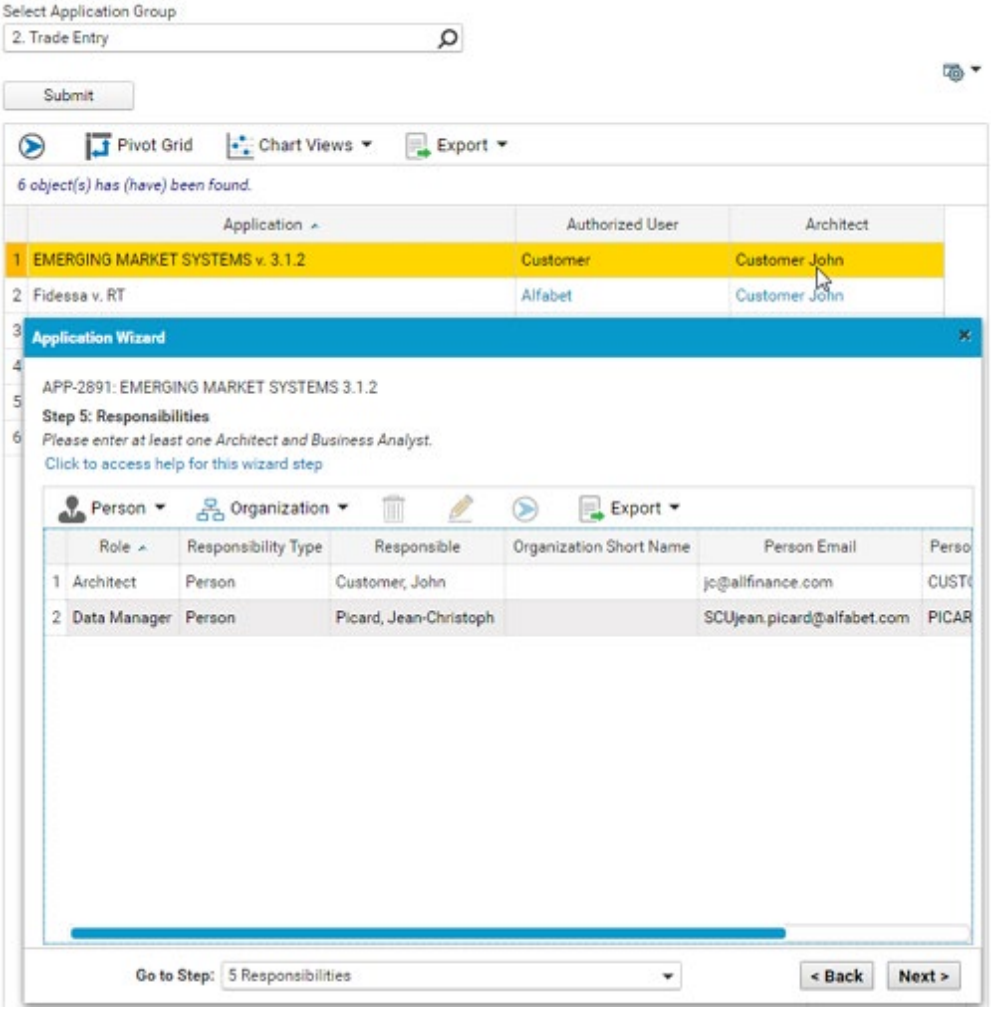
    </QueryDef>
```

Therefore, all editor or wizard links must be configured to open an editor or wizard for the class Application.

The user shall be able to open the standard editor for applications at the tab **Authorized Access**, which is the second tab of the editor, from all cells of the column **Authorized User**:



The user shall be able to open a customer configured wizard for the class Application at step 5, which displays the standard **Responsibilities** page view:



To open the editors, the following two `LinkAssignment_Edit` instructions are added to the query:

```
ALFABET_QUERY_500

FIND Application

InnerJoin Person ON Application.ResponsibleUser = Person.REFSTR

WHERE Application.ApplicationGroups CONTAINS:BASE

Instructions

    JoinColumns("Application.Name,Application.Version","Application.N
    ame", " v. ");

    LinkAssignment_Edit("Person.Name", Editor:APP_Editor,Page:2,
    "Change Responsible User");

    LinkAssignment_Edit(Application.Architect, Wizard:APP_Wizard,
    "Step:View_Responsibilities", "Change Architect");

EndOfInstructions

QUERY_XML

<QueryDef>

    <ShowProperty Type="Property" ClassName="Application" Name="Name"
    ShowName="Application" />
```

```
    <ShowProperty Type="Property" ClassName="Application"
    Name="Version" />

    <ShowProperty Type="Property" ClassName="Person" Name="Name"
    ShowName="Authorized User" />

    <ShowProperty Type="RoleType" ClassName="Application"
    Name="Architect" ShowName="Architect"
    ImageProps1="Name,FirstName" ImageProps2="Name" />

</QueryDef>
```

Opening Diffent Views, Wizards, or Editors for Search Results

Use the following instruction set a link to views, editors or wizards dynamically defined via the query of the report:

```
DynamicLinkAssignment("LinkColumnName",ViewColumnName,NavigationDetailsColum
nName,EditorTabPositionColumnName,TooltipTextColumnName);

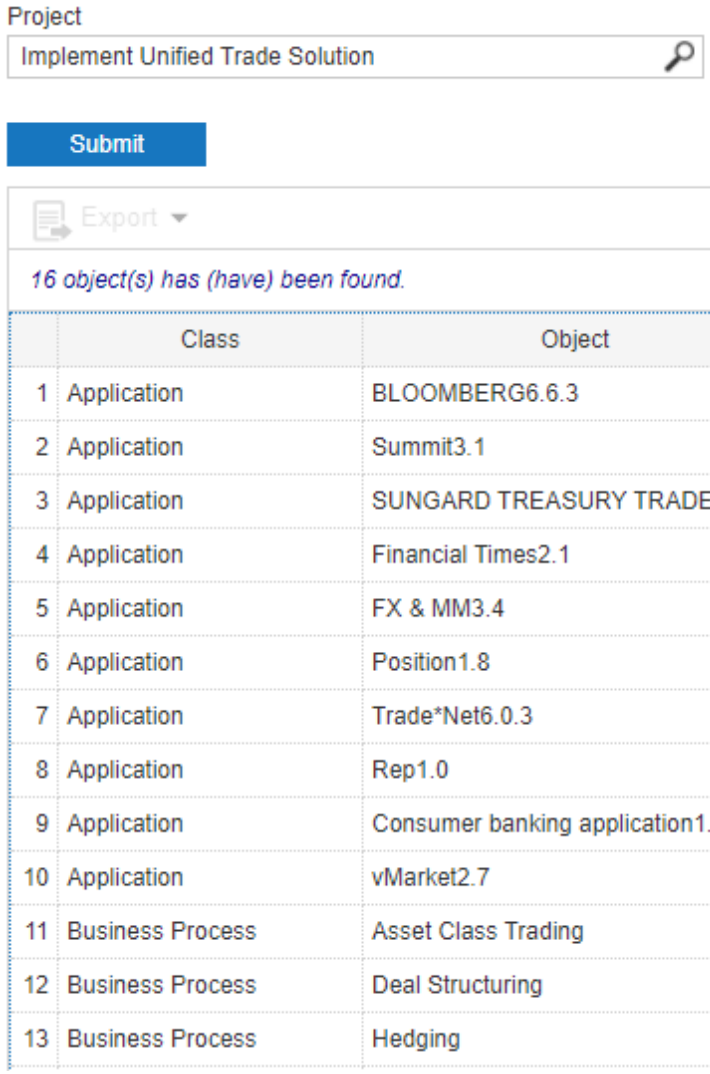
DynamicLinkAssignment(aLinkCol,
Editor|Wizard|GraphicView|Report|ObjectView:Name Col, [Step
Col(Editor/Wizard)]|["Col1,...,ColN"(GraphicView/Report)], [Page Number
Col(Editor/Wizard)], [Cell Tooltip Text Col]);
```

Use the following parameters:

Code Parameter	Description
`LinkColumnName`	The name of the column that shall contain the link. The content of the cell defined via the query of the report is displayed as link text. For information about the names of the columns resulting from Alfabet queries and native SQL queries, see Defining Column Names and Captions. Alternatively, the position of the column in the index of columns can be used to specify the column. For more information see Referencing Columns in Instructions by Index Number.
`ViewColumnName`	The name of the column in the report dataset that returns the view, wizard or editor that opens when the user clicks the link. The query must return the type of view and the name of the view separated by a colon, like For example,: `Editor:APP_Editor` Allowed view types are • `Editor` to open an editor. The view name is the value of the **Name** attribute of a standard editor. To open a custom editor, the name of the standard editor of the object class that the custom editor is defined for must be specified. Custom editors are additional tabs amended to standard editors. They can be opened by defining

Code Parameter	Description
	a landing tab for opening the editor with the `NavigationDetailsColumnName` parameter. • `Wizard` to open a wizard. The view name is the value of the **Name** attribute of a wizard. • `GraphicView` to open a page view. The view name is the value of the **Name** attribute of a standard page view. • `Report` to open a configured report. The view name is the value of the **Name** attribute of a configured report. • `ObjectView` to open an object profile or object cockpit. The definition of the view name is not required, but the colon is required as part of the definition. The object view or object cockpit defined to open for the object class via the configuration of the user profile opens.
`NavigationDetailsColumnName`	The name of the column in the report dataset that returns details for opening the view. Details are optional and only applicable for the following: • For opening a wizard you can define the wizard step at which the wizard shall open. The column must return the string `Step:` followed by the the value of the **Name** attribute of the wizard step. • For opening an editor you can define the position of the editor tab in the tab order of the editor at which the editor shall open. The column must return the string `Page:` followed by the the tab number. The first tab in the editor has the number 1. • For opening a page view or configured report with filters, you can set filter values on opening of the link target. The filter value must be returned in a column with a name identical to the filter parameter without the starting character @. Multiple columns with filter values can be defined in a comma-separated list.
`EditorTabPositionColumnName`	If a wizard shall open at a wizard step that is an editor with multiple tabs, you can define the editor tab that shall open in the query. The column must return the string `Page:` followed by the the tab number. The first tab in the editor has the number 1. This parameter must be set to the name of the column in the report dataset returning the information.
`TooltipTextColumnName`	The name of the column in the report dataset that returns a string that shall be displayed when the user moves the mouse over the link text. This parameter is optional.

For example, a configured report shall be created for redefining the authorized user for both applications and business processes relevant for a project. The report displays all applications and business processes of a selected project defined as base object of the report and informs about the current authorized user setting:



Project

Implement Unified Trade Solution

Submit

Export

16 object(s) has (have) been found.

	Class	Object	Authorized User
1	Application	BLOOMBERG6.6.3	PICARD
2	Application	Summit3.1	MUSTERMANN
3	Application	SUNGARD TREASURY TRADER3	CUSTOMER
4	Application	Financial Times2.1	PICARD
5	Application	FX & MM3.4	LEE
6	Application	Position1.8	LEE
7	Application	Trade*Net6.0.3	MUSTERMANN
8	Application	Rep1.0	GOSSARAH
9	Application	Consumer banking application1.2	CLIENTE
10	Application	vMarket2.7	KOWALSKI
11	Business Process	Asset Class Trading	NGOMBE
12	Business Process	Deal Structuring	NGOMBE
13	Business Process	Hedging	NGOMBE

To change the authorized user, a link from the Authorized User column shall open a wizard for the definition of applications on step one, opening the application editor, and the editor for the definition of business processes on tab two, which is the tab for the definition of the authorized user.

The configured report is based on the following native SQL query containing an instruction for dynamic link assignment that activates the link for both applications and business processes:

```
SELECT app.REFSTR, 'Application' As 'Class', app.NAME + app.VERSION
AS 'Object', per.USER_NAME AS 'Authorized User', 'Wizard:APP_Wizard'
As 'EditView', 'Step:Editor' As 'WizardStep', '' As 'EditorPage',
'Open Application Editor' AS 'EditTooltip'

FROM APPLICATION app

INNER JOIN PROJECT_ARCH projarch ON projarch.OBJECT = app.REFSTR

INNER JOIN PROJECT proj ON projarch.PROJECT = proj.REFSTR

INNER JOIN PERSON per on per.REFSTR = app.RESPONSIBLEUSER
```

```
WHERE proj.REFSTR = @BASE

UNION ALL

SELECT bp.REFSTR, 'Business Process' As 'Class', bp.NAME AS
'Object', per.USER_NAME AS 'Authorized User', 'Editor:PROC_Editor'
As 'EditView', NULL AS 'WizardStep', 'Page:2' AS 'EditorPage', 'Open
Business Process Editor' As 'EditTooltip'

FROM BUSINESSPROCESS bp

INNER JOIN PROJECT_ARCH projarch ON projarch.OBJECT = bp.REFSTR

INNER JOIN PROJECT proj ON projarch.PROJECT = proj.REFSTR

INNER JOIN PERSON per on per.REFSTR = bp.RESPONSIBLEUSER

WHERE proj.REFSTR = @BASE

/* Alfabet Instructions */

DynamicLinkAssignment_Edit("Authorized User",
EditView,WizardStep,EditorPage,EditTooltip);

RemoveColumns("EditView,WizardStep,EditorPage,EditTooltip");
```

Enabling a Stereotype-Specific Search in Custom Selectors

Custom selectors allows objects in an object class that are defined in the `ClassEntry` element in the custom selector definition to be searched. Objects of other classes cannot be selected but are nevertheless displayed in, For example, a **Browse** search to structure the objects in the explorer.

When object class stereotypes are defined for an object class, custom selectors can be defined to limit the search to only objects of a defined object class stereotype. For example, for views implementing a **Browse** functionality, the hierarchy can display a hierarchy of domains of different stereotypes per hierarchy level, but only domains of the object class stereotype specified in the class entry definition can be selected by the user.

When the `ClassEntry` element in the custom selector defines an object class stereotype, all queries defined for the pages of the class entry must include a stereotype definition as described below:

- The stereotype of the object class must be added to the Show properties of Alfabet queries or the `SELECT` statement of native SQL queries. That means that the dataset resulting from the query contains a column that lists the stereotype of the objects in the dataset. The column must be available for technical reasons to allow the software to control whether an object is selectable. The `RemoveColumns` instruction can be used to hide the column from display in the explorer.
- The instruction `SetRowsStereotypeIndex` must be included in the query to identify the column containing the stereotype information in the dataset for the process that checks whether an object is selectable in the explorer.

The column in the dataset listing the stereotype of the objects is defined using the following instruction:

```
SetRowsStereotypeIndex("ColumnName");
```

Use the following parameter(s):

Code Parameter	Description
`ColumnName`	The name of the column listing the stereotypes. For information about the names of the columns resulting from Alfabet queries and native SQL queries, see Defining Column Names and Captions.

Configuring Cells in a Data Table Report to Provide Navigation to an Object Profile

Data table reports are based on a large dataset that the user can build own reports from according to his/her current demand. The resulting reports are highly individual and it is Therefore, difficult to determine a base object per row. Navigation can Therefore, not be based on the same mechanisms as in other tabular reports.

Instead, drill down from this report to the object profile of the current object is provided per cell. Drill-down is not provided for all cells of the report but only for cells that contain information about the `REFSTR` of an object. While the `REFSTR` is required as technical information for the engine to provide the navigation, it is not suitable for the user to identify the object. The `CreateREfImage` instruction allows rows containing any string, For example, information about object name and version, to be merged with the row containing the technically required `REFSTR` information. The resulting column displays the string information about the object and at the same time provides navigation in data table reports because it contains the `REFSTR` in the background. The resulting column is the column that originally contained the `REFSTR`. The columns containing the string information will be removed from the visible dataset.

To define columns providing drill-down to object profiles from data table reports, the dataset must contain a column that returns the `REFSTR` and one or multiple other columns returning the property values that shall be displayed in the navigable cell. The columns can then be merged with the following instruction:

```
CreateRefImage("StringColumn1,StringColumn2","RefColumn","Delimiter")
```

Use the following parameters:

Code Parameter	Description
`StringColumn1,StringColumn2`	The name of the column containing the information that shall be visible to the user in the result dataset. Multiple columns can be defined in a comma separated list. For information about the names of the columns resulting from Alfabet queries and native SQL queries, see Defining Column Names and Captions.
`RefColumn`	The name of the column containing the `REFSTR` of the objects for that drill down to the object profile shall be enabled. This column is the column that will be visible and selectable in the data table report.

Code Parameter	Description
`Delimiter`	If multiple string columns have been defined with the first parameter, you can optionally define a delimiter string to be displayed between the values from the string columns.

The data table report shall contain a column that provides navigation to the object class Application and displays the name and version of the appplication separated by the string " v. ".

First, a dataset is created that contains a column returning the REFSTR, one returning the name and one returning the version of the application:

Application REFSTR	Application Name	Application Version	Applic
76-2518-0	Business EAI Platform	2.2	14/11/
76-2525-0	Groupware Services	2.2	12/02/
76-2538-0	Mafo-Portal	2.6	25/08/
76-2566-0	PS Global	2.5	24/03/

The `CreateRefImage` instruction is added to the Alfabet query, merging the columns for the application's name and version into the column for the application's REFSTR with the delimiter " v. ".

```
ALFABET_QUERY_500

FIND Application

Instructions

   CreateRefImage("Application.Name,Application.Version","Applicatio
   n.REFSTR", " v. ");

EndOfInstructions

QUERY_XML

<QueryDef>

   <ShowProperty Type="Property" ClassName="Application"
   Name="REFSTR" />

   <ShowProperty Type="Property" ClassName="Application" Name="Name"
   />

   <ShowProperty Type="Property" ClassName="Application"
   Name="Version" />

   <ShowProperty Type="Property" ClassName="Application"
   Name="StartDate" />

</QueryDef>
```

The resulting dataset no longer displays three columns for REFSTR, name and version, but the column for the REFSTR only, with the name and version information visible in the column.

Application REFSTR	Application Start Date
Business EAI Platform v. 2.2	14/11/2015
Groupware Services v. 2.2	12/02/2015
Mafo-Portal v. 2.6	25/08/2015
PS Global v. 2.5	24/03/2016
ALLFinance PISA v. 2.9	24/01/2015
SAP@OptiRetail v. 2.0	10/07/2015

Masking a Link Target in A Configured Report With a Text

Links in tabular configured reports can be masked with a text that is different than the link target URL.

Please note however that the object preview window will show the link with the original URL.

The dataset of the query the report is based on must return the URL and the text in two different columns. The text can then be displayed in the column containing the URL retaining the navigation capability to the underlying URL by adding the following instruction to the query:

```
JoinUrlLink(URL_Column, Column_with_replacing_text);
```

Use the following parameters:

Code Parameter	Description
`URL_Column`	The name of the column containing the link to the target URL. For information about the names of the columns resulting from Alfabet queries and native SQL queries, see Defining Column Names and Captions.
`Column_with_replacing_text`	The name of the column containing the text to mask the target URL in the column defined as `URL_Column`.

The column returning the text is not removed from the dataset by this instruction. Use a `RemoveColumns` instruction to remove this column. The `RemoveColumns` instruction must be defined after the `JoinUrlLink` instruction. For information about the `RemoveColumns` instruction, see Hiding a Column in a Configured Report.

Converting a String into a Link in a Configured Report using Reference Value

The dataset instruction `MakeReferenceValue` allows you to assign a reference link to a label string to be displayed in a defined column of a configured report. This link navigates to the object view or object cockpit for the object defined via a `REFSTR` value in the query.

The `MakeReferenceValue` instruction behaves identical to the `LinkAssignment` instruction in ordinary datasets.

Converting a label string into a link is done by adding the following instruction to the query:

```
MakeReferenceValue(RefStringColName, ValueStringColName);
```

The parameters to be defined are described in detail:

Code Parameter	Description
`RefStringColName`	The name of the column defined via the query which contains the string to be converted to the reference. For information about the names of the columns resulting from Alfabet queries and native SQL queries, see Defining Column Names and Captions.
`ValueStringColName`	The name of the column containing the string to be displayed as the value i.e. the label.

When the instruction is used, the dataset of the query the report is based on must return the resulting reference link and the label in two different columns. The label can then be displayed both in the column containing the reference link and in its original column which does not retain the navigation capability to the underlying link.

The column returning the label i.e. `ValueStringColName` is not removed from the resulting dataset by the `MakeReferenceValue` instruction automatically, but can be removed using a `RemoveColumns` instruction. The `RemoveColumns` instruction must be defined after the `MakeReferenceValue` instruction. For information about the `RemoveColumns` instruction, seeHiding a Column in a Configured Report.

See Creating a Card View Report for an example on how to use the `MakeReferenceValue` instruction along with the `RemoveColumns` instruction in a simple query for a Card View report.

Adding Dynamic Web Links to a Configured Report

The XML object ***WebViewManager*** allows you to configure dynamic web links referencing applications that are accessible via a URL. The dynamic web link references a specific location in the application, allowing you to access information in the application that is relevant to the object that the user is currently working with in Alfabet.

Dynamic web links configured in the XML object ***WebViewManager*** can be opened from a configured report.

For information about configuring dynamic web links in the XML object ***WebViewManager***, see Configuring Dynamic Web Links That Users Can Access.

The instruction `SetDynamicWebLink` will add an **Open Web Link** button to the report that opens the dynamic web link for the object selected in the configured report via a sub-menu option. Only one web link can be defined per object, but different objects can open different web links. For example, a configured report displaying applications and components can contain a link to an internal report about the application for each application and a link to a technical service repository for the components. The **Open Web Link** button will show a sub-menu option for each kind of dynamic web link added to the configured report. Only the sub-menu option valid for the currently selected object will be active.

In addition to the button interaction, the link can be opened via the **Operations** button in the object preview window.

The configured report must return the following data in the columns of the dataset returned by the query the configured report is based on:

- Each row must have a base object the row result is about. Please note that the report must be configured to display only one row for each found object. If the result dataset returns multiple rows with the same base object but different data, the dynamic web links cannot be set.

  In Alfabet queries, the base object of a result is the `FIND` class of the Alfabet query. In native SQL queries, the first argument in the `SELECT` statement must return the `REFSTR` of an object. This object is the base object of the row result. This first argument is not displayed in the configured report. For both Alfabet queries and native SQL queries, the base object of a row can be changed via a `SetRowReference` instruction. For more information, see Changing the Navigation Behavior of the Base Object Class in a Configured Report.

  For example,:

  - A configured report finds components as a base class and displays the component and the component category that the component is assigned to in a tabular data set. There will be only one row per component because each component can only be assigned to one component category. Dynamic web links can be added this configured report.
  - A configured report finds components as a base class and displays the component and the component groups that the component is assigned to in a tabular data set. Multiple rows might be displayed per component because each component can be assigned to multiple component groups. Dynamic web links cannot be added to this configured report.

- The value of the XML attribute `Caption` of an XML element `WebViewDef` in the XML object ***WebViewManager***. Please note that the attribute `ClassNames` of that XML element `WebViewDef` must include the base object of the row results in the configured report the dynamic web link shall be opened from.
- The value of the XML attribute `Caption` of one of the subordinate XML objects `WebLinkDef` of the defined XML element `WebViewDef`.
- The text that shall be displayed as the sub-menu item of the **Open Web Link** button in the toolbar.

- The text that shall be displayed as the sub-menu item of the **Operations** button of the preview window.
- The `REFSTR` of the object for which the link shall contain property values. The placeholders in the URL of the dynamic web link will be replaced with the values of the object class properties for the object referenced in this column of the configured report. Make sure that the object class properties defined in the XML attribute `PropNames` of the relevant `WebLinkDef` are available for the object class referenced by this column.
- A string to be used as a category name to differentiate different kind of dynamic web links. The following must apply for the category setting:
  - The toolbar button and preview button menu text must be different for different categories.
  - The toolbar button and preview button menu text as well as the selected `WebViewDef` and `WebLinkDef` must be identical for all rows having the same category definition. If For example, multiple toolbar button texts are defined for a category, each text will be displayed as separate sub-menu item. When the user selects an object assigned to that category, all sub-menu items that are created for the dynamic web link category will be active and perform the same action.

The column names must be added to the instruction that has the following syntax:

```
SetDynamicWebLink(ObjectReferenceColumn,WebViewCaptionColumn,WebLinkCaptionC
olumn,ToolbarButtonMenuTextColumn,PreviewButtonMenuTextColumn,CategoryColumn
)
```

The parameters are all mandatory. Use the following parameters:

Code Parameter	Description
`ObjectRefer-enceColumn`	The name of the column containing the `REFSTR` values of the objects for that the dynamic web link shall be opened. That means that the dynamic web link will open with object class property values for the object referenced in the `Object Refer-enceColumn`. For information about the names of the columns resulting from Alfabet queries and native SQL queries, see Defining Column Names and Captions.
`WebViewCap-tionColumn`	The name of the column returning the value of the XML attribute `Caption` of an XML element `WebViewDef` in the XML object ***WebViewManager***
`WebLinkCap-tionColumn`	The name of the column returning the value of the XML attribute `Caption` of one of the subordinate XML objects `WebLinkDef` of the defined XML element `Web-ViewDef`.
`ToolbarButton-MenuTextColumn`	The name of the column returning the string to be displayed as sub-menu item of the button **Open Web Link** in the toolbar of the configured report.
`PreviewButton-MenuTextColumn`	The name of the column returning the string to be displayed as sub-menu item of the button **Operations** in the preview window of the configured report.

Code Parameter	Description
`CategoryColumn`	The name of the column returning the category name to enable the instruction with the given category name for the row.

If dynamic web links shall be opened for the leaf level results in a grouped dataset, the `GroupBy_Ex` instruction for grouping of the dataset must be defined prior to the `SetDynamicWebLink` instruction in the order of instructions to ensure that dynamic web links are only applied to the subordinate rows.

Exporting Attachments to a Runtime Folder During Report Execution

The instruction `RetrieveIDOCPath` triggers the export of attachments to the runtime folder of the Alfabet Web Application during execution of a query that provides information about the attachments that are specified in the query . The path to the runtime directory is written in the configured report to inform about the location the file can be retrieved from.

This instruction is explicitly implemented for use with the JIRA integration feature for export of attachment with JIRA issues. Storage time and location are handled then handled by the JIRA integration mechanisms. If the configured report is executed directly in the Alfabet user interface, documents are stored in the temporary directory during the active user sesssion only and are removed automatically from the runtime folder on logout of the user.

The attachments are exported each time the report is executed. Each report will be stored with the file name of the attachment amended with a GUID that ensures that the file name is unique. The whitelist and blacklist defined for export actions is taken into account. If a file has an extension that is not allowed for export, the REFSTR of the ALFA_IDOCUMENT is written into the respective cell instead of the file path.

For information about whitelist and blacklist, see Configuring the Permissibility of Files and Web Links in Alfabet .

Attachments are stored in the Alfabet database as objects of the object class `ALFA_IDOCUMENT`. The query for that the instruction is defined must return the `REFSTR` of the relevant `ALFA_IDOCUMENT`s in a column of the result dataset. The following instruction can then be applied to that column:

```
RetrieveIDCOPath(ColumnName);
```

Use the following parameter:

Code Parameter	Description
`ColumnName`	The name of the column containing the `REFSTR` values of the `ALFA_IDOCUMENT`s to be exported. For information about the names of the columns resulting from Alfabet queries and native SQL queries, see Defining Column Names and Captions.

Displaying Translated Values of Enumerations, Object States, Statuses, Milestones and Indicators in Configured Reports

Values defined for object state and status definitions, indicator values, lifecycle status definitions, enterprise release and project milestone definitions and enumerations are translatable in the Alfabet vocabularies.

For a detailed description about the globalization capability, see Localization and Multi-Language Support for the Alfabet Interface

The translated values are displayed on the Alfabet interface when the user opens the user interface in the respective language with the following exceptions, whereby the values are displayed in English by default:

- The history tracking report provided by Software AG
- Configured reports.

For configured reports, instructions are provided that trigger the display of translated enumeration, indicator range, object state and status value, and lifecycle status values in the configured report.

If values that shall be translated are later concatenated with other values, For example, with a `JoinColumns` instruction, the instruction for translating the value must be added prior to the instruction concatenating the value.

To display history tracking information with translated enumeration, indicator range value, object state and status values, you can create a configured report displaying the history tracking information and use it instead of the standard history tracking report. For more information about creating a configured report to display history tracking information, see Defining Audit Management Related Configured Reports in the chapter Configuring Reports.

The translation of enumeration, indicator range, object state, milestone captions, lifecycle status values, and status values displayed in a configured report can be defined by adding one of the following instructions to the query:

- To display enumeration, object state, milestone caption and status values in the translation provided for the culture that the user is currently using:

  ```
  TranslateEnums("ColumnName,ColumnName,...");
  ```

- To display indicator range values in the translation provided for the culture that the user is currently using:

  ```
  TranslateIndicators("ColumnName,ColumnName,...");
  ```

  Reports based on Alfabet query language with indicators added via the Show properties does not require the use of the `TranslateIndicators` instruction to be displayed translated in the Alfabet user interface.

- To display lifecycle status values, that means the value of the property `Status` of the object class `TimeStatus`, in the translation provided for the culture that the user is currently using:

  ```
  TranslateTimeStatus("ColumnName,ColumnName,...");
  ```

Use the following parameter(s):

Code Parameter	Description
`ColumnName`	The name of the column in the tabular output of the report that contains the values to be translated. For information about the names of the columns resulting from Alfabet queries and native SQL queries, see Defining Column Names and Captions. If multiple columns contain values to be translated, the columns can be defined comma-separated. Alternatively, the position of the column in the index of columns can be used to specify the column. For more information see Referencing Columns in Instructions by Index Number.

Display Translated Values for Object Class Properties Subject to Data Translation in Configured Reports Based on Native SQL

Some predefined protected properties and custom properties of the type `String` and `Text` can be translated to the secondary languages for which data translation is enabled in the cultures.

For more information about object data translation, see the section Configuring the Translation of Object Data in the chapter Localization and Multi-Language Support for the Alfabet Interface.

For configured reports of the type `Query` the translated object data is automatically displayed in the report in the language currently displayed in the user interface. For native SQL queries the change to the current language must be included in the report. One of the available methods is the instruction `SetTranslatedValue`. Please note however, that a more convenient implementation method is available. This method does not involve an instruction and is described in the section Displaying Translated Object Data In the Current Language of the User Interface.

In the Alfabet database, the translated values for translatable object class properties are written to additional columns of the database table for the respective object class. The columns are named <ClassTechName>_<local ID>. For example, for a German translation of the obects's name and description, the columns would be named `NAME_1031` and `DESCRIPTION_1031`.

If you want a configured report based on a native SQL query to display the translations for the current language of the user interface, you must add all columns containing the translated values to the `SELECT` statement of your query. In addition, the `SetTranslatedValue` instruction must be added to the query definition:

```
SetTranslatedValue("ColumnName1,ColumnName2");
```

Use the following parameter(s):

Code Parameter	Description
`ColumnName`	The name of the column in the tabular output of the report that contains the value in the original language. For information about the names of the columns resulting from Alfabet queries and native SQL queries, see Defining Column Names and Captions. If multiple columns contain data to be translated, the columns can be defined comma-separated.

If the instruction is added, the following behavior applies:

- If the user opens the report in the original language, the columns containing translated values will be removed from the dataset.
- If the user opens the report in any other language for which a translation is included in the query, the values in the column for the base culture value will be substituted with the values from the respective language column. After that, columns containing translated values will be removed from the dataset

For example, if you translate data to German (locale ID = 1031) and French (locale ID = 1036), and the name of an application shall be displayed in the current language of the user interface, you must define the following for the `SELECT` statement to display the application name in the current language:

```
SELECT REFSTR, NAME, NAME_1031, NAME_1036, VERSION
FROM APPLICATION
```

In addition, the `SetTranslatedValue` instruction must be added to the query definition with the definition of the `NAME` column as the column in the report that shall contain the relevant translated data:

```
SetTranslatedValue("NAME");
```

Translating Text Defined Directly in the SELECT Statement of Native SQL Queries

In native SQL queries, static text can be defined as return value for a column in the `SELECT` statement.

For example, the following native SQL query contains the fixed strings `Action required` and `You are not in charge` in the column `Importance`:

```
SELECT app.REFSTR, app.NAME As 'Application', app.VERSION As
'Version', CASE WHEN app.RESPONSIBLEUSER = @CURRENT_USER THEN
'Action required' ELSE 'You are not in charge' END As 'Importance'
FROM APPLICATION app WHERE app.STATUS = 'Draft'
```

The strings are by default not translated if the user interface is rendered in a secondary language.

If you want a configured report based on a native SQL query to display translations for static strings defined in the `SELECT` argument as values for the cells in a column, the `SetTranslatedValue` instruction must be added to the query definition:

```
TranslateColumnContent("ColumnName","Untranslated value1,Untranslated
value2,...");
```

Use the following parameter(s):

Code Parameter	Description
`ColumnName`	The name of the column in the tabular output of the report that contains the strings. For information about the names of the columns resulting from native SQL queries, see Defining Column Names and Captions. Translation is limited to the defined column in the instruction. If the same strings are available in a second column as well, they will not be translated in that column, but only in the column defined in the instruction. You must add another `TranslateColumnContent` instruction for the second column to add translation to it.
`Untranslated value1, Untranslated value 2`	The values in the column that shall be translated in a comma separated list of strings. Please note the following: • Only strings that are listed in the instruction are displayed translated. If you do not add a string to the list, its translation will not be displayed, even if the translation is available in the `METAMODEL` vocabulary due to another context using an identical string. • A translation must be available for the string in the `METAMODEL` vocabulary. Translations in other vocabularies are ignored. If strings listed here are not available in the `METAMODEL` vocabulary due to another context using an identical string, they will automatically be added to the `METAMODEL` vocabulary on storage of the query containing the instruction. You must then provide a translation in the `METAMODEL` vocabulary for all applicable cultures to view a translation in the column in the configured report. For information about translating vocabulary strings, see Modifying, Translating and Managing the Vocabularies.

The instruction can be used in all native SQL queries defined for reports of the type `NativeSQL` or `Custom`.

Displaying the Sum of Multiple Values in a Table Row

For tabular configured reports with multiple columns that display data of the data type Real or Integer, the sum of the values in multiple columns can be calculated per row and displayed in a separate row in bold text.

Do the following to display the sum of multiple values in a row:

1) Add a new, empty column to the dataset.

   • If the report is based on an Alfabet query, a new column can be added using instructions. See Inserting One or Multiple Columns to a Report for information about the required instructions.

- If the report is based on a native SQL query, a new column can either be added using instructions (see Inserting One or Multiple Columns to a Report for details) or by adding a new column with static content directly in the `SELECT` statement.

In the following dataset, a column "`Risk Factor`" with the integer 1 as fixed value is added to the dataset in addition to the columns containing data from the Alfabet database.

```
SELECT RISK.REFSTR, RISK.NAME As 'Risk', RISK.DAMAGE As
'Damage', RISK.PROBABILITY As 'Probability',1 AS 'Risk
Factor'

FROM RISK
```

2) Add the following instruction to the report to fill the new column with the sum of the values of selected values of the type Real and Integer in each row:

```
CreateRowSum("ValueColumnNames","ResultColumnName");
```

Use the following parameter(s):

Code Parameter	Description
`ValueColumn-Names`	The column names of the columns containing the values for that the sum is calculated delimited with commas. The values must be of the data type Real or Integer. Alternatively, the position of the column in the index of columns can be used to specify the column. For more information see Referencing Columns in Instructions by Index Number.
`ResultColumn-Name`	The name of the column displaying the calculated sum. If you define a column that already contains data, the data is overwritten. Alternatively, the position of the column in the index of columns can be used to specify the column. For more information see Referencing Columns in Instructions by Index Number.

In the following Alfabet query based report, the risk evaluation for applications is displayed. The evaluations concerning the risk damage and risk probability are summed up in the last row to highlight the relevance of the risk.

Risk	Object	Damage	Probability	Ri
CVE-2013-1813	BLOOMBERG	1.00	3.00	4
Database-driven Application Failure	BLOOMBERG	1.00	2.00	3
Faulty Code Changes	BLOOMBERG	2.00	1.00	3
Lack of Storage	BLOOMBERG	2.00	2.00	4

The report is based on the following query:

```
ALFABET_QUERY_500
```

```
FIND Risk
InnerJoin Application ON Risk.Object = Application.REFSTR
Instructions
   AddColumns("Sum");
   CreateDSInfo("Risk.Name,Application.Name,Risk.Damage,Risk.Probabi
   lity,Sum", "Risk,Object,Damage,Probability,Risk Factor");
   CreateRowSum("Risk.Damage,Risk.Probability","Sum");
EndOfInstructions
AUTODSINFO
QUERY_XML
<QueryDef>
   <ShowProperty Type="Property" ClassName="Risk" Name="Name" />
   <ShowProperty Type="Property" ClassName="Application" Name="Name"
   />
   <ShowProperty Type="Property" ClassName="Risk" Name="Damage" />
   <ShowProperty Type="Property" ClassName="Risk" Name="Probability"
   />
</QueryDef>
```

Displaying the Sum of All Values in a Table Column

For tabular configured reports, the sum of the values in a column displaying Real or Integer values can be calculated per row and displayed in an additional row added below the result rows. Optionally, a text can be specified that is displayed in a selected column of the report. Both the text and the sum of values are displayed in bold text.

Use the following instruction to display the sum of all results in a column below the result column:

```
CreateColumnSum("ValueColumnName","CaptionColumnName","Caption");
```

Use the following parameter(s):

Code Parameter	Description
`ValueColumn-Name`	The name of the column containing the values for that the sum is calculated. The values must be of the data type Real or Integer.
`Caption-ColumnName`	The name of the column displaying the caption in the additional data set row for the sum.
`Caption`	The text displayed in the additional data set row for the sum in the column defined by `CaptionColumnName`.

In the following native SQL query based report, the current costs of an application are displayed. The report is applied to the class `Application`. The user can select the application for that the costs are displayed in the filter field on top of the report. The costs for each cost type is listed separately and the sum of all costs is displayed in the last row. The sum is added to the report via the `CreateColumnSum` instruction. The caption `OVERALL COSTS` is displayed in the row for the sum in the `CostType` column.

	CostType	Cost
1	Software Subscriptions	
2	Internal Maintenance Costs	
3	External Maintenance Costs	
4	Other Operational Costs	
5	**OVERALL COSTS**	

The report is based on the following native SQL query:

```
SELECT BV.REFSTR, ct.NAME As 'CostType', BV.VALUE As 'Cost'
FROM BUDGETVALUE BV, APPLICATION app, COSTTYPE ct
WHERE ct.REFSTR = BV.MONETARYTYPE
    AND BV.OWNER = app.REFSTR
    AND BV.MONETARYCODEID='Current'
    AND BV.YEAR = '2014'
    AND app.REFSTR = @BASE
```

The query is combined with the following instruction:

```
CreateColumnSum(Cost, CostType, "OVERALL COSTS");
```

Grouping Results by Weighting of Values in a Defined Column

For tabular configured reports with a column displaying data of the type Real or Integer, the results can be grouped according to the results in that column. The number of groups is configurable. The overall number of rows is divided by the number of groups to evaluate how many results belong to each group. If the number of results cannot be divided equally among the groups, the first groups each get one more member assigned until all value are assigned.

The assignments of the results to each group depends on the values in the column used for grouping. The results are sorted in descending order. The results with the lowest numbers are members of the first group. The next groups are each having higher numbers in the result data set.

Each of the resulting groups has a number, starting with 1. The group number is displayed in the report in a separate column.

Do the following to divide the data set into groups formed by weighting of values in a defined column.

1) Add a new, empty column to the dataset. The column must be of the data type Integer or Real.

It is not possible to add the new column to the dataset using instructions. The empty columns added to the data set via instructions do not have the data type Integer or Real.

- If the report is based on a native SQL query, add the new column directly in the `SELECT` statement. The static value for the column must be an integer or real number to set the data type of the column to Integer or Real.

In the following dataset, a column "`Weighting`" with the integer 1 as fixed value is added to the dataset in addition to the columns containing data from the Alfabet database.

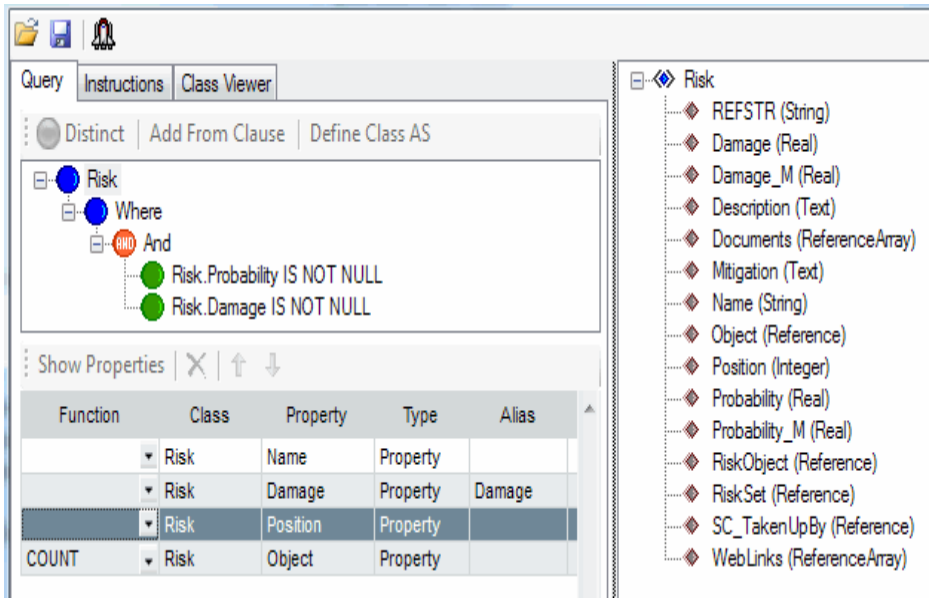
```
SELECT RISK.REFSTR, RISK.NAME As 'Risk', RISK.DAMAGE As
'Damage', RISK.PROBABILITY As 'Probability',1 AS
'Weighting'

FROM RISK
```

- If the report is based on an Alfabet query, a column containing integer data from the Alfabet database must be added to the report via a Show property. The data in the column is later overwritten by the grouping information. If the `FIND` class do not have a property of the type Integer or Real, you can For example, use a `COUNT` function on a property of the **Data Type** `Reference` or `ReferenceArray`.

For example, to add a new column to the data set defined for the class `Risk` that shall be used to display grouping performed by weighting of the risk damage value, there are two possibilities:

  - Add one of the other object class properties of the **Data Type** `Integer` or `Real` of the object class `Risk` to the Show properties, For example, the object class property `Position`.
  - Add an object class property of the **Data Type** `Reference`, For example, the property `Object`, to the Show properties and apply a `COUNT` function on that Show property.



2) Add the following instruction to the report to fill the new column with the weighted group information:

```
NTile_Weighted("ValueColumnName","GroupColumnName","Caption");
```

Use the following parameter(s):

Code Parameter	Description
`Value-ColumnName`	The column name of the columns containing the values used to define group assignment. The values must be of the data type Real or Integer.
`Group-ColumnName`	The name of the column displaying the group number. The data type of the column must be Real or Integer.
`Tile`	The number of groups the result set is split into.

In the following Alfabet query based report, the risk evaluation for applications is displayed. The evaluations concerning the risk probability are used to group the results into four groups. The group number is displayed in the column `Tile`. Sorting was performed on the column `Tile`.

	Application	NAME	Damage	Probability	Tile
1	Eurex	Availability	1.00	1.00	1
2	Eurex	Availability	1.00	1.00	1
3	Eurex	Integrity	1.00	1.00	1
4	Eurex	Integrity	1.00	1.00	1
5	GLOSS BUREAU	Confidentiality	1.00	1.00	1
6	SUNGARD TREASURY TRADER	Lack of Storage	1.00	1.00	1
7	BLOOMBERG	Faulty Code Changes	2.00	1.00	1
8	CRES	Integrity	2.00	1.00	1
9	GGM	Integrity	2.00	1.00	1
10	SUNGARD TREASURY TRADER	Spying of Critical Data	2.00	1.00	1
11	TradeThru	Spying of Critical Data	2.00	1.00	1
12	Wagner Classifier	Configuration Errors	2.00	1.00	1
13	EasiTrade Web	Accidental Grant of Access	3.00	1.00	1
14	EasiTrade Web	Power Failure	3.00	1.00	1
15	Wagner Classifier	Accidental Grant of Access	3.00	1.00	1
16	Wagner Classifier	Catastrophic Events	3.00	1.00	1
17	Links	Catastrophic Events	4.00	1.00	1
18	Trade*Net	Catastrophic Events	4.00	1.00	1
19	Trade*Net	Spying of Critical Data	4.00	1.00	1
20	BLOOMBERG	Database-driven Application Failure	1.00	2.00	2
21	CRES	Availability	1.00	2.00	2
22	BLOOMBERG	Lack of Storage	2.00	2.00	2
23	Eurex	Confidentiality	2.00	2.00	2
24	Fed Ex	Confidentiality	2.00	2.00	2

The report is based on the following native SQL query:

```
SELECT RISK.REFSTR, app.NAME As 'Application', RISK.NAME,
RISK.DAMAGE As 'Damage', RISK.PROBABILITY As 'Probability', 1 AS
Tile FROM RISK, APPLICATION app WHERE RISK.DAMAGE IS NOT NULL AND
app.REFSTR = RISK.OBJECT;
```

The query is combined with the following instruction:

```
NTile_Weighted(Probability,Tile, 4);
```

Defining Queries in XML Elements

The configuration of some Alfabet functionalities requires the definition of queries in XML objects. For example, this applies to the definition of custom selectors, the full-text search index, and rule-based access permissions. In this case, the query is defined as a value of an attribute of the relevant XML element.

For example,:

```
<Query
   Class="Application"
   Query="ALFABET_QUERY_500 FIND Application WHERE Application.Name
   LIKE 'CRM%'
   SHOW Application.Name"/>
```

Please take the following into account when specifying a query in an XML element.

- If you want to enter a string that contains special characters (For example, a greater then (>) or lesser then (<) symbol), you must replace the special characters with respective XML compliant code. For example:
  - > for >
  - < for <
  - " for "
  - [for [
  -] for]
- If you define an Alfabet query, the default specification of show and sort properties that is the standard output of the **Alfabet Query Builder** is an XML definition that cannot be pasted as-is into an XML attribute. Therefore, the show and sort properties have either to be defined escaped, in other words, all brackets must be written in XML compliant code, or defined as follows:

`SHOW` (for show properties) or `SORT` (for sort properties) followed by *ObjectClassName.PropertyName*.

You can define multiple properties separated by a whitespace.

For example,:

```
SHOW Application.Name Application.ID Application.StartDate
SORT Application.Name
```

When instructions are used in a query, you must define the show property as XML and substitute all brackets with either < for < and > for >. The alternative syntax listed above cannot be used in combination with instructions.

Creating an Index to Improve Performance for Query Searches in Database Tables

A database index is an ordered and thus quickly searched part of a database table. If the database must search in a particular table for entries matching a specified value, then this process will be significantly sped up if the database can use an index for finding the data instead of requiring a full table scan.

You can configure the Alfabet database to create indices for all object data that is frequently used. Index creation is a side effect of a class key definition. Usually, class keys are defined to implement uniqueness constraints. For each class key that is configured for an object class in Alfabet Expand, an index is created. Each class key has a **Unique** attribute that can be set to `False` to allow an index to be created for the class key without implementing a uniqueness constraint for the class. Thus, the definition of class keys can be used to speed up query-based searches.

In addition to using class keys to define an index created for data in a database table, audit keys can be defined to trigger index creation for audit tables. Each object class for which auditing is activated can have audit keys defined. For example, if you have specific custom reports that take a significant amount of time to be executed, the execution of the report can often be significantly sped-up by creating proper indices.

Please be aware that every index defined for a database table slightly reduces the data update and insert performance for entries in the table. Therefore, you should create indices only where it is specifically useful or necessary.

Class keys and audit keys must be unique within an object class. You cannot create a key that duplicates existing public or preconfigured key of the same type for the same object class. Two class keys are identical if the values for their attributes **Properties**, **Unique** and **Strict Null Handling** are identical. For audit keys, the value of the **Columns** attribute must be unique.

The two sections below explain the creation of indices via a class key and the creation of indices via an audit key.

To create a class key to define an index without uniqueness constraints for a selected object class:

1) In the **Meta-Model** tab, right-click the protected class  that you want to create the class key for and select **Add New Class Key**. You will see the **Class Key Group** folder and the new class key subordinate to the selected object class.

2) Click the new class key  to open the attribute window. In the attribute window, edit the name for the class key in the **Name** field, if necessary.

3) Click the cell to the right of the **Properties** field and click the **Browse**  button. You will see the dialog box in which you can define the properties to be included into the index.

4) Click each property that you want to include in the index. After all necessary properties have been selected, click **OK**. You will see the new key below the **Class Key Group** folder.

5) In the attribute window, set the **Unique** attribute to `False`.

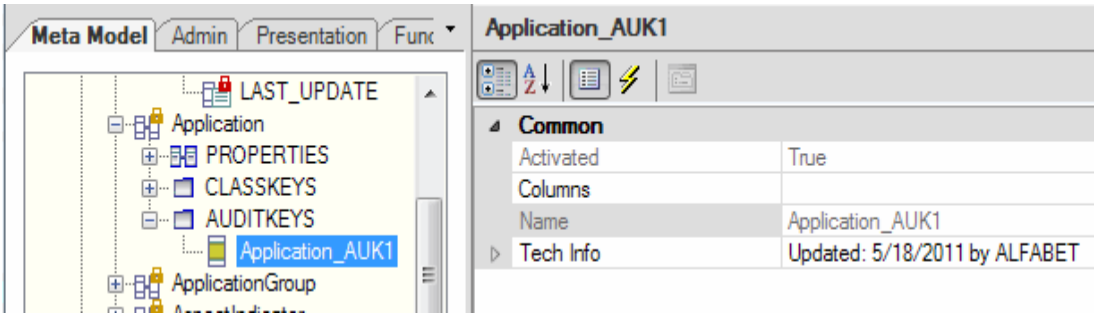
6) In the toolbar, click the **Save**  button to save your changes.

To delete all protected and custom class keys that have been configured for a protected or custom object class, click the **Class Key Group** node below the relevant object class and select **Delete All Public/Protected Class Keys**. The protected and public class keys will be deleted and no longer displayed below the **Class Key Group** node. Private class keys that have been configured by Software AG will not be deleted.

To create an audit key defining an index for audit table data:

1) In the **Meta-Model** tab, right-click the protected class  that you want to create the audit key for and select **Add New Audit Key**. You will see the **Audit Key Group** folder and the new audit key subordinate to the selected object class.

The **Audit Key Group** node is only displayed if the **Audit** attribute of the object class is set to `True`.



The **Audit** attribute can be set to `True` for all object classes by clicking the **Classes** node and selecting **Turn Audit On for All Protected/Public Classes**. If selected The **Audit** attribute will be set to `True` for all protected and public object classes. The **Audit** attribute can be set to `False` for individual classes or set to `False` for all protected and public classes by selecting **Turn Audit Off for All Protected/Public Classes**.

2) Click the new audit key to open the attribute window.

3) Click the cell to the right of the **Columns** field and click the **Browse** button. You will see the dialog box in which you can select the data from the audit table for the index created on basis of the audit key.

4) Click each property that you want to include in the index. After all necessary properties have been selected, click **OK**. You will see the new key below the **Audit Key Group** folder.

Please note that the attribute **Columns** must be unique for audit keys of the same object class.

5) In the toolbar, click the **Save** button to save your changes.

Some processes like ADIF imports or rescan of indicators either via the command line tool `RescanIndicatorsConsole.exe` or via the **Job Scheduler** functionality may trigger a high number of single database insert and delete transactions. This can have a negative impact on fragmentation of indices. As a result, CPU usage is increased and performance is reduced. It is recommended to rebuilt indexes in regular intervals for object classes subject to ADIF import or rescan of indicators. This can be done using the command line tool `AlfaAdministratorConsole.exe`. For more information, see *Rebuilding Indexes on Database Tables* in the reference manual *System Administration*.

To delete all protected and custom audit keys that have been configured for a protected or custom object class, click the **Audit Key Group** node below the relevant object class and select **Delete All Public/Protected Audit Keys**. The protected and public audit keys will be deleted and no longer displayed below the **Audit Key Group** node. Private audit keys that have been configured by Software AG will not be deleted.

Creating Database Views To Enhance Performance And Support Search Functionalities

Database views are searchable database constructs based on a native SQL query with a `SELECT` statement or an Alfabet query. A database view is like a virtual table represented by the native SQL query or Alfabet query. The query syntax used to define database views in native SQL on the database server level is:

```
CREATE VIEW ViewTableName AS SELECT ViewContentDefinition
```

For the Alfabet database, database views can be created and maintained in the tool Alfabet Expand without the need to directly access and configure the database server.

A configuration object **Database View** is available for defining the database view. The name of the database view table and the `SELECT` statement for the content of the database view are defined in separate attributes of the configuration object. When the configuration is saved, the `CREATE_VIEW` statement for creating the view is automatically built and executed based on the defined information.

The content of the table resulting from the output of the native SQL query or Alfabet query defined as `ViewContentDefinition` is not stored in the database. Instead, the native SQL query is executed each time data is requested from the database view table defined with `ViewTableName` by any other native SQL query targeting the database view table. Targeting the database view table in a native SQL query is done in the same way as targeting a standard database table. In the Alfabet query language targeting of a database view table is not supported.

Database views do not store data and Therefore, take up very little database space. They offer the following advantages for building queries For example, for reporting:

- **Simplicity**: Complex parts of queries with For example, multiple joins across multiple database tables can be stored in a database view. Query definition during solution configuration can then be based on simple queries referencing the columns of the database view without any joins required.
- **Reusability**: If multiple queries in the configuration gather the same information from the tables in the database as part of the query output, a database view can be created to implement the part that is identical for all the queries.
- **Consistency**: The way For example, complex KPI calculations are done in queries can be defined in database views and the results are then consistent in all queries defined for Alfabet.
- **Easy debugging in case of database changes**: Changes to the class model, For example, when upgrading to a new Alfabet release or when deleting custom object class properties, may require re-definition of queries defined for configuring Alfabet. If information is first gathered in a database view and then re-used in many queries that are defined for configuring Alfabet, you do not have to change all queries but only the underlying database view query if a change in the class model requires a re-definition of the query content. In addition, a mechanism is implemented in Alfabet Expand that can be used to detect errors in database view configurations after changes to the class model.

In addition, database views can be used to support the automatic generation of reports for the faceted semantic search provided via the `Analyze` intent of the AlfaBot.

The content of a database view can either be defined as a native SQL query or an Alfabet query. The result dataset is built as follows depending on the type of query defined:

- **Native SQL**

For native SQL queries, the columns and column name of the database view table are derived from the `SELECT` statement of the native SQL query. Unlike all other native SQL query definitions for configuring Alfabet, the first definition of the `SELECT` statement is NOT removed from the resulting dataset. The complete definition in the `SELECT` statement results in database view table columns.

The table names defined as For example, `APPLICATION.NAME` will result in a column name `NAME` only. To avoid problems with name specifications it is recommended to define an alias with the desired name in the `SELECT` statement for the database view.

- **Alfabet Query**

Which properties of the object classes added to the query are added to the database view as table columns depend on the following settings:

- If Show properties are defined for the Alfabet query, the number of columns correspond to the number of show properties defined. Please note that Show Properties of the type `RoleType` and `Indicator` are ignored. Only Show Properties of the type `Property` are used to create columns in the database view.
- If no show properties are defined, all properties except for properties of the type `ReferenceArray` are added to the database view. Optionally, properties of defined data types can be excluded from the database view table by setting the attribute **Filter Show Properties** of the database view.

The column names in the database view are derived from the query in the following way:

- The column name is concatenated as object class caption followed by property caption delimited by a whitespace. For example, for the property `Start Date` of an `Application`, the resulting column name is `Application Start Date`. Please note that special characters are not stripped from the captions when building the database view column captions. If no caption is defined, the Name of the object class or object class property is used.
- If Show Properties are defined and an Alias is defined for a property in the Show Properties, the defined Alias is used instead of the concatenated column name.
- If an Alias is defined for the object class in the Alfabet query, the alias is used in the column name instead of the class name. An alias can be used For example, to avoid name abbreviation by the system for column names longer than 30 characters.
- If the resulting column name is longer than 30 characters, the name will be cut after 30 characters, corresponding to the string length restrictions that apply on Oracle® database servers. Depending on the property caption, this might cause problems if the resulting column names are identical in the first 30 characters. Alias definitions in the query can help solving such problems.

The following information is available:

- Creating a Database View Based on a Native SQL Query
- Creating a Database View Based on an Alfabet Query
- Targeting a Database View in Queries and Other Database Views
- Changing the Order of Execution for Database Views
- Checking the Consistency of the Database View With the Meta-Model

Creating a Database View Based on a Native SQL Query

To create a database view based on native SQL in Alfabet Expand:

1) Open the **Meta-Model** tab
2) Right-click the explorer node **Database Views** and select **Add New Database View** from the context menu. The new database view is displayed as new explorer node under the **Database Views** node and the attribute window of the new database view node opens.
3) In the attribute window of the new database view, set the following attributes:
   - **Type**: Select `NativeSQL`.
   - **Name**: Define a name for the Database View configuration object. The name must be unique. It is used to identify the Database View object in the explorer of Alfabet Expand.
   - **Technical Name**: Define the name of the virtual database table that shall be created via the database view. Queries that want to read data from the database view must refer to the database view with this name. The technical name must be in compliance with the rules that apply to table names on your database server, that means special characters and reserved keywords as well as names of already existing database tables must not be used.
   - **Query/Native SQL Query as Text**: Define the content of the database view via a native SQL query in a simple text editor (**Native SQL Query as Text**) or in an Alfabet specific text editor with integrated help that provides information about the Alfabet meta-model (**Query**). The query must have a `SELECT` statement. The column names defined in the `SELECT` statements are the column names for the database view. Queries defined to read data from the database view must use the defined names to refer to columns of the database view table.

     Please note the following:
     - Unlike all other native SQL query definitions for configuring Alfabet, the first definition of the `SELECT` statement is NOT removed from the resulting dataset. The complete definition in the SELECT statement results in database view table columns.
     - The table names defined as For example, `APPLICATION.NAME` will result in a column name `NAME` only. To avoid problems with name specifications it is recommended to define an alias with the desired name in the `SELECT` statement for the database view.
   - **Description**: Optionally, enter information about the purpose of the database view. This information is displayed to solution designers in Alfabet Expand only.

- **Applicable for AlfaBot**: Set this attribute to `True` if the database view should be used to automatically generate reports for the `Analyze` intent of the AlfaBot which can be used to search for information in configured reports. The mechanism for generation of ad-hoc reports will then scan the **Semantic Analysis** explorer of the database view to find out whether the database view provides information a user is currently searching for. If the scan is positiv, a configured tabular report targeting the database view will be generated and provided to the user as one of the search results. By default, the attribute is set to `False`.

For more information about the faceted semantic search provided by the `Analyze` intent of the AlfaBot, see Define AlfaBot Search Capabilities for Configured Reports.

- **Base Class**: If the **Applicable for AlfaBot** attribute is set to `True`, select a base class from the list of object classes identified from the query of the database view. Automatically generated reports for the `Analyze` intent of the AlfaBot will only be created on basis of this database view if the **Base Class** attribute is set to the object class identified to be the object class the user is currently searching for. If the base class is not defined, the database view will not be used for automatic generation of reports.

4) In the toolbar, click the **Save** button to save your changes.
5) Right-click the explorer node **Database Views** and select **Recreate Database Views** from the context menu to create the database view in the Alfabet database. The attribute **Created** of the database view should then be set to `True`. If it is set to `False`, and an error message is displayed in the attribute **Last Error**, the query defined for the query attribute needs correction.

Clicking the **Save** button will store your configuration and create the database view in the Alfabet database. The attribute **Created** of the database view should then be set to `True`. If it is set to `False`, and an error message is displayed in the attribute **Last Error**, the query defined for the query attribute needs correction.

Creating a Database View Based on an Alfabet Query

To create a database view based on an Alfabet query in Alfabet Expand:

1) Open the **Meta-Model** tab
2) Right-click the explorer node **Database Views** and select **Add New Database View** from the context menu. The new database view is displayed as new explorer node under the **Database Views** node and the attribute window of the new database view node opens.
3) In the attribute window of the new database view, set the **Type** attribute to `AQL`. The attributes are changing to the attributes relevant for Alfabet query language based attributes.
4) Set the following attributes:

- **Name**: Define a name for the Database View configuration object. The name must be unique. It is used to identify the Database View object in the explorer of Alfabet Expand.
- **Technical Name**: Define the name of the virtual database table that shall be created via the database view. Queries that want to read data from the database view must refer to the database view with this name. The technical name must be in compliance with the rules that apply to table names on your database server, that means special characters and reserved keywords as well as names of already existing database tables must not be used.

- **Description**: Optionally, enter information about the purpose of the database view. This information is displayed to solution designers in Alfabet Expand only.
- **Query/AQL Query as Text**: Define the content of the database view via an Alfabet query in a simple text editor (**AQL Query as Text**) or in the Alfabet query builder (**Query**). Sort properties and Alfabet query language instructions must not be defined for the Alfabet query. The definition of Show Properties is optional.

Which properties of the object classes added to the query are added to the database view as table columns depend on the following settings:

- If Show properties are defined for the Alfabet query, the number of columns correspond to the number of show properties defined. Please note that Show Properties of the type `RoleType` and `Indicator` are ignored. Only Show Properties of the type `Property` are used to create columns in the database view.
- If no show properties are defined, all properties except for properties of the type `ReferenceArray` are added to the database view. Optionally, properties of defined data types can be excluded from the database view table by setting the attribute **Filter Show Properties** of the database view.

The column names in the database view are derived from the query in the following way:

- The column name is concatenated as object class caption followed by property caption delimited by a whitespace. For example, for the property `Start Date` of an `Application`, the resulting column name is `Application Start Date`. Please note that special characters are not stripped from the captions when building the database view column captions. If no caption is defined, the Name of the object class or object class property is used.
- If Show Properties are defined and an Alias is defined for a property in the Show Properties, the defined Alias is used instead of the concatenated column name.
- If an Alias is defined for the object class in the Alfabet query, the alias is used in the column name instead of the class name. An alias can be used For example, to avoid name abbreviation by the system for column names longer than 30 characters.
- If the resulting column name is longer than 30 characters, the name will be cut after 30 characters, corresponding to the string length restrictions that apply on Oracle® database servers. Depending on the property caption, this might cause problems if the resulting column names are identical in the first 30 characters. Alias definitions in the query can help solving such problems.

- **Filter Show Properties**: This attribute is only relevant if the Alfabet query defining the database view has no Show Properties. If set to `True`, the following additional attributes are added to the attribute section. You can use the attributes to exclude object class properties with a defined data type from the database table view:
  - **Exclude Boolean Properties**: Select `True` to exclude all object class properties with the attribute **Property Type** set to `Boolean` from the database view.
  - **Exclude Color Properties**: Select `True` to exclude all object class properties with the attribute **Name** containing the string `Color` from the database view.
  - **Exclude Icons**: Select `True` to exclude all object class properties with the attribute **Name** containing the string `Icon` from the database view.

- **Exclude Last Update**: Select `True` to exclude all object class properties the attribute **Name** set to either `LAST_UPDATE`, `LAST_UPDATE_USER`, `CREATION_DATE` or `CREATION_USER` from the database view.
- **Exclude Reference Properties**: Select `True` to exclude all object class properties with the attribute **Property Type** set to `Reference` from the database view.

- **Applicable for AlfaBot**: Set this attribute to `True` if the database view should be used to automatically generate reports for the `Analyze` intent of the AlfaBot which can be used to search for information in configured reports. The mechanism for generation of ad-hoc reports will then scan the **Semantic Analysis** explorer of the database view to find out whether the database view provides information a user is currently searching for. If the scan is positiv, a configured tabular report targeting the database view will be generated and provided to the user as one of the search results. By default, the attribute is set to `False`.

For more information about the faceted semantic search provided by the `Analyze` intent of the AlfaBot, see Define AlfaBot Search Capabilities for Configured Reports.

- **Base Class**: If the **Applicable for AlfaBot** attribute is set to `True`, select a base class from the list of object classes identified from the query of the database view. Automatically generated reports for the `Analyze` intent of the AlfaBot will only be created on basis of this database view if the **Base Class** attribute is set to the object class identified to be the object class the user is currently searching for. If the base class is not defined, the database view will not be used for automatic generation of reports.

5) In the toolbar, click the **Save** button to save your changes.

Targeting a Database View in Queries and Other Database Views

Database views can be used as searchable data set in native SQL queries. Use of database views in Alfabet query language is not supported.

When data from a database view is included into the `SELECT` statement of a native SQL query, the call to the database view causes the query of the database view to be executed with the filter conditions defined in the native SQL query that calls the database view data.

The column names in database views based on an Alfabet query usually contain white spaces and might also contain special characters. Column names should be written into the select statement of the native SQL query targeting the database view in inverted commas.

```
SELECT "Application Name", "Application Property #1" FROM
ApplicationBasedDatabaseView
```

A native SQL query defined for creating a database view can also call data from other database views. If you create a database view that calls data from another database view, you must make sure that the configuration object for that database view is located beneath the configuration object for the called database view in the **Database Views** node of the **Meta-Model** explorer in Alfabet Expand.

Changing the Order of Execution for Database Views

Database views are not sorted alphabetically in the explorer, but are listed in the order of definition. The order of definition equals the order of execution of the database views For example, when recreating all database views for debugging. A database view can target another database view and these views must be executed after the targeted database views are executed. This can be ensured by execution in definition order.

You can change the order of execution by re-defining the sort order in the explorer:

1) Open the **Meta-Model** tab
2) Click the explorer node **Database Views**. The attribute window of the node opens.
3) Click the **Browse** button in the field of the **Database Views** attributes. The **Sort Entries** button window opens.
4) Click a database view in the list and move it in the list with the **Up** and **Down** buttons at the upper right of the **Sort Entries** window.
5) Click **OK** to save your changes.

Checking the Consistency of the Database View With the Meta-Model

After changes have been made to the class model, database views might require adaptations to the changes.

To check whether the database views are still valid, a mechanism is implemented in Alfabet Expand that recreates all database views in the database and displays error messages for errors that occurred during recreation.

To check the database views for consistency with the meta-model:

- Open the **Meta-Model** tab
- Right-click the explorer node **Database Views** and select **Recreate Database Views** from the context menu. All database views are recreated in the Alfabet database in the order of definition.

  A database view can target another database view and these views must be executed after the targeted database views are executed. This can be ensured by execution in definition order.

- Click on each database view in the explorer to check whether errors occurred. Errors can be read from the following read only attributes of the database view configuration object:
  - **Created**: Displays `True` if the database view has been created. Displays `False` if the database view has not been created. Database views with the attribute **Created** set to `False` need to be corrected.
  - **Last Error**: Displays the error that occurred during database view creation.

If you have defined a high number of database views, you can avoid clicking each node in the explorer by creating a configured report based on a native SQL query that reads the information which database views were not created because of an error during creation from the database

table that stores the Database View configuration object. The following native SQL query will return the name of all database views that require re-configuration:

```
SELECT REFSTR, NAME
FROM ALFA_DB_EXT
WHERE ISCREATED = 'False'
```

You can then directly open the explorer nodes of the database views returned by the report to see the error message and correct the query of the database view accordingly.

Database views are recreated after each **Update Meta-Model** or **Restore Database Archive** action and need to be checked as described above afterwards. The recreation ensures that new database views added to the configuration via the **Update Meta-Model** or **Restore Database Archive** action are created and that database views that are not compatible with the changes to the meta-model applied via Meta-Model Update are removed. For more information about update of the meta-model or restore of a database archive see the reference manual *System Administration*.

Maintaining the Information in the Semantic Analysis Sub-Node of the Database View

The semantic analysis functionality for database views scans all queries in a database view for references to Alfabet object classes and object class properties thereof.

The information is used for the following functionalities:

- The **Show Usage** functionality in the context menu of object class properties evaluates the use of the object class property in configured reports on basis of the semantic analysis results.
- The AlfaBot uses the semantic analysis to build automatically generated reports from the database view to provide additional search results for the `Analyze` intent finding configured reports displaying information about defined object class properties and values thereof.

The results are listed in a node **Semantic Analysis** beneath the node of each datase view in a hierarchical structure going down from object classes to object class properties to values of object class properties. The Name property of object classes and object class properties is used in the explorer.

If object class properties restrict the content of the database view via a `WHERE` clause definition in the underlying query, the values will be included into the semantic analysis for object class properties returning one of the following:

- The value of a standard `Stereotype` object class property.

The semantic analysis ignores value definitions including a wildcard and checks whether the object class stereotype name equals a stereotype name defined for the object class. Only existing object class stereotypes are listed.

- The value of a the `Name` of an object.

The semantic analysis ignores value definitions including a wildcard.

- A Boolean value.

- A value from an enumeration.

The semantic analysis ignores value definitions including a wildcard and checks whether the enumeration value is defined for the enumeration defined for the object class property. Only existing enumeration items are listed.

In addition, the semantic analysis maps all column names in the database view with the object class and object class property for which data is returned in the column. The results are listed in a sub-folder **Aliases**. this information is used by the mechanism for automatic generation reports to find the correct database views for generation of meaningful ad-hoc reports for the current user request.

Scanning is done automatically after the query for the database view has been defined.

Please note the following:

- If the **Semantic Analysis** node is empty, this is an idicator for an error in the underlying query, For example, a typo in an object class name.

The analysis scans both Alfabet queries and native SQL queries. It comprises object class properties referenced by any part of the query including joins and the object class properties of the type `ReferenceArray` which are included in native SQL queries via the `PROPERTY` column of the `RELATIONS` database table.

Alfabet queries and native SQL queries are handled differently:

- The semantic analysis for database views based on Alfabet queries is not editable.

Indicator and role definitions added via the show properties of the type `Indicator` or `Role` are not included into the semantic analysis results.

The `REFSTR` object class property of the `FIND` class of the Alfabet Alfabet query is added as object class property to the semantic analysis.

- Native SQL queries can be very complex and in some cases, the scanning mechanism may not find all relevant object classes and object class properties. Therefore, the solution designer can add missing information to the semantic analysis via the **Add Properties** option in the context menu of the **Semantic Analysis** node. Object class property values included in the semantic analysis are ReadOnly and excluded from editing. The semantic analysis is executed each time the native SQL query of the database view is changed. The manually-added semantic analysis results will be left unchanged during a subsequent semantic analysis.

Information about object classes and object class properties may be missing in the analysis for one of the following reasons:

- The query definition is incorrect. For example, an object class or object class property name may have been added with a typo. It is recommended to check the query definition for correctness if the semantic analysis is missing or incomplete.
- Native SQL queries can be very complex and the scanning mechanism for semantic analysis may fail to identify object class or object class property specification.

If the semantic analysis of a correct native SQL query is incomplete, missing information can be added manually to complete the analysis:

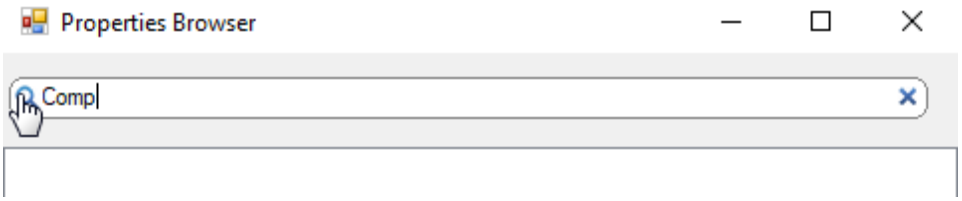
- Adding an Object Class to the Semantic Analysis
- Adding an Object Class Property to the Semantic Analysis

- Removing Manually Added Entries From the Semantic Analysis

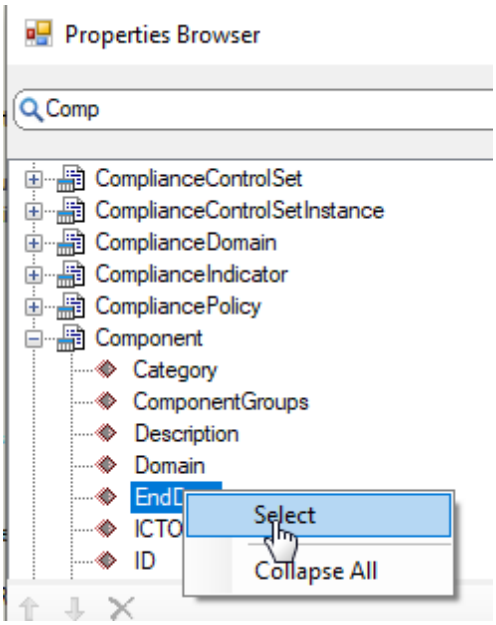
Adding an Object Class to the Semantic Analysis

To add information about an object class missing in the automatic semantic analysis output:

1) Right-click the **Semantic Analysis** node and select **Add Properties**.
2) In the selector window, type at least the first three letters of the object class name into the search field and click the search icon on the left of the field.



3) All object classes matching your search are listed in the middle field of the selector. Expand the relevant object class node, right-click the relevant property and select **Select** from the context menu.



4) Click OK. The object class and the selected object class property is added to the semantic analysis explorer persistently.

Adding an Object Class Property to the Semantic Analysis

To add information about an object class property missing in the automatic semantic analysis output for an object class already included in the semantic analysis:

1) Right-click the object class node and select **Add Properties**.
2) In the selector window, right-click the relevant property and select **Select** from the context menu.

3) Click **OK**. The object class property is added to the semantic analysis explorer persistently.

Removing Manually Added Entries From the Semantic Analysis

If you added an object class property manually to the semantic analysis, it will not be removed the next time the native SQL query of the database view is updated, even if it is no longer used in the query. Manually added entries in the semantic analysis can only be removed manually:

- To remove a manually added object class property from the semantic analysis, right-click the object class property node and select **Remove Property**.
- To remove a manually added object class including all object class properties thereof from the semantic analysis, right-click the object class node and select **Remove Class**

Deleting a Database View

If you delete a database view configuration object from the Meta-Model tab in Alfabet Expand, the database view is irrevocably deleted from the Alfabet database and the configuration object is removed from the Alfabet database table that stores the database view configuration objects.

Prior to deleting a database view, you should check that neither queries nor other database views read data from the database view.

To delete a database view:

1) Open the **Meta-Model** tab and expand the explorer node **Database Views**.
2) Right-click the database view that you want to delete and select **Delete** from the context menu.

Testing Queries for Compliance with the Current Release

Alfabet queries and native SQL queries are defined for a number of custom configurations, including For example, workflows, custom explorers, custom object profiles and custom reports.

After replacing or merging a configuration with the configuration in an XML file and after upgrading to another Alfabet release, it is recommended that you test whether changes to the Alfabet query language require you to adapt existing Alfabet queries in the configuration or whether changes in the version of the SQL parser require you to adapt existing native SQL queries.

To ease testing of the queries, a test and export functionality is available for queries defined in the following parts of the configuration:

- Color Rules
- Compliance Reports
- Custom Explorers
- Custom Editors
- Editors

- Export
- Indicator Types
- Monitors
- Object Selectors
- Object Views including Object Cockpits
- Reports including Report Views
- Rights Manager
- Search Manager
- Selectors
- Text Templates
- Wizards
- Workflow Templates
- XML Objects

Alfabet queries defined in these configuration objects can both be checked directly in Alfabet Expand or exported for test purposes.

Native SQL queries cannot be checked for compliance with the current parser version directly in Alfabet Expand. Nevertheless, native SQL queries are included into the list of queries to enable use of the export mechansims provided by the test functionality for native SQL queries.

Via the export mechanisms available in the test functionality all queries in the configuration can be exported to a single Microsoft Excel file or written into a database table to ease analysis of existing queries by mechanisms outside of Alfabet.

The following information is available:

- Testing Alfabet Queries In Alfabet Expand
- Saving All Queries For External Testing

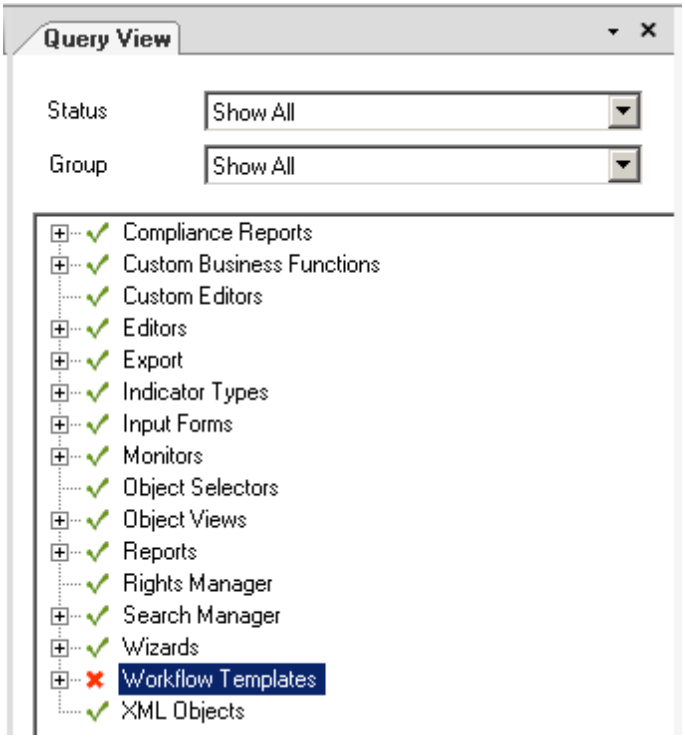
Testing Alfabet Queries In Alfabet Expand

The testing capability exclusively tests whether the Alfabet query matches the current syntax of the Alfabet query language and whether object class and object class properties written into the query are available in the Alfabet meta-model. It is not designed to test the validity of the query in the context of the configuration it is written for. Even if the Alfabet query is correct, a configuration may not work because the results delivered by the query do not match the requirements or the surrounding configuration made in an XML object or in attributes of the configuration object may not be correct.

To test the Alfabet queries in your configuration:

1) In the Alfabet Expand menu bar, select **Meta-Model** > **Check All Queries**. The **Query View** opens in the editor window of Alfabet Expand.

2) Click the **Refresh** button. The editor window displays all types of configurations for which queries are defined. If all Alfabet queries match the current Alfabet query language and the current meta-model, the section will be checked green, otherwise, a red cross will be displayed.



3) Optionally, set the following filters:

- **Status**: Select **Show All** to view all queries including native SQL queries, select **Show Errors** to view only Alfabet queries that need correction or select **Show Passed** to view only Alfabet queries that are correct.
- **Group**: Select the part of the configuration you are interested in or select **Show All** to see all queries in all parts of the configuration.
- **Include Retired Reports**: By default, retired reports are regarded as irrelevant and are not included into the view. Select the checkbox to also check and display queries in retired reports.

4) When a red cross is displayed in the report, click the + symbol in front of the red cross to expand the relevant section. If required, further expand the tree until the level of a single Alfabet query is reached at the leaf level.

5) Click the Alfabet query that needs correction. In the property section of Alfabet Expand, a report about the Alfabet query is displayed that provides the following information:

- **Caption**: The caption of the configuration object for which the Alfabet query is defined.
- **Error Code**: The type of error that occurred. The error code for wrong Alfabet queries is `ErrorInQuery`. for correct Alfabet queries it is `None` and for native SQL queries it is `NotApplicable`, because native SQL queries are not tested.
- **Message**: The kind of error that occurred in the Alfabet query. For example, if an object class that is no longer part of the meta-model is referenced in the Alfabet query, the message "Can't find class: <class name>" is displayed.

- **Owner Type**: The owner type is only specified for a subset of Alfabet queries and gives information about the use of the Alfabet query. In workflows, For example, an Alfabet query defined for to find responsible users for a workflow step has the **Owner Type** `WorkflowObjectQuery`.
- **Path**: The path to the Alfabet query in the configuration.
- **Query**: Allows to open the Alfabet query in a text editor that is read only.

6) To correct the Alfabet query, double-click the Alfabet query in the report tree. In the explorer window of Alfabet Expand, the explorer containing the relevant configuration opens with the location of the Alfabet query expanded. You can now access the Alfabet query from the explorer and make the required corrections.

   If the query is defined via the user interface, which is the case for queries in color rules, For example, the Alfabet interface opens in a new window when you double-click the Alfabet query in the report tree. The object view of the object for which the Alfabet query was defined is displayed. .

   Note the following regarding access to queries via the **Check All AQL Queries** capability:

   - The **Alfabet Query Builder** cannot build an incorrect Alfabet query and will not open when the Alfabet query definition is incorrect. To correct an Alfabet query that contains an error, use the text editor to alter the existing Alfabet query or delete the complete Alfabet query from the text editor and rewrite the Alfabet query in the **Alfabet Query Builder**.

7) In the **Query View**, click the **Refresh** button. The corrected Alfabet query is now displayed with a green checkmark.

Saving All Queries For External Testing

Alfabet Expand provides export mechanisms to save a list of all Alfabet queries and native SQL queries found in Alfabet configuration objects.

The export includes the following:

- The queries are stored in a database table in the Alfabet database for access via a configured report or external test tools.
- The queries are stored in a Microsoft® Excel® file for external analysis.

To store a list of configured reports for analysis:

1) In the Alfabet Expand menu bar, select **Meta-Model** > **Check All Queries**. The **Query View** opens in the editor window of Alfabet Expand.
2) Click the **Refresh** button. The editor window displays all types of configurations for which queries are defined.
3) Optionally, set the following filters. All other filters will have no effect on export:
   - **Include Alfabet Queries**: Select this option to include Alfabet queries into the export.
   - **Include Native Sql Queries**: Select this option to include native SQL queries into the export.

- **Include Retired Reports**: By default, retired reports are regarded as irrelevant and are not included. Select this option if you want queries from retired reports to be included.

4) Do one of the following:

- Click the **Save into Database**  button to save the queries to the `ALFA_QUERY_CHECK` database table only.

- Click the **Export As Excel**  button to save the queries to a Microsoft® Excel® file and to the `ALFA_QUERY_CHECK` database table.

The following information is saved: The title displayed below corresponds to the column name in the `ALFA_QUERY_CHECK` database table and the column headers in the Microsoft® Excel® sheet:

- `ID`: The `ID` is a consecutive number assigned to each query found in the configuration. Saving of the queries overwrites the information in the `ALFA_QUERY_CHECK` database table and re-generates the information written to the Microsoft® Excel® file. The `ID` of a query can Therefore, be different after each re-use of the export functionality.

- `OBJECT_TYPE`: The type of configuration object that the query is found in. The type refers to the parent containing the query. For example, the `OBJECT_TYPE` for queries defined within a workflow template, like For example, a query to find responsible users or a query defined for a pre-condition, the `OBJECT_TYPE` is **Workflow Templates**, independent from the subordinate configuration object containing the query.

- `OBJECT_NAME`: The name of the configuration object. For configuration objects defined in Alfabet Expand, this is the value of the **Name** attribute. For the parts of the configuration that are defined as configuration data on the Alfabet user interface, like For example, indicator types or color rule groups, this is the value of the **Name** property of the respective object class.

- `QUERY_PATH`: If the query location beneath the parent object can be further specified, the subordinate configuration object is returned. For example, for wizards the wizard step containing the query is returned as path information.

- `QUERY_TYPE`: The query type is Native for native SQL queries and AQL for Alfabet queries.

- `QUERY_CAPTION`: If a caption is defined for the part of the configuration containing the query, it is returned in this column. For example, for custom editors, the caption of the editor control containing the query is returned.

- `QUERY_NAME`: The name of the subordinate configuration object or attribute containing the query. For example, for custom editors, the name of the editor control containing the query is returned.

- `ORIGINAL_QUERY`: The query in the configuration object. Please note that only 32767 characters can be written into a Cell in Microsoft® Excel®. If the query exceeds the allowed number of characters in Excel, it is truncated.

Chapter 20: Configuring Surveys for Data Capture Campaigns

The Surveys capability allows for stakeholder surveys or data acquisition campaigns to be configured. Such surveys are typically driven by regulatory or senior management requests. Alfabet Expand provides a capability that allows surveys to be configured so that the data collection process is standardized by a high degree of automation and can be conducted in a timely manner.

Surveys integrates several standard capabilities available in Alfabet Expand including the configuration of wizards for the structured collection of data as well as the configuration of workflow templates that allow the Alfabet objects targeted by the survey to be identified and a workflow initiated for each surveyed object. The configured workflow ensures that the data collection tasks required for the survey are distributed to responsible users, that if/then scenarios can be implemented for the data input, and that all data collection tasks are completed by their specified deadlines.

To configure a survey, you must create a custom object class that serves as the container in which to collect data about objects in the Alfabet database. If one survey object is to be generated for the standard Alfabet object (in other worlds, one survey object per authorized user), then a workflow template should be configured for the survey. In the context of a workflow template, the custom survey class is associated with a standard Alfabet object class that the data inquiry targets. An object based on the custom survey class will be generated for each Alfabet object determined via a query to be relevant for the survey.

Alternatively, if multiple survey objects are to be created for a standard Alfabet object (in other words, if multiple survey objects are needed because multiple users will be providing input), then an ADIF scheme should be configured to create the survey objects. A workflow template should be configured for the data inquiry. For more information about the configuration of an ADIF scheme, see the reference manual *Alfabet Data Integration Framework*.

Users responsible for a workflow step may access the Alfabet object in order to gather the necessary information required for the data input. Because the data collection occurs on the object created for the custom survey class, users with access permissions to only the base objects will not have access to the survey data unless they are explicitly granted access permissions via the workflow template or relevant user profile.

The enterprise decides it is necessary to conduct a survey to assess all applications that are not assigned to a domain assignment to determine their readiness to migrate to a Windows® 7 client.

To this end, a survey is created with the custom survey class named Windows7Readiness. The custom survey class has 3 custom object class properties defined to evaluate compatibility for a 64-bit system, 32-bit system, and XP-emulation system. Enumerations are created for each custom object class property that allows the user evaluating the application to select a pre-configured value. A fourth object class property allows the evaluating user to provide comments regarding, For example, installation, execution, or run-time behavior. The user will be provided with a custom editor defined for the custom survey class Windows7Readiness in which the values can be defined.

A workflow template is also configured whereby the custom survey class Windows7Readiness is defined in the **Start Base Class** attribute and the class Application is defined in the **Source Base Class** attribute. A query is defined that finds all applications that have no domain assignment. A workflow is thus generated for each application found by the query and a new survey object based on the custom object class Windows7Readiness will be created for every application. A user evaluating an application in the context of the survey can provide the relevant data input about the application in an editor or wizard created for the custom survey class Windows7Readiness.

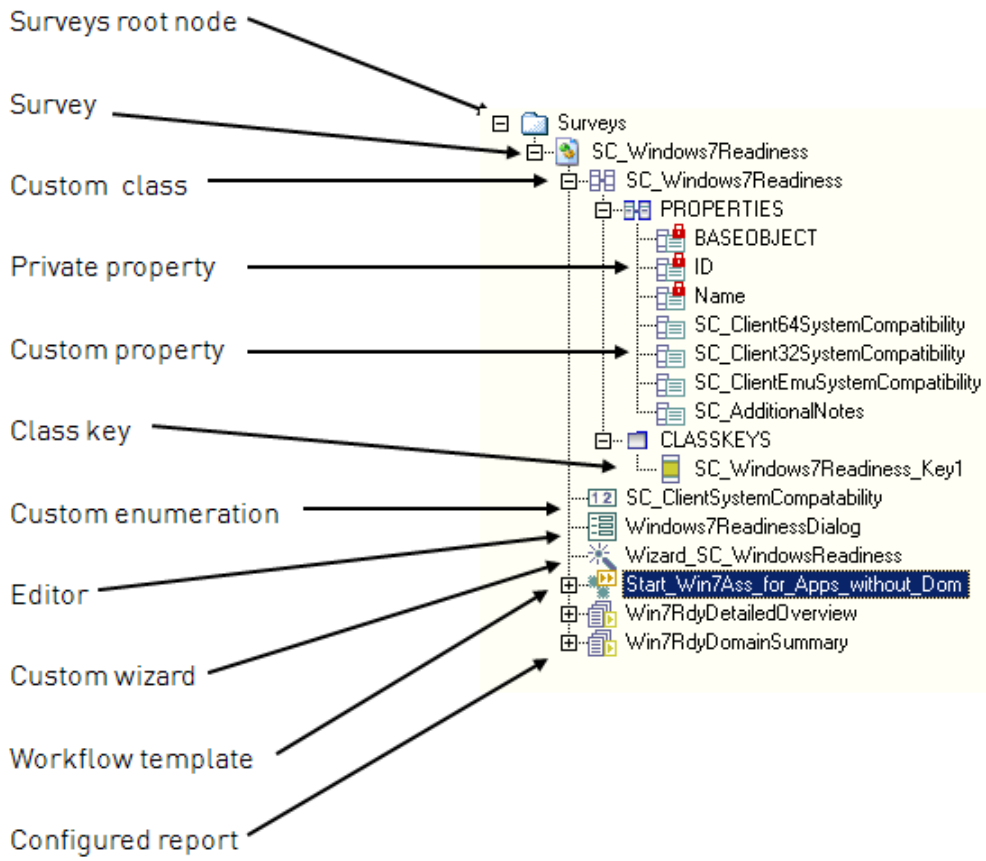


FIGURE: The Surveys tab in Alfabet Expand

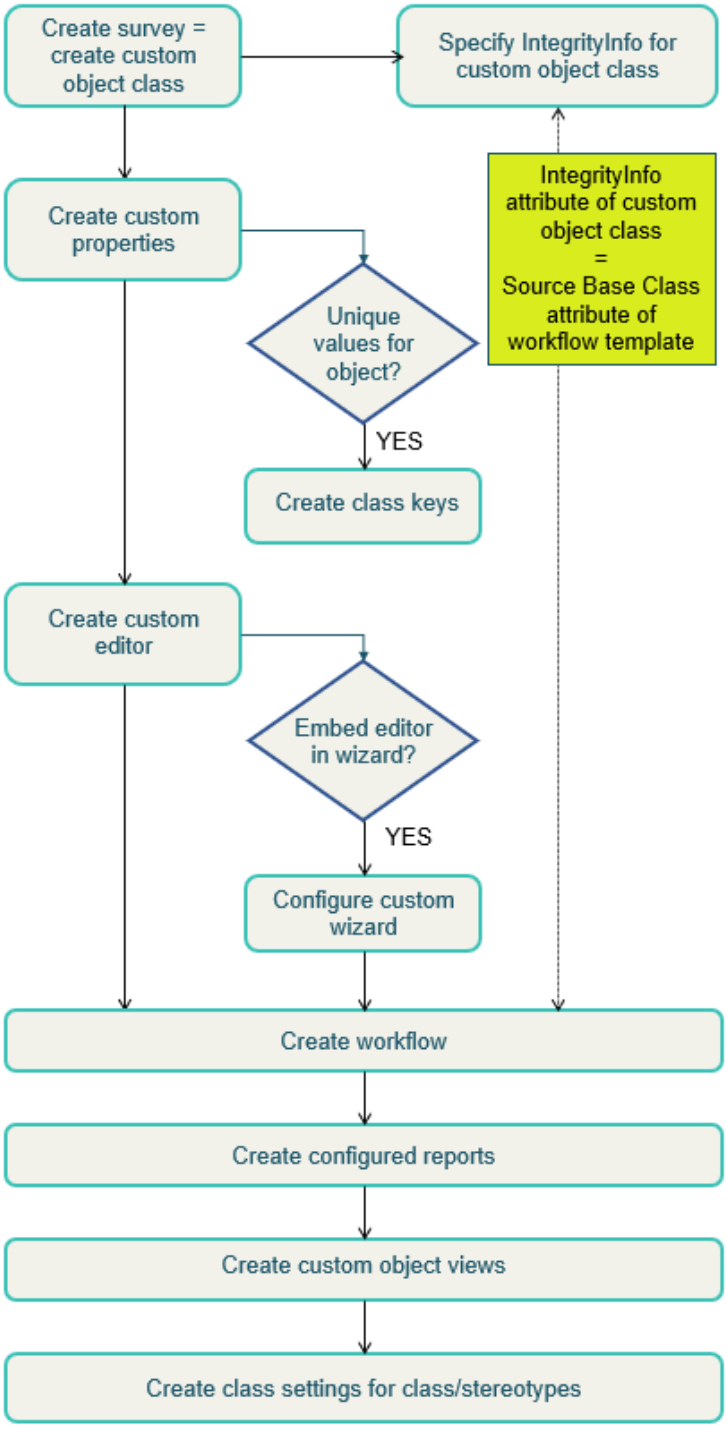
The following steps must be carried out in order to configure and implement a survey:



- The information model must be configured. In this phase, you must determine which data is to be captured in the survey. This entails the following configuration:
  - The creation of the survey and specification of the custom survey class for which the data will be captured. A default object profile will be available in the Alfabet interface for each survey class with the following buttons potentially available:
    - **Workflow**: This button will only be available if workflows exist for the survey objects based on the custom object class.

        - **Edit**: This button will only be available if a custom editor or custom wizard is assigned to the class setting relevant for the custom object class.
        - **Audit Trail**: This button will only be available if auditing is configured as permissible for the custom object class.
    - The creation of all necessary custom object class properties and enumerations required to capture the information about the objects surveyed.
- The means to capture the data required for the information model. This entails the following configuration:
    - The creation and specification of one or more custom editors to capture the data.
    - If necessary, the configuration of a wizard in order to structure the data capture process. Pre-conditions can be stipulated for each wizard step and the completion of data input can be checked before the user can move on to the next step in the wizard.
- A workflow to implement, standardize and manage the collection of data for the survey. The configuration of a workflow template allows you to determine the Alfabet objects that should be assessed in the survey, the various tasks involved in the data collection process, and the users who are responsible for providing input at each stage of the survey. This entails the following configuration:
    - The creation and specification of one or more workflow templates made up of workflow steps.
    - The workflow template associates the custom survey class created for the survey with the object class in Alfabet that is targeted by the survey. The workflow template must include a query that finds the Alfabet objects that are to be surveyed. A new survey object based on the custom survey class will be automatically created for each Alfabet object found by the query.
    - Pre-conditions can be stipulated for each workflow step and the completion of data input can be checked before the user can move on to the next step in the workflow.
- If necessary, the configuration of reports to display, For example, the results of the survey or the progress of the data capture campaign. A custom object view can be created if the data collected for individual survey objects should be displayed on an object-by-object basis.

The custom object classes configured for surveys will be available in the **Class Configuration** functionality in the Alfabet user interface. Indicators and roles can be configured for the custom object classes that are targeted by a survey. For more information, see the sections *Configuring Evaluations, Prioritization Schemes, and Portfolios* and *Configuring Role Types to Define Roles in the Responsibilities Page View* in the reference manual *Configuring Evaluation and Reference Data in Alfabet*.

The definition of the information model as well as the execution of the workflows to capture the data occurs at server run-time.

The following information is available:

- Creating the Survey and Custom Survey Class
- Creating Custom Object Class Properties and Enums for the Custom Survey Class
- Creating Uniqueness Constraints for the Custom Survey Class

- Configuring Editors and Wizards for the Survey
- Configuring a Workflow for the Survey
- Configuring Reports for the Survey
- Configuring Object Views for the Custom Survey Class
- Making the Survey Class Searchable
- Configuring Class Settings for the Custom Survey Class

Creating the Survey and Custom Survey Class

When you create a survey, you automatically generate a new custom survey class. Only one custom survey class can be created per survey. When the survey is executed, survey objects will be created based on the custom survey class via a configured workflow template.

Any custom object class you create for a survey will also be displayed below the **Classes** node in the **Meta-Model** tab in Alfabet Expand.

To create a survey:

1) Go to the **Surveys** tab, right-click the root node **Surveys**  and select **New Survey**. The **Create New Class** editor will open.

   If you want to copy an existing survey as the basis of a new survey, right-click the survey node  and select **New Survey as Copy**. Proceed as described below.

2) In the **Class Name** field, enter the name of the custom survey class. This value is displayed in the solution interface if the **Caption** attribute has not been defined for the custom survey class.
3) Click in the **Technical Name** field. The class name will appear in capital letters. The technical name can be edited, if necessary. Click **OK** to save the custom survey class to the database.

   Please keep the following in mind:

   - The technical name may not begin with an empty space nor include special characters. For a list of the special characters that are not allowed, see the section Defining Attributes for Configuration Objects in the chapter Getting Started with Alfabet Expand.
   - The technical name should only contain standard `ASCII` characters.
   - The technical name should consist of upper-case letters only.
   - The maximum length of a technical name may not exceed 30 characters.
   - The technical name may not coincide with any of the reserved key words of the relational database management system.

   A validation mechanism checks for correct syntax when defining a technical name. Please note that if the technical name of a configuration object is changed, the name will be correctly updated in other configuration objects referencing the changed object

during design time. However, the name of a changed configuration object will not be updated in guide pages nor if the guide pages reference a configuration object listed in the **Show Usage** functionality. If you plan to change the name of a configuration object, the reference in the guide page should be changed prior to changing the configuration object name.

4) The survey is displayed in the **Surveys** explorer. Expand the custom survey class node and then expand the **PROPERTIES** node . You will see three private object class properties labelled `BASEOBJECT`, `ID`, and `NAME`. These standard object class properties have been automatically generated for the custom survey class and can be implemented later in queries defined for the workflow template. These object class properties cannot be deleted. Typically, no further definition is required for these object class properties.

5) Click the custom survey class node to activate the attribute window. With the exception of the **Integrity Info** attribute, the available attributes can be optionally defined, as described for a conventional object class.

6) To define the **Integrity Info** attribute, click the **Browse** button to open the XML editor. In this editor, you specify the dependency between the custom object class and the object class that will be defined in the workflow template as the **Source Base Class**. The definition of the **Integrity Info** attribute is important so that if a source object is deleted from the Alfabet database, the associated survey object will also be deleted.

For example, if a survey object is created for the custom survey class Windows7Readiness and the associated application targeted by the survey is deleted, then the associated Windows7Readiness object should also be automatically deleted.

7) Define the following XML attributes:

Definition of the **Integrity Info** attribute for a custom object class:

```
<ClassIntegrityInfo>
   <IntegrityInfo MasterClassName="Application"
   ClassName="Windows7Readiness" PropertyNames="BASEOBJECT"
   />
</ClassIntegrityInfo>
```

- In the XML attribute `IntegrityInfo MasterClassName`, enter the Alfabet object class that is the target of the survey. This is the object class that you will later define as the source base class for the workflow template.
- In the XML attribute `ClassName`, enter the name of the custom survey object class.
- In the XML attribute `PropertyNames`, ensure that the value `BASEOBJECT` is entered.

8) Click **OK** to save the XML definition and to close the editor.

9) In the toolbar, click the **Save** button to save your changes. The survey with a custom survey class has been created. You should now create the custom object class properties and enumerations required to capture the data collected in the survey.

Creating Custom Object Class Properties and Enums for the Custom Survey Class

The procedure to create custom object class properties and enumerations for a custom survey class is the same as the procedure to create custom object class properties and enumerations for a standard object class. The attributes available in the attribute window will depend on the property type that you select for the custom property.

It is highly recommended that you create all custom object class properties required for the survey in the context of the survey configuration in the **Surveys** tab. To create a custom object class property for the survey, right-click the custom survey class node  and selecting **Add New Property**. Define the **Property Name** and **Technical Name** fields as described for the survey class. The custom object class property  will be displayed below the **PROPERTIES** node  . The custom object class property should be defined according to the standard conventions described in this reference manual.

Any custom object class property you create for a survey will also be displayed below the **PROPERTIES** node of the custom object class in the **Meta-Model** tab in Alfabet Expand.

The following information is available to help you:

- For an overview of all property types, see the section Overview of Data Types Available for Custom Properties in the chapter Configuring the Class Model.
- For a general description about how to create a custom object class property, see the section Configuring Custom Properties for Protected or Public Object Classes in the chapter Configuring the Class Model.

If enumerations are required for one or more custom object class properties, then it is highly recommended that you create the enumerations in the context of the survey configuration in the **Surveys** tab. To create an enumeration for the survey, right-click the survey node  and select **New Enum** . The public enumeration  will be displayed below the survey node  . The enumeration should be defined according to the standard conventions described in this reference manual and then assigned to the relevant custom object class property in the **Enum** field of that object class property.

Any public enumeration you create for a survey will also be displayed below the **Enums** node in the **Meta-Model** tab in Alfabet Expand. For information about how to create an enumeration, see the section Defining Protected and Custom Enumerations in the chapter Configuring the Class Model.

Creating Uniqueness Constraints for the Custom Survey Class

If a class key is required in order to require users to enter a unique combination of values for a specified set of custom object class properties when defining data for the custom survey class, then you must create the class key in the context of the survey. To create a class key for the survey, right-click the custom survey class node  and select **Add New Class Key** . The class key should be defined according to the standard conventions described in this reference manual. The class key  will be displayed below the **CLASSKEYS** node below the custom survey class  .

Any class key you create for a survey will also be displayed below the **CLASSKEYS** node of the custom object class in the **Meta-Model** tab in Alfabet Expand. For information about how to create a class key, see the section Configuring Class Keys for Object Classes in the chapter Configuring the Class Model.

Configuring Editors and Wizards for the Survey

The configuration of editors and wizards provides the means for users to capture the data required for the survey. It is highly recommended that you create all editors and custom wizards required for the survey in the context of the survey configuration in the **Surveys** tab. You can define multiple editors and wizards for the custom object class.

As with the general configuration of custom editors, the editors you create for a survey can be assigned to wizards and workflow steps. Please note that in the context of surveys, you will be creating an editor and not a custom editor (which is always appended to a standard editor). Any editor you create for a survey will also be displayed below the **Editors** node in the **Presentation** tab in Alfabet Expand.

To create an editor for the survey, right click the survey node  and select **New Editor** . The editor  is displayed below the survey node  . The editor should be defined according to the standard conventions for custom editors described in this reference manual. For a general description about how to create an editor, see the chapter Configuring Custom Editors.

To implement an editor in the survey, you must assign the editor to either a custom wizard or the relevant workflow step. To assign the editor to a workflow step, select `Editor` in the **Type** attribute of the relevant step and select the editor in the **View** attribute. Please note that you cannot select the editor in the **Custom Editor** attribute of the workflow step.

To create a custom wizard for the survey, right click the survey node  and select **New Wizard** . The custom wizard  is displayed below the survey node  . The custom wizards should also be defined according to the standard conventions for custom wizards described in this reference manual. Pre-conditions can be stipulated for each wizard step and the completion of data input can be checked before the user can move on to the next step in the wizard. For a general description about how to create a custom wizard, see the chapter Configuring Wizards.

To implement the custom wizard in the survey, you must assign the custom wizard to the relevant workflow step. To do so, select `Wizard` in the **Type** attribute of the relevant step and select the custom wizard in the **View** attribute.

Configuring a Workflow for the Survey

A workflow template is required to implement the survey capability. The configuration of a workflow template allows you to determine the Alfabet objects that should be assessed in the survey, the various tasks involved in the data collection process, and the users who are responsible for providing input at each stage of the survey.

It is highly recommended that you create all workflow templates required for the survey in the context of the survey configuration in the **Surveys** tab. You can define one or more workflow templates per survey. Any workflow template you create for a survey will also be displayed below the **Workflow Templates** node of the custom object class in the **Workflows** tab in Alfabet Expand.

Please note the following information relevant to the configuration of a workflow template in the context of a survey:

- To create a workflow template for the survey, right-click the survey node and select **New Workflow** . The workflow template is displayed below the survey node . The **Workflow State** attribute for the workflow template will automatically be set to `Plan`.
- Click the new workflow template and in the attribute window, set the **Automatic Start** attribute to `True`.
- Define the base class for the workflow template. This is the survey class that the workflow begins with when the initial workflow step is performed. Survey objects will be initially created for this object class. In the **Start Base Class** attribute, select the base class for the workflow template.
- Next, define the source base class for the workflow template. This is the object class containing objects in the Alfabet inventory that the survey targets. A workflow will be started for each object found by the query in the source base class. The data for the source base objects will be copied to the survey objects (based on the start base class) when the workflows are created. In the **Source Base Class** field, select the source base class for the workflow template.
- Define an Alfabet query in the **Source Objects via Query** attribute or native SQL query in the **Source Objects via Query as Text** attribute to find the Alfabet objects that should be surveyed. A workflow will be started for each object found by the query.

  For example, the survey is targeted at the creation of workflows for all applications that are not yet allocated domains in the enterprise. The **Start Base Class** attribute of the workflow template specifies the survey class. The **Source Base Class** attribute is specified as `Application`. The following Alfabet query searches for existing active applications in the inventory that have no domain assignment.

  ```
  ALFABET_QUERY_500
  FIND Application
  WHERE (AND Application.Domain IS NULL
      Application.ResponsibleUser IS NOT NULL
      Application.ObjectState = 'Active')
  ```

  For general information about defining an Alfabet query or SQL query, see the chapter Defining Queries.

- Next, create and define the initial workflow step . For the workflow step, create a workflow step action via the **Action On Entered Step** node. For the workflow step action, set the **Type** attribute to `Script`. In the **Statements** attribute, specify the object class properties of the source object class that should be automatically written to the survey objects.

  For example, to copy the applications Name and ID to the survey object.

  ```
  Set(WORKFLOWBASE.BASEOBJECT,SOURCE.REFSTR);
  Set(WORKFLOWBASE.ID,SOURCE.ID);
  Set(WORKFLOWBASE.Name,SOURCE.Name);
  ```

  For more configuration of a object class property update of the type `Script`, see the section Configuring Automatic Property Updates for a Workflow Step.

- To implement an editor created for the survey, select `Editor` in the **Type** attribute of the relevant workflow step and select the editor in the **View** attribute. Please note that you cannot select the editor in the **Custom Editor** attribute of the workflow step.
- To implement a custom wizard created for the survey, select `Wizard` in the **Type** attribute of the relevant step and select the custom wizard in the **View** attribute.
- All other aspects of the workflow template configuration should be defined according to the standard conventions described in this reference manual for workflow templates. For example, pre-conditions can be stipulated for each workflow step and the completion of data input can be checked before the user can move on to the next step in the workflow. Likewise, other workflow templates configured for the survey can be triggered based on the fulfillment of a workflow step's pre- and post-conditions. For information about the configuration of a workflow template, see the chapter Configuring Workflows.
- The **Workflow State** of the workflow must be set to `Retired` in order to delete the workflow from the survey.

Configuring Reports for the Survey

Configured reports of any type can be configured for the survey. You can configure, For example, to display the results of the survey or the progress of the data capture campaign. Any reports configured for the survey can be accessed in the **Reports** functionality in Alfabet.

It is highly recommended that you create all configured reports required for the survey in the context of the survey configuration in the **Surveys** tab. You can define one or more configured reports per survey.

To create a configured report for the survey, right-click the survey node  and select **New Report** . The configured reports  is displayed below the survey node  . The **State** attribute for the configured reports will automatically be set to `Plan`. Any configured report you create for a survey will also be displayed below the **Reports** node of the custom object class in the **Reports** tab in Alfabet Expand. Configured reports should be defined according to the standard conventions described in this reference manual. For information about the specification of a configured reports, see the chapter Configuring Reports.

Configuring Object Views for the Custom Survey Class

A custom object view can be created if the data collected for individual survey objects should be displayed on an object-by-object basis. The object view can be implemented to display an Attributes section and configured reports. Views cannot be added to the object view since no views for the custom object class exist in the configuration.

To ensure that the users can navigate to the object view of the source objects found by the query defined for the workflow template, you should configure a link in the Attributes section to the base class (**Start Base Class** attribute).

It is highly recommended that you create custom object views required for the survey in the context of the survey configuration in the **Surveys** tab. You can define multiple custom object views for the custom object class. Each custom object view should have a unique name. Only one custom object view can be assigned per object class to a view scheme. The configuration of a custom object view is not mandatory.

To create a custom object view for the survey, right-click the survey node  and select **New Object View** . The custom object view  is displayed below the survey node  .

Custom object views should be defined according to the standard conventions described in this reference manual. For information about the configuration of a custom object view, see the chapter Configuring Object Views.

Making the Survey Class Searchable

Survey classes may be configured to be searchable in the **Simple Search** functionalities. A custom selector, custom object view, and custom editor must be configured for the survey class.

The following should be specified in the class setting of the survey class:

- Survey classes may be configured to be searchable in the **Simple Search** functionalities. A custom selector, custom object view, and custom editor must be configured for the survey class. The following should be specified in the class setting of the survey class:
  - **Selector Definition** attribute must specify the custom selector defined for the survey class
  - **Object View** attribute must specify the custom object view defined for the survey class
  - **Edit View** attribute must specify the custom editor defined for the survey class
  - **Searchable** attribute must be set to `True`
  - **Preview Properties** attribute and **Icon** attribute should be defined

Configuring Class Settings for the Custom Survey Class

The configuration of class settings allows you to specify information about the standard or custom object view to implement for the source object class. This will allow users executing the survey to access the relevant information about the object that is the target of the survey in the **Workflow Activities** views.

For example, if users are evaluating applications in the context of a survey object created for the custom object class Windows7Readiness, then they may need to navigate to the application for which they are providing information. If no class settings are defined, then users cannot navigate to the application in the workflow. In this case, the **Navigate to Artifact** option in the **Workflow Activities** views will provide navigation to the object view for the current workflow step.

It is highly recommended that you create class settings required for the survey in the context of the survey configuration in the **Surveys** tab. You can define multiple class settings for the custom object class. Each class setting should have a unique name. Only one class setting can be assigned per object class to a view scheme. The configuration of a class setting is not mandatory.

To create a class setting for the survey, right-click the custom survey class node and select **Add New Class Settings**. The class setting is displayed below the custom object class node.

Please note that when a custom object class is created, the custom object class will automatically be displayed below the **Class Settings** node in the **Presentation** tab only after Alfabet Expand has been closed and reopened.

Any class setting you create for a survey will then be displayed below the relevant custom object class under the **Class Settings** node in the **Presentation** tab in Alfabet Expand.

The class setting should be defined according to the standard conventions described in this reference manual. The following information is available to help you: For a general description about how to create a custom object class property, see the section Configuring Class Settings for Object Classes and Object Class Stereotypes in the chapter Configuring User Profiles for the User Community.

Appendix 1: Glossary

This glossary defines terms that are often used in the Alfabet Expand Online Help or when working with Alfabet Expand.

activity monitor 

An activity monitor is a type of monitor that alerts subscribed users about changes that have been made to objects in a specified object class. The monitor owner must specify a set of properties that are to be monitored and a set of users that are to be alerted if the monitor is triggered. These users as well as the monitor owner will be informed via email notification if a specified attribute for any object in the class is changed. Monitoring is typically performed in regular intervals over a specific period of time.

Alfabet query

An Alfabet query is a means to efficiently search and retrieve information in Alfabet by means of object attributes and relationships. Alfabet queries are based on a class-oriented query language and may be configured in a variety of contexts in Alfabet, including rule-based permissions, pre- and post-conditions for workflow steps, full-text searches, configured reports, computation rules, notification monitors, and consistency monitors, for example. Typically, an Alfabet query is defined for a base class. However, it can also be defined to traverse object classes.

As an alternative to the Alfabet query language, native SQL queries may be specified for many of the configurable functionalities in Alfabet.

analytics dashboard

An analytic dashboard is an ad-hoc information-rich data visualization designed by a user based on the embedded third-party tool DevExpress® Dashboard. One or more dashboard items such as charts, scatter charts, grids, cards, gauges, pivots, range maps, treemaps, etc. can be added to the analytics dashboard and filtering options such as combo-boxes, list boxes, and tree views can be leveraged. A configured analytics dashboard data provider is specified for the analytics dashboard in order to fetch the data to display in the analytics dashboard. Analytics dashboards may be shared with other users.

architecture element

An architecture element is an object in the inventory defined to capture the as-is architecture.

archive object

An archive object is a snapshot of a deleted Alfabet object. When an Alfabet object is archived, a ZIP file is created containing HTML files that display the object profile for the archived object as well as the object

profiles of its dependent objects. Each archived object profile displays a preconfigured set of page views, whereby the visibility of these views will depend on the class setting configured for the object class. If a page view displays dependent objects, a user can click the dependent object in the HTML view in order to open another HTML file showing the archived object profile of the selected dependent object.

Alfabet objects are typically archived by a solution administrator. The ZIP file may be downloaded to a local disk and extracted. The relevant HTML file can then be viewed in a browser window. An archive object will be created for each culture setting supported by your enterprise.

aspect evaluation

An aspect evaluation is a qualitative assessment of the performance of applications or components assigned to one or more respective application groups or component groups according to defined evaluation criteria. Because an application, for example, may be a member of several different application groups, different qualitative assessments of the same application using the same evaluation criteria are possible for each application group that the application is assigned to.

For example, the component TradeNet may be relevant for different purposes in the enterprise architecture. The component may be suitable to varying degrees both as a business intelligence solution and as an OLAP database. An aspect evaluation would allow you to examine components in a component group based on specific aspect evaluation types, such as business importance or usage. Like conventional evaluation types, aspect evaluation type comprises one or more indicator types that are used to evaluate objects.

An aspect evaluation is based on one or more evaluation types, which are then assigned as aspect evaluation types to the object classes Application or Component. Like conventional evaluation types, aspect evaluation types comprise one or more indicator types that are used to evaluate objects.

Aspect evaluations are currently only available for the object classes Application or Component.

assignment

An assignment is a task that is defined for a selected object and assigned to a specific user. The assignee is expected to provide the required input for the object by a specified due date. Assignments can be defined to be optional or mandatory. Email notifications may be configured to be sent in the context of the assignment capability.

authorized user

An authorized user is the Alfabet user that has primary responsibility for an object. The authorized user has Read/Write access permissions to the objects that he/she is defined to be the authorized user of. The authorized user is often referred to as the owner of the object and the objects that he/she owns are commonly referred to as his/her personal objects.

The authorized user may specify another user to be a deputy for any object that he/she owns. Any user that is defined as a member of an authorized user group will automatically have authorization to the objects assigned to the authorized user group.

In addition to authorized users, the concept of roles allows persons and organizations with a functional relationship to an object to be defined.

authorized user group

An authorized user group is a user group that has been assigned to an object. Like the object's authorized user, all users in the authorized user group have Read/Write access permissions to the object. A user group may have an unlimited number of subordinate user groups.

A solution designer may configure the Inheritance and/or propagation of access permissions for authorized user groups. If the inheritance of access permissions has been specified, then all user groups in the user group hierarchy that are descendant to a user group should have the same access permissions to that object. If the propagation of access permissions has been specified, then all user groups in the user group hierarchy that are ascendant to a selected user group should have the same access permissions to that object.

base class

The base class is the object class for which a user is seeking results for. For example, a base class is relevant for an alfabet query, native SQL query, or computation rule.

blueprint

A blueprint is a master plan or IT strategy that serves as a guideline for planning business support across organizations in the enterprise. In the blueprint planning process, master planners and strategic planners can refer to a blueprint to plan tactical business supports or strategic business supports in business support maps. The blueprint planning process supports the standardization of business support and efficiency in the roll-out of IT support in the enterprise.

business appraisal

Business appraisal is a means for an enterprise to gain an initial understanding of the alignment between the business and the supporting IT. Business appraisals are defined in the context of a business support map. The definition of business supports is not required to conduct a business appraisal.

The business appraisal is an evaluation of the as-is and to-be support for the business process or domain for a selected organization or market product in regard to a specific operational aspect. Once values have been defined for the indicator types configured for the business appraisal, the gaps between the to-be and as-is support can be assessed allowing the enterprise to determine priorities for future projects or its IT strategy in order to align the business and IT.

business capability map 

A business capability map allows you to define the guidelines to evaluate the business capabilities defined for the enterprise. The performance of domains and business functions associated with a business capability can be evaluated according to specific business capability aspects and evaluation types by a defined group of evaluators. Mandates are not supported in the context of business capability maps.

business case

The business case is defined for a project and provides a structured approach to estimating the investment and operating costs and benefits associated with a project, and computes standard performance measures such as return on investment or depreciated cash flow.

business function 

See functionality.

business service 

A business service is an IT service that can be provided by an application, component, local component, organization, market product, business process, ICT object, or solution building block in order to realize a specific business function. Depending on the solution configuration, applications and components may provide one or more business services for the same business function. A business service thus fulfills a specific business service request that is posed by a business process for that specific business function.

business support

A business support defines an object such as an application that provides support to the enterprise to carry out its business. Business supports typically provide support to business processes, although an enterprise may describe its business support to domains instead. Furthermore, business supports are typically executed by organizations responsible for the business processes/domains. Some enterprises may specify market products instead of organizations. Alfabet supports the definition and analysis of operational business supports, solution business supports, strategic business supports, and tactical business supports.

business support map

A business support map is the graphic visualization of the business support provided by specified objects in order to support the planning of the short-term, medium term, and long-term to-be architecture. The map is visualized as a matrix with an X-axis and a Y-axis. The X-axis of a standard business support map will display business processes and the Y-axis will display organizations that are supported. In some industry segments, it is more relevant to analyze the business support for market products than for organizations. If

this is the case, market products may be configured for the Y-dimension of the business support. Furthermore, some enterprises may describe business supports to provide support to domains of the business rather than business processes. If this is the case, domains may be configured for the X-dimension of the business support.

The matrix cells consist of the business supports that support the corresponding X-axis object and Y-axis object. In the context of master plans or IT strategies, business support matrices may display operational business supports, tactical business supports, strategic business supports. In the case of a solution map, solution business supports will be displayed.

A business support map may be specified for an IT strategy or master plan that is specified as a blueprint. The definition of the business support map for a blueprint strategy or master plan may be embedded in another business support map to serve as a guideline for planning and standardizing business support across organizations when planning the enterprise's business architecture.

Alfabet supports the configuration of customized business support matrices to allow large numbers of business supports to be simultaneously captured for a specified set of organizations/market products or business processes/domains.

class

See object class.

class key

A class key is the specification of one or a combination of standard and custom object class property for an object class. Typically, class keys are defined to implement uniqueness constraints. A standard or configured class key provides an enforcement mechanism for the definition of standard properties and custom object class properties when an object is created. In this case, the combination of properties must be unique for all objects in the object class. If the uniqueness constraint is violated by a user when defining data, a message will be displayed prompting the user to provide a unique combination of values. For example, class keys for the object class Application could require a unique combination of values for the object class properties Name, Version, and Object State.

Index creation is a side effect of a class key definition. For each class key that is configured for the object classes in Alfabet Expand, an index is created. The definition of class keys can therefore be used to speed up query-based searches and thus increase performance.

Please note the following:

- Multiple class keys can be defined as needed for an object class. All custom class keys are public class keys.
- Private class keys  cannot be edited or deleted. Private class keys are typically preconfigured for indexing purposes.
- Protected class keys  may be edited but not deleted.
- Public class keys  may be edited and deleted.

class setting

A class setting is a specification about an object class or object class stereotype. A class setting is associated with a view scheme which is assigned to a user profile. The class setting therefore specifies what the user can see and do with an object class in the context of the user profile that he/she uses to access Alfabet. The class setting includes such information as which standard or custom object view is displayed, whether users will enter data in a standard or custom editor vs. a standard or custom wizard, whether a standard or custom selector will be used to find objects in the object class, and which standard and custom object class properties will be hidden from view.

Multiple settings can be defined for an object class. However, only one class setting per object class can be assigned to a view scheme so that only one class setting will be available for an object class in a given user profile.

color rule

A color rule is based on one or more Alfabet queries or native SQL queries that are configured to color a found set of objects in standard Alfabet business support maps and diagrams. If the color rule functionality is activated for a business support map, all activated color rules will be executed and the matrix cells colored accordingly. In order to visualize color rules in diagrams, color rules must be assigned to a diagram view. When the diagram view is selected in a diagram, all activated color rules will be executed and the diagram objects will be colored accordingly. The color rules are automatically added to legends where they are applicable.

Additionally, color rule specifications can be defined for configured reports and color instructions can be configured to color cells based on property values in configured reports and object cockpits.

consistency monitor 

A consistency monitor is a type of monitor that supports the system-wide maintenance of objects in the Alfabet database. The consistency monitor is specified to periodically search for inconsistencies among objects. Each consistency monitor is based on an alfabet query or native SQL query that defines the object classes targeted by the query as well as the inconsistent properties to be detected. If an inconsistency is found by the query, the monitor alerts the authorized user of the object via an assignment about the inconsistency. The timely completion of the assignment triggered by a consistency monitor can be tracked by the solution administrator.

contract

A contract is a legal document that stipulates the terms of agreement between organizations buying products and services and organizations or vendors providing the products and services.

A contract may be referenced as a master contract by multiple contracts.

cost type

A cost type is a classification of costs. Cost types are defined by the enterprise to ensure comparability in the definition and evaluation of the investment and operation costs associated with ICT objects, applications, deployments, projects, and service products. Cost types are critical for the definition of business cases as well as for cost planning for projects. An unlimited number of subordinate cost types may be defined for any cost type in order to allow for bottom-up cost estimation and analysis.

culture

A culture constitutes the base configuration of the default primary language displayed on the user interface when the user first logs in as well as the date, time, and number formats, etc. used to capture and render dates, times and numbers in the Alfabet user interface.

custom editor

A custom editor is a customized data entry view that allows users to capture data for the custom object class properties that have been created for a protected or public (custom) object class. A custom editor is typically configured for the needs of users working with a specific user profile. A custom editor can only be created for an object class that has custom object class properties defined. A custom editor cannot be created for a protected class that has no custom object class properties defined.

A custom editor typically consists of one or more tabbed pages that are automatically appended to the standard editor available for the object class. The solution designer designs the interface controls such as combo boxes, checkboxes, etc. that users need to capture the required data. Additional text fields or URLs may be included in the custom editor in order to provide users with additional information to help them define data. All captions created for the interface controls can be translated for the languages implemented in the Alfabet interface.

Custom editors are displayed in the context of standard data capture editors but can also be implemented in wizards and workflows configured for the enterprise. Multiple custom editors can be created for an object class, but only one custom editor can be assigned to a class setting. Therefore, only one custom editor can be implemented per object class per user profile.

custom property

A custom property is an object class property that has been configured in order to capture enterprise-specific data for a specified object class.

Multiple custom properties can be created for each object class. Like private properties, custom properties (also referred to as public properties) can be excluded from a class setting and therefore be hidden for users accessing Alfabet with the associated user profiles. Custom properties can also be included in the definition of a class key requiring users to enter unique values for a set of standard and custom properties when defining objects in the object class.

In order for users in the user community to define values for the custom properties, the properties must be associated with data entry fields in custom editors. Custom properties can be displayed in object views and

object cockpits. Additionally, custom properties can be used to search for objects in Alfabet 's search functionalities and can be specified in alfabet queries and native SQL queries that are used in, for example, configured reports.

date monitor 

A date monitor is a type of monitor that alerts subscribed users about approaching dates that have been defined for objects in a specified object class (for example, the approach of an object's start or end date). Two kinds of date monitors are available in Alfabet: object-specific date monitors and system-wide date monitors that target all objects in a specified object class.

Object-specific date monitors are defined by an individual user to keep track of the approach of a date for specified objects. The monitor owner must specify a set of properties that are to be monitored and a set of users that are to be alerted if the monitor is triggered. These users as well as the monitor owner are informed when the target date approaches for the specified attribute and can then decide upon the appropriate action to take. Monitoring is performed in regular intervals over a specified period of time.

In addition to the conventional Alfabet date monitors, system-wide defined date monitors can be configured for an object class. When a specified date approaches, all authorized users responsible for objects in the relevant object class will be sent notifications per email asking them to review the objects that they are responsible for.

deputy

A deputy is an Alfabet user granted Read/Write access permissions to an object in order to act on behalf of the authorized user.

diagram view

A diagram view is a configuration that is associated with a diagram. It allows users to superimpose qualitative information - such as aggregated indicators or attribute values - associated with these architectural elements. Diagram views can be implemented in diagrams displaying applications, business processes, devices, domains, frameworks, platforms, and solution building blocks. Multiple diagram views may be defined and made available for a diagram. A diagram view may be reused for multiple diagrams.

discussion group 

A discussion group is a preconfigured group of users that have been defined permission to discuss objects in specified object classes.

domain glossary

A domain glossary allows users to define and search for domain-specific terminology defined for objects that are assigned to a domain. Domain-specific terminology includes aliases and descriptions of the objects.

The solution designer must specify a search group including an alfabet query for each object class that can be associated with a domain and for which users will be defining glossary items. Possible classes include: Application, Business Function, Business Object, Component, Functional Module, ICT Object, Business Process, Standard Platform, and Vendor Product.

enterprise architecture

An enterprise architecture is a comprehensive method and framework used to manage and align an enterprise's business processes, organizations, information technology (IT), software and hardware, local and wide area networks, people, operations, and projects with the enterprise's overall strategy.

enterprise release

An enterprise release is the process in which changes to the enterprise architecture are planned and managed via a governed process. For each enterprise release, a set of milestones are specified that constitute the stage gates for the approval and execution of the release and thus allow the enterprise release cycle to be managed.

enterprise release item

An enterprise release item expresses the deliverables that will be provided for an enterprise release. Typically, an enterprise release item is based on a project that has been defined to provide the architectural change. Alternatively, enterprise release items can be based on applications, components, or standard platforms. In this case, the architecture element constitutes the deliverable to the enterprise release.

enumeration

An enumeration is a set of preconfigured enumeration items available to users when defining an object class property in Alfabet. An enumeration is associated with a standard or custom object class property. Enumerations are reusable and the same enumeration may be assigned to multiple custom object class properties in different object classes. An enumeration has two or more enumeration items.

The enumeration items represent the values that users can select in a combo-box, checked combo box, list box or checked list box in a standard or custom editor or in standard object filters available in relevant views. For example, an enumeration could consist of the four enumeration items `Mainframe`, `Client Server`, `eBusiness`, and `Other` that are assigned to the custom object class property `Application Type`.

There are two types of enumerations displayed in the **Class Model** explorer in Alfabet Expand:

- A protected enumeration  is an enumeration that has been preconfigured by Alfabet Expand. A protected enumeration cannot be deleted but the enumeration items can be modified according to the needs of your enterprise.
- A public enumeration  is a custom enumeration created by your enterprise. A custom enumeration can be created and configured for custom object class properties of the type `String`, `Text`, `Real`, `Integer`, or `StringArray`. A custom enumeration can be edited and deleted, if necessary.

evaluation type

An evaluation type bundles one or more indicator types for use in the evaluation of a specific dimension of an object's performance. Users define an indicator for each indicator type bundled in the evaluation. For example, typical evaluation types could be Complexity and Standardization Status. The evaluation type Complexity might have the indicator types Number of Interfaces, Number of Modules, and State of the Art, and the evaluation type Standardization Status might have one indicator type also named Standardization Status.

An evaluation type may be configured once and reused for multiple object classes. In this way, all system-related classes such as Application, Component, and Standard Platform, for example, could be evaluated for their complexity, standardization, etc.

Evaluation types can also be grouped into prioritization schemes that, in turn, may be implemented as axes in portfolios.

Access to the evaluation types used in Alfabet evaluations can be controlled via user profiles. A user can view any evaluation type that has either no user profile defined or the same user profile as that which he/she is currently logged in with.

Evaluation types can be used in Alfabet queries and native SQL queries written for configured reports. Evaluation types are configured in the Configuration module.

express view

An express view is a link to a specific Alfabet view or explorer displaying data that allows individuals inside or outside of the Alfabet user community to view Alfabet information. When the express view is created, an email notification is automatically mailed to the specified recipient who receives a URL that allows him/her to access the current page view in Alfabet.

federated architecture

A federated architecture is an architecture that is typically managed in silos. Such an architecture allows a holding company to structure and communicate the elements that are shared across the enterprise, the elements that are common to some but not all organizations in the enterprise, and the elements that are exclusive to a specific organization. The assignment of mandates to Alfabet objects allows the holding company to structure the objects in the enterprise architecture and regulate their visibility to only those users who should see them.

functionality

A functionality is a set of capabilities that allow users to carry out a specific tasks in the Alfabet solution. The functionalities (technically called business functions) available in Alfabet Expand are preconfigured and their content cannot be redefined.

Functionalities are made accessible to a user profile via menu items or a navigation page. For each user profile, the assigned view scheme determines the visibility of specified object classes as well as the exclusion of custom and non-mandatory standard properties, workspaces and page views, and functionalities available in toolbars in page views and object views.

icon gallery

An icon gallery is a configurable collection of icons that can be used to graphically visualize the quantitative value of indicators in evaluations and diagrams. An icon gallery is typically a set of mutually related images whereby each icon represents a specific value range. For example, the three stages of a traffic light signal could represent 3 different indicators.

icon group

An icon group allows custom and standard icons to be bundled and made available in an icon gallery.

ICT object

An ICT object (ICT = Information and Communication Technology) is an abstract object that can represent either an architecture element (for example, an application, solution building block, component, device, standard platform, or vendor product) regardless of its versioning, or multiple architecture elements that are related for business or financial reasons.

An ICT object is owned by an organization that is usually responsible for the budget of the architecture elements assigned to the ICT object. As such, ICT objects are key to enterprise strategy and master planning. The use of ICT objects is advantageous in that the planner must not initially commit him/herself to a certain version of, for example, an application. Later, at the stage of detailed planning, the ICT object can be replaced by a specific concrete version.

Object class stereotypes may be configured for the class **ICT Object**.

inactivity monitor

An inactivity monitor is a type of monitor that alerts subscribed users about the absence of activity occurring to objects in a specified object class. The monitor owner must specify a set of objects that are to be monitored and a set of users that are defined as listeners to be alerted if the monitor is triggered. The monitor owner is typically the user responsible for the objects defined for the monitor. The monitor owner as well as the listeners will be informed via email notification if a specified object has not been edited or

reviewed within a specified period of time. If the monitored object does not need to be changed, the monitor owner can mark the object as reviewed.

income type

An income type is a classification of income. Income types typically represent benefits in a business case and are defined by the enterprise to ensure comparability in the monetary evaluation of activities and services for projects. Income types are critical for the definition of business cases in Alfabet.

indicator

An indicator is the qualitative or quantitative measurement of an object's performance. Indicators may be entered manually, by means of an external system interfacing with Alfabet, or computed or aggregated within Alfabet. Each indicator is based on an indicator type that defines the dimension and scale of measurement. One or more indicator types are bundled in an evaluation type and may be implemented in evaluations, prioritization schemes, and portfolios.

indicator type

An indicator type defines a dimension of measurement regarding the performance of an object in the IT landscape. The indicator is the value defined for an indicator type in the context of an object in the IT landscape.

A single indicator type or multiple indicator types can be bundled in an evaluation type that is used to evaluate an object. For example, the indicator types Number of Interfaces, Number of Modules, and State of the Art could be assigned to the evaluation type Complexity, and the indicator type Standardization Status could be assigned to the evaluation type also named Standardization Status.

Each evaluation type may have one indicator or more assigned to it. An indicator can be either:

- manually entered by a user
- selected from a predefined set of values by a user
- calculated by Alfabet according to defined computation rules
- calculated based on customer-specific code provided by Alfabet
- imported via an interfacing system such as ADIF

Indicator types having a predefined set of values may be associated with an icon gallery, allowing for indicators to be visualized in diagram views as well as other configured reports by means of an icon rather than a numeric value.

Indicator types are configured in the Configuration module in Alfabet.

information flow 

An information flow describes the exchange of business data between source and target applications, components, devices, or peripherals. The interface logic that is required for the exchange of information is an integral part of the information flow. Information flows between applications are realized through concrete interface systems which are typically embedded in the application's platform as a platform component. Within an application's platform, a local component can also be specified as a source or target interface enabling the data transfer of the information flow. An information flow may possess source and target interfaces as well as interface systems. Information flows can be classified by the connection type, connection method, connection frequency of the information exchange, and the connection data format describing the data exchange.

IT landscape

The IT landscape describes the entirety of architecture elements and their relationships in the enterprise, including the application architecture, business architecture, information architecture, technical architecture, and deployment architecture.

lifecycle

A lifecycle describes the succession of stages that an architecture element goes through. Many objects (for example, applications, components, standard platforms, business supports) in Alfabet have a lifecycle, although a lifecycle does not have to be defined for all objects. A lifecycle is comprised of lifecycle phases that describe the object's status of activity or production over time. Each lifecycle phase is aligned with its proceeding and succeeding lifecycle phase.

The lifecycle definition also includes the definition of the object's active period. The active period of an object is considered the period that the object is in production. Therefore, the active period of an object corresponds to the object's start and end dates. The active period may be configured to be aligned with one or more specified lifecycle phases that represent the period when the object is in production. Typically, the object state of the object will be specified as Active in the period between the start and end date.

The lifecycle definitions of dependent objects should be aligned with the lifecycle of the object that they have been defined for. For example, the lifecycles of any local components, information flows, and business supports should be aligned with the lifecycle of the application that they are assigned to. In the case of components, the lifecycles of any local components, information flows, and technical services should be aligned with the component's lifecycle.

Furthermore, the lifecycle definition for an application may include the specification of predecessor and successor versions and the lifecycle definition of components may have successor versions. Successor versions will be assigned per default to the same ICT object as the original application/component, but this can be modified, as needed.

lifecycle phase

A lifecycle phase describes a status of activity or production in the lifecycle of an object. Typical lifecycle phases include, for example, Evaluation, Pilot, Production, Limited Production and Shut Down. The active

period of the lifecycle is the period that the object is in production and is thus aligned with the object's start and end dates. One or more lifecycle phases may be left undefined. In this case, they are skipped. Each lifecycle phase is aligned with the proceeding and succeeding lifecycle phase that has been defined.

Lifecycle phases are configurable per object class. The number of lifecycle phases, their sequence, and their mapping to the active period of an object can be specified per object class by a solution designer. The active period may be mapped to one or more consecutive lifecycle phases. The active period as well as the object's start and end dates will thus align with the start date of the first lifecycle phase mapped to the active period and the end date of the last lifecycle phase mapped to the active period.

lifecycle status

See lifecycle phase.

locale text template

A locale text template is a localized version of a standard or custom text template in which the text can be translated to another language. Text templates can be generated in multiple languages, allowing the translated email notifications generated within Alfabet to be displayed for a selected culture.

mandate

A mandate is a means to organize and structure the federated architecture of a holding company. The assignment of mandates to objects allows the holding company to structure the objects in the enterprise architecture in order to regulate visibility to objects across some or all subsidiaries. Only users explicitly assigned to a mandate will see objects with that mandate definition. An object that has not been assigned to a mandate is considered not to be owned by a mandate and is thus visible throughout the holding company to users with relevant access permissions.

The use of mandates in the Alfabet solution is optional. If mandates are implemented in an enterprise, the visibility of an object with a mandate assignment will take precedence over other concepts of access permissions in Alfabet. For example, an authorized user of an object must be assigned the relevant mandate to access the object that he/she is the owner of.

Within the context of mandates, the conventional rules governing access permissions apply. Thus, a user assigned to a mandate will only have Read/Write access permission to the objects made visible by the mandate if he/she has authorized access to the object as an authorized user, deputy, member of an authorized user group or discussion group or via rule-based access permissions, workflow contributor or assignee of an assignment.

mandatory property

Each object class in the class model has a preconfigured set of properties that serve to semantically describe the object class. Some standard properties are mandatory properties and are highlighted with a red star in editors. Mandatory properties are highlighted yellow in the class model explorer.

No enforcement mechanism is implemented if a mandatory property is undefined unless the property is included in a standard or configured class key that enforces the unique definition of a new object. If the mandatory property is included in a class key, then an error message will be displayed if the property is not defined.

monitor 

Alfabet provides a variety of monitors to alert users about changes that have occurred to specific objects and may require further activity, reviews that did not occur as intended, or transactions that were planned to occur according to the documented plans. Such monitors alert the subscribed users through e-mail notifications. Monitoring is performed in regular intervals for a specific period of time. Alfabet currently provides activity monitors, date monitors, inactivity monitors, notification monitors, and consistency monitors.

monitor template

A monitor templates is configuration file that allows you to specify the use of monitors by the user community. You can enable or disable a specific monitor template, thus allowing or disallowing monitors to be created by users for the object class that the monitor template is associated with. Monitor templates are available for activity monitors, inactivity monitors, and date monitors.

A monitor alerts user about changes that have occurred to specific objects which may require further activity (activity monitor), reviews that did not occur as intended (inactivity monitor), or transactions that were planned to occur according to the documented plans (date monitor). Such monitors alert the subscribed users through e-mail notifications. Monitoring is performed in regular intervals for a specific period of time.

The monitor template allows you to specify the object classes for which monitors can be created, the properties that can be monitored for an object class as well as the monitored contexts that users can select to be monitored. Monitored contexts allow users to monitor a specific context, such as the lifecycle or information flows associated with an object. Monitor contexts are predefined.

navigation page

Navigation pages allow an enterprise to configure a pages with links and information for the enterprise's users in order to efficiently guide them to specific functionalities in the Alfabet interface. The navigation page that serves as the start page is assigned to a user profile. Navigations page can be configured to provide a variety of different kinds of support to users in their work in Alfabet. A navigation page can be freely configured and could include, for example, links to specific functionalities in Alfabet, links to other navigation pages, informational text or images about enterprise-specific workflows in the Alfabet solution, standard framework approaches like Zachmann, or URL links to internal documents or the Web.

The technical term for a navigation page is a guide page. One guide page can be assigned to a user profile as the start page for the user profile.

notification monitor

A notification monitor is a type of monitor that allows email notifications to be automatically triggered based on configured Alfabet queries or native SQL queries. The queries specify the targeted objects and their object class properties as well as the users who shall be notified about the objects found by the queries.

object

An object is a constituent of the Alfabet architecture that generally describes an element in the enterprise architecture. An object belongs to an object class defined for the Alfabet meta-model. Specific objects may also be referred to as architecture elements, artifacts, or instances. Many objects in Alfabet have a start and end date that specifies the planned period of activity for the object, a lifecycle definition, and an object state that distinguishes an object as actively used, planned to be used, or to have been used in the past.

object class

An object class is a construct that semantically describes the objects that are instantiated for that class. Object classes in the class model have a specified set of standard object class properties and may also have custom properties that have been configured by a solution designer. Object classes typically reference other object classes, thus creating a semantic network that can, for example, describe the enterprise's IT landscape.

The Alfabet class model constitutes a standard set of object classes. Please note the following information about the types of classes available:

- Private classes  cannot be edited but are visible in the class model in order to make them available for definition in an Alfabet query.
- Protected classes  may have both private properties  that cannot be edited and protected properties  that may be edited. Furthermore, public (custom) properties  may be created for a protected class.
- Public (custom) classes  should only be created in conjunction with Software AG Support . Any class that is not part of the standard class model is a public class. Public (custom) properties  must be created for a public class.

object class property

Each object class in the class model has a preconfigured set of properties that serve to semantically describe the object class. Some standard properties are mandatory properties and are highlighted yellow in Alfabet editors. Mandatory properties are highlighted yellow in the class model explorer.

Please note the following about the types of object class properties available:

- Private properties  cannot be edited. Private properties can be excluded for specified user profiles.
- Protected properties  are typically standard properties with limited editability. For example, you can edit the caption or hint attributes and specify whether a protected property can be translated. Protected properties can be excluded for specified user profiles.
- Public properties  are also referred to as custom properties and are typically created by a solution designer. Thus, custom properties may be defined, edited and deleted in accordance with the needs of the enterprise. Like private and protected properties, custom properties can also be excluded for specified user profiles.

object class stereotype

An object class stereotype is a sub-classification of an object class. A permissible object class can have multiple object class stereotypes, each of which captures a specified set of attributes, reference data, and class configurations. For example, the object class Application that may have the object class stereotypes Business Applications and Technical Applications.

Only a limited number of object classes support the configuration of object class stereotypes.

object cockpit

An object cockpit provides users with an immediate and transparent overview of data for a selected object. It is as an abbreviated and focused presentation of object data, typically from a particular perspective such as an architecture perspective or a strategy perspective.

Multiple object cockpits can be available per object profile. For example, one object cockpit for the object class Application might display data relevant for understanding the application in the as-is architecture, another cockpit might display data relevant to master planning issues, and a third cockpit might display relevant data for cost and budget issues. The object cockpit is a configuration that is available in addition to the more comprehensive object profile.

An object cockpit can be created and configured in the context of a custom object view. Although an object view may have multiple object cockpits defined, it is possible to hide object cockpits in the context of the view scheme configuration. In this case, only the object cockpits visible for the view scheme will be available to the associated user profile.

object profile

The object profile summarizes information that is relevant to a selected object. The object profile typically displays object class properties and their values for the object as well as workspaces with views and reports relevant to the selected object. Users can open the available views and define or edit the data about the selected object.

Typically, object profiles are configured specifically for the needs of the user community. Thus, various object profiles with different data and functionality may be available for the same object class, depending on

the user profile with which users access Alfabet. Each object profile may have multiple object cockpits associated with it that have been configured to visualize a specific set of data about the object.

The object profile can be configured in the context of a custom object view. It is possible to hide the object profile in the context of the view scheme configuration. In this case, only the object cockpits visible for the view scheme will be available to the associated user profile.

object state

An object state describes the operational status of an object in the enterprise. The object state indicates whether an object is actively used, planned to be used, or has been used in the past. Because an object's start and end dates specify the planned period of activity for the object, the object state should be changed from **Plan** to **Active** once the object's start date is reached. Equally, the object state should be changed from **Active** to **Retired** when the object's end date is reached. If the lifecycle concept is available for an object class the object's start and end dates will initially be aligned with the active period of the object.

An object's object state can be changed by a user with Read/Write access permissions. For objects like applications or components, relevant object dependencies must be taken into consideration when the object state is changed. For applications, for example, the user changing the object state should consider whether the object state should be propagated to the application's associated information flows or business supports.

The number of available states Retired, Active, and Plan cannot be changed, however the names of the preconfigured object states can be customized per object class.

object view

An object view is the configuration object that typically consists of an object profile as well as any object cockpits that have been configured for the object view. A standard object view  is available for all object classes that require an object profile. The object profile is a standard overview that displays the basic information about an object with topical workspaces grouping all standard page views available for the object class. Object cockpits are not available in standard object views. Multiple custom object views  may be configured for an object class or object class stereotype, whereby only one object view can be assigned per class setting per user profile.

The solution design can specify which standard and custom object class properties, page views, configured reports, and object cockpits should be visible or hidden for a custom object view. Each custom object view may include the standard object profile or a customized object profile as well as multiple configured object cockpits. The object cockpit is typically a focused and abbreviated set of data for a particular topic that includes pertinent attribute information as well as a few relevant page views or configured reports that are embedded in the object cockpit.

operational aspect

An operational aspect is a facet of the business that may be supported by the IT. Standard classes that represent operational aspects in Alfabet include Brand, Customer Segment, Market, and Sales Channel although other object classes or object class stereotypes may be implemented as operational aspects.

Multiple operational aspects can be created for each configured aspect class to express the individuals facets of business that require support. For example, aspects for the class Market could be Capital Markets, Retail Banking, Emerging Markets, and Direct Banking.

Operational aspects are relevant in the context of business support planning and analysis and allow the planner to understand the aspects of the business that an organization, market product, business process, or domain contribute to. Understanding the contribution of individual business supports to operational aspects of the business sheds light on where future support is required in order to realize the enterprise's IT strategy. Operational aspects can be defined for operational business supports, tactical business supports, strategic business supports, and solution business supports. Potential gaps or redundancy in the support of operational aspects can be understood and analyzed in the context of business support maps.

Please note that the concept of operational aspects has no association with the concept of aspect evaluations, which are implemented to assess the performance of applications and components.

organization 

An organization describes an administrative or functional unit in the enterprise. Organizations form a self-referential hierarchy. An organization may have an unlimited number of subordinate organizations but only one ascendant organization. An organization may have primary responsibility for an object in the same way that an authorized user has or it may by defined as having an important role in relation to an object. Organizations are supported in their business activities through the business support and business services provided by applications.

Object class stereotypes may be configured for the class **Organization**.

prioritization scheme

A prioritization scheme is a weighted composite of a set of evaluation types. A prioritization scheme is typically used to determine a prioritized ranking for a set of objects, for instance during budgeting and prioritization of projects or to define the axis of a portfolio.

Prioritization schemes aim at aggregating evaluations along complementary evaluation dimensions. Whereas evaluation types are aggregates of indicators for semantically-related performance measurements of objects, prioritization schemes are typically aggregates of semantically-unrelated (or loosely related) performance measurements for objects. However, prioritization schemes are assigned to a portfolio usually describe performance along dependent dimensions.

project

A project is an activity undertaken in order to achieve a specified goal in the IT landscape. Typically, projects are based on configured project stereotypes. A project may have unlimited sub-projects (projects of the subordinate project stereotype) but only one ascendant project (a project of the ascendant project stereotype). Projects may be grouped into project groups as well as assigned to buckets for budgeting and prioritization purposes.

Depending on the configuration defined for a project stereotype, it may be possible to bundle demands to projects, document the as-is architecture that may be impacted by the project, plan the to-be architecture for the IT landscape, plan and assess the project's costs in a business case, capture the skill requests and resource requests needed for the project and manage the project resource plan, and monitor project target dates via milestones.

Furthermore, you can also work with project scenarios based on an existing project in order to plan alternative what-if scenarios in terms of costs, resources, scheduling, and to-be architectures. Finally, project baselines may be created for a project in order to understand the scope of changes that have occurred in a project.

project baseline

A project baseline captures the scope of its base project at the time that the project baseline is created. The project baseline provides a ReadOnly view of the base project's data and allows the deviation of the base project from its original scope to be tracked over time in terms of the total project costs and income, skill request and resource request costs, evaluations, scheduling and achievement of project milestones, and the changes made to the to-be architecture.

project solution

A project solution allows alternative projects to be drafted and considered. Multiple project solutions may be defined for a specific project, but only one project solution can be selected as the approved project solution. Once a project solution is selected, it is considered a project in its own right and replaces the original project that it was defined for in the project hierarchy. Project scenarios are an extension of the project solutions concept but provide much more flexibility and functionality in the planning and implementation of what-if scenarios.

project scenario

A project scenario is an alternative what-if scenario to be explored, planned, and potentially implemented for the project. The project scenario may target alternative to-be architectures, project costs and income, the scope of skill request and resource request required for the project, various evaluations of different aspects of the project, and different versions of project dependencies and time schedules.

A project scenario is an independent copy of the project and includes its start date and end date, custom properties as well as the base project's business case as-is architecture, to-be architecture, requested skills and resources, value nodes, contract deliverables, and input demands. All subordinate projects will also be copied.

Each project scenario can be further defined and modified without impacting the base project. ´The project scenario can be merged at any time to the base project in order to update the base project. The project scenario as well as the base project continue to exist and both can be further modified, if needed.

project stereotype

A project stereotype represents a level in the project management framework. The project hierarchy is made up of an arbitrary number of object class stereotypes defined for the class `Project`. An unlimited number of objects can be created in Alfabet for each project stereotype.

The project hierarchy can be configured as a linear hierarchy or as a branched tree structure that allows complex project structures and hierarchies of stereotypes to be captured. Each project stereotype may define multiple subordinate project stereotypes. The top-level project stereotype represents the most abstract level of a project and the lowest level project stereotype represents the most granular level of project tasks that must be acted upon in order to realize the project. For example, a typical linear project might be made up of the following project stereotypes: Level 1: Program, Level 2: Statement of Work, Level 3: Project, Level 4: Sub-Project, Level 5: Project Activity.

The name, number, and hierarchical ordering of the project stereotypes are configurable. A project stereotype is similar to an object class. Like an object class, the projects based on a project stereotype are instances of the project stereotype. For example, the project stereotype Project Activity will have objects called project activity. Each project stereotype may have only one ascendant project stereotype and only one subordinate project stereotype. However, projects of a specific stereotype do not have to be to be associated with a project of the ascendant project stereotype nor with projects of the subordinate project stereotype.

The definitions that can be made for each project stereotype must be configured. Therefore the views that are available may differ for each project stereotype in the hierarchy. For example, the configuration will determine for which project stereotype users can bundle demands to projects, document the as-is architecture, plan a to-be architecture, assess alternative project scenarios, track costs via cost centers, and monitor projects via milestones.

query

See alfabet query.

release status

A release status describes the state of approval for or agreement about an object in the enterprise. Typical status values could be, for example, `Draft`, `Described`, `Reviewed`, `Approved`,`Rejected`, and `Retired`. However the release statuses will largely depend on the object class that they describe. For example, the release statuses for an architecture element such as an application, component, or standard platform is typically used to express agreement to the state of the documented information whereas, the release statuses for a planning artifact like a demand or project reflects an approval status. The release status for an assignment describes the state of progress or completion of the task that the assignment is about.

An object's release status can be changed by a user with Read/Write access permissions. For all release statuses that are configured as non-editable release statuses, users will not be able to edit the attributes in the object's editor and page views. Users will see the  icon at the top of the object profile of an object that may not be edited due to its current release status definition.

Release status definitions can be customized per object class.

report

A report is a configured display of data from the Alfabet database. Alfabet provides a number of standard reports, however customized reports can also be configured by a solution designer.

A configured report can either be generated by mechanisms internal to alfabet via alfabet queries or native SQL queries or by means of an external reporting tool that searches the Alfabet database for current results using SQL query language. Alfabet internal reports are based on preconfigured design types such as tabular reports, treemap reports or layered diagram reports. Once a report has been configured, it can be made available to the user community in the Alfabet interface.

resource

A resource is any entity that is needed as a source of support for another entity in the enterprise. A resource may be provided by many different object classes such as an organization, application, device, deployment, etc. A resource is typically requested by a project, service product, or organization.

role

A role defines the functional relationship or responsibility that a user or organization has to an object. A role is based upon a configured role type that is configured for an object class. Roles are defined for informational purposes only and provide detail about users or organizations that may have information about or a stake in the object. The definition of a role for an object does not impact access permissions.

role type

A role type is configured in order to allow a functional role to be defined for objects in a specified object class. Role types can be configured to be explicitly available for a user or organization or both.

rule-based access permission

A rule-based access permission is a rule based on an alfabet query or native SQL query that specifies access permissions for a found set of objects or object class.

service level agreement (SLA)

An SLA is a service level agreement that is defined for a service product. The SLA captures information such as a volume base that is relevant for the service product (for example, Service Desk Support Hours, Target Resolution Time, Defect Backlog Size Limit, Maximum Number of Test Failures, etc). Only one SLA may be assigned to a service product. The service level agreement automatically inherits the authorized user definition of the service product that it is assigned to.

Object class stereotypes may be configured for the object class **Service Level Agreement**. This allows for different attributes to be used for different types of service level agreements.

service product

A service product is a service that is owned by an organization and made available to other entities. A service product consists of one or more service product items, which constitute the service product. Each service product item is associated with an object such as an application, component, ICT object, deployment, device, standard platform, organization, or other service product, which provides the service product item to the service product.

Each service product may have one SLA (service level agreement) assigned to it.

Service products are organized according to the organization that owns them. Each organization and the service products that it owns constitute a service product catalog. Additionally, service products may be structured in one or more service product groups independent of the organization that provides the service products.

A service product may be defined as a contract deliverable for a contract, whereby the service product is consumed by the contract. A service product may be assigned to a market product in order to indicate that the service product is made available via the market product.

service product item

A service product item is an entity that supports a service product. The service product may be constituted by one or more service product items. Each service product item is associated with an object from a permissible object class (such as an application, component, ICT object, deployment, device, standard platform, organization, or other service product) that provides the service product item to the service product.

A name may be defined for the service product item to capture the purpose of the object associated with the service product item. For example, the service product User Support Service might consist of the service product items Application User Support Services which is provided by applications, Deployment User Support Services which is provided by deployments, and Device User Support Services which is provided by devices.

skill request template

A skill request template allows skills to be specified in order to plan resources for a project. A skill request template specifies the head count or man days required for the skill and the expected cost required by the

skill in the context of a particular kind of project. Users making a skill request thus have predefined information that helps to estimate the resources and costs involved if the skill is implemented in the project. Skill request templates can be assigned to a project template in order to streamline the process of project planning.

solution object

A solution object is any architecture element that is proposed in the context of a to-be architecture for a project. Solution objects may be based on objects assigned to the project's as-is architecture or may be created from scratch in the context of the to-be architecture. Solution objects include solution applications, solution components, solution devices, solution information flows, solution local components, solution peripherals, solution standard platforms, solution technical services, and solution business supports. A solution object exists outside the inventory until the architectural changes proposed in the to-be architecture are checked in to the inventory. After check-in, the solution object becomes a real inventory object and will have the object state **Plan**. The object state must be manually changed to **Active** when operation begins.

strategic business support

A strategic business support is a targeted business support defined for an unspecified timeframe in the context of the long-term target architecture. A strategic business support is typically provided by an existing or planned ICT object. However, strategic business support may also be configured to be provided by a virtual ICT object to define an ad-hoc ICT object that does not yet exist in the inventory, a solution building block to describe functional planning as endorsed by TOGAF, or an organization to describe non-IT support such as internal or external services.

technical service

A technical service is a service provided by a component in order to fulfill technical needs that are necessary to support business service requests. A technical service may define technical service operations that support the technical realization of business functions.

Technical services can be defined for components and local components for which the **Component Type** attribute is set to `Service`. When a local component of the type `Service` is embedded into the architecture of an application or another component (of the type `Infrastructure` or `Business`, for example), the technical service operations of the embedded component can be mapped to the business services provided by the application or the local component.

Object class stereotypes may be configured for the class **Technical Service**.

technical service operation

A technical service operation is a detailed description about how a technical service is to be provided by a component in order to support a component in providing a business service. An operation is defined for the specific technical service that it helps to realize. The operation defined for a technical service can be

assigned to the business services that are provided by the component that the component supports. A technical service can have multiple technical service operations defined for it.

Object class stereotypes may be configured for the class **Technical Service Operation**.

text template

A text template is the predefined text in an email that is automatically generated as the result of an action triggered by a user. Text templates for email messages are available for the following contexts:

The text template defines the email text in English, the relevant references to objects and object class properties in Alfabet, and hyperlinks to the relevant objects in Alfabet. The content displayed in the English-language text template can be edited to suit the needs of your enterprise. Locale text templates can be created in order to translate the content of the text template to the non-English languages implemented in your solution interface.

to-be architecture

The to-be architecture is a medium-term plan for the enterprise's architecture and defines a clearly approved strategic guideline. The planned consolidated to-be architecture is captured in one or more master plans, which define the planned tactical business support. The realization of the to-be architecture is addressed in the context of projects.

A project's to-be architecture typically includes inventory objects from the as-is architecture that may be affected by proposed architectural changes as well as new solutions objects such as solution applications, solution components, solution devices, solution information flows, solution local components, solution peripherals, solution standard platforms, solution technical services, and solution business supports created in the context of the to-be architecture. The solution objects are considered to be "shadow" objects — copies of the base applications, information flows, etc. that they were derived from. The solution objects exist only in the context of the to-be architecture definition and may be modified within the context of the to-be architecture without affecting the inventory objects they are based on. The architectural changes defined in the context of the proposed to-be architecture can be checked in to the inventory, whereby the solution objects that are based on inventory objects overwrite their corresponding inventory object. All architecture elements added to the inventory via the proposed to-be architecture will have an object state indicating that the object is planned. The object state must be manually changed to an active object state when operational use of the to-be architecture element begins, which is typically upon completion of the project's implementation.

user

A user is a person that is known to the Alfabet system. Users have access permissions and are associated with one or more user profiles, which control accessibility to the functionalities. A user may or may not be an authorized user for an object. Authentication and authorization are also controlled by means of the user definition.

user group 

A user group bundles a set of users. Once a user group is assigned to an object, it is referred to as the object's authorized user group.

user profile

User profiles are the basis of user administration in Alfabet and serve as the entry point when accessing Alfabet. Every user must log in with a user profile that has been assigned to him/her by a user administrator. Therefore, all users accessing Alfabet must be assigned at least one user profile. However, users may possess multiple user profiles in accordance with their responsibilities in the user community and in the enterprise as a whole. A user can switch to another permissible user profile at any point during a user session.

A user profile specifies the Alfabet functionalities available to a user, the visibility and editability of object classes and object class attributes, as well as the availability of associated capabilities including, for example, wizards and workflows.

Each user profile must have one view scheme assigned to it that bundles various class settings. The user profile may have only one class setting defined per object class.

value node

A value node represents a strategic intention at a specific level of abstraction. The level of abstraction is determined by the value node stereotype that the value node belongs to. Value nodes assigned to a top-level value node stereotype represent a highly abstract strategic intention (for example, Become an Integrated Financial Service Provider) whereas the leaf-level value nodes typically describe the action needed to realize the ascendant strategic intention. Thus the value node stereotype at the lowest level usually represents strategic initiatives (for example, Establish New Credit & Loans Management Solution).

value node stereotype

A strategy network is made up of an arbitrary number of levels called value node stereotypes. The top-level value node stereotype represents the most abstract level of strategic intention and the lowest leaf-level value node stereotype represents those strategic initiatives that must be acted upon in order to realize the abstract strategic intentions. For example, a typical strategy network might be made up of the following value node stereotypes: Level 1: Vision, Level 2; External Trends, Level 3: Business Drivers, Level 4: Business Requirements, Level 5: Architectural Requirements, Level 6: Initiatives. The name, number, and hierarchical ordering of value node stereotypes is configurable.

A value node is thus defined for a specific value node stereotype. Any pair of value nodes that are related to one another in the strategy network must belong to different value node stereotypes that are adjacent to each other in the hierarchy. In other words, value nodes are related via a parent-child relationship. The relationship between two value nodes is represented by value node arcs, which allow the relative ranking of the strategic intentions to be computed.

vendor product 

A vendor product is a good or service that is provided by a vendor to the company. A vendor product may be associated with one or more technical components. For example, the vendor product Oracle RDBMS may be split into the components Oracle 11i Server, Oracle 11i Client, and Oracle 11i OCL. Further, a component may reference a vendor product, thus indicating that it has been derived from the vendor product.

Vendor products may be created directly in Alfabet or, depending on the configuration of your Alfabet solution, imported from the Technopedia® repository. Vendor products may only be imported from Technopedia® product categories that are on the leaf level of the product category hierarchy.

Object class stereotypes may be configured for the object class **Vendor Product**.

view scheme

A view scheme is associated with a user profile and groups a set of class settings that describe the visibility of objects in the associated object classes. Only one class setting per object class may be assigned to a view scheme.

The view scheme also contains the definition about the functionalities available in the object views accessible via the view scheme. For each standard and configured object view available to the view scheme, workspaces, page views, and toolbar buttons that allow object data to be created, edited, and deleted, for example, can be hidden.

virtual ICT object 

A virtual ICT object represents a visionary ICT object that may not yet be defined in the inventory but is needed to represent a strategic business support or tactical business support defined in an IT strategy map or a master plan map. A virtual ICT object is for planning purposes only and is not visible anywhere outside of the areas of strategy planning or master planning.

After a virtual ICT object is defined in a business support map, it can later be replaced with a real ICT object or application. In this case, the real ICT object replaces all business supports associated with that virtual ICT object.

vocabulary

A vocabulary constitutes the set of original and translated strings that are displayed in Alfabet. The translatable strings are divided into separate terminology sets based on their source of origin in the software. These include `METAMODEL`, `ITPlan`, `Platform`, and `GUIDEPAGES`.

wizard

A wizard is an assistant that consists of a configured set of standard editors, custom editors, standard views, and configured reports. The wizard will typically guide a user through a linear multi-step process to capture data for an object that the user has access permissions to.

Standard data capture wizards are available for commodity classes in which a large number of objects are typically documented. An unlimited number of custom wizards may be configured for an object class in order to allow different users working in different contexts to capture the object data that they are responsible for. However, only one wizard may be available for an object class per user profile.

wizard step

A wizard step is an editor, view, or report in a wizard. The wizard step constitutes one aspect of data entry or review that is required in the data collection process. A wizard step may be reused for multiple wizards for the same object class.

Each wizard step may have instructions configured that are displayed in the header of the wizard step. The current step that the user is currently processing vs. the total number of wizard steps are automatically generated and displayed in the header of the wizard step.

A wizard step may consist of any of the following:

An editor, view, or report can be reused in the configuration of multiple wizard steps in the same wizard, thus enabling the user to enter the data in multiple steps rather than having to complete the data entry process all at once. Furthermore, each wizard step can be configured so that only the relevant standard and custom object class properties are displayed for a wizard step.

A wizard step may have an unlimited number of subordinate wizard steps that can constitute a branch in the wizard process. Any wizard step or subordinate wizard steps may be controlled by pre-conditions that determine whether the wizard step should be entered or skipped. The pre-conditions are configured as Alfabet queries or SQL queries that determine the criteria that must be fulfilled in order to enter a specified step. Multiple post-conditions may be defined per wizard step in order to prompt users to provide data for specified standard or custom object class properties before proceeding to the next wizard step.

workflow

A workflow is a collaborative process made up of workflow steps that are typically carried out by one or more users. A workflow is based on a configured workflow template that determines the sequence of workflow steps that are to be performed on a specific object and its references by specified user(s). Workflow steps may have specific pre- and post-conditions that determine different paths to take in the workflow depending on whether the conditions are or are not met.

Typically, the workflow owner is the user who initiates and is responsible for maintaining the workflow. When a workflow is initiated by the workflow owner and when a workflow advances to the next workflow step, relevant users may be informed via automatically-generated emails of their impending responsibility for the workflow step. This functionality ensures that all relevant users are informed and reminded of their responsibilities in the collaborative workflow. The option to refuse, delegate, and pause workflow steps, remind users of an impending target date for a workflow step as well as redirect a workflow that has

encountered an error enables workflow owners and workflow administrators to keep track, coordinate, and manage the completion of each workflow step and the workflow as a whole.

workflow post-condition

A post-condition is based on a query that checks whether a workflow step has been completed. Each workflow step may have multiple post-conditions defined. All post-conditions must be fulfilled in order to confirm and complete a workflow step and advance to the subsequent workflow step.

workflow pre-condition

A pre-condition is based on an Alfabet query or an SQL query that checks whether a workflow step may or may not be executed. Each workflow step may have multiple pre-conditions defined. All pre-conditions must be fulfilled before the workflow step may be started. Pre-conditions are required, for example, when a workflow step has multiple next workflow steps defined. Each next workflow step must have one or more pre-conditions defined in order to determine which of the potential next workflow steps should be the subsequent next workflow step.

workflow step

A workflow step is an activity or task in a workflow that must be performed. The workflow template may have as many workflow steps as needed to complete the relevant task. Standard and custom editors, wizards, page views, configured reports, and object profiles may be implemented in the workflow step so that users can complete the task. A workflow step may entail entering, modifying or reviewing data, or a workflow step may be configured to be automatically executed by the Alfabet system. If the workflow step is not automatically executed by the system, one or more users may be defined as responsible to perform the workflow step. A user may delegate a workflow step to another user or refuse a workflow step. Depending on the configuration of the workflow step, a user may be required to confirm a workflow step before the workflow can advance to the next workflow steps, or the confirmation of the workflow step may occur automatically. A workflow step may also have one or more associated workflow step actions which allow various operations to be performed when the workflow step is entered, exited, refused, or expired. Additionally, each workflow step may have one or more pre-conditions or post-conditions that must be fulfilled in order to enter or exit the workflow step.

workflow step action

A workflow step action is a configured operation that is automatically executed when a workflow step is entered, exited, refused, or expired. A workflow step action may consist of a property being updated for the targeted object, an e-mail notification being set to users, or a sub-workflow being triggered.

Additional workflow step actions are available for administrative purposes such as stopping a running workflow or closing steps for a sub-workflow that has stagnated.

workflow template

A workflow template is a customer-defined blueprint for one or more workflows. The template specifies what object class is the point-of-departure in the workflow, which user groups and/or user profiles may initiate and administrate the workflow, which workflow steps comprise the workflow as well as their sequence, any possible per- and post-conditions or update actions associated with a workflow step, and what kinds of workflow notifications should be sent to collaborating users in which contexts. The user who creates the workflow template is the workflow template owner.

A workflow template must have the attribute **Workflow State** attribute set to `Plan` to be configured and validated. Once the workflow template is completed and approved, the attribute **Workflow State** must be switched to `Active` in order to make it available to the user community. Once the workflow template is available in Alfabet, a permitted user may initiate a workflow based on the workflow template. Multiple workflows may be simultaneously initiated and running for a workflow template.

XML object

An XML object is a configuration file made up of XML elements that allows definitions to be specified for diverse objects and functionalities in the solution environment. In Alfabet Expand, you will find a variety of existing preconfigured XML objects  that serve as templates to configure the XML objects relevant to your enterprise.

INDEX
