
Configuring Alfabet with Alfabet Expand

Alfabet Reference Manual

Documentation Version Alfabet 10.11.0

CONVENTIONS USED IN THE DOCUMENTATION

Convention	Meaning
Bold	Used for all elements displayed in the Alfabet interface including, for example, menu items, tabs, buttons, dialog boxes, page view names, and commands. Example: Click **Finish** when setup is completed.
Italics	Used for emphasis, titles of chapters and manuals. this Example: see the *Administration* reference manual.
Initial Capitals	Used for attribute or property values. Example: The object state Active describes...
All Capitals	Keyboard keys Example: CTRL+SHIFT
File > Open	Used for menu actions that are to be performed by the user. Example: To exit an application, select File > Exit
< >	Variable user input Example: Create a new user and enter <User Name>. (Replace < > with variable data.)
	This is a note providing additional information.
	This is a note providing procedural information.
	This is a note providing an example.
	This is a note providing warning information.

TABLE OF CONTENTS

Chapter 1: Getting Started with Alfabet Expand

Welcome to the configuration tool Alfabet Expand!

This software tool allows you to carry out a number of administrative tasks required to maintain the Alfabet database as well as to configure the Alfabet solution to meet your company's needs.

When you work with the tool Alfabet Expand, you will typically be making changes to the meta-model. The meta-model defines the constructs, rules, and class ontology of Alfabet and constitutes a part of the Alfabet database. Meta-model changes include, for example, the creation of custom properties for object classes, customization of the solution environment, and configuration of user profiles.

You must ensure that Alfabet Expand is only accessible to those individuals in your company that make up the core team of solution designers who are authorized to make changes to the meta-model. Access to Alfabet Expand as well as the availability of specific functionalities in Alfabet Expand is controlled on a per-user basis. Each user must be explicitly specified to have access permission to Alfabet Expand as well as to the individual tabs and menus providing the various functionalities. This ensures that access to the functionalities in Alfabet Expand is explicitly differentiated based on the configuration tasks and responsibilities of the individual user.

The definition of user access permissions to Alfabet Expand is defined by the user administrator in the context of the **Users Administration** functionality that can be accessed in the user interface via an administrative user profile. For more information about specifying access permission for Alfabet Expand, see the section *Creating a User* in the reference manual *User and Solution Administration*.

Please note the following:

- Your licensing agreement with Software AG for Alfabet Expand functionalities will not impact which functionalities are listed in the **Expand Access Options** attribute in the **User** editor. All functionalities are displayed regardless of the content of license agreement. However, regardless the definition of **Expand Access Options** attribute, the licensing agreement will override. The definition of the **Expand Access Options** attribute specifies the visibility in both Alfabet Expand Web and Alfabet Expand Windows.
- If the XML object ***PlatformConfiguration*** is specified in Alfabet Expand, it will override the definition of the **Expand Access Options** attribute in the **User** editor in Alfabet Expand Windows.

The primary tasks that are carried out in Alfabet Expand and described in the remainder of this manual include:

- Executing Administrative Tasks in Alfabet Expand: The most important administrative tasks that you carry out in Alfabet Expand include backing-up and restoring the Alfabet database, updating the configuration, creating user profiles and mandates for the user community, and configuring the visibility of functionality in Alfabet Expand.
- Configuring Access Permissions for Alfabet : Alfabet offers various levels of access control. Access permissions are regulated via user profiles, mandates, user and user group authorization, rule-based access permissions, and object release status definitions. Furthermore, access permissions control the visibility and participation in assignments, workflows, and discussion groups.
- Localization and Multi-Language Support for the Alfabet Interface: Alfabet provides multi-language support as well as localization possibilities to adapt the Alfabet interface to suit the needs and

expectations of the various locales in which your enterprise operates. Information is provided to configure cultures, create custom terminology, and translate the Alfabet interface and online Help.

- Configuring the Class Model: All semantic object classes in Alfabet have a preconfigured set of standard object class properties. With Alfabet Expand, you can create additional properties for a specific class, design the layout of these custom properties in tabulated pages displayed in the relevant editor, and translate the custom properties for the interface languages your company uses. Class keys can be defined for one or more properties available to a class. Additionally, you can define object class stereotype for a specified set of object classes. The release statuses, object states, and lifecycle definitions of objects in an object class are also configurable.
- Configuring Custom Editors: Custom editors can be created for an object class and designed to allow users to enter values for the custom properties configured for your enterprise. Custom editors can be implemented in the context of standard data capture editors, surveys, wizards, and workflows.
- Configuring Custom Selectors and Search Functionalities: Alfabet provides a number of methods to search for and find objects. Object classes and object class stereotypes may be configured to be searchable in the standard Alfabet search functionalities. Additionally, custom selectors can be created and implemented in the standard search functionalities as well as in page views, standard or custom editors, workflows, and configured reports. The solution designer can further configure whether a wildcard <*> should be automatically implemented when a user enters search criteria.
- Configuring Wizards: Wizards provide an efficient means to guide users through a specific set of activities. You can configure multiple wizards per object class, defining the set of page views, their sequence, and prompts that remind a user that a specific field has not been filled out.
- Configuring Standard Business Functions and Custom Explorers: Custom explorers can be configured and assigned to user profiles as Alfabet functionalities.
- Configuring Object Views: A custom object view allows the object profile displayed for an object class to be customized and implemented for a specific user profile. Object cockpits can be further configured for an object view in order to provide the user with various options of viewing specified sets of data in a dashboard form.
- Configuring User Profiles for the User Community: Alfabet functionalities can be combined in a package for various user profiles in your company. With Alfabet Expand, you can define a set of functionalities relevant for each user profile as well as refine the configuration by determining which object classes, object class properties, and page views should be excluded from view from each user profile. Furthermore, you can assign HTML-based guide pages that serve as a start page that guide a user via hyperlinks to the relevant functionalities. Guide pages are configured in the Guide Pages Designer. For more information, see the reference manual *Designing Guide Pages for Alfabet*.
- Configuring Workflows: Workflows can be configured to guide users through a multi-step workflow process. To make the workflow functionality available to the user community, workflow templates with workflow steps must be configured in Alfabet Expand.
- Configuring Alfabet Functionalities Implemented in the Solution Environment: There are a number of functionalities that must be configured before they can be implemented in the Alfabet software. These functionalities include, for example, data capture environments such as the **Capture Applications** functionality as well as the **Project Management**, **Strategy Deduction**, **Compliance Management**, **Capture Enterprise Releases**, **Contract Management** capabilities. Further, a wide variety of aspects in the solution environment can be configured by means of XML objects located in Alfabet Expand. Topics include, for example, the assignment capability, the automatic generation of e-mails, monitors, custom diagram definitions and the default settings for the Alfabet Diagram Designer, and currency units for cost estimation. Please see the overview at the beginning of the chapter for a list of topics available regarding the configuration of the solution environment.

- Configuring the Visualization of the Alfabet Interface: The visualization of the Alfabet interface can be specified in a variety of ways to align with your corporate guidelines. This includes, for example, the font family and colors used in the interface, the inclusion of the company logo in the header, the icons used to visualize indicators in object cockpits, configured reports, custom editors, the images used to visualize enterprise milestones as well as object classes in the interface.
- Configuring Reports: You can configure reports that can be executed by users to search for objects that match customer-specific criteria. In the report, users will be able to navigate to the object in the Alfabet interface. You can either provide reports by defining an Alfabet query or native SQL query to find objects directly in Alfabet, or you can search the Alfabet database with external reporting tools and link to the resulting report from within the Alfabet interface. Report results are either displayed in a tabular report or in a preconfigured graphic report. Many types of graphic representations are available including, for example, treemap reports, layered diagrams, grid reports, matrix reports, HTML reports, portfolio reports, Gantt chart reports, lane reports, and reports to analyze data cubes.
- Defining Queries: Alfabet supports native SQL queries as well as Alfabet queries, a powerful query language that allows a wide variety of information to be retrieved from the Alfabet database. Alfabet queries can be defined for the search functionality, export definitions, custom reports, and form-based data collection as well as for other aspects that can be customized in Alfabet.
- Publishing Data In Microsoft® Word Format: The Alfabet Publication Framework (APF) allows you to publish Microsoft® Word documents about data in the Alfabet database.
- Configuring Surveys for Data Capture Campaigns: The Surveys capability allows for stakeholder surveys or data acquisition campaigns to be configured. Such surveys are typically driven by regulatory or senior management requests. Alfabet Expand provides a capability that allows surveys to be configured so that the data collection process is standardized by a high degree of automation and can be conducted in a timely manner.

Please note that changes to the Alfabet database structure shall only be performed via the official Alfabet components such as Alfabet Expand or Alfabet Administrator. Software AG cannot be held responsible for any damage done to the Alfabet database by changes to the database caused by customers with direct access to the database (for example, via direct execution of SQL commands such as `DROP`, `ADD`, etc. that alter the database structure).

Overview of Alfabet Expand Windows and Alfabet Expand Web

Alfabet Expand is available either as a Web-based tool (Alfabet Expand Web) or as an application (Alfabet Expand Windows) that allows different users configuring Alfabet solutions:

- The configuration tool Alfabet Expand Windows offers the complete range of configuration functionalities and is the preferred tool for solution designers configuring an Alfabet solution installed at the customer.
- Alfabet Expand Web offers most common configuration functionalities for solution designers using an Alfabet Cloud solution including he tool Guide Pages Designer that is required to design and upload guide pages for the Alfabet interface. For detailed information about the configuration of guide pages, see the reference manual *Designing Guide Pages for Alfabet*.

Technically, multiple instances of both Alfabet Expand Windows and Alfabet Expand Web can connect to the Alfabet database in parallel. When multiple instances of Alfabet Expand are used in parallel with a connection to the same Alfabet database, the following problems occur:

- Changes made to the meta-model by one user might be overwritten by changes made by another user working with another instance of Alfabet Expand if they are attempting to save the same configuration object.
- All instances of Alfabet Expand load a working copy of the meta-model during connection to the meta-model. If the meta-model is changed by another user working with another instance of Alfabet Expand, the changes are not automatically uploaded to the currently active Alfabet Expand sessions. The solution designer will not be aware of changes unless he/she uses the menu option **Meta-Model** > **Reread Meta-Model**.

The following is recommended to prevent overwriting data and inconsistencies in the Alfabet database when using Alfabet Expand:

- Do not work with Alfabet Expand in conjunction with a Alfabet database in a production environment. Configuration should be carried out in a configuration environment and stored in an AMM file. The meta-model of the production environment should only be updated with the AMM file after the configuration environment, or a test environment has been tested and approved.
- Only one instance of Alfabet Expand should be used at a time. If it is necessary to use multiple instances in parallel, only instances of Alfabet Expand Windows that connect by means of a server alias to the Alfabet database should be used. The tracking of meta-model changes should be activated in the server alias configurations of all Alfabet Expand instances.
- A backup of the Alfabet database should always be made before making changes in order to prevent the inadvertent and irrevocable loss of important configuration data.

The following mechanisms are implemented to reduce the risk of overwriting concurrently made changes:

- When a user saves changes to object classes, object class properties and class keys, the connection of all other Alfabet components to the Alfabet database will be closed to inhibit the overwriting of changes by other active Alfabet Expand instances and prevent inconsistencies that may result from users checking in data for which the configuration has changed. This applies to changes made in both Alfabet Expand Windows and in Alfabet Expand Web.
- Alfabet Expand Windows can be configured to detect the changes made by other instances. If the meta-model is changed in one of the instances of Alfabet Expand and the changes are saved to the meta-model, the users of the other Alfabet Expand instances are informed via a message on the Alfabet Expand host that the meta-model has changed. Clicking on the message opens a report in the center pane of Alfabet Expand providing information about the change made to the meta-model and the user performing the change. This mechanism is only valid if the following applies:

- Both instances are Alfabet Expand Windows.
- Both Alfabet Expand Windows instances connect directly to the Alfabet database with a server alias.
- The **Track Meta-Model Changes** parameter is activated in the server alias of the Alfabet Expand instances as described in the reference manual *System Administration*. Please note that meta-model changes cannot be traced for instances of Alfabet Expand Web.
- A different username is used for login to the Alfabet Expand instances.

Access to the Alfabet solution is not defined in Alfabet Expand. Access to the Alfabet solution is defined by a system administrator using the tool Alfabet Administrator or by a user administrator working in the **User Administration** functionality that can be accessed via an administrative user profile. For more information, see the reference manual *System Administration* or the reference manual *User and Solution Administration*.

Installation

Instructions on the setup and installation of Alfabet and the Alfabet components including Alfabet Expand can be found in the reference manual *System Administration*. This manual is available in PDF format and is found on the Alfabet installation CD-ROM.

Please note that your enterprise will be provided with a mechanism that specifies the licensing information regarding the visibility of tabs in Alfabet Expand during software setup. This reference manual provides documentation for all functions available in the configuration tool Alfabet Expand. Therefore, depending on your licensing agreement, you may not see all functions described here.

Starting and Logging in to Alfabet Expand Windows

You must ensure that Alfabet Expand is only accessible to those individuals in your company that make up the core team of solution designers who are authorized to make changes to the metamodel. Access to Alfabet Expand as well as the availability of specific functionalities in Alfabet Expand is controlled on a per-user basis. Each user must be explicitly specified to have access permission to Alfabet Expand as well as to the individual tabs and menus providing the various functionalities. This ensures that access to the functionalities in Alfabet Expand is explicitly differentiated based on the configuration tasks and responsibilities of the individual user.

The definition of user access permissions to Alfabet Expand is defined by the user administrator in the context of the **Users Administration** functionality that can be accessed in the user interface via an administrative user profile. For more information about specifying access permission for Alfabet Expand, see the section *Creating a User* in the reference manual *User and Solution Administration*.

Please note the following:

- Your licensing agreement with Software AG for Alfabet Expand functionalities will not impact which functionalities are listed in the **Expand Access Options** attribute in the **User** editor. All functionalities are displayed regardless of the content of license agreement. However, regardless the definition of **Expand Access Options** attribute, the licensing agreement will override. The definition of the **Expand Access Options** attribute specifies the visibility in both Alfabet Expand Web and Alfabet Expand Windows.
- If the XML object ***PlatformConfiguration*** is specified in Alfabet Expand, it will override the definition of the **Expand Access Options** attribute in the **User** editor in Alfabet Expand Windows.

Alfabet Expand connects directly to the Alfabet database in parallel with a running Alfabet Web Application. Configuration at runtime no longer requires the connection of Alfabet Expand to the Alfabet Server and all

functionality of Alfabet Expand is available at runtime of the Alfabet Web Application. There is no limitation to the number of connections made by Alfabet Expand to the Alfabet database. In other words, multiple instances of Alfabet Expand may connect concurrently to the same database. The following applies when changes are made in Alfabet Expand and saved to the database:

- A change made to the meta-model (in other words, any change made to the class model in the **Meta-Model** tab in Alfabet Expand) will cause a semantic lock to the database. All currently open connections from browser clients and other Alfabet Expand clients will be closed. A message will be displayed to the other Alfabet Expand clients informing them about the lock to the database and that changes can be saved to an AMM file. The meta-model changes will then be updated to the Alfabet database. The Web server must be restarted after an update to the meta-model. Users can then reconnect to the Web server by either implicitly or explicitly logging in. Please note that updating the meta-model via an AMM file is considered a meta-model change regardless of whether the class model has been changed.
- Any change that does not involve a change to the meta-model will be immediately updated to the database with no interruption of the connection to the Web server. The changes made to the database will only be applied after the Web server has been restarted/refreshed.
- When two instances of Alfabet Expand are used in parallel, each instance can scan the Alfabet database for changes performed via other active instances of Alfabet Expand. If a change is saved by another instance of Alfabet Expand, a message will be displayed in the Windows® toolbar. Clicking the link in the message opens a report that provides details about the changes. The system administrator can activate scanning of the Alfabet database for changes via the **Track Meta-Model Changes** parameter in the tab **Expand** of the server alias in the Alfabet Administrator application. For more information, see the section *Configuring Alfabet Expand Windows to Scan the Meta-Model for Changes* in the reference manual *User and Solution Administration*.
- When a change in the meta-model is saved by a running instance of Alfabet Expand, the solution designer of a parallel instance of Alfabet Expand should save the changes to an AMM file by means of the menu option **Meta-Model** > **Reread Meta-Model** in order to load the changed meta-model and update the meta-model with his/her configuration changes to the AMM file. Please note that changes made in Alfabet Expand Web, for example, do not trigger a notification about a change. Therefore, the option **Meta-Model** > **Reread Meta-Model** in the menu should be used prior to each critical action to ensure working with the correct meta-model.
- Because an unambiguous identification of the configuration objects is required to support the parallel connection of Alfabet Expand to the Alfabet database, a unique key constraint has been set for the **Name** attribute of configuration objects in Alfabet Expand. If two existing configuration objects have the same name in the Alfabet meta-model, the name of one of the objects will be changed automatically during migration to the next release. A message about the change will be written to the migration log file.

To start Alfabet Expand:

1) Choose **Start** > **Programs** > **Alfabet** > **Alfabet Expand**.
2) In the **Connect To the Server** field, select a server alias for login. For assistance regarding the correct server alias o to use, contact your system administrator.
3) Enter your user name in the **User Name** field and password in the **Password** field and click **OK**. The tool Alfabet Expand opens.

Alfabet Expand Web for Alfabet Cloud Enterprise

The core functionalities of Alfabet Expand are available in a Web browser for customers using Alfabet Cloud Enterprise. Users can leverage the browsers tabbing feature, printing, and scroll bars and search capability allows to find text in the current view. The following describes the most significant features and user interactions:

- Alfabet Expand Web will be available to all Alfabet Cloud Enterprise customers that have purchased the associated license. Please direct any questions about your license key to Software AG Support.
- The path to enter in the browser address field is: `https:`<URL of the Alfabet Web Application>`/expand.aspx`. The Alfabet Expand login screen will be displayed directly in a browser tab. Upon login, the user will land directly on a start page in the same browser tab. When the solution designer clicks a tile representing a configuration functionality, the selected designer will open in the same browser tab, overlaying the previous view in the tab. Please note that multiple browser tabs are not supported in Alfabet Expand Web. The following tiles are displayed:

- **Class Designer**: Allows the solution designer to configure the class model including enumerations and cultures.
- **Presentation Model Designer**: Allows the solution designer to configure custom editors, class settings, view schemes, object views, wizards, text and monitor templates, HTML templates, selectors, and XML objects.
- **Icon Gallery**: Allows the solution designer to upload icons to the Alfabet database and structure them in icon galleries.
- **Report Designer**: Allows the solution designer to configure reports. Please note that currently the report assistants for Business Chart Report, Portfolio Chart, Matrix Report, Gantt Report, Evaluation Report, and Grid Report can be used in Alfabet Expand Web. If other report assistants are required, the solution designer is advised to use Alfabet Expand Windows.
- **View Designer**: Allows the solution designer to open the designer to configure the visualization of custom editors, object cockpits, selectors, and configured reports. Please note that only one custom editor, object cockpit, selector, or configured report can be configured at a time.
- **Guide Page Designer**: Allows the solution designer to configure start pages for user profiles.
- **ADIF Designer**: Allows the solution designer to view ADIF schemes. Please note that the configuration and import/export of ADIF schemes must be executed in the Alfabet Expand Windows interface (Windows client).
- **Administrator**: Allows the solution designer to configure user profiles and mandates as well as define custom business functions/explorers.
- **Utilities**: Allows the solution designer to export the configuration as an AMM file and upload custom translations (XLS and VOC files) to the Alfabet database.
- Please note that the configuration of workflows, Alfabet publications, and ADIF schemes is only possible in Alfabet Expand Windows interface.

- It is possible to open multiple instances of Alfabet Expand Web in parallel and to use Alfabet Expand Web in parallel with Alfabet Expand applications. Please note however, that it is recommended that only one Alfabet Expand Web session is open at a time. The following problems occur when working with multiple instances of Alfabet Expand:

- If a configuration object is simultaneously being edited by multiple solution designers, the most recent configuration that is saved to the Alfabet database will overwrite any previous configurations saved.
- The solution designers working with Alfabet Expand Web will not be notified if a configuration object is simultaneously being edited or saved via other instances of Alfabet Expand Web or via an instance of Alfabet Expand Windows.
- Alfabet Expand Web is working with a working copy of the meta-model uploaded to the Web Server. If a solution designer is working with Alfabet Expand Web and the meta-model is changed via a simultaneously used instance of Alfabet Expand Web or Alfabet Expand Windows, the changes are not automatically uploaded to the Web Server and the solution designer will not see them in the explorer trees and attributes settings displayed in his/her current session. The solution designer must use the option **Meta-Model** > **Re-Read Meta-Model**.
- A change made to the meta-model (in other words, any change made to the class model in the **Meta-Model** tab in Alfabet Expand) will cause a semantic lock to the Alfabet database. All currently open connections from browser clients and other Alfabet Expand clients will be closed. A message will be displayed to the other Alfabet Expand clients informing them about the lock to the database and that changes can be saved to an AMM file. The meta-model changes will then be updated to the Alfabet database. The Web server must be restarted after an update to the meta-model. Users can then reconnect to the Web server by either implicitly or explicitly logging in. Please note that updating the meta-model via an AMM file is considered a meta-model change regardless of whether the class model has been changed.
- Any change that does not involve a change to the meta-model will be immediately updated to the Alfabet database with no interruption of the connection to the Web server. The changes made to the Alfabet database will only be applied after the Web server has been restarted/refreshed. A Web Server restart can be invoked via the option **Meta-Model** > **Restart Web Application** to make changes visible to users concurrently working with the Alfabet user interface.
- The **Clear Changes** button allows the solution designer to undo all changes that have been made in the current Alfabet Expand Web session since the last time the **Save** button was clicked.
- The options (such as **Create**..., **Design**..., etc.) available to define configuration objects are displayed by clicking the arrow to the right of the object to open a drop-down menu. The right-click action in Alfabet Expand Web is reserved for browser-based actions such as Back, Forward, Save as, etc. Please note however that these actions have no relevance for Alfabet Expand Web, which operates in the same browser tab with the same URL during the entire session.
- The browser's pop-up blocker must be disabled in order to use the **Show Usage** functionality available for most configuration objects.
- All interactions in Alfabet Expand must be explicitly saved via the **Save** button in order to be saved in the Alfabet database.
- The browser Back button is not supported in the context of Alfabet Expand Web. To switch to the start page for Alfabet Expand Web, click the **Home** button. To switch to a different functionality, select an option in the Expand Designers menu available in the standard toolbar. The URL and the browser tab caption will not change when navigating through the Alfabet Expand Web.
- The **Alfabet Query Builder** is not available in Alfabet Expand Web. If the Alfabet query language is used in the configuration instead of native SQL, the Alfabet query must be entered in the **Query as Text** field available for the relevant configuration object.
- The Actipro Syntax Editor Software© technology, which is available in the Alfabet Expand Windows to verify the XML syntax in XML objects, is not available in Alfabet Expand Web. Solution designers

working with Alfabet Expand Web can refer to the default definition in the **XML Def** and **XML XSD** attributes of the XML object. The default definition can be copied to an XML editor, revised as needed using the syntax validation functionality in the editor, and then copied to the **XML Def** attribute in the Alfabet Expand Web.

- The standard documentation (*Configuring Alfabet with Alfabet Expand*) that is available for Alfabet Expand Windows is also available via the Help button for the browser-based version of Alfabet Expand. Please not that although this documentation provides configuration information, it has not been adjusted to reflect the interface of Alfabet Expand Web.
- The interface of Alfabet Expand Web is displayed in English only.

Defining the Language Setting for the Alfabet Expand Interface

The interface of Alfabet Expand is available in the same languages that are supported for the Alfabet interface:

The Alfabet interface is available in the following languages:

Language	Locale ID
Arabic (Saudi Arabia)	1025
German (Germany)	1031
English (United States)	1033
French (France)	1036
Portuguese (Brazil)	1046
Polish (Poland)	1045

To specify the language of the interface for Alfabet Expand, select the language in the drop-down list available in the **Change Language** field in the toolbar in Alfabet Expand. The next time you log in, the selected language will be displayed.

Please note that the language of buttons in system windows (`Yes`, `No`, `OK`, `Cancel`) as well as such headers of system message dialogs (for example, `Warning`) depend on the language settings of your operating system.

Understanding the Alfabet Expand Interface

The following section contains detailed information about the interface elements in Alfabet Expand. You should take some time to familiarize yourself with the various elements in the interface and acquaint yourself with the terminology used in the rest of this manual.

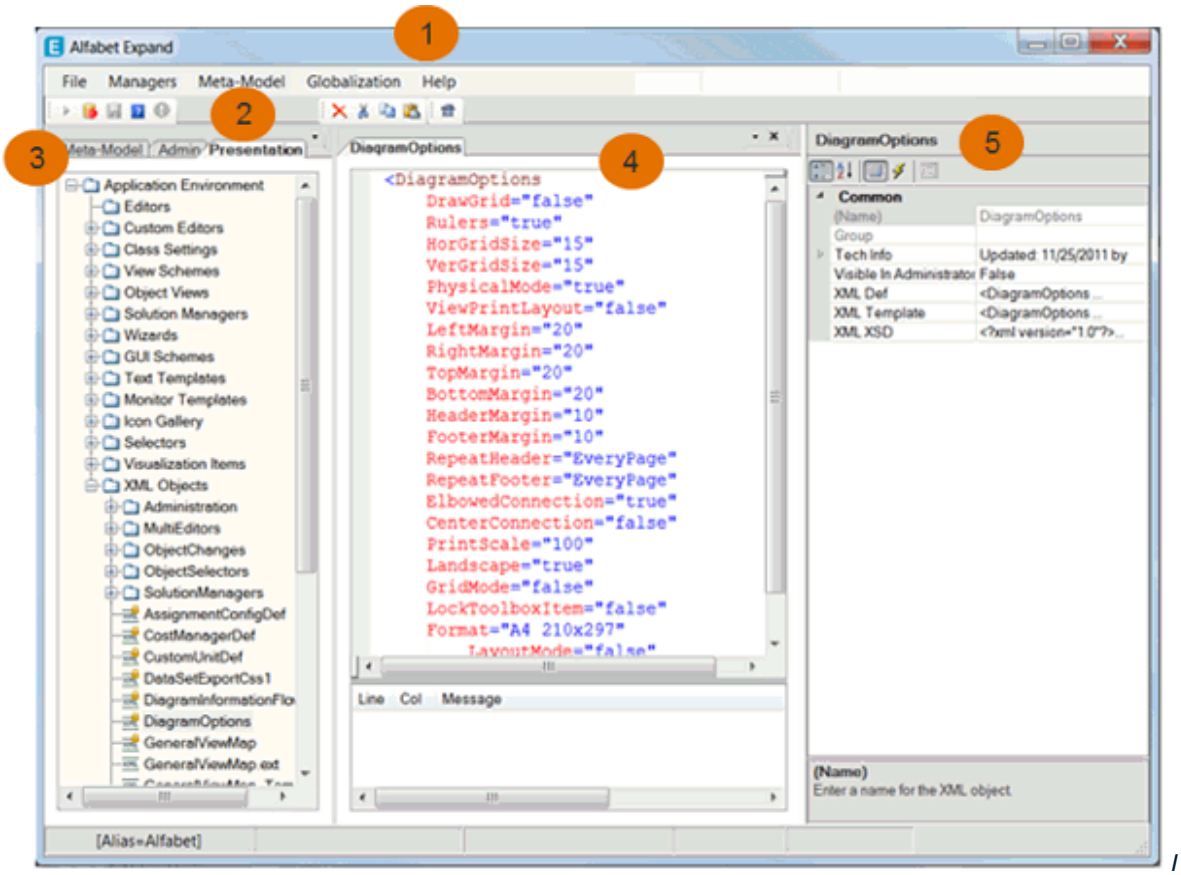

FIGURE: Interface in Alfabet Expand

1. Menus	Menus providing access to options to carry out tasks in Alfabet Expand.
2. Toolbar	The tools displayed may vary depending on the configuration object selected in the explorer or in the center pane.
3. Tabs	Tabs provide access to explorers containing configuration objects.
4. Editor	The center pane displays editors to design or edit configuration objects such as custom editors, object cockpits, and XML objects.
5. Attribute Window	The attribute window contains the attributes that can be defined for the configuration object currently selected in the explorer.

The following interface elements are described in more detail below:

- Overview of the Menus and Toolbar Buttons in Alfabet Expand

- Understanding the Tabs and Explorer Structures in Alfabet Expand
- Meta-Model Tab
- Admin Tab
- Presentation Tab
- Functions Tab
- Workflows Tab
- Reports Tab
- Diagrams Tab
- Publications Tab
- Surveys Tab
- Diagrams Tab
- ADIF Tab

Overview of the Menus and Toolbar Buttons in Alfabet Expand

A standard menu bar and toolbar provides you with a number of basic functions necessary for working with Alfabet Expand. In addition to the standard menu and toolbar, context-sensitive menus and toolbars will be displayed depending on the object you have selected. The following standard menus and menu items are available in Alfabet Expand.

File Menu	
Open Database	Select to open the database.
Close Database	Select to close the database. Saves all non meta-model changes (for example, export definitions and custom reports) to the database.
Save Changes to Database	Select to save meta-model changes (for example, changes to classes or new custom properties), changes to the solution environment (for example, custom editors and wizards) and changes to the business model (for example, business applications) to the database.
Activate Advanced Mode / **Deactivate Advanced Mode**	Select to switch between advanced and normal mode. Advanced mode is only required if custom buttons have been implemented for configured reports by Software AG Support. These buttons are only displayed for further configuration in advanced mode.

Managers Menu

Search Manager	Select to open a full-text search functionality in order to search for objects in the Alfabet database.
Database Manager	Select to either backup the current database in an archive file or restore the current database with another database stored in an archive file located in a local or network folder. **NOTE**: Prior to using the restore functionality, make sure that no Alfabet components are currently connected to the Alfabet database. This applies for example to the Alfabet Web Application, the Alfabet Server (service), Alfabet Expand or batch utilities. The functionality is only available if Alfabet Expand is not currently connected to an Alfabet database.
Object Configuration Manager	Select to recreate, rescan, archive, and restore the object settings that are defined in the **Configure** menu in the clipboard of Alfabet. Object settings configure the presentation of objects.
Context Settings Manager	Select to recreate, rescan, archive, and restore context settings. Context settings include most recent field definitions, filter settings, and views.
ARIS Interoperability	Select to create a user token for the setup of the ARIS - Alfabet Interoperability Interface. For more information, see the reference manual *ARIS - Alfabet Interoperability*.
Guide Page Designer	Select to configure guide pages as start pages for the user interface. The Guide Pages Designer is available in your browser. For more information about designing guide pages and using the Guide Pages Designer, see the reference manual *Designing Guide Pages for Alfabet*.

Meta-Model Menu

Update Meta-Model	Select to overwrite or merge the custom configuration of this Alfabet database with a custom configuration of the meta-model from another database stored in an AMM file. For more information, see the section.
Update Meta-Model Configuration from Master Database	This option is for configuration of Cloud services and for internal use of Software AG Support only. In a customer installation, it is usually deactivated.
Show Update Meta-Model Configuration History	This option is for configuration of Cloud services and for internal use of Software AG Support only. In a customer installation, it is usually not showing any data.

Reread Meta-Model	Select to reload a custom configuration of the meta-model saved in the Alfabet database. Any changes not saved before clicking the **Reread Meta-Model** button will be lost. For more information, see the section About Storage of Changes to the Meta-Model Performed with Alfabet Expand in the Alfabet database .
Clear Meta-Model Changes	Select to remove all changes performed to the meta-model since the last saving of the configuration via the **Save**  button.
Create Configuration Meta-Model Update File	Select to store the customer configuration of the meta-model in an AMM update file. For more information, see the section Saving the Configuration of the Alfabet Solution to an AMM File.
Find Meta-Model Objects for Deployment	Select to store selected objects of the customer configuration of the meta-model into an AMM update file. For more information, see the section Saving the Configuration of the Alfabet Solution to an AMM File.
Set Current Tag	Select to define a tag which will be added to all configuration objects that you generate during the current session to mark them as part of the same configuration. For more information, see Identifying Configuration Objects via Solution Tagging.
Save Meta-Model Objects marked by Current Tag	Select to create an AMM update file containing all configurations that are tagged with the tag defined with the object **Set Current Tag**. Form ore information, see Storing all Objects Tagged With a Selected Tag to an AMM File.
Save Configuration	Select to save the entire configuration as an XML file.
Compare Configurations	Select to compare the current configuration with a configuration stored in an AMM update file or to compare the configurations in two different AMM update files. For more information, see Comparing Database Configurations.
Check Meta-Model for Database Consistency	Select to check whether the current database is in accordance with the current meta-model. for more information, see the section Saving the Configuration of the Alfabet Solution to an AMM File.
Check All Queries	Select to test whether changes to the Alfabet query language require you to adapt existing Alfabet queries in the configuration. For more information, see the section Testing Queries for Compliance with the Current Release.
Compile All Dynamic Assemblies	Select to compile customer specific assemblies delivered by Software AG after upload to the Alfabet database. For more information, see Managing Assemblies

Globalization Menu	
Edit Translation	Select to choose a translation language for the custom editors and custom properties. In the window that opens, you can translate the custom editor captions. **NOTE**: Every caption will be extracted only once in the dictionary. Duplicate parameters entered in the Translation Manager will not be extracted. For more information, see the section Modifying, Translating and Managing the Vocabularies in the chapter Localization and Multi-Language Support for the Alfabet Interface.
Update Guide Pages Translation	Upload the translation of your company's navigation pages. For more information, see the section Modifying, Translating and Managing the Vocabularies in the chapter Localization and Multi-Language Support for the Alfabet Interface.
Help Menu	
F1	Open the Online Help for the node or property grid that is currently selected.
About	View information about the installation of Alfabet Expand.
Toolbar	
	Open database.
	Close database.
	Save meta-model changes to database. You should save frequently when working in Alfabet Expand. Oftentimes you will not be able to select another functionality until you have saved the data.

Understanding the Tabs and Explorer Structures in Alfabet Expand

At the top of the right pane, you will see a row of tabs labeled **Meta-Model**, **Admin**, **Presentation**, **Functions**, **Reports, Publications, Workflow**, **ADIF**, and **Surveys**. Click a tab to view an explorer and its nodes. Each node provides functionalities that allow you to configure your Alfabet solution.

Please note that your enterprise will be provided with a mechanism that specifies the licensing information regarding the visibility of tabs in Alfabet Expand during software setup. This reference manual provides documentation for all functions available in the configuration tool Alfabet Expand. Therefore, depending on your licensing agreement, you may not see all functions described here.

To access a functionality for a node, right-click the node in the explorer. A context menu will open that allows you to select a functionality. If a functionality is greyed out and cannot be selected, click the **Save** button in the toolbar.

The purpose of each tab is explained below.

Meta-Model Tab

The **Meta-Model** tab allows you to view and, to some extent, modify the class model. The primary activity that occurs in the **Meta-Model** tab is the creation and definition of new custom properties required to meet the specific data input needs of your organization.

When you expand the **Classes** node, you may see any of the following:

- A private object class cannot be modified. Custom object class properties cannot be configured for private object classes. Private object classes are displayed for informational purposes and can be configured in Alfabet queries.
- A protected object class can be edited in a limited way. A protected object class typically has private object class properties that cannot be edited, protected object class properties that may be edited (for example, `ResponsibleUser`, `Documents`, `CREATION_DATE`, etc.) but allows for custom object class properties to be created and configured for a protected object class.
- A public object class is a custom class that has typically been created by your enterprise with the help of Software AG Support. All relevant object class properties may be edited and the custom class may be deleted. The attribute **Tech Name** must be explicitly defined for call custom object classes. Custom object class properties can be created and configured for a public object class.
- Some private and protected object class properties are highlighted yellow in the **Class Model** explorer. These are standard object class properties that are recommended by Software AG to be mandatory properties. No enforcement mechanism is implemented if the object class property is undefined. However, if the object class property is included in a class key definition, an error will occur if the object class property is not defined. Therefore, if you include a mandatory object class property in a class key, the object class property may not be hidden in the editor or wizard used to create new objects of the relevant property class.

In Alfabet Expand, object classes are displayed with their names, which means the value of the **Name** attribute of the object class. In some cases, this may differ from the caption used in the standard Alfabet user interface.

When you expand the **Properties** node below an object class, you may see any of the following:

- A private object class property cannot be modified. Private object class properties are displayed to provide guidance in defining new objects.

Please note that the **Hint** attribute cannot be defined for private object class properties . If you need to provide custom tooltips for private object class properties, you can either:

- Display the object class property in an object cockpit and configure a hint for the interface control. In this way, you can define a customized tooltip for the specific context that the object class property is displayed in each relevant object cockpit. For more information, see the section Configuring Object Cockpits for a Custom Object View.
- Define a custom translation to replace the standard tooltip via the translation capability available in Alfabet. The translation of the standard tooltip will be displayed in all instances in Alfabet in which it appears. For inherited object class properties such as `Name` and `ID` which are used in most protected object classes in Alfabet, the custom translations will be displayed for all `Name` and `ID` properties for all relevant object classes. For more information, see the chapter Localization and Multi-Language Support for the Alfabet Interface.

- A protected object class property is a standard property that allows some attributes for the object class property to be edited including, for example, the **Caption** attribute, which is displayed for the object class property in the Alfabet interface, and the **Hint** attribute, which is the text for the tooltip that is displayed in the **Attributes** section of an object view and the editor. Both the **Caption** attribute and **Hint** attribute can be translated for the Alfabet interface. A protected object class property may not be deleted.
- A public object class property is a custom object class property that has typically been created by your enterprise. All relevant attributes may be edited and the custom object class property may be deleted.

Click any object class node in the **Class Model** explorer to display its attributes in the attribute window. These attributes specify the technical data about the object class property. The attributes displayed in the attribute window will depend on the object class property type definition in the **Type** attribute. For more information about configuring object classes and object class properties, see the chapter Configuring the Class Model.

Some object classes have a **Class Key Group** node below the object class which will display any existing class keys. A class key allows for the specification of a unique combination of values for a specified set of standard or custom object class properties. This may be implemented to specify uniqueness constraints for the definition of an object in the object class as well as to create indexes to improve performance. For more information about the configuration of class keys, see the section Configuring Class Keys for Object Classes.

Below the **Class Model** node, you will also see a node labelled **Enums**, which may contain private, protected, and public enumerations. Enumerations allow you to define values that can be selected in combo-box or checked list box interface controls. Once an enumeration is defined, you may assign it to any custom object class property of the type `String`, `Real`, or `Integer` associated with a protected object class. An enumeration can be reused for numerous object class properties for multiple object classes. For more information about the configuration of enumerations, see the section Defining Protected and Custom Enumerations.

You may see any of the following under the **Enums** node:

- Private enumerations  are for reference purposes only and cannot be edited.
- Protected enumerations  are created by Software AG. The enumeration name cannot be changed but you can edit the values specified in the **Sort Enumeration Items** attribute in order to determine which values should be displayed to users in the Alfabet interface.
- Public enumerations  are custom enumerations. All attributes can be edited.

The folder labelled **Cultures**  displays all languages supported for your Alfabet product.

The folder labelled **API Cultures** is only relevant if your company uses the Alfabet RESTful services and wants to define date and number formats for the service calls that differ from the formats used on the Alfabet user interface. No private or protected API cultures are available. For information about the functionality provided via this folder, see the reference manual *Alfabet RESTful API*.

The folder labelled **Database Views** is relevant for performance enhancement and usability enhancement when defining queries for configured reports and other configurations of Alfabet. A database view creates a new table based on a native SQL query that may, for example, collect data from multiple database tables of the Alfabet meta-model. A query in a configured report can then read the data directly from the database view instead of searching for the data in multiple database tables. No private or protected database views are available. Database views are exclusively created by the customer on demand. For more information about the functionality provided via this folder, see the section Creating Database Views To Enhance Performance And Support Search Functionalities.

Admin Tab

The **Admin** tab allows you to create and define user profiles and mandates for the user community.

Please note that changes made to user profiles via the **User Profiles Administration** functionality that can be accessed via the `Admin` user profile are not automatically updated to the user profile configuration in the configuration tool Alfabet Expand that is concurrently in use. The solution designer working in Alfabet Expand must either use the **Rescan Tree** functionality or close and reopen the database to view the updated user profiles.

Presentation Tab

The **Presentation** tab provides functionalities that allow you to configure various aspects of the solution environment. When you click the **Presentation** tab, you will see the **Application Environment** tree structure with the following nodes:

- The **Editors** folder contains editors that have been made available upon request to your enterprise by Software AG Support.
- The **Custom Editors** folder contains the custom editors you have created. You can manually create and design custom editors here.
- The **Class Settings** folder allows you to define class settings that you can assign to view schemes.
- The **View Schemes** folder allows you to define view schemes that you can assign to user profiles.

- The **Object Views** folder allows you to configure custom object views for the user community.
- The **Solution Managers** folder contains XML objects that allow you to configure various solution functionalities.
- The **Wizards** folder allows you to define wizards for the maintenance of data in the Alfabet solution.
- The **GUI Schemes** folder allows you to specify the visualization of the Alfabet user interface.
- The **Text Templates** folder contains all text templates used for automatic e-mails executed via batch processes for assignments, monitors, and workflows. Text templates are predefined for the relevant contexts in Alfabet in which they are used. New text templates should only be created for the workflow functionality. However, you can edit all existing text templates as well as define localized (translated) versions of the existing text templates.
- The **Monitor Templates** folder allows you to edit predefined templates that define which properties may be monitored for a select class by a monitors created in the Alfabet solution.
- The **Icon Gallery** folder allows you to define groups comprising icons that may be defined to represent qualitative or performance information (such as indicators) or associated with functionalities. The icon gallery includes a predefined set of icons. However, custom icons can be uploaded to Alfabet in the **Icons** tab.
- The **Selectors** folder allows you to define custom selectors that can be implemented in Alfabet search functionalities as well as selectors available in editors and page views.
- The **Visualization Items** folder allows you to define HTML templates that can be implemented in the workflow capability.
- The **Widgets** folder allows you to configure widgets to use in the configured widget reports that can be embedded in custom object views and object cockpits.
- The **XML Objects** folder contains XML objects that enable you to configure many aspects of the Alfabet solution environment.

Functions Tab

The **Functions** tab allows you to configure custom explorers. Custom explorers are implemented as functionalities and can be assigned to menu items or navigation pages.

Workflows Tab

The **Workflows** tab allows you to configure workflow templates in order to make Alfabet 's workflow functionality available to your user community.

Reports Tab

In the **Reports** tab, you can configure reports available in the Alfabet solution.

Diagrams Tab

n the **Diagrams** tab, you can configure custom diagram item templates that can be made available in diagrams by means of the Alfabet Diagram Designer.

Publications Tab

In the **Reports** tab, you can configure export of data to Microsoft® Word-based publications.

Surveys Tab

In the **Surveys** tab, you can configure data capture campaigns that consist of the definition of customized object classes, object class properties, class settings, enumerations, custom editors, wizards, workflows, and configured reports to support the data capture process.

Diagrams Tab

In the Diagrams tab, you can configure custom diagram item templates that allow alternative visualizations of the objects displayed in diagrams. They can be designed with a different shape, size, color, graphic icon, attributes and text than the standard diagram item template used for the object.

ADIF Tab

In the **ADIF** tab, you can access the Alfabet Data Integration Framework (ADIF) capability that supports the batch import, export, and manipulation of large amounts of data in the Alfabet database. The ADIF scheme is an involved process and information about ADIF is provided separately in the reference manual *Alfabet Data Integration Framework*.

Working with Configuration Objects

Any new object that you create in Alfabet Expand is a configuration object. This includes, for example, custom editors, custom wizards, custom object views and object cockpits, workflows and workflow steps, configured reports, class settings, etc. Configuration objects are displayed as nodes in the explorers available in Alfabet Expand.

Keep the following in mind when working with configuration objects:

- **Most functionalities in Alfabet Expand are available by right-clicking a node in the explorer.** To access functionalities associated with a selected object (for example, to create new objects or subordinate objects), right-click the object in the explorer tree to open a menu displaying the functionalities.
- To display an attribute window in the right pane in which you can define the objects attributes, click the object in the explorer tree. In the attribute window, click an attribute to display instructional text

at the bottom of the screen providing useful information about the attribute. This information will help you understand and define a value for the attribute.

- Objects in the explorers display icons that indicate the editability of the object:
- A private object  with a red lock is ReadOnly and is displayed to provide guidance in defining new objects.
- A protected object  with an orange lock may have some property values that can be changed but the object may not be deleted.
- A public object  with no lock may have all relevant property values changed and may be deleted.
- Some objects in explorers may displays icons indicating their object state (for example, workflows).To update the icon in the explorer after the **State** attribute has been changed for a configuration object, you must right-click the object in the explorer and select **Rescan Tree**. The following states are displayed in Alfabet Expand:
- An active object  will have a green symbol.
- A plan object  will have an orange symbol.
- A retired object  will have a red symbol.
- To ease the configuration of some configuration objects, an editor pane is available by double-clicking the object in its explorer. For example, the following editors are available:
- A design functionality supports the definition and visual design of custom editors  . The editor allows you to select view controls via buttons in the toolbar and place them in the custom editor. Clicking the view control refreshes the attribute window in the right pane in which the view controls attributes can be defined.
- The XML object editor supports the definition of a selected XML object  . XML elements and attributes can be defined directly in an easy-to-use editor interface as well as the conventional XML format. The new editor provides verification of the XML syntax by means of Microsoft® IntelliSense® technology. Any errors in syntax are reporting with color-coding and can be immediately corrected by the solution designer. For more information about editing an XML object and XML syntax verification, see the section Working with XML Objects.
- You must always click the **Save**  button in the Alfabet Expand toolbar to save your changes to configuration objects.

Using the Show Usage Functionality

The **Show Usage** functionality is available for most configuration objects and allows you to understand where a selected configuration object is used by another configuration object. For example, you may want to clean up the wizards folder and delete wizards that are obsolete and no longer in use. Or perhaps you no longer know where your configured wizards are used. By right-clicking a wizard and selecting the **Show Usage** option, you will see the class settings and workflow templates where the wizard is implemented.

Please note that guide pages/guide views may have configured reports embedded in them. The **Show Usage** functionality does not list any configured reports that are embedded in guide pages/guide views.

Most configuration objects will display the **Show Usage** option when you select the object and open the context menu. When you open **Show Usage** dialog, the information about the selected configuration object's usage is displayed in a matrix. The selected configuration object is displayed on the X-axis and the path to the object referring to the selected configuration object is displayed on the Y-axis. A filter is available that allows you to limit the information to configurations relevant for a specified class.

Using the Delete, Cut, Copy, and Paste Functionalities

Before you use the **Delete** or **Cut** operations, you should first use the **Show Usage** functionality in order to understand where the configuration object you are removing may be used. The **Delete** or **Cut** operations may lead to an object being irrevocably deleted from the Alfabet database, thus causing inconsistencies if the configuration object is referenced by other configuration objects in your solution configuration. For more information about the **Show Usage** functionality, see the section Using the Show Usage Functionality.

- The **Delete** operation allows you to select a configuration object in order to remove it from the solution configuration. The configuration object will be irrevocably deleted from the Alfabet database.
- The **Cut** operation allows you to select a configuration object in order to paste its definition (attributes) to another object. When you cut the source object, it will be removed from the configuration object that you are removing it from. Depending on the type of configuration object that you are cutting, the configuration object may be deleted from the Alfabet database. To cut the selected object, right-click the object and select **Cut** . Confirm the warning message explaining that the object will be deleted.
- The **Copy** operation allows you to select a configuration object in order to paste its definition (attributes) to another object. When you copy the source object, it will not be deleted from the explorer. To copy the selected object, right-click the object and select **Copy** .
- The **Paste** operation allows you to take the cut or copied definition of a source object and use it to replace the definition of a selected target object. When you paste to a target object, you will replace the existing definition of the target object with the definition of the source object you have cut or copied. To paste a cut or copied definition to the selected object, right-click the object and select **Paste** .

  There is no Undo action! Cut and **Paste** actions are not reversible. Therefore, you should be certain that a source object may be deleted as the result of the **Cut** action and the definition of a target object may be overwritten as the result of a **Paste** action.

Searching for a Configuration Object in the Explorer Tree

To search for a specific configuration object in the explorer tree, right-click the selected node and select **Navigation** > **Find Node**. In the editor that opens, enter the name of the node in the **Find What** field. You can use the * symbol as a wildcard if you do not know the node's complete name. Click **Find Next** until you find the relevant node.

Defining Attributes for Configuration Objects

If you click a configurable object in an explorer, an attribute window will be displayed on the right side of the screen. The attribute window displays various attributes for the selected object. Please keep the following in mind when working with the attribute window:

- The attribute fields displayed may depend on the values entered for other fields. For example, when defining a custom property  , the fields available will depend on the **Property Type** attribute that you define for the custom property. In this case, the attribute window will be automatically updated to show the relevant attributes.
- Attributes displayed in black text can be edited. Attributes displayed in grey text cannot be edited.
- Click an attribute to display instructional text at the bottom of the screen providing useful information about the attribute. This information will help you understand and define a value for the attribute.
- To define an attribute in the attribute window, click the cell to the right of the attribute field that you want to edit. Fields can be edited in different ways.
- Click in an attribute's cell and enter text directly in the cell.
- Click the **Drop-Down**  button to select an item in a drop-down menu.
- Click the **Browse**  button to open an editor or dialog box.
- A validation mechanism checks for correct syntax when defining the **Name** attribute for most configuration objects. The technical name of a configuration object may not begin with an empty space nor include any of the following special characters: **\ / * ? " > < | ':**
- If the technical name of a configuration object (such as a custom wizard, custom editor, object view, etc.) is changed, the name will be correctly updated in the class setting referencing the changed object during design time. Please note that the name of a changed configuration object will not be updated in guide pages nor are the guide pages referencing a configuration object listed in the **Show Usage** functionality. If you plan to change the name of a configuration object, the reference in the guide page should be changed prior to changing the configuration object name. For more information about configuring guide pages, see the reference manual *Designing Guide Pages for Alfabet*.
- Because an unambiguous identification of configuration object is required to support the parallel connection of Alfabet Expand to the Alfabet database, a unique key constraint has been set for the `Name` attribute of configuration objects in Alfabet Expand. If two existing configuration objects have the same name in the Alfabet meta-model, the name of one of the objects will be changed automatically during migration to a new version of Alfabet. A message about the change will be written to the migration log file.

- If a configuration object requires an XML definition, the syntax specified in the XML editor will be validated when the XML editor is closed.
- You must always click the **Save** button in the Alfabet Expand toolbar to save your changes.

Working with XML Objects

An XML object is a configuration file made up of XML elements that allows definitions to be specified for diverse objects and functionalities in the solution environment. In Alfabet Expand, you will find a variety of existing preconfigured XML objects that serve as templates to configure the XML objects relevant to your enterprise.

Alfabet Expand provides an XML editor that allows you to edit the XML objects. XML attributes can be defined directly in an easy-to-use editor in the context of Alfabet Expand. The editor provides verification of the XML syntax by means of Microsoft® IntelliSense® technology. Any errors in syntax will be reported with color-coding and can be immediately corrected.

Please note that the XML objects ***CUST_LDAP_PERS_Selector***, ***CUST_SQLDB_PERSON_SelectorDef***, and ***OracleSOAManager*** are relevant for enabling interoperability with external systems. Customers will receive specific instructions from Software AG Support if interoperability is required.

You can edit the configuration to suit the needs of your company or user community. You can use the preconfigured XML object provided by Software AG as a reference for your XML definitions.

For details about the specific definition of the XML objects provided by Software AG, search for the XML object name in the index of the documentation (PDF or online Help) to locate the relevant information describing the meaning of the XML elements.

To configure an XML object:

1) In the **Presentation** tab, expand the **XML Objects** folder and navigate to the relevant XML object that you want to define.
2) Right-click an existing protected XML object that you want to define and select **Edit XML Object**. The XML editor opens in the center pane.

Please keep the following in mind when defining XML elements in an XML object:

- The **XML XSD** attribute displays the XML schema definition relevant for the XML object.
- The **XML Template** attribute displays the standard definition for the XML object. Before you edit the XML object, you can copy and paste the predefined information in a standard text editor as a reference for the initial definition provided by Software AG. At any point, you can replace your configuration with the standard definition provided by Software AG. To do so, right-click the XML object and select **Replace Configuration with Default Values** to view all possible.

- The **XML Definition** attribute is where you must specify the XML object for your solution configuration.
- The **Visible in Administrator** attribute allows you to specify whether the XML object shall be available in the tool Alfabet Administrator (= `True`).
- In some cases, you may need to add additional elements to the XML object. For example, you can configure an unlimited number of XML elements `Stereotype` in the XML object `ValueManager`. To add additional elements, you must copy an existing XML element, paste it correctly in the XML object, and modify the attributes.
- If you enter the name of an object class or property (standard and custom), you must enter the correct value of the **Name** attribute of the object class. In some cases, the name deviates from the caption of the object class displayed in the Alfabet interface. A misspelled name will be ignored and could be a source of error in the solution.
- Boolean values should be written in lower-case letters (`true` / `false`). Please note that errors may occur in the implementation if Boolean values are entered in upper-case letters (`TRUE` / `FALSE`).
- Lists must be comma-separated with no empty spaces. For example, for the XML attribute `MappingClasses`, you would enter: `Domain,BusinessFunction,ITMasterPlanMap,ITStrategyMap`
- If a color is to be defined for an XML attribute, you must enter a Windows, Web, hexadecimal, or RGB color value.
- Special characters should be avoided unless explicitly required for an XML attribute.
- If you want to enter a string that contains special characters (for example, a greater than (>) or lesser than (<) symbol), you must replace the special characters with respective XML compliant code, for example:
  - > for >
  - < for <
  - " for "
  - [for [
  -] for]
- For more information about including queries in XML objects, see the section Defining Filters for Configured Reports and Selectors.

3) In the XML editor, edit the necessary XML attributes, as needed. To do so, edit the value in the apostrophe marks ("XXX").

4) In the toolbar, click the **Save**  button to save your changes. Review the bottom pane to determine if there are any errors in the XML syntax.

- Purple errors represent mistakes in the XML element.
- Red errors represent mistakes in the XML attribute.
- Blue errors represent mistakes in the XML attribute value.
- The order of child elements in an XML element should not be changed.
- Errors are only reported for mistakes in the XML syntax. You must ensure that the value defined for the XML attribute is relevant. (For example, that class names are correctly spelled, that "`true`" or "`false`" is entered for a Boolean property type, that lists are comma-separated with no empty spaces, etc.)

5) Make corrections to the syntax as needed and click the **Save**  button to save your changes and recheck the syntax. If errors continue to exist, continue this procedure until all errors have been resolved, or refer to the **XML XSD** attribute to understand the XML schema definition relevant for the XML object.

Using Server Variables in Configurations

A value for an XML attribute can either be defined as a string directly in the XML element or via a server variable. It is not possible to define a value with a server variable written as part of a string. The complete value of the XML element in the XML object must be substituted with a server variable. In an XML object, the server variable definition must be specified with the equal symbol followed by the value to be assigned to the XML attribute in double quotes. For example: `<XML attribute>="$SQLSERVER"`. The server variable is referenced in the relevant XML attribute as: `$`<server variable name>. For example, a server variable called `SQLSERVER` is referenced as `$SQLSERVER` in the XML object.

Server variables are defined in the Alfabet Administrator. To define a server variable to use in XML objects:

1) In the Alfabet Administrator, click the **Alfabet Aliases** node in the **Administrator** explorer.
2) In the table on the right, select the server alias that you want to define a server variable for and click the **Edit**  button. The alias editor opens.
3) Go to the **Variables** tab and click the **New** button. A dialog box opens.
4) In the **Variable Name** field, enter a unique name for the server variable.

   The server variable name may only contain letters (English alphabet), numbers, and the underscore symbol.

5) In the **Variable Value** field, specify the value to use for the server variable.

   If the variable value contains a special character according to XML standards (for example: &, %, ;,<,>), these characters must be replaced by with their respective XML compliant code (for example: `&` for &)

6) Click **OK** to save your changes. The server variable definition appears in the list of server variables.

To edit or delete the server variable, select the server variable in the table and click the **Edit** or **Delete** button below the table.

7) Click **OK** to save your changes and close the editor. The server variable definition is now available in the server alias configuration and can be used in the relevant XML objects available in the **Integration Solutions** folder in Alfabet Expand.

Accessing and Editing Objects in Alfabet

Sometimes Alfabet objects must be accessed and edited for administrative reasons. For example, it may be necessary to reassign objects to a new authorized user if the previous user who was responsible for those objects is no longer part of the Alfabet user community. Or it may be necessary to correct an object's release status that may have accidentally been set to a non-editable release status.

Normally, this type of object maintenance is carried out by a user administrator accessing the Alfabet solution by means of the `Admin` user profile but it can also be done by accessing the Alfabet solution from Alfabet Expand.

User administrators and users of Alfabet Expand have complete access to all objects in Alfabet regardless of the access permissions defined for such objects. You can make specific changes to the solution environment by working directly in the Alfabet solution that you access in Alfabet Expand.

To access the Alfabet solution from Alfabet Expand:

1) Go to the **Admin** tab and expand the **User Profiles** node.
2) Right-click the user profile that provides access to the object you want to edit and select **Run Application with Selected User Profile**. The Alfabet solution opens.
3) Navigate to the object that must be modified and make the relevant changes.
4) When the changes have been made, close Alfabet. In the toolbar, click the **Save**  button to save your changes. The changes are saved to the Alfabet database.

Getting An Overview of the Current Configuration

Several object classes in the Alfabet meta-model store information about the current structure of the object class model including both standard and customer defined configurations performed on Alfabet object classes as well as the current configuration of the presentation model, like the configuration of object profiles. The information stored in these tables can be used to build configured reports that inform about selected aspects of the configuration.

Each of these object classes has class settings, a simple object profile with an attribute section only and a selector assigned.

Each object in the `ALFA_MM_*` and `ALFA_PM_*` tables has a unique `REFSTR`. References between the tables are provided via properties of the type `Reference`.

The following object classes are available to inform about the meta-model structure:

- ALFA_MM_CLASS_INFO: Each object class in the Alfabet meta-model is stored as an object of the ALFA_MM_CLASS_INFO class. The properties of the ALFA_MM_CLASS_INFO object class return relevant attributes of the object class, like for example the **Tech Name** and **Caption** and whether the object class can have mandates. The table only stores information about object classes that are visible in the Meta-Model tab in Alfabet Expand.

- ALFA_MM_STEREOTYPE_INFO: Each stereotype defined in the XML object in the attribute **Stereotypes** of an object class is stored as an object of the ALFA_MM_STEREOTYPE_INFO class. The properties of the ALFA_MM_STEREOTYPE_INFO class inform about the object class the stereotype is defined for and relevant attributes of the relevant XML element Stereotype.

- ALFA_MM_PROP_INFO: Each object class property in the Alfabet meta-model is stored as an object the ALFA_MM_PROP_INFO class. The properties of the ALFA_MM_PROP_INFO class inform about the object class the object class property belongs to and relevant attributes of the object class property, like for example the data type.

- ALFA_MM_RELATION_INFO: Each relation established via an object class property in the Alfabet meta-model is stored as an object of the object class ALFA_MM_RELATION_INFO. The properties of the ALFA_MM_RELATION_INFO store the information about the object class property establishing the relation, the object classes the relation is established from and pointing to and whether the relation is a one to one, one to multiple, or multiple to multiple relation. If an object class property in the Alfabet meta-model stores references to multiple object classes, a separate object of the object class ALFA_MM_RELATIONS_INFO is created for each target object class.

- ALFA_MM_ENUM_INFO: Each enumeration item created for an enumeration in the Alfabet meta-model is stored as an object of the object class ALFA_MM_ENUM_INFO. The properties of the ALFA_MM_ENUM_INFO object class store information about the enumeration the enumeration item is defined for and the relevant attributes of the enumeration item.

- ALFA_MM_INTEGRITY_INFO: The attribute **Integrity Info** of an object class defines which objects referenced by an object of the current class via defined object class properties are dependent objects. If an object is deleted, all objects that are referenced via one of the properties defined in the **Integrity Info** attribute are also automatically deleted. Each object class property in the Alfabet meta-model that is part of an **Integrity Info** definition is stored as an object of the object class ALFA_MM_INTEGRITY_INFO. The properties of the object class ALFA_MM_INTEGRITY_INFO store information about the master object class, which is the one for that an object is actively deleted, the object class for those referenced objects is automatically deleted as well, and the object class property that is establishing the dependent relation.

  Please note the following about the information stored in the ALFA_MM_INTEGRITY_INFO table.

  - Integrity references are only stored in the ALFA_MM_INTEGRITY_INFO table if both the master class and the referenced object class are visible in the **Meta-Model** tab in Alfabet Expand.

  - The **Integrity Info** attribute is inherited within the hierarchy of object classes. The hierarchical structuring of object classes is not visible in the **Meta-Model** tab in Alfabet Expand. Customers with a license for ADIF can see the object classes within the hierarchical structure in the **Meta-Model** node of the **ADIF** tab explorer. If an integrity reference is not included in the **Integrity Info** attribute of the master object class or the referenced object class but nevertheless stored in the ALFA_MM_INTEGRITY_INFO table, it is inherited from a hierarchical parent class.

- ALFA_MM_CAPABILITY: Each object class of the Alfabet meta-model is assigned to one or multiple Alfabet capabilities. Each combination of object class and capability is stored as an object of the object class ALFA_MM_CAPABILITY.
- ALFA_MM_CULTURE_INFO: Each culture defined in the Alfabet meta-model is stored as an object of the ALFA_MM_CULTURE_INFO object class. The properties of the ALFA_MM_CULTURE_INFO object class return relevant attributes if the culture, like for example the setting for the data translation capability.
- ALFA_PM_OBJECTVIEW_INFO: Stores information about the object views in the Alfabet meta-model. The properties of the ALFA_PM_OBJECTVIEW_INFO object class return relevant attributes of the Object View configuration object, like for example the **Name** and **Caption** and the object class the object view is defined for.
- ALFA_PM_OBJECTVIEWDETAIL_INFO: This object class stores information about which page views, configured reports, and object cockpits are assigned to the object view in the object view configuration of the Alfabet meta-model. The information about the page view and report configuration includes information about the relevant work space. The information is stored as references to the ALFA_PM_*_INFO object classes storing information about the configuration objects assigned to the object cockpit as well as the ALFA_REPORT table for configured reports.
- ALFA_PM_COCKPIT_INFO: This object class stores information about the object cockpit configuration of the current Alfabet meta-model. The properties of the ALFA_PM_COCKPIT_INFO object class return a reference to the relevant object view information in the ALFA_PM_OBJECTVIEW_INFO object class and relevant attributes of the object cockpit configuration object, like for example the **Name** and **Caption**, defined visibility conditions and which kind of help is provided for the object cockpit.
- ALFA_PM_COCKPITDETAIL_INFO: This object class stores information about which page views and configured reports are included in object cockpits. The information includes a reference to the information about the relevant object cockpit information in the ALFA_PM_COCKPIT_INFO object class and references to the relevant information about the standard page view or configured report in the ALFA_PM_PAGEVIEW_INFO object class or ALFA_REPORT object class respectively.
- ALFA_PM_PAGEVIEW_INFO: This object class stores information about the standard page views in the Alfabet meta-model.
- ALFA_PM_WORKSPACE_INFO: This object class stores information about the work spaces in the object profile configuration of the Alfabet meta-model.
- ALFA_PM_EDITOR_INFO: This object class stores information about the editors configured in the Alfabet meta-model.
- ALFA_PM_WIZARD_INFO: This object class stores information about the wizards configured in the Alfabet meta-model.
- ALFA_PM_WIZARDSTEP_INFO: This object class stores information about the wizard steps configured for the wizards in the Alfabet meta-model, including a reference to the information about the relevant wizard in the ALFA_PM_WIZARD_INFO object class.
- ALFA_PM_CONDITION_INFO: This object class stores information about the **Condition** s configured in the **Presentation** tab of Alfabet Expand. ALFA_PM_*_INFO object classes storing information about configuration objects with a visibility condition reference this object class.

For information about the object class properties of the ALFA_MM_* and ALFA_PM_* object classes, see the reference manual *Alfabet Meta-Model*.

The content of these database table will not be updated automatically when a new configuration is added to the meta-model using Alfabet Expand.

To update the information after having performed a change to the configuration of the Alfabet class model:

1) In the menu of Alfabet Expand click **Meta-Model** > **Generate Meta-Model Information** to update the `ALFA_MM_*` object class tables or **Meta-Model** > **Generate Presentation Model Information** to update the `ALFA_PM_*` object class tables.

The information is updated automatically during update of the meta-model from an AMM file or a master database.

The content of the table must not be altered by any other mechanisms.

Tools and Alfabet Functionalities for Configuration

Software AG provides a number of tools to simplify the tasks of configuration. If a specific tool is not described in this documentation, the respective manual describing the tool will be referenced.

The following Alfabet tools and functionalities are described below:

Use the Configuration Tool...	In Order To...
Alfabet Administrator	Configure the Alfabet components and manage the Alfabet database. Configure access rights to Alfabet and track Alfabet usage and audit history. The Alfabet Administrator is described in the reference manual *System Administration*.
Alfabet Expand	Configure the Alfabet solution. Many Alfabet functionalities as well as administrative tasks are based on a specific solution configuration defined in Alfabet Expand. For information about the configuration tool Alfabet Expand, see the reference manual *Configuring Alfabet with Alfabet Expand*. This is available as a PDF document on your installation CD. Alfabet Expand is currently available as either Alfabet Expand Windows or as Alfabet Expand Web. Alfabet Expand Web is available for the Alfabet Cloud Enterprise and is a web-based tool that supports most core configuration tasks. Alfabet Expand Windows is required for more complex configuration tasks including workflow configuration, ADIF, and APF.
Guide Pages Designer	Create customized as start pages for the user profiles in your user community. The Guide Pages Designer is available as a web-based tool. For information about the Guide Pages Designer, see the reference manual *Designing Guide Pages for Alfabet*. This is available as a PDF document on your installation CD.

Use the Functionality in Alfabet...	In Order To...
Administration application	The **Administration** application is accessible via the Alfabet interface by using the `Admin` user profile. For more information, see the reference manual *User and Solution Administration*. The **Administration** application contains the following modules and functionalities: • User Administration • User Profiles Administration • Users Administration • User Groups Administration • Reports Administration • Solution Administration • Monitors • Date Monitors • Consistency Monitors • Notification Monitors • Monitor Management • Workflow Administration • Internal Documents • Archive Manager • Broadcast Messages • Discussion Groups • Risk Management Templates • Technical Environments • Time Series Manager • Publications Manager • Risk Mitigation Templates by Risk Mitigation Category • ADIF Jobs Administration • Email Messages logging • Automated Data Translations • Event Administration

Use the Functionality in Alfabet...	In Order To...
	• Questionnaire Indicators • Configuration • Reference Data • Evaluations and Portfolios • Class Configuration • Diagram Views • Costs Centers • Manage Business Documents • Color Rules Manager • Enterprise Calendars • Integration Solutions Configuration • Search • Simple Search • Browse • Full-Text Search • Glossary • Reports • Publication • Admin Desktops • Organization Admin • Application Group Admin • Component Group Admin • Domain Admin • ICT Object Category Admin • Data • Capture Data • ADIF Jobs Administration

Use the Functionality in Alfabet...	In Order To...
Configuration module	The **Configuration** module is accessible via the Alfabet interface. For more information, see the reference manual *Configuring Evaluation and Reference Data in Alfabet*. The **Configuration** module contains the following functionalities: • Reference Data • Evaluations and Portfolios • Class Configuration • Diagram Views • Costs Centers • Manage Business Documents • Color Rules Manager • Enterprise Calendars • Integration Solutions Configuration

The configuration tools Alfabet Expand and the Guide Pages Designer are optional components. Their availability is regulated by your enterprise's licensing agreement with Software AG. In addition to the configuration tools, a number of small executables for batch job processing are available. Their functionality is described in the reference manual *System Administration* in conjunction with the relevant tasks to be performed.

Chapter 2: Executing Administrative Tasks in Alfabet Expand

This chapter describes the tasks that are not directly related to the configuration of an Alfabet functionality but are required to administrate the configurations performed with Alfabet Expand and to support system administration tasks.

The following administrative tasks can be carried out in Alfabet Expand:

- Anonymizing All Relevant Data in the Alfabet database
- Anonymizing Data of Selected Users
- Creating a Database Archive File Containing Anonymized Data
- Checking Anonymization Actions
- Configuring Default User Settings for the User Community
- Configuring the Use of External Sources with Alfabet
- Configuring Selectors for Data Synchronization with External Sources
- Configuring the Alfabet User Interface to Map Standard Configuration Objects to Custom Configuration Objects
- Configuring the Visibility of Tabs in Alfabet Expand

Applying Configuration Changes to Other Databases

The Alfabet database is the basis of the Alfabet software. Software AG provides mechanisms to archive part or all of the configuration performed in an Alfabet database and restore it to another Alfabet database. These mechanisms enable configuration based on a copy of a production database in a configuration environment as well as the testing of the new configuration prior to implementing it in the production environment.

Software AG provides the proprietary file format AMM for storing the configuration of an Alfabet solution in one Alfabet database and restoring it in another Alfabet database. This is the central mechanism for configuration exchange. For special data types that cannot be included in AMM files, the **Import Data Search** capability can be used to import data from one Alfabet database to another Alfabet database.

The following information is available:

- About the Storage of the Configuration in the Alfabet database
- About Storage of Changes to the Meta-Model Performed with Alfabet Expand in the Alfabet database
- Overview of Administrative Tasks Related to Solution Design
- Taking Over Configurations Performed in Alfabet Expand With AMM Based Mechanisms
- Identifying Configuration Objects via Solution Tagging
- Setting Tags for a Single Configuration Object
- Setting or Removing Tags For Multiple Configuration Objects Simultaneously
- Setting a Default Tag Automatically Applied to New and Changed Objects
- Versioning of Configurations
- Saving the Configuration of the Alfabet Solution to an AMM File
- Saving Complete or Tagged Types of Configuration Objects or the Complete Configuration with Alfabet Expand

- Saving Selected Objects of the Configuration with Alfabet Expand
- Storing all Objects Tagged With a Selected Tag to an AMM File
- Updating the Configuration of the Alfabet Solution Environment with Alfabet Expand
- Direct Import of the Solution Configuration from a Master Database
- Overwriting the Solution Configuration with the Configuration of a Master Database
- Merging the Solution Configuration with the Configuration of a Master Database
- Checking and Repairing the Configuration Updates From a Master Database
- Correcting Issues that Occurred During Meta-Model Update
- Checking the Success of Meta-Model Updates
- Securing and Checking Database Consistency with the Meta-Model
- Comparing Database Configurations
- Exporting Information About the Custom Configuration in an XML File
- Building Custom Reports that Inform About the Current Structure of the Standard And Custom Meta-Model
- Importing Objects of Configuration Relevant Object Classes from a Master Database
- Configuring the Connection Between the Source and Target Database
- Configuring the Source Database to Provide Access to the Relevant Data via the Alfabet RESTful Services
- Configuring the XML Object AlfabetIntegrationConfig of the Target Database
- Creating an Alfabet Database Connection in the Target Database
- Providing Access to the Import Data Search Functionality
- Optional Configuration for Detection of Changes to Configuration Object
- Importing Configuration Objects from a Source Database
- Managing Assemblies
- Uploading Assemblies from One Database to Another Database via AMM File

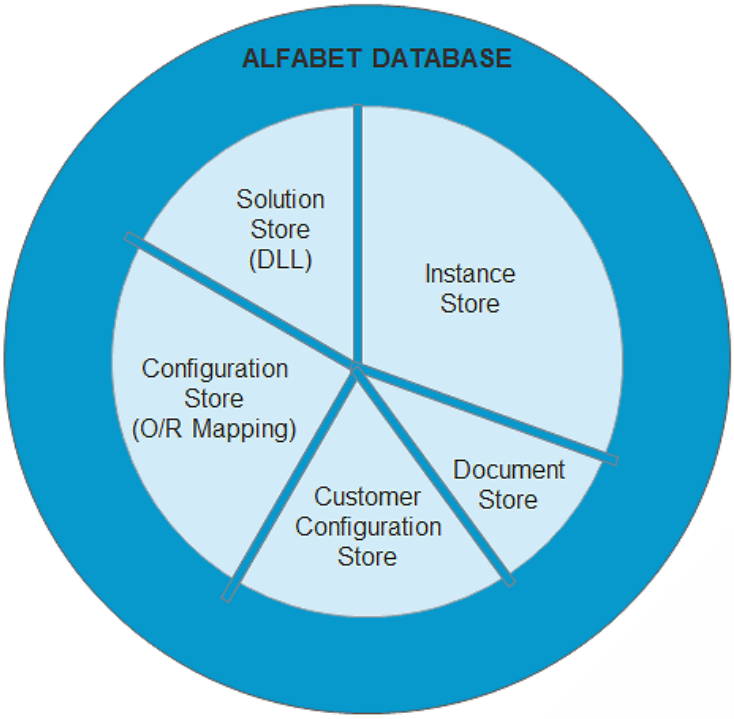
About the Storage of the Configuration in the Alfabet database

The Alfabet database comprises the following information:

- The functionality of the Alfabet solution (solution store). The software functionality is delivered by Software AG as a DLL file. The main solution assembly is typically uploaded to the Alfabet database by Software AG Support only during the upgrade to new Alfabet versions. Special assemblies delivered to the customer upon request can be uploaded using the **Assemblies** functionality in the tool Alfabet Administrator. For more information about managing assemblies, see the section

Managing Assemblies in the reference manual *System Administration*. Assemblies uploaded to one Alfabet database can then be stored to AMM files and transferred to other Alfabet database s.

- The configuration and database structure provided by Software AG for the Alfabet solution (configuration store). This meta-model information is typically updated by Software AG Support only during upgrade to a new Alfabet version. The update is executed via an AMM file that includes all meta-model related information.
- The configuration performed by the customer using Alfabet Expand or Alfabet Administrator (customer configuration store). Customers can save the configuration in AMM files and merge the configuration to another Alfabet database or overwrite the existing configuration with the customer configuration stored in an AMM file. For more information about saving and restoring the configuration store, see Saving the Configuration of the Alfabet Solution to an AMM File.
- The instances in the Alfabet inventory created by users in the Alfabet user interface (instance store). The instance store cannot be stored in AMM files. Nevertheless, the instance can include configuration relevant data such as, for example, reference data that includes indicator types and role types defined via the **Configuration** functionalities in the Alfabet user interface. To transfer data over to another Alfabet database, a direct connection between the source and target database can be configured by the solution designer and the data can then be integrated to the target database via the Alfabet user interface of the target database. Integration can be performed on an object-by-object basis.
- The documents uploaded to the **Internal Document Selector** (document store). The customer-defined guide pages that are created to provide guide pages for the Alfabet user interface are the only part of the document store that can be saved to an AMM file that can then be used to overwrite guide pages of a target database with the version stored in the AMM file. All other documents in the **Internal Document Selector** can only be stored in normal database backup files on the database server level.



About Storage of Changes to the Meta-Model Performed with Alfabet Expand in the Alfabet database

Technically, changes to the meta-model may be performed via Alfabet Expand while at the same time:

- users are currently changing the data in the same database via a running Alfabet Web Application.
- the meta-model is changed by another solution designer in another instance of Alfabet Expand connected to the same database.

It is highly recommended to change the configuration via Alfabet Expand in a solution environment that is not connected to the production database to avoid that configuration changes interfere with users changing the data in the same database.

It is also highly recommended to change a database with one Alfabet Expand instance at a time.

Even if only one solution designer is changing the configuration in a development environment, it is useful to know how and when the configuration changes performed in Alfabet Expand are available in the Alfabet database and to the user connected to the Alfabet database via a running Alfabet Web Application. The solution designer might want to check the configuration by accessing the Alfabet user interface via a running Alfabet Web Application in the development environment.

Alfabet Expand Windows, Alfabet Expand Web and the Alfabet Web Application are loading a working copy of the configuration available in the Alfabet database at startup. The following applies for configuration changes:

- If a solution designer changes the configuration via Alfabet Expand Windows or Web, the changes are instantly applied to the working copy her/his Alfabet Expand instance, but they are only stored into the Alfabet database when the solution designer clicks the **Save** button in the toolbar of Alfabet Expand.
- This option re-loads the configuration from the Alfabet database into the local working copy of the configuration, overwriting any local changes.
- If a solution designer saves the configuration via the **Save** button, the configuration of the Alfabet database is changed, but changes are not instantly visible on an Alfabet user interface that is connected to the Alfabet database via a running Alfabet Web Application. The Alfabet Web Application also uses a working copy that is updated in regular intervals. Changes to the configuration of the Alfabet database might therefore only be visible to the user after several minutes. To ensure that the changes are visible in the user interface, the solution designer should re-start the web server hosting the Alfabet Web Application prior to checking new changes in the user interface.

  The Alfabet Web Application can be configured to work in `Design` mode for testing purposes. One of the options available in design mode is a button **Meta-Model** in the user interface with options to re-read the meta-model or to re-start the web server. For more information, see *Special Configuration of Testing Environments* in the reference manual *System Administration*.

- The working version of the meta-model in Alfabet Expand is not updated automatically. Therefore, if one Alfabet Expand instance saves configuration changes to the database, the working version of the meta-model of all concurrently active Alfabet Expand instances is outdated. To update the working version of Alfabet Expand with the current version of the meta-model configuration in the Alfabet database, click **Meta-Model** > **Reread Meta-Model** in the menu of your Alfabet Expand instance.

- Changes to object classes, like for example introducing a new custom property, are central changes that might interfere with the storage of object data that is stored when a user creates objects of the class. To ensure that the central class model a user is working with is always identical with the class model stored in the Alfabet database, saving a change to the object class model via the **Save** button will cause a semantic lock to the Alfabet database. All currently open connections from Alfabet components will be closed. A message will be displayed to solution designers concurrently working with other Alfabet Expand Windows instances, informing them about the lock to the database. Alfabet users currently working on the same Alfabet database in the Alfabet user interface or with Alfabet Expand Web are informed that their session expired. The meta-model changes will then be updated to the Alfabet database. The Web server must be restarted.

  If the connection to the database is closed while you have already created or changed configurations, you can save your unsaved changes into an AMM update file, reconnect to the Alfabet database, and check in the configuration change via the AMM update file. Please note that this automatically saves the changes. For information about storing and re-storing configurations in AMM files, see Saving the Configuration of the Alfabet Solution to an AMM File. In the functionality to selectively store configuration objects in AMM files a search for unsaved objects is available that eases the storing of unsaved configuration in this context.

- A backup of the Alfabet database should always be made before making changes in order to prevent the inadvertent and irrevocable loss of important configuration data.

Overview of Administrative Tasks Related to Solution Design

It is recommended that all changes to the solution configuration are performed in a development environment and tested in a test environment before the solution configuration is migrated to the production environment. All development and test environments should be based on copies of the production database. An overview of the development, test, and production environments is provided in the section *Best Practice Installation and Workflow* in the reference manual *System Administration*.

Software AG provides mechanism that allows the customer configuration specified in the development environment to be saved and restored in another database independent of other parts of the database. With these mechanisms, the configuration developed by a solution designer in a test environment can be first taken over to a test database and, after successful testing, to a production database without affecting the content of the instance store, which means the data created by users via the Alfabet user interface.

In general, two main mechanisms are available for taking over configurations from one database to another database:

- The customer configuration store and optionally the solution store can be saved to an AMM updater file. The updater file allows the configuration of a target database to either be merged or replaced by the configuration stored in the AMM updater file.
- Configuration relevant objects stored in the instance store of the Alfabet database can be imported to a target database via a direct connection between the source (master) database and the target database. The target database must be configured to connect to the source database prior to using this functionality. The configuration can then be transferred via an administrator that is logged in to the Alfabet user interface and has access to the import functionality.

For best practice solution configuration and database maintenance, it is recommended that a solution designer should be responsible for the development database, whereas any tasks performed on the database

in the production environments should be performed by a system administrator. The tool Alfabet Administrator allows all tasks that are required for database maintenance to be performed by the system administrator. Most of the tasks can also be performed by the solution designer using Alfabet Expand. Depending on your enterprise's policies, the solution designer could optionally carry out system administration tasks on the development and test database independent of the system administrator.

A typical solution design cycle includes the following database maintenance tasks:

- A new configuration is best carried out on an up-to-date copy of the production database. Backup files created during regular backup on the database level can be used to restore a copy of the production database in a test environment.

The following is possible:

- The solution designer can restore the current database and start working with the exact copy of the production database, thus overwriting any configuration steps done in the development environment that have not yet been applied to the production environment
- The solution designer can conserve current changes to the configuration in the development environment. He/she can save the current customized configuration of his/her development database to an AMM file before overwriting the development database with the database backup file of the production database and restore the customized configuration he/she is currently working on from the AMM after database restore.
- After performing the required solution configurations, the solution designer can then save the configuration to an AMM update file. This file is then used to replace the configuration of an up-to-date copy of the production database in a test environment, for example by a system administrator using the tool Alfabet Administrator. Alternatively, a direct connection from the test environment to the development environment can be established that allows either the solution designer or the tester to update the test environment configuration using Alfabet Expand.
- Once tests have indicated that the configuration is correct, the configuration of the production database can be replaced or merged with the new configuration.
- Whether configurations have to be merged or replaced with a new configuration depends on the configuration steps performed. The AMM file includes information about the update mechanism. It can exclusively be generated with the configuration tool Alfabet Expand because the solution designer can best decide on the update requirements to be specified for the AMM file.

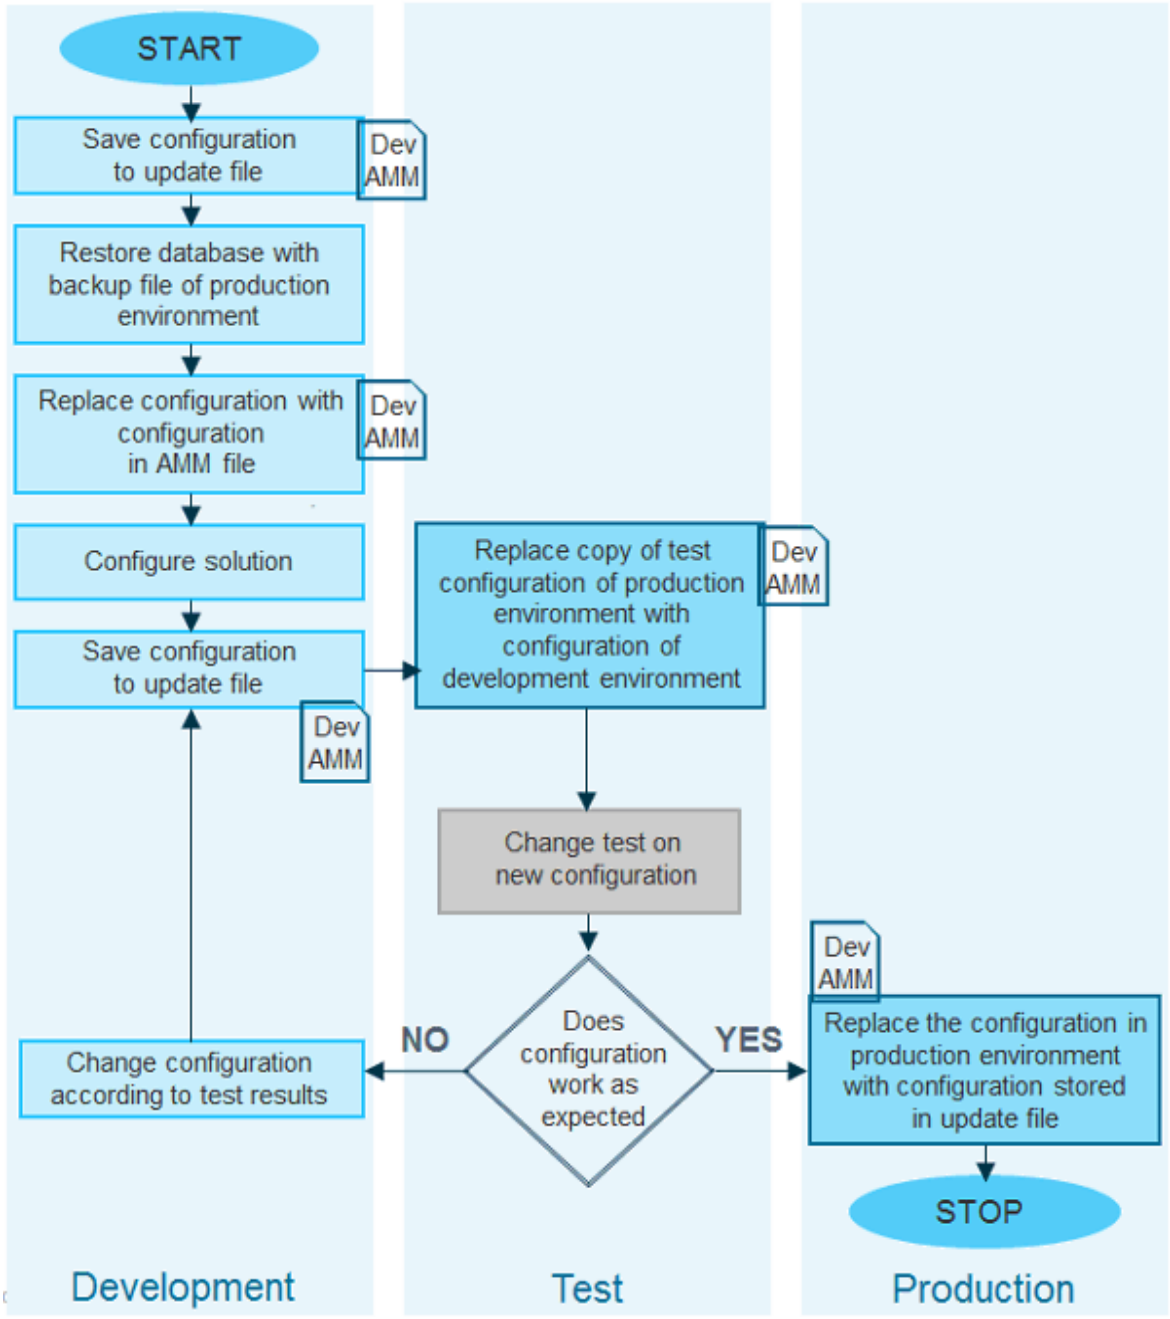


FIGURE: Best practice for the configuration of the Alfabet solution

The figure above does not include the mechanisms for transferring configuration objects via a direct connection between databases. For the update via an AMM file from another Alfabet database in the test and production environment, an AMM based update via a direct connection can alternatively be performed. If required, the import of configuration objects in the instance store shall be executed afterward the update of the configuration via the AMM based mechanisms via the **Import Data Search** functionality.

Taking Over Configurations Performed in Alfabet Expand with AMM Based Mechanisms

Different AMM mechanisms are available that allow to take over the configuration, that means all configuration objects defined in Alfabet Expand and a subset of the reference data defined in the **Configuration** functionalities in the Alfabet user interface.

Some configurations in Alfabet are not stored as part of the meta-model configuration and must be saved to a target database using other mechanisms. This applies to the following configurations:

- **Configuration of some reference data configured in the Configuration module in the Alfabet user interface**: These configurations are saved in the instance store of the database. Only the selected subset of configurations listed above can be included in AMM files. The functionality **Import Data Search** can be used for import of the reference data that cannot be included into the AMM file. For more information, see Importing Objects of Configuration Relevant Object Classes from a Master Database.
- **Mandate configuration**: The configuration of mandates is saved in the instance store of the database. The functionality **Import Data Search** can be used for import of mandate configurations. For more information, see Importing Objects of Configuration Relevant Object Classes from a Master Database.
- **Documents uploaded to the Internal Document Selector**: Documents in the **Internal Document Selector** can only be stored in normal database backup files on the database server level or added to the target database manually. This may impact the images and stylesheet files stored in the **Internal Document Selector** that are to be used in HTML templates implemented in the workflow capability. Although HTML templates can be saved to an AMM file and uploaded to a target database via the meta-model update, the images and stylesheet files must be uploaded to the **Internal Document Selector** of the target database via **Internal Documents** functionality in the Alfabet user interface, which is accessible via the `Admin` user profile.

During the creation of an AMM update file, the solution designer can decide about the scope of the configuration that shall be taken over to the target database. He/she can decide to select:

- The complete configuration.
- All configuration objects of selected types of configuration objects such as all workflows or all diagram view items.
- All configuration objects tagged with a defined tag that is set by the solution designer as part of the configuration process. It is additionally possible to store only tagged objects of selected configuration object types into the AMM file.
- A subset of configuration objects selected by the solution designer from a list of all available configuration objects according to his/her demand prior to creating the AMM file.

During the restore process, the parts of the configuration saved in the AMM file are merged with the corresponding configuration of the target database. The parts of the configuration that are not included in the AMM file are not affected by the merge action. Alternatively, the entire existing configuration in the target database can be replaced with the configuration in the AMM file. If this option is selected, the solution designer must make sure that the complete configuration is stored in the update file.

Alfabet Expand basically offers two mechanisms to take over configurations stored into AMM files to a target database:

- The AMM file is created by a solution designer from the development database in an Alfabet Expand connected to the development database. The solution designer can decide with maximum flexibility about which configuration objects to take over to the target database. The AMM file is then used to update the target database.
- The creation of the AMM file and the update of the configuration are both performed via an Alfabet Expand connected to the target database. In this case, a direct connection between the source and the target database must first be configured in the server alias of the target database. The complete update process including storage of data from the source database in the AMM file and update of the meta-model in the target database is performed on the target database, most likely by someone that did not change the configuration in the source database personally. Therefore, the selection mechanisms for taking over solution objects are restricted for this mechanism and the basic decision about overwriting the configuration in the target database or merging the configurations is defined in the server alias of the Alfabet Expand connecting to the target database.

For all AMM file-based mechanisms, translations provided in the source database for the solution configuration objects stored in the AMM file are automatically also stored in the AMM file and added to the vocabulary of the target database during update of the meta-model with the AMM file. Vocabulary review information like proposed changes and reviewer information is not stored in the AMM file. The following columns of the ***ALFA_SYS_VOCABULARY*** database table are included into the update via AMM file: `ORIGINAL`, `SOURCE`, `ACCESSIBILITY`, `HASHED_ID`, `OBSOLETE`, `CREATE_DATE`, `OBSOLETE_DATE`, and `REPLACES`.

The following information is available:

- Identifying Configuration Objects via Solution Tagging
- Setting Tags for a Single Configuration Object
- Setting or Removing Tags For Multiple Configuration Objects Simultaneously
- Setting a Default Tag Automatically Applied to New and Changed Objects
- Versioning of Configurations
- Saving the Configuration of the Alfabet Solution to an AMM File
- Saving Complete or Tagged Types of Configuration Objects or the Complete Configuration with Alfabet Expand
- Saving Selected Objects of the Configuration with Alfabet Expand
- Searching for Objects in the Find Results Table of the Meta-Model Objects Editor
- Storing all Objects Tagged With a Selected Tag to an AMM File
- Updating the Configuration of the Alfabet Solution Environment with Alfabet Expand
- Direct Import of the Solution Configuration from a Master Database
- Overwriting the Solution Configuration with the Configuration of a Master Database
- Merging the Solution Configuration with the Configuration of a Master Database
- Checking and Repairing the Configuration Updates From a Master Database
- Correcting Issues that Occurred During Meta-Model Update

- Checking the Success of Meta-Model Updates
- Securing and Checking Database Consistency with the Meta-Model
- Comparing Database Configurations
- Exporting Information About the Custom Configuration in an XML File
- Building Custom Reports that Inform About the Current Structure of the Standard And Custom Meta-Model

Identifying Configuration Objects via Solution Tagging

Solution objects can be marked with one or multiple tag names to define which solution configuration project the configuration is relevant for. This is useful to ease the selection of meta-model objects for deployment because you can search for a defined solution tag. The main reason for tagging, however, is to identify the objects that are part of a selected configuration when the configuration must be changed.

For example, a company-specific process requires the maintenance of custom attributes for an object class. The custom attributes defined for the process as well as the custom editor, the custom reports, and the workflow designed for the process are all tagged with the name of the process. After the solution is complete and successfully migrated to the production environment, an additional custom attribute was required as well as modification of the custom editor and the design of a completely different workflow.

During redesign in the development database, the solution designer is able to identify which objects might be affected by searching for the relevant solution tags. After changing the configuration, the production database must be updated. The solution designer selects all configuration objects tagged with the process name to upload to the AMM file.

During update of the production database, these objects will be updated. But in the case of the workflow template, the update is not sufficient because the old workflow template for the solution is not updated but deleted and replaced by a new workflow template with a different name. The solution designer can now configure the AMM file to trigger automatic deletion of all configuration objects tagged with the process name from the target database prior to writing the configuration stored in the AMM file to the database. In this way, the old workflow will be deleted from the target database and the new workflow template will be added.

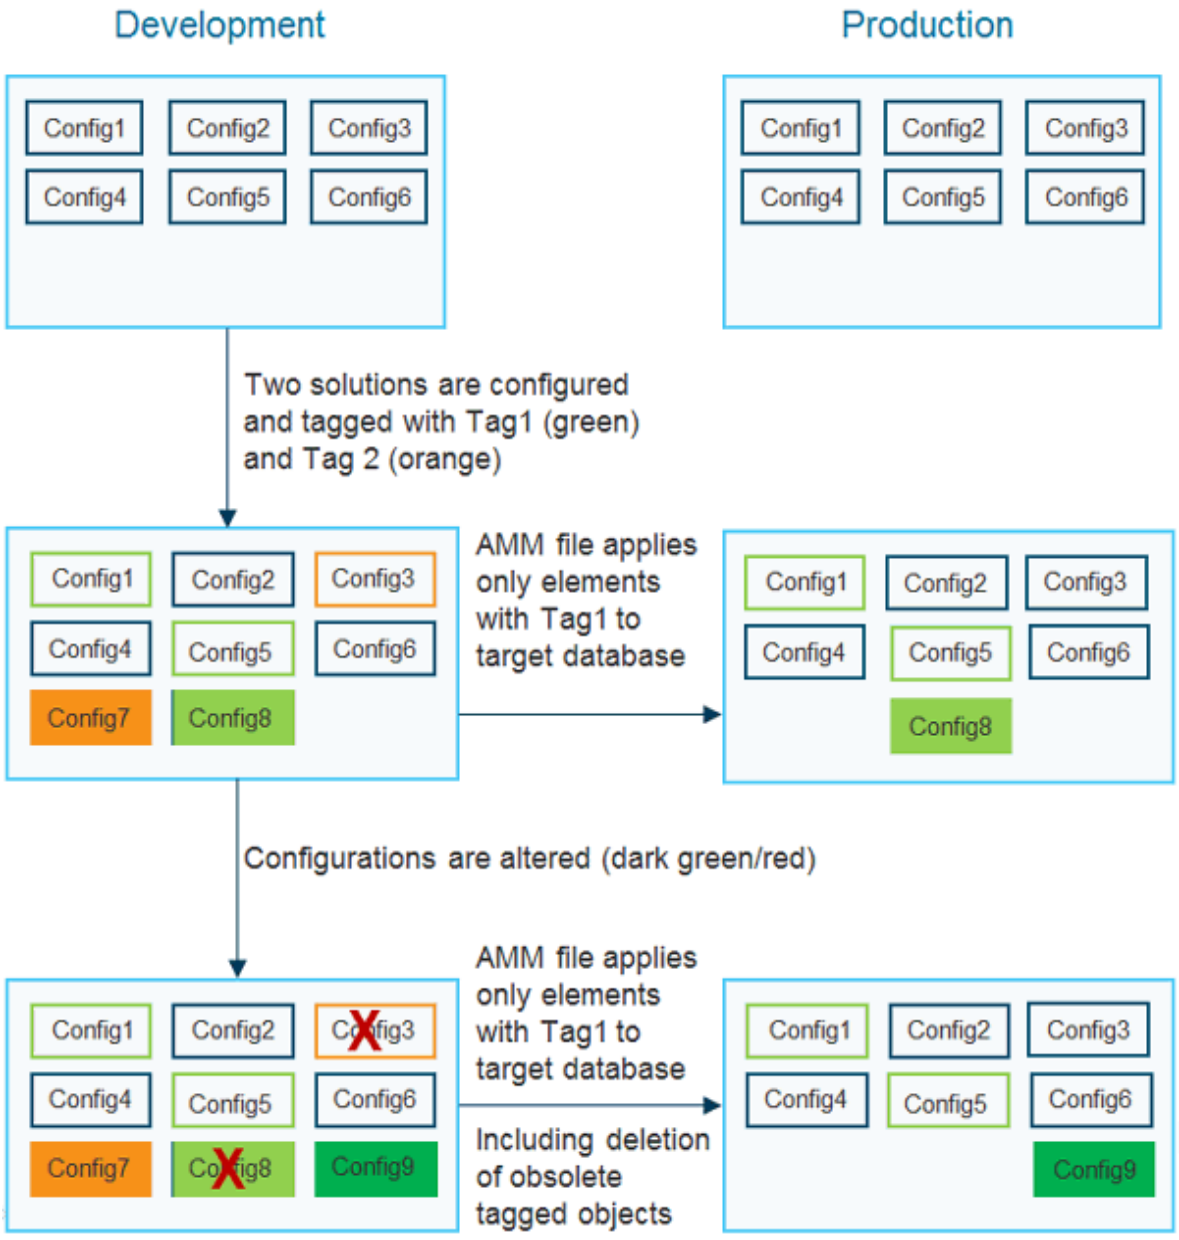

FIGURE: Configuration changes applied to a target database using solution tagging mechanisms in AMM files

In addition to applying a tag to configuration objects, you can also alter the attribute **Version** of an object each time a reconfiguration is done to specify for which version of a feature this configuration is done. The **Version** attribute is part of the **Tech Info** specification for a configuration object.

Solution tags can be added to single objects while the object is configured or to a bundle of configuration objects during selection of the configuration objects for upload to an AMM file.

To avoid errors caused by misspelling solution tag names, the tag name will be defined only once the first time it is applied and is then selected from a selector for all subsequent tagging actions. The names of the solution tags are case-sensitive.

Instead of setting the tags for each individual configuration object or a bundle of configuration objects manually, you can configure Alfabet Expand to mark all new or changed configuration objects with a default tag. A solution designer can set the default tag to the task he/she is currently working with to ensure that all objects are correctly tagged and change the default tag when starting the configuration of the next feature. If you change an existing configuration object that is tagged with a tag different to the selected default tag, the default tag is added to the list of tags for the configuration object. Existing tagging is not overwritten.

The default tag setting is removed when the user logs out from Alfabet Expand and must be re-set if required after re-login.

Once objects are tagged, you can create a AMM file including only the tagged objects via the mechanism described in the section Saving the Configuration of the Alfabet Solution to an AMM File.

If you want to delete obsolete tagged objects in the target database, make sure that the AMM file contains all objects currently tagged with the tag name are included in the AMM file and enter the name of the tag in the field **Provide comma-separated tags to find objects to be removed**. It is recommended that you use this mechanism if you want to only replace (rather than merge) the configuration of reports, workflows or ADIF schemes.

Changes to the class model, that means custom object classes and object class properties, cannot be removed via this mechanism.

Setting Tags for a Single Configuration Object

To tag a single configuration object:

1) Select the configuration object that you want to tag in the explorer.
2) In the attribute window of the configuration object, expand the **Tech Info** section.
3) Click the **Browse**  button in the **Tags** field to open the **Meta-Model Tags** window.
4) Click into the field for the attribute **Tags** to open the **Meta-Model Tags** window.
5) In the toolbar, click the **Rescan Tags**  button to update the display of available tags in the list.
6) If you want to add a new tag to the list, click the **New Tag**  button, enter a name for the tag in the **Name** field of the input dialog window and click **OK**. The names of the solution tags are case-sensitive.
7) Select the one or more checkboxes for the listed tags to apply the tags to the configuration object.

   Selecting and clearing tags in this search field can only be performed via selecting or clearing tags from the **Meta-Model Tags** window. If you try to write content directly to the field or delete the field content, an error message will be displayed informing you that the field content is invalid. To correct this error, click **Cancel** in the error message. The old content will be displayed and can be altered via the **Meta-Model Tags** window.

8) Click **OK** to close the dialog.

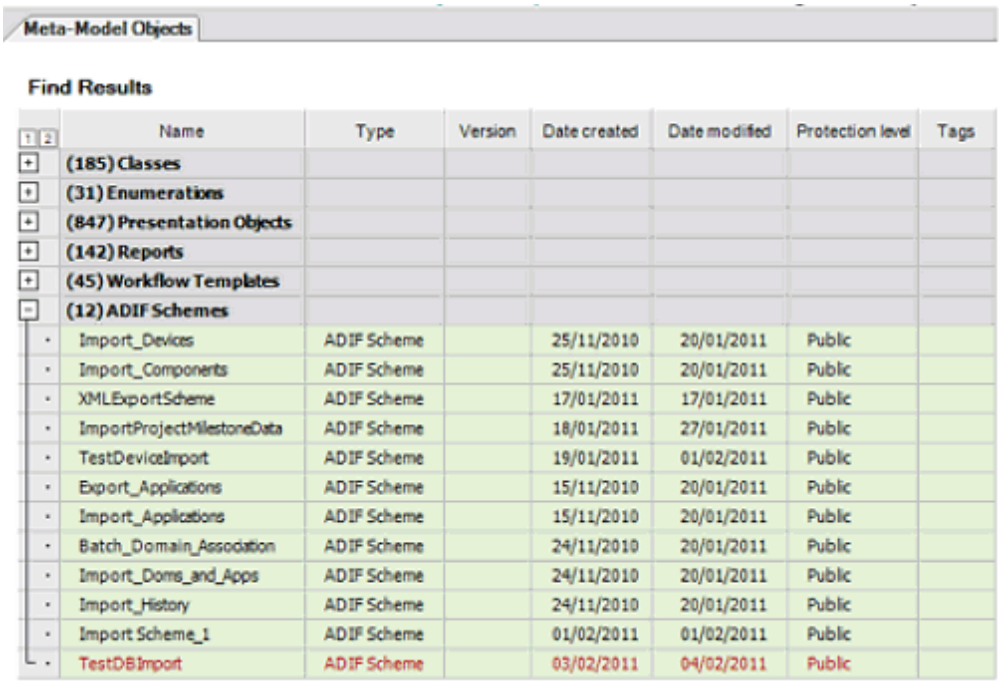
Setting or Removing Tags For Multiple Configuration Objects Simultaneously

To simultaneously set a tag or remove tags from multiple configuration objects:

1) In the Alfabet Expand menu bar, select **Meta-Model** > **Find Meta-Model Objects for Deployment**. A new **Meta-Model Objects** editor opens in the center pane between the explorer window and the attribute window.

2) In the toolbar, click the **Refresh Find Results** button.

3) All customer configured configuration objects are displayed in the **Meta-Model Objects** editor, sorted by category. The number of selectable objects in each category is displayed in front of the category name. To view the objects in a category, expand the category by clicking the sign in front of the category header. Alternatively, you can expand all categories by clicking the in the first column header.



4) Select the objects that you want to alter the tag setting for in the **Find Results** table. You can select several objects in the table at the same time by holding down the CTRL key while selecting.

> Optionally, you can use the search functionality of the **Meta-Model Objects** editor to limit the display of objects in the table to objects matching a defined search condition.
>
> For more information, see Saving Selected Objects of the Configuration with Alfabet Expand.

5) Do one of the following to alter the tag setting of the selected objects:

- To tag all selected objects, click the **Set Tag(s)** option in the toolbar to open the **Meta-Model Tags** window and click the **Rescan Tags** button to update the display of available tags in the list.

If you want to add a new tag to the list, click the **New Tag** button, enter a name for the tag in the **Name** field of the input dialog window and click **OK**. The names of the solution tags are case-sensitive.

Select one or more of the listed tags to apply the tags to the selected configuration objects.

- To remove selected tags from the selected objects, click the **Select Tags To Be Removed** button in the toolbar of the **Find Results** table. In the **Meta-Model Tags** window that opens, select the tags that you want to delete from the selected objects and click **OK** to save your changes.
- To remove all tags from the selected objects, click the **Remove All Tags from Selected Objects** button in the toolbar of the **Find Results** table.

Setting a Default Tag Automatically Applied to New and Changed Objects

To set a default tag:

1) In the toolbar of Alfabet Expand select **Meta-Model** > **Set Current Tag**.
2) If you want to add a new tag to the list, click the **New Tag** button, enter a name for the tag in the **Name** field of the input dialog window and click **OK**. The names of the solution tags are case-sensitive.
3) In the list of tags, click the link that you want to set as default tag to all new and changed configuration objects.

   The selection is removed when the user logs out of Alfabet Expand. If the selection shall be used again in the new session, the selection has to be repeated.

   Within the current session, you can revert to working without a default tag by selecting `None` from the list.
4) Click **OK** to close the window.

Versioning of Configurations

Optionally the solution designer can provide a name and version number for the configuration defined for the company. The configuration name and version defined in Alfabet Expand is written to all AMM files generated from the database and will overwrite a configuration name and version in the target database on update of the meta-model with the AMM files. the system administrator updating a database configuration with the AMM file can view the configuration name and version in the summary or the AMM content.

If a configuration name and version is defined, it will be displayed to users clicking **Help** > **About Alfabet** in the main menu of the Alfabet user interface on top of the Alfabet version information:

To define a configuration name and version:

1) In Alfabet Expand, go to the **Admin** tab.
2) In the explorer, click the **Environment** node.
3) In the attribute window, define the name and version for the configuration in the **Configuration Name** and **Configuration Version** attributes.
4) Click the **Save** button to save your changes.

Two new **Configuration Name** and **Configuration Version** attributes have been added to the **Utilities** node in Alfabet Expand Web. These attributes have already been available in Alfabet Expand Windows in the **Environment** node in the **Admin** tab. The name and version defined with these attributes will be written to all AMM files generated from the database and will be overwritten in the target database with the values in the AMM file on update of the meta-model. Solution designers can optionally use these attributes to manage the version history of changes applied to a production environment. The **Configuration Name** and **Configuration Version** values are shown in the **About Alfabet** screen.

Saving the Configuration of the Alfabet Solution to an AMM File

You can save the customized meta-model configuration of the Alfabet solution to AMM update files. An AMM file can then be used to replace or modify the configuration in an existing database. Not only is information about the database configuration contained in the AMM files. The AMM files also control how the information is updated in the target database. The decision to replace or merge the configuration with that of the target database or to migrate workflows during the configuration update is made when the AMM file is created.

AMM is a proprietary file format and therefore not recognized by Web browsers during download. If you want to store AMM files in a Web-based content management system or intranet for download, you must create a ZIP file containing the AMM file and store the ZIP file so that you can download the file via a Web browser to your local file system.

Usually, the system administrator will restore a custom configuration in the test and production environments using the Alfabet Administrator. Nevertheless, the functionality is also available in Alfabet Expand to allow the solution designer to restore a configuration.

Alfabet Expand offers different mechanisms for creation of an AMM file. The mechanisms differ in the way objects are selected for upload to the AMM file and in the availability of selection whether the configuration in the AMM file overwrites or changes the configuration in the target database.

Mechanism	Selection of objects	Overwriting or Changing the Configuration of the Target Database
Create Configuration Meta-Model Update File For more information, see Saving Complete or Tagged Types of Configuration	• Complete configuration • Selected types of configuration objects only, for example only all workflows.	Merge or replace

Mechanism	Selection of objects	Overwriting or Changing the Configuration of the Target Database
Objects or the Complete Configuration with Alfabet Expand.	• Only configuration objects tagged with a defined tag and belonging to selected configuration object types.	
Find Meta-Model Objects for Deployment For more information, see Saving Selected Objects of the Configuration with Alfabet Expand.	The solution designer can choose any combination of available configuration objects for upload to the AMM file. For configuration object types for that no objects are selected individually for upload, either all or none of the available configuration objects can be uploaded. Solution tagging can be taken into account.	Merge only
Save Meta-Model Objects Marked by Current Tag For more information, see Storing all Objects Tagged With a Selected Tag to an AMM File.	If all configuration objects that shall be merged into a target database configuration are tagged with the same tag, the tag can be set as current tag and an AMM file can be created that includes only the tagged objects.	Merge only

Saving Complete or Tagged Types of Configuration Objects or the Complete Configuration with Alfabet Expand

To save a custom configuration to an AMM file:

1) In the menu bar in Alfabet Expand, select **Meta-Model** > **Create Configuration Meta-Model Update File**. The **Create Configuration Meta-Model Update** editor opens:
2) In the **General** tab, select the location to store the information in the **Select Output File** field.
3) Provide a meaningful name and description for the update performed by the AMM file when applied to the target database in the fields **Name** and **Description**. The name and description are displayed in the **Update Meta-Model** dialog box when the AMM file is used to update the configuration in a database. It allows the person performing the update to be informed about the content of the configuration in the AMM file.
4) In the **Meta-Model Content** tab, select the configuration that you want to add to the AMM file:

- **Save Configuration**: Select the checkbox to save custom object class properties, custom enumerations and all customer defined configuration objects in the **Presentation**, **Functions**, and **Surveys** tabs in Alfabet Expand.

- **Save Reports**: Select the checkbox to save the content of the **Reports** root node of the explorer in the **Reports** tab in Alfabet Expand. If the report structure in the target database will change with the update, bookmarks linking to configured reports will be automatically updated when the configuration is merged.

  If a configured report that exists both in the target database and in the AMM file is updated, and a user or solution designer has restricted the display of columns of the configured report via the **Configure** button, new columns added to the configured reports will be hidden because they are not selected in the visibility setting.

  For information about hiding columns in configured reports, see the section Defining the Visibility of Page Views/Configured Reports Available at the Root Node of an Explorer in the chapter Configuring User Profiles for the User Community.

- **Save Workflow Templates**: Select the checkbox to save the content of the explorer of the **Workflow** tab of Alfabet Expand.
- **Save ADIF Schemes**: Select the checkbox to save the content of the explorer of the `ADIF` tab in Alfabet Expand.

  After the target database is updated by means of the AMM file, all ADIF import schemes in the target database that have the **Auto-Run** attribute set to `True` will be automatically executed. For more information about automatic execution of ADIF schemes, see *Configuring ADIF Schemes to be Automatically Executed on Update of the Meta-Model* in the reference manual *Alfabet Data Integration Framework*.

- **Save Event Templates**: Select the checkbox to save the content of the explorer of the **Events** tab in Alfabet Expand.
- **Save Diagrams**: Select the checkbox to save the custom diagram definitions and custom diagram item templates defined in the **Diagrams** tab in Alfabet Expand.

  Icons are not automatically saved if they are included in a diagram item template and the diagram item template is stored in the AMM file. If your configuration includes icons that are not available in the target database, make sure to also select **Save Icons**.

- **Save Publications**: Select the checkbox to save the content of the **Publications** tab in Alfabet Expand.
- **Save Database Views**: Select the checkbox to save the database views defined in the **Meta-Model** tab in Alfabet Expand.

  When the configuration is restored to the target database, all database views in the target database that are created based on a **Database View** configuration object will be recreated, even if **Save Database Views** is not checked. The solution designer should then check whether the creation of database views was successful. The required procedure is described in the section Saving the Configuration of the Alfabet Solution to an AMM File in the reference manual *Configuring Alfabet with Alfabet Expand*.

- **Save Icons**: Select the checkbox to save the icons uploaded to the Alfabet database.

Please note that the **Save Icons** checkbox in the **Meta-Model Content** tab must be selected in order to include any images included in the configuration of guide views.

- **Save Culture Settings**: Select the checkbox to save the content of the **Cultures** and **API Cultures** explorer nodes of the **Meta-Model** tab in Alfabet Expand.
- **Save Translation**: Select the checkbox to save the custom translation of strings displayed in the Alfabet user interface that are customized via the **Translation Editor** in Alfabet Expand.

When the translation includes the caption and description of configured reports, the **Update Translation** functionality available in the **Report** root node in Alfabet Expand must be executed on the target database after update with the AMM file.

5) Select the following options, if applicable for your configuration:

- **Replace Entire Existing Configuration**: Select the checkbox if you want the configuration in the AMM update file to overwrite an existing configuration in the target database during the **Update Meta-Model** action. If the checkbox is not selected, the configuration in the AMM update file is merged with the configuration in the target database.

If the **Replace Entire Existing Configuration** checkbox is selected, the configuration of the target database will be deleted prior to saving the configuration in the AMM file to the target database. All customer configurations that are part of the configuration of the target database but not part of the configuration saved in the AMM file will be lost. The replace mechanism deletes all parts of the configuration including the parts that are not selected to be part of the AMM update. The **Replace Entire Existing Configuration** checkbox should only be selected for AMM files when the parts of the configuration to be replaced have been selected.

Please note that reference data, assemblies and guide pages are not deleted prior to applying the configuration stored in the AMM file.

Cultures in the target database are removed with the exception of the primary culture (en-US), the default culture and the configuration culture. Any settings in the AMM file about the default culture or the configuration culture are ignored and the settings in the target database are maintained.

Configured reports that are automatically generated for the faceted semantic search functionality of the AlfaBot will not be deleted from the target database. For more information about automatically generated reports, see Managing Automatically Generated Reports.

If you want to replace only part of the configuration (for example, the configuration of workflows only), it is recommended that you use the solution tagging option. For more information about solution tagging, see Identifying Configuration Objects via Solution Tagging in the reference manual *Configuring Alfabet with Alfabet Expand*.

- **Automatically Migrate Affected Workflows**: Select the checkbox if you want the workflow templates to be automatically migrated to the target database. Migration of workflows is a complex process that is described in detail in the section Creating a Migration Definition to Update Running Workflows in the chapter Configuring Workflows.
- **Only Include Objects with the Following Tags**: The box lists all solution tags available in the current configuration. If you do not select any checkboxes, all configuration parts selected in the **Meta-Model** tab are saved without taking solution tagging into account. If you select one or multiple checkboxes, only solution objects which are both marked with a selected tag and are of a configuration object type selected in the Meta-Model tab are included into the AMM file. If solution tagging is not available for a

configuration object type that is selected, all objects of that type will be saved independent of selected tags. For more information about solution tagging, see the section Identifying Configuration Objects via Solution Tagging in the reference manual *Configuring Alfabet with Alfabet Expand*.

For example, the configuration includes 20 configured reports and 5 publications.

You have tagged two configured reports and two publications with a tag **PublicationReports** and select this tag in the **Only Include Objects with the Following Tags** field.

In addition, you have selected the **Save Reports** checkbox, but you have not selected the for **Save Publications** checkbox.

The AMM file will include the two tagged configured reports. It will not include any other configured reports because they are not tagged. It will not include an tagged or untagged publications because publications were not selected for upload.

- **Provide comma-separated tags to find objects to be removed**: Enter the name of a solution tag or a comma-separated list of multiple solution tag names to delete all public (customer-defined) configuration objects tagged with the specified tag name(s) from the target database prior. This option is useful if a tagged configuration has been changed in a way that includes the deletion of objects. The obsolete objects can be removed form the target database as well. For more information about solution tagging, see the section Identifying Configuration Objects via Solution Tagging in the reference manual *Configuring Alfabet with Alfabet Expand*.

Make sure that all objects required for the tagged solution are available in the AMM file when setting this option. All objects with the solution tag not included in the AMM file will be deleted from the target database.

If the tag name(s) that shall be used to remove objects is also used in the database you are currently connected with to tag configuration objects, you can select the tag name(s) from a multi-select combo-box instead of typing them in the field. Click the button on the right of the field to open the multi-select combo-box and select the checkbox of all tags in the current configuration for that all configuration objects shall be deleted in the target database prior to import of the configuration objects in the AMM file.

6) The **Guide Pages** tab displays all guide page projects in the current database. Select the checkbox for all guide page projects that should be merged to the existing guide page configuration of the target database. Guide pages are merged to the target database independent of the setting of the **Replace Entire Existing Configuration** field in the **Meta-Model** tab. Optionally, you can select the **Remove All Guide Pages from Target Database Before Updating** checkbox to overwrite the complete guide page configuration of the target database with the guide pages in the AMM file. If the checkbox is not selected, guide pages in the AMM file will be added to existing guide pages in the target database, thus overwriting guide pages with the same name.

Please note that the **Save Icons** checkbox in the **Meta-Model Content** tab must be selected in order to include any images included in the configuration of guide views.

The styles configured in the guide pages stored in the AMM file will overwrite the styles of the guide pages in the target database. You should ensure that the styles relevant for your enterprise are correctly configured in the guide pages before importing them via an AMM file to the production environment. For more information about the configuration of

guide pages and their styles, see the section *Formatting and Designing the Guide Pages* in the reference manual *Designing Guide Pages for Alfabet*.

7) In the **Reference Data** tab, user profiles and a specified subset of configurations performed in the **Configuration** functionalities in the Alfabet user interface can be optionally uploaded to the AMM file. These objects are stored in the instance store of the database. In contrast to the other configuration objects, they can be created and edited by users via the Alfabet user interface. Independent of the setting of the **Replace Entire Existing Configuration** field in the **Meta-Model** tab, they are always merged with the existing configuration in the target database.

Note the following about the update of user profiles and reference data via AMM files:

- **User profile configuration**: User profiles in the AMM file are added to the existing user profile configuration in the target database. User profiles with the same name will be overwritten in the target database.

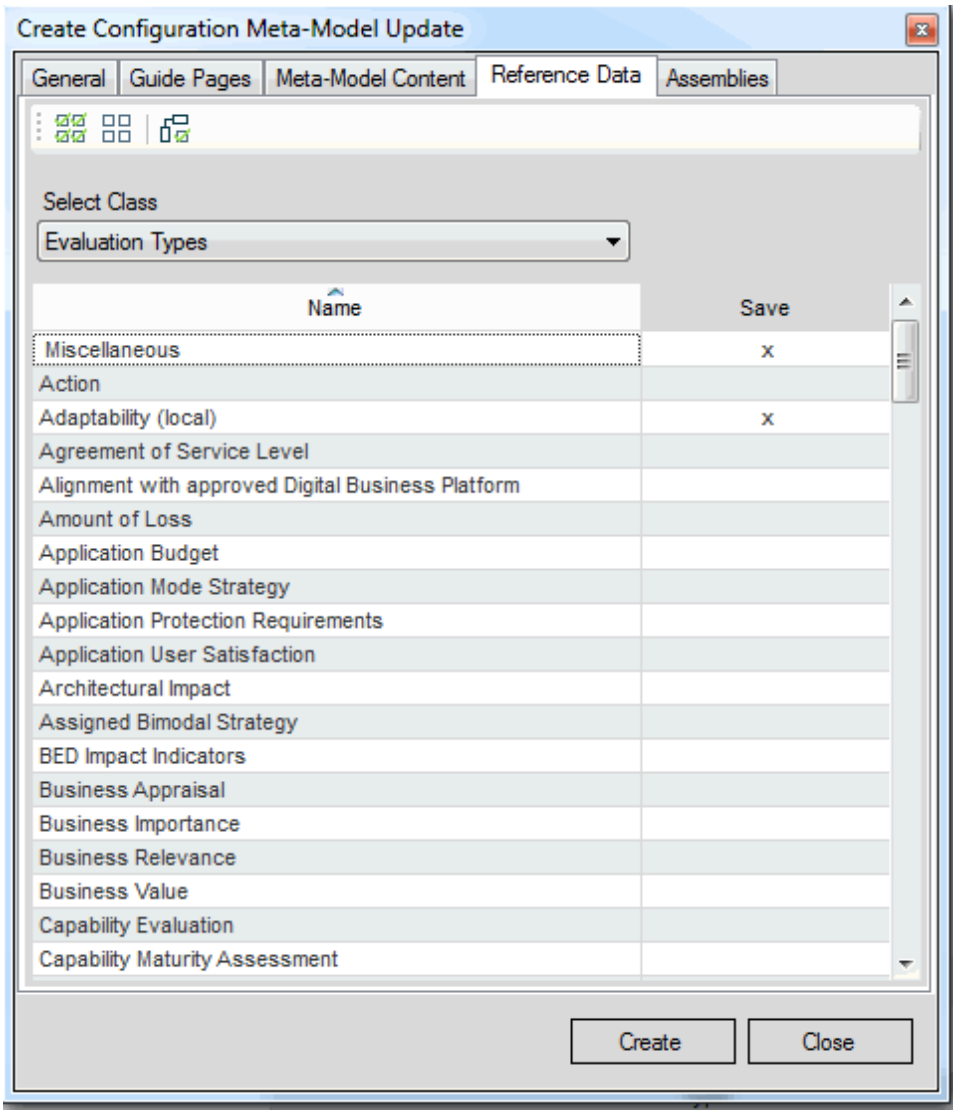
  If a guide page/guide view is defined as the start page for a user profile, you must explicitly include the guide page/guide view in the AMM update. If the guide page/guide view is not included, then the user will see an empty start page.

- **Configuration of reference data and evaluations**: Existing objects in the Alfabet database are overwritten if the key property for identification of the object is identical. The following table lists the configured objects that can be migrated via AMM, the key used to identify the objects, and whether the objects can be added to the AMM file by direct selection of objects or as sub-objects of a selectable parent object:

Object Class	Key	Selection
`EvaluationType`	Name	Directly
`IndicatorType`	Evaluation Type, Name	Included with selection of the evaluation type they are assigned to.
`RoleType`	Name	Directly
`PrioritizationScheme`	Name	Directly
`ITPortfolio`	Name	Directly
`DiagramView`	Name	Directly

DiagramView-Item	Name	Included with selection of the diagram view they are assigned to.
ColorRuleGroup	Name	Directly
ColorRule	Name	Directly or included with selection of the color rule group they are assigned to.
ClassConfiguration	Class Name	Directly

A table lists all configuration objects available for the type of configuration object selected in the **Select Class** field above the table. Select the type of configuration object in the **Select Class** field and click the cell in the **Save** column of the table for all configuration objects of the selected type that are to be saved to the AMM file:



To save all configuration objects or user profiles currently displayed in the table to the AMM file, click the **Check All** button.

When you select **Class Configuration** in the **Select Class** field and stereotypes are defined for an object class, each stereotype is listed in a separate row of the table with the **Name** defined as "Name (Stereotype)".

Color rules that are assigned to a color rule group cannot be included separately. Select **Color Rule Groups** in the **Select Class** field and select a color rule group to include the color rule group and all color rules that are assigned to the color rule group to the AMM update file. When you select Color Rules in the Select Class field, the table only displays color rules that are not assigned to a color rule group. These color rules can be selected separately.

Select the **Check Dependent Objects** button to select objects that depend on other objects that you have currently selected in the list. When you click the button, the dependent objects will be automatically selected:

- For each evaluation type currently selected in the list, the following dependent objects are also selected:
- all prioritization schemes to which the evaluation type or any of the indicator types assigned to the evaluation type are assigned
- all IT portfolios to which the evaluation type or any of the indicator types assigned to the evaluation type are assigned
- all diagram views to which any of the indicator types assigned to the evaluation type are assigned
- class configurations to which the evaluation type is assigned
- For each prioritization scheme currently selected in the list, the following dependent objects are also selected:
- all IT portfolios to which the prioritization scheme is assigned
- class configurations to which the prioritization scheme is assigned
- For each IT Portfolio currently selected in the list, the following dependent objects are also selected:
- class configurations to which the IT portfolio is assigned.

8) In the **Assemblies** tab, assemblies can be optionally uploaded to the AMM file if the configuration has been specified via a DLL file delivered by Software AG. If you need to include assemblies in the AMM file, see the section Managing Assemblies for detailed information.

9) Click the **Create** button to generate the AMM update file. A message will be displayed once the AMM has been successfully created.

Saving Selected Objects of the Configuration with Alfabet Expand

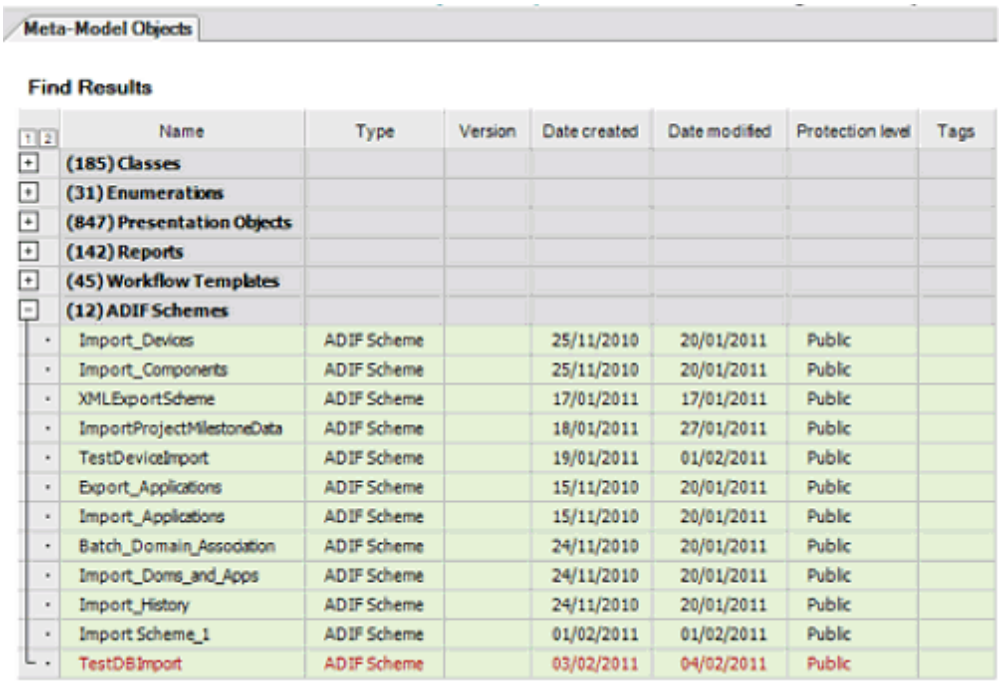
Alfabet Expand provides a mechanism that allows you to select parts of the configuration of a database to be migrated via an AMM file to a target database. Only the selected elements in the configuration will be saved to the AMM file and merged to the configuration of the target database. Substitution of the complete configuration cannot be performed with AMM files that are created from a selection of available

configuration objects, with the exception of selected object class configurations. Whether the configuration of an object class is merged or overwritten in the target database can be selected individually for each object class added to the AMM file.

The selected elements in the configuration can be tagged with a solution name that makes it possible to categorize the elements according to configuration projects, identify the elements via search mechanisms, and delete the elements from the target database. For more information about solution tagging, see Identifying Configuration Objects via Solution Tagging.

To upload selected configuration objects to an AMM file.

1) In the menu of Alfabet Expand, select **Meta-Model** > **Reread Meta-Model** to ensure that the locally cached version of the Meta-Model is consistent with the Meta-Model saved in the Alfabet database.
2) In the menu of Alfabet Expand, select **Meta-Model** > **Find Meta-Model Objects for Deployment**. A new pane **Meta-Model Objects** opens between the explorer window and the attribute window.
3) In the toolbar, click the **Refresh Find Results** button. All configuration objects are displayed and sorted according to category in the **Find Results** table.



Note the following about working with the **Find Results** table:

- The number of selectable objects in each category is displayed in parentheses behind the category name.
- To view the objects in a category, expand the category by clicking the ⊞ sign in front of the category header. Alternatively, you can expand all categories by clicking the 2 in the first column header.
- The table displays the following information about the configuration object:

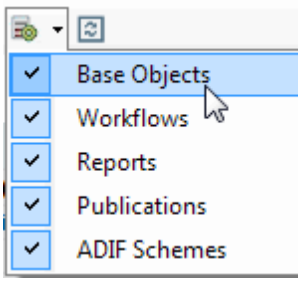
- **Name**: The value of the **Name** attribute of the configuration object.

- **Type**: The type of configuration object in the Alfabet meta-model. When exporting the information about the meta-model to an XML file with the functionality **Meta-Model** > **Save Configuration** of Alfabet Expand, information about the object is stored in an XML element with the name given as **Type** here.
- **Version**: The value of the **Tech Info** > **Version** attribute of the configuration object.
- **Date created**: The value of the **Tech Info** > **Creation Date** attribute of the configuration object.
- **Date modified**: The value of the **Tech Info** > **Last Update** attribute of the configuration object.
- **Protection Level**: `Public` objects are created by the customer, `Protected` objects are standard configuration objects of the Alfabet meta-model that may have been modified by the customer.
- **Tags**: The value of the **Tech Info** > **Tags** attribute of the configuration object. Solution tagging is designed to mark all configuration objects that are required for a specific functionality with a tag to ease the identification of relevant objects. For more information, see Identifying Configuration Objects via Solution Tagging.
- **Notes**: The value of the **Tech Info** > **Implementation Notes** attribute of the configuration object.

4) Select the objects that you want to upload to the AMM file in the **Find Results** table. You can select several objects in the table at the same time by holding down the CTRL key while selecting.

The following functionalities can help you to select the relevant objects:

- You can restrict the number of categories displayed in the table by selecting or clearing areas of configuration in the sub-menu of the **Restrict Configuration Object Types To Be Searched For** button in the toolbar of the **Find Results** table:



- Optionally, you can use the search functionality of the **Meta-Model Objects** pane to limit the display of objects in the table to objects matching a defined search condition.
- Optionally, you can use solution tagging to mark all objects that are relevant for a specific configuration task with the same tag and search for the object in the table via the search functionality. For more information, see Identifying Configuration Objects via Solution Tagging.
- To make sure that all relevant configuration objects required to merge a configured feature into a target database are added to the selection container,

you can use the **Show Usage for Selected Objects** button in the toolbar of the **Find Results** table to see a report that informs about the usage of the selected objects within the configuration. The button is also available in the toolbar of the selection container to view a report about the usage of all configuration objects already added to the selection container.

The report displays the selected objects on the x axis and the path to the location in the configuration referring to the selected objects on the y axis.

On top of the report, a filter allows you to limit the information to configuration relevant for a defined object class.

- The results of the search displayed in the table can be exported to a Microsoft® Excel® file to provide the information about selection of objects to persons that do not have access to Alfabet Expand or to archive the content of an AMM file in a readable format. To save the content of the **Find Results** table, click the **Export to Excel** button in the toolbar of the table.

5) The **Selection Container** table is displayed below the **Find Results** table. In the toolbar above the **Selection Container** table, click the **Add Selected Objects from Find Results to Selection Container** button. The objects which you selected in the table are added to the selection container. To remove a subset of the selected objects from the selection container, select the objects in the selection container and click the **Remove Selected Objects from Selection Container** button in the toolbar of the selection container. To remove all selected objects from the selection container, click the **Remove all objects from the Selection Container** button in the toolbar of the selection container.

It is recommended that you tag the selected objects with a solution tag prior to adding them to the selection container. Tagging allows objects in both the source and the target database to be identified.

You can save the configuration in the selection container in a Microsoft® Excel® file or in an XML file. This feature may be useful to generate reports about the configuration update, compare different stages of configuration, or to archive different stages of configuration. In the toolbar of the selection container, click the **Export to Excel** button and select **Create XML File** to save the information about the configuration elements in the selection container as XML output. Click the **Export to Excel** button and select **Create XML File** to save the information about the configuration elements in the selection container as XML output.

6) If the selection includes object classes, you can optionally change the update mode in the target database for each object class from `Merge` to `Replace`. Select the required update mode in the drop-down list in the **UpdateMode** column.

If you merge a class configuration, new custom properties are added to the object class in the target database and changes to object class properties are applied, but custom object class properties that have been removed in the configuration saved to the AMM file are not deleted in the configuration of the target database.

7) In the toolbar of the selection container, click the **Create Configuration Update File**  button and select **Create AMM File**. The **Create Configuration Meta-Model Update** editor opens.

8) Select the location for storing the information in the field **Select Output File**.

9) Provide a meaningful name and description for the update performed by the AMM file when applied to the target database in the fields **Name** and **Description** in the section **General**. The name and description are displayed in the **Update Meta-Model** dialog box when the AMM file is used to update the configuration in a database. It allows the person performing the update to be informed about the content of the configuration in the `AMM` file.

10) The objects that were added to the selection container are already added to the AMM file. Optionally, you can select additional configuration parts that you want to add to the AMM file in the **Meta-Model Content** tab:

- **Save Icons**: Select the checkbox to save the icons uploaded to the Alfabet database. If the checkbox is not selected, the configuration is saved without icons. If icons have been added to the selection container, the option is deactivated.
- **Save Culture Settings**: Select the checkbox to save the content of the **Cultures** and **API Cultures** explorer nodes of the **Meta-Model** tab of Alfabet Expand. If the checkbox is not selected, the configuration is saved without the configured culture settings.
- **Save Translation**: Select the checkbox to save the custom translation of strings displayed on the Alfabet user interface that are customized via the **Translation Editor** in Alfabet Expand. If the checkbox is not selected, the configuration is saved without translations.

11) Select the following options, if applicable for your configuration:

- **Automatically Migrate Affected Workflows**: Select the checkbox in the **Meta-Model Content** tab if you have included workflow template configuration in the `AMM` file and want the workflow templates to be automatically migrated to the target database.

Migration of workflows is a complex process that is described in detail in the section Creating a Migration Definition to Update Running Workflows in the chapter Configuring Workflows.

- **Provide comma-separated tags to find objects to be removed**: Enter the name of a solution tag or a comma-separated list of multiple solution tag names to delete all public (customer-defined) configuration objects tagged with the specified name(s) from the target database prior. This option is useful if a tagged configuration has been changed in a way that includes the deletion of objects. The obsolete objects can be removed form the target database as well. For more information about solution tagging, see the section Identifying Configuration Objects via Solution Tagging.

Make sure that all objects required for the tagged solution are available in the AMM file when setting this option. All objects with the solution tag not included in the AMM file will be deleted from the target database.

12) The **Guide Pages** tab displays all guide page projects in the current database. Select the checkbox for all guide page projects that should be merged to the existing guide page configuration of the target database. Guide pages are merged to the target database independent of the setting of the **Replace Entire Existing Configuration** field in the **Meta-Model** tab. Optionally, you can select the **Remove All Guide Pages from Target Database Before Updating** checkbox to overwrite the complete guide page configuration of the target database with the guide pages in the AMM file. If

the checkbox is not selected, guide pages in the AMM file will be added to existing guide pages in the target database, thus overwriting guide pages with the same name.

Please note that the **Save Icons** checkbox in the **Meta-Model Content** tab must be selected in order to include any images included in the configuration of guide views.

The styles configured in the guide pages stored in the AMM file will overwrite the styles of the guide pages in the target database. You should ensure that the styles relevant for your enterprise are correctly configured in the guide pages before importing them via an AMM file to the production environment. For more information about the configuration of guide pages and their styles, see the section *Formatting and Designing the Guide Pages* in the reference manual *Designing Guide Pages for Alfabet*.

13) In the **Reference Data** tab, user profiles and a specified subset of configurations performed in the **Configuration** functionalities in the Alfabet user interface can be optionally uploaded to the AMM file. These objects are stored in the instance store of the database. In contrast to the other configuration objects, they can be created and edited by users via the Alfabet user interface. Independent of the setting of the **Replace Entire Existing Configuration** field in the **Meta-Model** tab, they are always merged with the existing configuration in the target database.

Note the following about the update of user profiles and reference data via AMM files:

- **User profile configuration**: User profiles in the AMM file are added to the existing user profile configuration in the target database. User profiles with the same name will be overwritten in the target database.

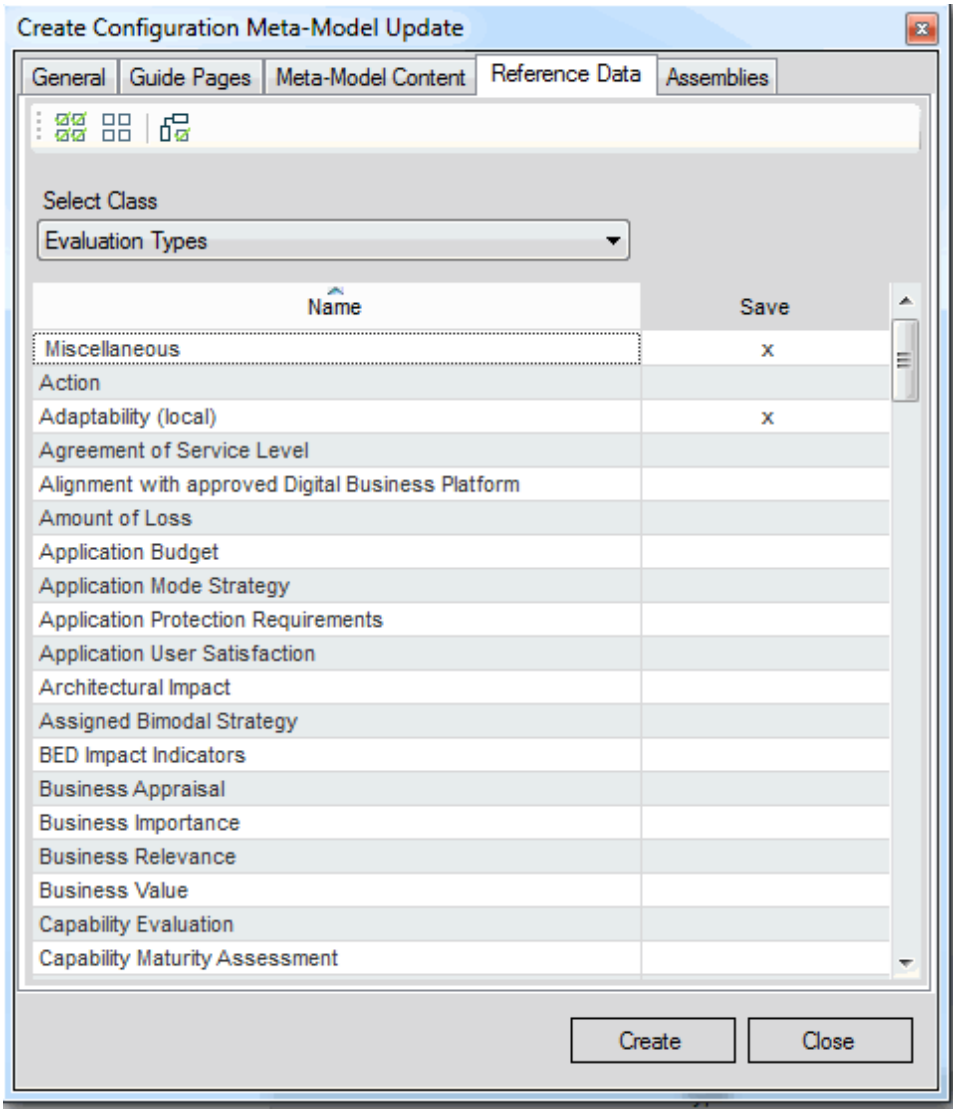
  If a guide page/guide view is defined as the start page for a user profile, you must explicitly include the guide page/guide view in the AMM update. If the guide page/guide view is not included, then the user will see an empty start page.

- **Configuration of reference data and evaluations**: Existing objects in the Alfabet database are overwritten if the key property for identification of the object is identical. The following table lists the configured objects that can be migrated via AMM, the key used to identify the objects, and whether the objects can be added to the AMM file by direct selection of objects or as sub-objects of a selectable parent object:

Object Class	Key	Selection
`EvaluationType`	Name	Directly

IndicatorType	Evaluation Type, Name	Included with selection of the evaluation type they are assigned to.
RoleType	Name	Directly
PrioritizationScheme	Name	Directly
ITPortfolio	Name	Directly
DiagramView	Name	Directly
DiagramViewItem	Name	Included with selection of the diagram view they are assigned to.
ColorRuleGroup	Name	Directly
ColorRule	Name	Directly or included with selection of the color rule group they are assigned to.
ClassConfiguration	Class Name	Directly

A table lists all configuration objects available for the type of configuration object selected in the **Select Class** field above the table. Select the type of configuration object in the **Select Class** field and click the cell in the **Save** column of the table for all configuration objects of the selected type that are to be saved to the AMM file:



To save all configuration objects or user profiles currently displayed in the table to the AMM file, click the **Check All** button.

When you select **Class Configuration** in the **Select Class** field and stereotypes are defined for an object class, each stereotype is listed in a separate row of the table with the **Name** defined as "Name (Stereotype)".

Color rules that are assigned to a color rule group cannot be included separately. Select **Color Rule Groups** in the **Select Class** field and select a color rule group to include the color rule group and all color rules that are assigned to the color rule group to the AMM update file. When you select Color Rules in the Select Class field, the table only displays color rules that are not assigned to a color rule group. These color rules can be selected separately.

Select the **Check Dependent Objects** button to select objects that depend on other objects that you have currently selected in the list. When you click the button, the dependent objects will be automatically selected:

- For each evaluation type currently selected in the list, the following dependent objects are also selected:

- all prioritization schemes to which the evaluation type or any of the indicator types assigned to the evaluation type are assigned
- all IT portfolios to which the evaluation type or any of the indicator types assigned to the evaluation type are assigned
- all diagram views to which any of the indicator types assigned to the evaluation type are assigned
- class configurations to which the evaluation type is assigned
- For each prioritization scheme currently selected in the list, the following dependent objects are also selected:
- all IT portfolios to which the prioritization scheme is assigned
- class configurations to which the prioritization scheme is assigned
- For each IT Portfolio currently selected in the list, the following dependent objects are also selected:
- class configurations to which the IT portfolio is assigned.

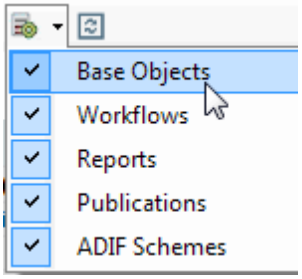
14) In the **Assemblies** tab, assemblies can be optionally uploaded to the AMM file if the configuration has been specified via a DLL file delivered by Software AG. If you need to include assemblies in the AMM file, see the section Managing Assemblies for detailed information.

15) Click the **Create** button to generate the AMM update file. A message will be displayed once the AMM has been successfully created.

Searching for Objects in the Find Results Table of the Meta-Model Objects Editor

A customer configuration may have a high number of configuration objects. To ease the selection of objects in the **Find Results** table, a number of sorting and search options are available:

- The **Find Results** table lists objects via categories. To view the objects in a category, expand the category by clicking the ⊞ sign in front of the category header.
- The columns in the **Find Results** table provide information about relevant attributes of the configuration object. If you click a table header, the table is sorted by the property displayed in the column.
- You can restrict the number of categories displayed in the table by selecting or clearing areas of configuration in the sub-menu of the **Restrict Configuration Object Types To Be Searched For** button in the toolbar of the **Find Results** table:



- A search mechanism allows objects to be displayed in the **Find Results** table to be limited to objects that match defined search criteria. The search mechanism is described below.

The search functionality is available when you currently navigate in the **Find Results** table:

1) Click anywhere inside the **Find Results** table to open the attribute window of the **Find Results** table.
2) In the attribute window, define your search condition by setting any or a combination of the following attributes:

- **Creator**: Enter the user name of a Alfabet user to find all objects that the user created. The user logged in to Alfabet Expand when the configuration object was created is stored as creator.
- **Creation Date After**: Select a date from the calendar to find all objects created after that date.
- **Creation Date Before**: Select a date from the calendar to find all objects created before that date.
- **Last Update After**: Select a date from the calendar to find all objects last updated after that date.
- **Last Update Before**: Select a date from the calendar to find all objects last updated before that date.
- **Last Update User**: Enter the user name of a Alfabet user to find all configuration objects last updated by the user. The user logged in to Alfabet Expand when the configuration object was saved the last time is stored as last update user.
- **Name**: Enter the name or part of the name of a configuration object to find all objects with a **Name** attribute matching the defined search string. An asterisk can be used as wildcard.
- **Version**: Enter the version or part of the version information to find all objects with a **Version** attribute matching the defined string. An asterisk can be used as wildcard.
- **Tags**: Click the **Browse** button in the **Tags** attribute field to open the **Meta-Model Tags** window. In the toolbar, click the **Rescan Tags** button to update the display of available tags in the list. Select one or more of the listed tags to find all objects that are tagged with at least one of the selected tag names. For more information about solution tagging, see the section Identifying Configuration Objects via Solution Tagging.

  Selecting and also clearing tags in this search field can only be performed via selecting or clearing tags from the **Meta-Model Tags** window. If you try to write content directly to the field or delete the field content, an error message will be displayed that informs you that the field content is invalid. To correct this error, click **Cancel** in the error message. The old content is displayed and can be altered via the **Meta-Model Tags** window.

- **Survey**: Select a survey from the drop-down list of available survey configurations to find all objects configured for the survey. If you add a configuration object belonging to a survey configuration to an AMM file, the survey will be created in a target database updated with the AMM file, but it will only contain the added configuration object. Make sure to add all configuration objects belonging to the survey to the AMM file to take over the correct survey definition.
- **Unsaved Objects**: Select `True` to find only configuration objects that have not currently been saved in the current configuration and therefore not been saved to the Alfabet database. Select `False` to view both saved and unsaved configuration objects.

3) In the toolbar, click the **Refresh Find Results** button. The display of objects in the **Find Results** table is limited to the objects matching the defined search criteria.

Storing all Objects Tagged With a Selected Tag to an AMM File

If you have tagged all objects that you want to merge with a selected database with the same tag without having tagged other objects with this tag, you can create an AMM file only containing the selected objects in a simple action.

Please note the following about this mechanism:

- Workflows, Guide Pages, Reference Data and Assemblies cannot be added to the AMM file created via this mechanism.
- The configuration is always merged into the target database.

To create an AMM file containing tagged objects only:

1) In the menu of Alfabet Expand, select **Meta-Model** > **Reread Meta-Model** to ensure that the locally cached version of the Meta-Model is consistent with the Meta-Model saved in the Alfabet database.
2) In the toolbar of Alfabet Expand select **Meta-Model** > **Set Current Tag**.
3) In the list of tags, click the link that you want to set as default tag to all new and changed configuration objects.

   The selection is removed when the user logs out of Alfabet Expand. If the selection shall be used again in the new session, the selection has to be repeated.

4) In the menu of Alfabet Expand, select **Meta-Model** > **Save Meta-Model Objects Marked by Current Tag**. An explorer window opens.
5) Select a location for storage of the AMM file on the local file system. Optionally you can alter the default name of the file, that is concatenated from the tag name and a time stamp. The file extension must be `.amm`.
6) Click **Save** to save the AMM file in the selected location.

Updating the Configuration of the Alfabet Solution Environment with Alfabet Expand

Please note the following about the process to update the meta-model with AMM files:

- During update of the meta-model with an AMM file the database is run in a restricted mode. That means that all connections to the database except for the one required to update the meta-model are closed and new connections cannot be established. The restricted mode ends automatically when the update process is finished. If the restricted mode persists after the update is finished, it can be manually released via the Alfabet Administrator. For more information about manually releasing the restricted mode, see *Releasing the Restricted Mode* in the reference manual *System Administration*.
- Shut down all other Alfabet components except the database server hosting the Alfabet database prior to update of the meta-model. For more information about planned shutdown of the Alfabet components, see *Planned Outages of the Alfabet Components* in the reference manual *System Administration*.
- Prior to update of the meta-model, database replication mechanisms targeting the Alfabet database must be shut down.

- Login to the Alfabet database on the database server for database update is not performed with the database user defined in the server alias configuration, but rather by means of the database user `AlfaRuntimeUser` that is automatically generated for the process by the system. This database user has Read/Write access to the database during the update of the meta-model. It is not possible to access the Alfabet database with a user `AlfaRuntimeUser` in other contexts.
- A number of mechanisms are available that ensure that the translation settings of the target database are not corrupted via a meta-model update with an AMM file:

- Information about the configuration language of the source databse is stored in the AMM file. Update of the meta-model via the AMM file will fail if the settings for the configuration language are different in the AMM file and the target database.
- On update of the meta-model with an AMM file which is configured to replace the culture configuration of the target database, the cultures in the target database are removed with the exception of the primary culture (en-US), the default culture and the configuration culture. Any settings in the AMM file about the default culture or the configuration culture are ignored and the settings in the target database are maintained.

- The case sensitivity setting from the collation of the source database is stored in the AMM file. Update of the meta-model via the AMM file will fail if the case sensitivity setting in the AMM file differs from the case sensitivity setting of the target database.
- Length limitation for database table columns on an Oracle® database server is more restrictive than on a Microsoft® SQL Server®. The allowed length on Oracle® database servers for the **Tech Name** attribute of custom object class properties in Alfabet depends on the configuration of data translation. The maximum length of a technical name may not exceed 25 characters for properties that have the **Enable Data Translation** attribute set to `True`. For properties that are not translatable, the maximum length of a technical name may not exceed 30 characters. To avoid problems on migration of the database from a Microsoft® SQL Server® to an Oracle® database server because of **Tech Name** attributes of custom object class properties not matching the restrictions, a check for database server compatibility is available. A read-only **Database Platform Compatibility** attribute is available. The attribute is set to `Oracle` if the database is hosted on an Oracle® database server. If the database is hosted on a Microsoft® SQL Server®, the **Database Platform Compatibility** attribute is set to `SqlServer` if the database contains **Tech Name** attributes that violate the size restriction and will be set to `Common` if the database does not violate the size restriction. On creation of an AMM file, the **Database Platform Compatibility** attribute of the current database is written to the AMM file. On update of the meta-model with the AMM file, the **Database Platform Compatibility** attribute value in the target database is compared with the value in the AMM file. Updating the meta-model will fail if the Alfabet database is hosted on an Oracle® database server and the AMM file has the **Database Platform Compatibility** value set to `SqlServer`. The database will remain unchanged and offending **Tech Name** values will be written to a log file.

Before you update a production database with an AMM file created with an Update Solution option, you must backup the target database for security reasons. Solution tagging is a sensitive process that can lead to data loss if not carefully planned and executed. It is strongly recommended that you perform solution tagging with the help of your consultant from Alfabet only. The update of a database via an AMM file created with an **Update Solution** option should be thoroughly tested on a test database before the production environment is updated. For more information about solution tagging, see the section Identifying Configuration Objects via Solution Tagging.

If you merge the solution configuration in the AMM file with the configuration of a target database, only the configuration objects that are stored in the AMM file will be overwritten.

Overwriting configuration objects is especially important for the update of configuration objects with sub-objects. For example:

- Updating an object class with information in the AMM file will delete all custom object class properties and numeration information for the class in the target database and substitute it with the information in the AMM file.
- Updating a report folder will delete all reports from the report folder in the target database and substitute it with the reports available in the AMM file configuration.

Therefore, prior to creating an AMM update file, you must ensure that the configuration in the development database is identical to the configuration in the target database (with the exception of the desired configuration change).

Update of the meta-model with an AMM update file changes the configuration of the meta-model in your database. Please note the following about the restore of the configuration:

- **Clarify any concerns regarding your specific customization before initiating the Update Meta-Model functionality!** Some customizable features in Alfabet may not be part of the meta-model configuration. They are stored in the instance store and could be lost/damaged when a configuration is saved and restored to another database with an AMM file. This applies to the following configurations:

- **Export definitions**: To save and restore the export definitions, the export definitions must be saved and restored separately using the tool Alfabet Expand. In Alfabet Expand, the context menu of the root explorer nodes for the respective configurations offer a **Save as** functionality that allows you to save the specific part of the configuration as an XML file and a **Read from File** functionality and **Merge from File(s)** functionality to restore the specific configuration.
- **Mandate configuration**: The configuration of mandates is saved in the instance store of the database and can only be saved and read/merge to another database by using the **Import Data Search** functionality or by manually recreating the configuration in the target database using Alfabet Expand or the Alfabet Administrator. For more information about the activation and use of the **Import Data Search** functionality, see the section Importing Objects of Configuration Relevant Object Classes from a Master Database in the reference manual *Configuring Alfabet with Alfabet Expand*.
- **Most reference and evaluation data configured in the Configuration functionalities in the Alfabet user interface**: For example, reference data such as role types, cost types, indicator types, or portfolios are configured in Alfabet configuration functionalities in the Alfabet user interface. These configurations are saved in the instance store of the database. Only the following subset of these configurations can be included in the AMM file:
- Evaluation Types
- Portfolios
- Prioritization Schemes
- Diagram Views
- Color Rule Groups
- Color Rules
- Class Configurations
- Roles

Other configuration data can only be saved and read/merge to another database by using the **Import Data Search** functionality or by manually recreating the configuration in the target database using Alfabet Expand or the Alfabet Administrator. For more information about the activation and use of the **Import Data Search** functionality, see the section Importing Objects of Configuration Relevant Object Classes from a Master Database in the reference manual *Configuring Alfabet with Alfabet Expand*.

- **Documents uploaded to the Internal Document Selector**: Documents in the **Internal Document Selector** can only be stored in normal database backup files on the database server level or added to the target database manually. This may impact the images and style sheet files uploaded to be used for visualization items (configured HTML templates for the workflows functionality). While the visualization item can be saved to an AMM file and uploaded to a target database via meta-model update, the images and style sheet files must be uploaded to the **Internal Document Selector** of the target database via Alfabet Expand or the Alfabet user interface.
- All database views in the target database are recreated after a meta-model update and need to be checked for consistency afterwards as described in the section Checking the Consistency of the Database View With the Meta-Model. The recreation ensures that new database views added to the configuration via the meta-model update are created and that database views that are not compatible with the changes to the meta-model applied via meta-model update are removed.
- AMM files can be configured to either replace or merge the configuration stored in the AMM file with the configuration in the target database:
- **Replace Configuration**: The whole customer configuration in the target database will be deleted prior to writing the content of the AMM file to the target database. Configurations that have no corresponding object in the AMM file will be deleted.

  Configured reports that are automatically generated for the faceted semantic search functionality of the AlfaBot will not be deleted from the target database. For more information about automatically generated reports, see Managing Automatically Generated Reports.

- **Merge Configuration**: All objects in the configuration will overwrite corresponding objects in the database. Database objects that have no corresponding object in the AMM will remain unchanged. Objects that are only available in the AMM will be added.

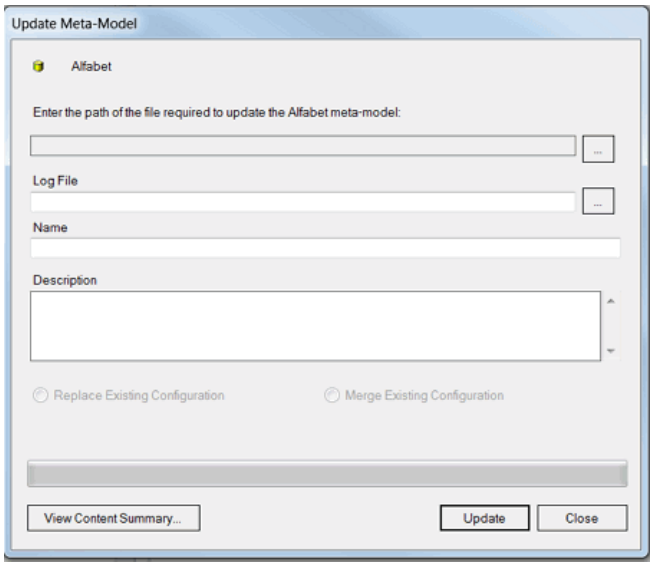
Alfabet provides mechanism to check the content of an AMM file prior to update of the meta-model and to control the success of the update action:

- When updating the meta-model using Alfabet Expand or the Alfabet Administrator, a window for selection of the AMM file that shall be used for update opens. After having selected an AMM file, you can click the button **View Content Summary** to see a summary of the content of the AMM file.
- You can use the **Compare Configurations** functionality of Alfabet Expand to view the differences between the configuration in the AMM file with the configuration of the target database that you are planning to replace or merge. For more information, see *Comparing Database Configurations* in the reference manual *Configuring Alfabet with Alfabet Expand*.
- A log file is created during update of the meta-model. The log file is written to the directory that contains the AMM file and has the name <Name of the AMM file>_<Time Stamp>.log. You can consult the log file to view any issues that occurred during update.
- After update, you should check the consistency of the update with the standard meta-model. A consistency check can be performed via Alfabet Expand. For more information, see in the reference manual *Configuring Alfabet with Alfabet Expand*.

If the functionality for update of the meta-model is not working, please check the alias configuration of Alfabet Expand. The option **File-Based Update Permitted** must be activated in the **Expand** tab of the alias configuration editor. This option is activated by default.

Prior to updating the meta-model, ensure that no Alfabet components are currently connected to the Alfabet database and that replication mechanisms that target the Alfabet database are shut down.

1) Open the tool Alfabet Expand without logging in to a database.
2) In the menu bar in Alfabet Expand, select **Meta-Model** > **Update Meta-Model**. A new window opens.
3) Select a server alias for connection to the Alfabet database that you want to update and click **OK**. A window for login to the database opens
4) Enter the user name and password defined for login to the Alfabet database or, if Windows sign on is configured for connections to the Alfabet database, click **OK** without entering a user name and password.
5) Click **OK**. A new window opens:



6) Click the **Browse** button next to the field **Enter the path of the file required to update the Alfabet meta-model**. An explorer opens.
7) Navigate to the folder where the AMM file with your saved configuration is located and click **Open**. The path to the update file is displayed.

   The following information about the selected file is displayed after the file was selected:

- If a name was specified during the creation of the update file, it will be displayed in the **Operation** field.
- If a description was specified during creation of the update file, it will be displayed in the **Description** field.
- The relevant field of the options **Replace Existing Configuration** or **Merge Existing Configuration** is automatically selected depending on whether a merge or replace action is being executed.

- To view a summary of the content of the file, click **View Content Summary**. A new window opens that provides information about the options selected during creation of the file. Verify that the correct update file is being used and click **Close**.

8) Optionally, you can change the location for the log file created during the update process in the field **Log File**. By default, the log file is stored in the directory of the AMM file used for the update. The default log file is automatically specified in the field **Log File**.

Changes in the vocabularies that might affect custom translations are logged separately in a Microsoft Excel file. The log file for the update process includes a link to the translation log.

9) Click **Update**. The configuration stored in the update file replaces or merges with the configuration of your current database.

After the update of the configuration, all ADIF import schemes that are available in the target database after the update and have the attribute **Auto-Run** set to `True` will be automatically executed in the order specified via the context menu of the root node of the ADIF explorer in Alfabet Expand. For more information about automatic execution of ADIF schemes, see *Configuring ADIF Schemes to be Automatically Executed on Update of the Meta-Model* in the reference manual *Alfabet Data Integration Framework*

If the automated data translation feature is implemented, update of the meta-model will take significantly longer than without the feature being implemented.

10) A message is displayed informing you about the success of the update action and advising you to check the log file. Confirm the message and open the log file to see whether the changes performed via the update conflict with any of the existing objects or configurations in your database. The messages also inform about translation issues caused by changes of strings during update.

After applying a configuration to an Alfabet database, it is recommended that you review the Alfabet database for consistency with the meta-model as described in the section Securing and Checking Database Consistency with the Meta-Model.

Direct Import of the Solution Configuration from a Master Database

This functionality is only available if the server alias used to connect with Alfabet Expand to the target database is configured to establish a connection to the source database.

The server alias configuration also includes a setting that decides about the update method. Configurations can either be taken over completely, which means that the configuration of the target database is overwritten, or the configuration of the source database can be merged into the configuration of the target database. In the latter case, the user triggering the configuration update with Alfabet Expand on the target database can decide about which part of the configuration shall be included in the update.

For the update of the solution configuration from a master database, a restore mechanism is available. The history of performed updates can be displayed and logging information can be checked for each import. If the import has failed, the configuration of any point in the update history can be restored in the target database.

Please note the following about the process to update the meta-model from a master database:

- During update of the meta-model the database is run in a restricted mode. That means that all connections to the database except for the one required to update the meta-model are closed and new connections cannot be established. The restricted mode ends automatically when the update process is finished. If the restricted mode persists after the update is finished, it can be manually released via the Alfabet Administrator. For more information about manually releasing the restricted mode, see *Releasing the Restricted Mode* in the reference manual *System Administration*.

Before you update a production database, you must backup the target database for security reasons.

Update of the meta-model from a master database changes the configuration of the meta-model in your database. Please note the following about the restore of the configuration:

- **Clarify any concerns regarding your specific customization before initiating the update from master database functionality!** Some customizable features in Alfabet may not be part of the meta-model configuration. They are stored in the instance store and could be lost/damaged when a configuration is taken over via master database update. This applies to the following configurations:

- **Export definitions**: To save and restore the export definitions, the export definitions must be saved and restored separately using the tool Alfabet Expand. In Alfabet Expand, the context menu of the root explorer nodes for the respective configurations offer a **Save as** functionality that allows you to save the specific part of the configuration as an XML file and a **Read from File** functionality and **Merge from File(s)** functionality to restore the specific configuration.

- **Mandate configuration**: The configuration of mandates is saved in the instance store of the database and can only be saved and read/merge into another database by using the **Import Data Search** functionality or by manually recreating the configuration in the target database using Alfabet Expand or the Alfabet Administrator. For more information about the activation and use of the **Import Data Search** functionality, see the section Importing Objects of Configuration Relevant Object Classes from a Master Database in the reference manual *Configuring Alfabet with Alfabet Expand*.

- **Most reference and evaluation data configured in the Configuration functionalities in the Alfabet user interface**: For example, reference data like role types and cost types or indicator types and portfolios are configured in Alfabet configuration functionalities in the Alfabet user interface. These configurations are saved in the instance store of the database. Only the following subset of these configurations can be included into the AMM file:

- Evaluation Types
- Portfolios
- Prioritization Schemes
- Diagram Views
- Color Rule Groups
- Color Rules
- Class Configurations
- Roles

Other configuration data can only be saved and read/merge into another database by using the **Import Data Search** functionality or by manually recreating the configuration in the target database using Alfabet Expand or the Alfabet Administrator. For more information about the activation and use of the **Import Data**

Search functionality, see the section Importing Objects of Configuration Relevant Object Classes from a Master Database in the reference manual *Configuring Alfabet with Alfabet Expand*.

- **Documents uploaded to the Internal Document Selector**: Documents in the **Internal Document Selector** can only be stored in normal database backup files on the database server level or added to the target database manually. This may impact the images and style sheet files uploaded to be used for visualization items (configured HTML templates for the workflows functionality). While the visualization item can be saved to an AMM file and uploaded to a target database via meta-model update, the images and style sheet files must be uploaded to the **Internal Document Selector** of the target database via Alfabet Expand or the Alfabet user interface.
- All database views in the target database are recreated after a meta-model update and need to be checked for consistency afterwards as described in the section Checking the Consistency of the Database View With the Meta-Model. The recreation ensures that new database views added to the configuration via the meta-model update are created and that database views that are not compatible with the changes to the meta-model applied via meta-model update are removed.

The following information is available:

- Overwriting the Solution Configuration with the Configuration of a Master Database
- Merging the Solution Configuration with the Configuration of a Master Database
- Checking and Repairing the Configuration Updates From a Master Database

Overwriting the Solution Configuration with the Configuration of a Master Database

Complete updates will be performed if the update of the configuration from a master database is triggered with a server alias of Alfabet Expand that is configured to perform complete updates.

The method is recommended to take over configurations from a development to a test environment after complete performance of a configuration. The tester can take over the configuration without any knowledge about configuration details.

Do the following to overwrite the configuration in your current database with the configuration in a master database:

1) In the toolbar, select **Meta-Model** > **Update Meta-Model Configuration from Master Database**. The **Update from Master Database <Database Name>** dialog opens.
2) In the **General** tab, define the following fields:

- **Name**: Enter a meaningful name for the update. The name is used in the update history to identify the update.
- **Description**: Optionally a description that is displayed in the update history to provide more information about the update.

3) Optionally, go to the **Reference Data** tab and select user profiles and a specified subset of configurations performed in the **Configuration** module in Alfabet to be uploaded. These objects are stored in the instance store of the database. In contrast to the other configuration objects, they can be created and edited by users via the Alfabet user interface. In contrast to solution configurations performed in Alfabet Expand, solution objects stored in the instance store are not overwriting the instance store tables in the target database. Instead, the configuration is merged.

Note the following about the update of user profiles and reference data via AMM files:

- **User profile configuration**: User profiles in the AMM file are added to the existing user profile configuration in the target database. User profiles with the same name will be overwritten in the target database.

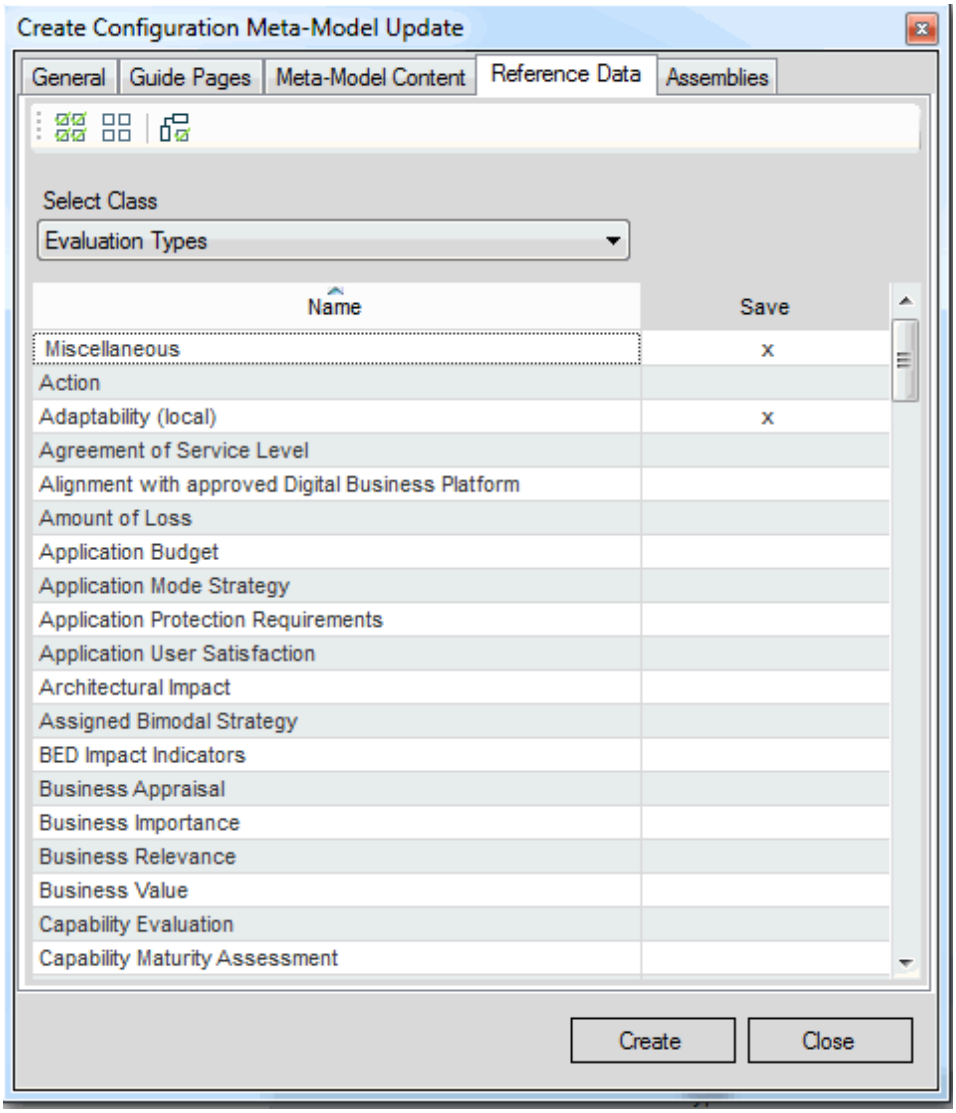
  

  If a guide page/guide view is defined as the start page for a user profile, you must explicitly include the guide page/guide view in the AMM update. If the guide page/guide view is not included, then the user will see an empty start page.

- **Configuration of reference data and evaluations**: Existing objects in the Alfabet database are overwritten if the key property for identification of the object is identical. The following table lists the configured objects that can be migrated via AMM, the key used to identify the objects, and whether the objects can be added to the AMM file by direct selection of objects or as sub-objects of a selectable parent object:

Object Class	Key	Selection
EvaluationType	Name	Directly
IndicatorType	Evaluation Type, Name	Included with selection of the evaluation type they are assigned to.
RoleType	Name	Directly
PrioritizationScheme	Name	Directly
ITPortfolio	Name	Directly
DiagramView	Name	Directly
DiagramViewItem	Name	Included with selection of the diagram view they are assigned to.
ColorRuleGroup	Name	Directly
ColorRule	Name	Directly or included with selection of the color rule group they are assigned to.
ClassConfiguration	Class Name	Directly

A table lists all configuration objects available for the type of configuration object selected in the **Select Class** field above the table. Select the type of configuration object in the **Select Class** field and click the cell in the **Save** column of the table for all configuration objects of the selected type that are to be saved to the AMM file:



To save all configuration objects or user profiles currently displayed in the table to the AMM file, click the **Check All** button.

When you select **Class Configuration** in the **Select Class** field and stereotypes are defined for an object class, each stereotype is listed in a separate row of the table with the **Name** defined as "Name (Stereotype)".

Color rules that are assigned to a color rule group cannot be included separately. Select **Color Rule Groups** in the **Select Class** field and select a color rule group to include the color rule group and all color rules that are assigned to the color rule group into the AMM update file. When you select Color Rules in the Select Class field, the table only displays color rules that are not assigned to a color rule group. These color rules can be selected separately.

Select the **Check Dependent Objects** button to select objects that depend on other objects that you have currently selected in the list. When you click the button, the dependent objects will be automatically selected:

- For each evaluation type currently selected in the list, the following dependent objects are also selected:
- all prioritization schemes to which the evaluation type or any of the indicator types assigned to the evaluation type are assigned
- all IT portfolios to which the evaluation type or any of the indicator types assigned to the evaluation type are assigned
- all diagram views to which any of the indicator types assigned to the evaluation type are assigned
- class configurations to which the evaluation type is assigned
- For each prioritization scheme currently selected in the list, the following dependent objects are also selected:
- all IT portfolios to which the prioritization scheme is assigned
- class configurations to which the prioritization scheme is assigned
- For each IT Portfolio currently selected in the list, the following dependent objects are also selected:
- class configurations to which the IT portfolio is assigned.

4) In the tab **Assemblies** tab, assemblies can be optionally uploaded to the AMM file if the configuration has been specified via a DLL file delivered by Software AG. The functionality on this tab is limited to upload of assemblies already available in the master database.

For an overview about assemblies and their role in configuration, see the section Managing Assemblies.

5) Confirm the message by clicking **OK**. All connections to the Alfabet database are closed during update.

Merging the Solution Configuration with the Configuration of a Master Database

Updates of selected parts of the configuration will be performed if the update of the configuration from a master database is triggered with a server alias of Alfabet Expand that is configured to perform selective updates.

The method is recommended to take over defined parts of the configurations from a development to a test environment. A solution designer can for example tag all configurations for a defined feature with a specific test and the tester can be advised to take over all configuration objects with that tag. Additional, incomplete configurations that are currently available in the master database are not taken over to the test environment during the selective update, because they are tagged differently.

Selective updates are highly flexible. During the update, the person performing the update decides whether to take over

- the complete configuration,
- only selected types of configuration objects, like for example configured reports only, or

- only objects tagged with a defined tag.

It is also both possible to overwrite the existing configuration or to merge the configuration from the master database into the existing configuration of the target database.

Do the following to take over selected parts of the configuration in a master database to your current database:

1) In the toolbar, select **Meta-Model** > **Update Meta-Model Configuration from Master Database**. The **Update from Master Database <Database Name>** dialog opens.
2) In the **General** tab, define the following fields:

- **Name**: Enter a meaningful name for the update. The name is used in the update history to identify the update.
- **Description**: Optionally a description that is displayed in the update history to provide more information about the update.

3) In the **Meta-Model Content** tab, select the configuration that you want to add to the AMM file:

- **Save Configuration**: Select the checkbox to save custom object class properties, custom enumerations and all customer defined configuration objects in the **Presentation**, **Functions**, and **Surveys** tabs in Alfabet Expand.
- **Save Reports**: Select the checkbox to save the content of the **Reports** root node of the explorer in the **Reports** tab in Alfabet Expand. If the report structure in the target database will change with the update, bookmarks linking to configured reports will be automatically updated when the configuration is merged.

  If a configured report that exists both in the target database and in the AMM file is updated, and a user or solution designer has restricted the display of columns of the configured report via the **Configure** button, new columns added to the configured reports will be hidden because they are not selected in the visibility setting.

  For information about hiding columns in configured reports, see the section Defining the Visibility of Page Views/Configured Reports Available at the Root Node of an Explorer in the chapter Configuring User Profiles for the User Community.

- **Save Workflow Templates**: Select the checkbox to save the content of the explorer of the **Workflow** tab of Alfabet Expand.
- **Save ADIF Schemes**: Select the checkbox to save the content of the explorer of the `ADIF` tab in Alfabet Expand.

  After the target database is updated by means of the AMM file, all ADIF import schemes in the target database that have the **Auto-Run** attribute set to `True` will be automatically executed. For more information about automatic execution of ADIF schemes, see *Configuring ADIF Schemes to be Automatically Executed on Update of the Meta-Model* in the reference manual *Alfabet Data Integration Framework*.

- **Save Event Templates**: Select the checkbox to save the content of the explorer of the **Events** tab in Alfabet Expand.
- **Save Diagrams**: Select the checkbox to save the custom diagram definitions and custom diagram item templates defined in the **Diagrams** tab in Alfabet Expand.

Icons are not automatically saved if they are included in a diagram item template and the diagram item template is stored in the AMM file. If your configuration includes icons that are not available in the target database, make sure to also select **Save Icons**.

- **Save Publications**: Select the checkbox to save the content of the **Publications** tab in Alfabet Expand.
- **Save Database Views**: Select the checkbox to save the database views defined in the **Meta-Model** tab in Alfabet Expand.

When the configuration is restored to the target database, all database views in the target database that are created based on a **Database View** configuration object will be recreated, even if **Save Database Views** is not checked. The solution designer should then check whether the creation of database views was successful. The required procedure is described in the section Saving the Configuration of the Alfabet Solution to an AMM File in the reference manual *Configuring Alfabet with Alfabet Expand*.

- **Save Icons**: Select the checkbox to save the icons uploaded to the Alfabet database.

Please note that the **Save Icons** checkbox in the **Meta-Model Content** tab must be selected in order to include any images included in the configuration of guide views.

- **Save Culture Settings**: Select the checkbox to save the content of the **Cultures** and **API Cultures** explorer nodes of the **Meta-Model** tab in Alfabet Expand.
- **Save Translation**: Select the checkbox to save the custom translation of strings displayed in the Alfabet user interface that are customized via the **Translation Editor** in Alfabet Expand.

When the translation includes the caption and description of configured reports, the **Update Translation** functionality available in the **Report** root node in Alfabet Expand must be executed on the target database after update with the AMM file.

4) Select the following options, if applicable for your configuration:

- **Replace Entire Existing Configuration**: Select the checkbox if you want the configuration in the AMM update file to overwrite an existing configuration in the target database during the **Update Meta-Model** action. If the checkbox is not selected, the configuration in the AMM update file is merged with the configuration in the target database.

If the **Replace Entire Existing Configuration** checkbox is selected, the configuration of the target database will be deleted prior to saving the configuration in the AMM file to the target database. All customer configurations that are part of the configuration of the target database but not part of the configuration saved in the AMM file will be lost. The replace mechanism deletes all parts of the configuration including the parts that are not selected to be part of the AMM update. The **Replace Entire Existing Configuration** checkbox should only be selected for AMM files when the parts of the configuration to be replaced have been selected.

Please note that reference data, assemblies and guide pages are not deleted prior to applying the configuration stored in the AMM file.

Cultures in the target database are removed with the exception of the primary culture (en-US), the default culture and the configuration culture. Any settings in the

AMM file about the default culture or the configuration culture are ignored and the settings in the target database are maintained.

Configured reports that are automatically generated for the faceted semantic search functionality of the AlfaBot will not be deleted from the target database. For more information about automatically generated reports, see Managing Automatically Generated Reports.

If you want to replace only part of the configuration (for example, the configuration of workflows only), it is recommended that you use the solution tagging option. For more information about solution tagging, see Identifying Configuration Objects via Solution Tagging in the reference manual *Configuring Alfabet with Alfabet Expand*.

- **Automatically Migrate Affected Workflows**: Select the checkbox if you want the workflow templates to be automatically migrated to the target database. Migration of workflows is a complex process that is described in detail in the section Creating a Migration Definition to Update Running Workflows in the chapter Configuring Workflows.
- **Only Include Objects with the Following Tags**: The box lists all solution tags available in the current configuration. If you do not select any checkboxes, all configuration parts selected in the **Meta-Model** tab are is saved without taking solution tagging into account. If you select one or multiple checkboxes, only solution objects which are both marked with a selected tag and are of a configuration object type selected in the Meta-Model tab are included into the AMM file. If solution tagging is not available for a configuration object type that is selected, all objects of that type will be saved independent of selected tags. For more information about solution tagging, see the section Identifying Configuration Objects via Solution Tagging in the reference manual *Configuring Alfabet with Alfabet Expand*.

  For example, the configuration includes 20 configured reports and 5 publications.

  You have tagged two configured reports and two publications with a tag **PublicationReports** and select this tag in the **Only Include Objects with the Following Tags** field.

  In addition, you have selected the **Save Reports** checkbox, but you have not selected the for **Save Publications** checkbox.

  The AMM file will include the two tagged configured reports. It will not include any other configured reports because they are not tagged. It will not include an tagged or untagged publications because publications were not selected for upload.

- **Provide comma-separated tags to find objects to be removed**: Enter the name of a solution tag or a comma-separated list of multiple solution tag names to delete all public (customer-defined) configuration objects tagged with the specified tag name(s) from the target database prior. This option is useful if a tagged configuration has been changed in a way that includes the deletion of objects. The obsolete objects can be removed form the target database as well. For more information about solution tagging, see the section Identifying Configuration Objects via Solution Tagging in the reference manual *Configuring Alfabet with Alfabet Expand*.

  Make sure that all objects required for the tagged solution are available in the AMM file when setting this option. All objects with the solution tag not included in the AMM file will be deleted from the target database.

  If the tag name(s) that shall be used to remove objects is also used in the database you are currently connected with to tag configuration objects, you can select the tag name(s) from a multi-select combo-box instead of typing them in the field. Click the button on the right of the field to open the multi-select combo-box and select

the checkbox of all tags in the current configuration for that all configuration objects shall be deleted in the target database prior to import of the configuration objects in the AMM file.

5) The **Guide Pages** tab displays all guide page projects in the current database. Select the checkbox for all guide page projects that should be merged to the existing guide page configuration of the target database. Guide pages are merged to the target database independent of the setting of the **Replace Entire Existing Configuration** field in the **Meta-Model** tab. Optionally, you can select the **Remove All Guide Pages from Target Database Before Updating** checkbox to overwrite the complete guide page configuration of the target database with the guide pages in the AMM file. If the checkbox is not selected, guide pages in the AMM file will be added to existing guide pages in the target database, thus overwriting guide pages with the same name.

Please note that the **Save Icons** checkbox in the **Meta-Model Content** tab must be selected in order to include any images included in the configuration of guide views.

The styles configured in the guide pages stored in the AMM file will overwrite the styles of the guide pages in the target database. You should ensure that the styles relevant for your enterprise are correctly configured in the guide pages before importing them via an AMM file to the production environment. For more information about the configuration of guide pages and their styles, see the section *Formatting and Designing the Guide Pages* in the reference manual *Designing Guide Pages for Alfabet*.

6) In the **Reference Data** tab, user profiles and a specified subset of configurations performed in the **Configuration** functionalities in the Alfabet user interface can be optionally uploaded to the AMM file. These objects are stored in the instance store of the database. In contrast to the other configuration objects, they can be created and edited by users via the Alfabet user interface. Independent of the setting of the **Replace Entire Existing Configuration** field in the **Meta-Model** tab, they are always merged with the existing configuration in the target database.

Note the following about the update of user profiles and reference data via AMM files:

- **User profile configuration**: User profiles in the AMM file are added to the existing user profile configuration in the target database. User profiles with the same name will be overwritten in the target database.

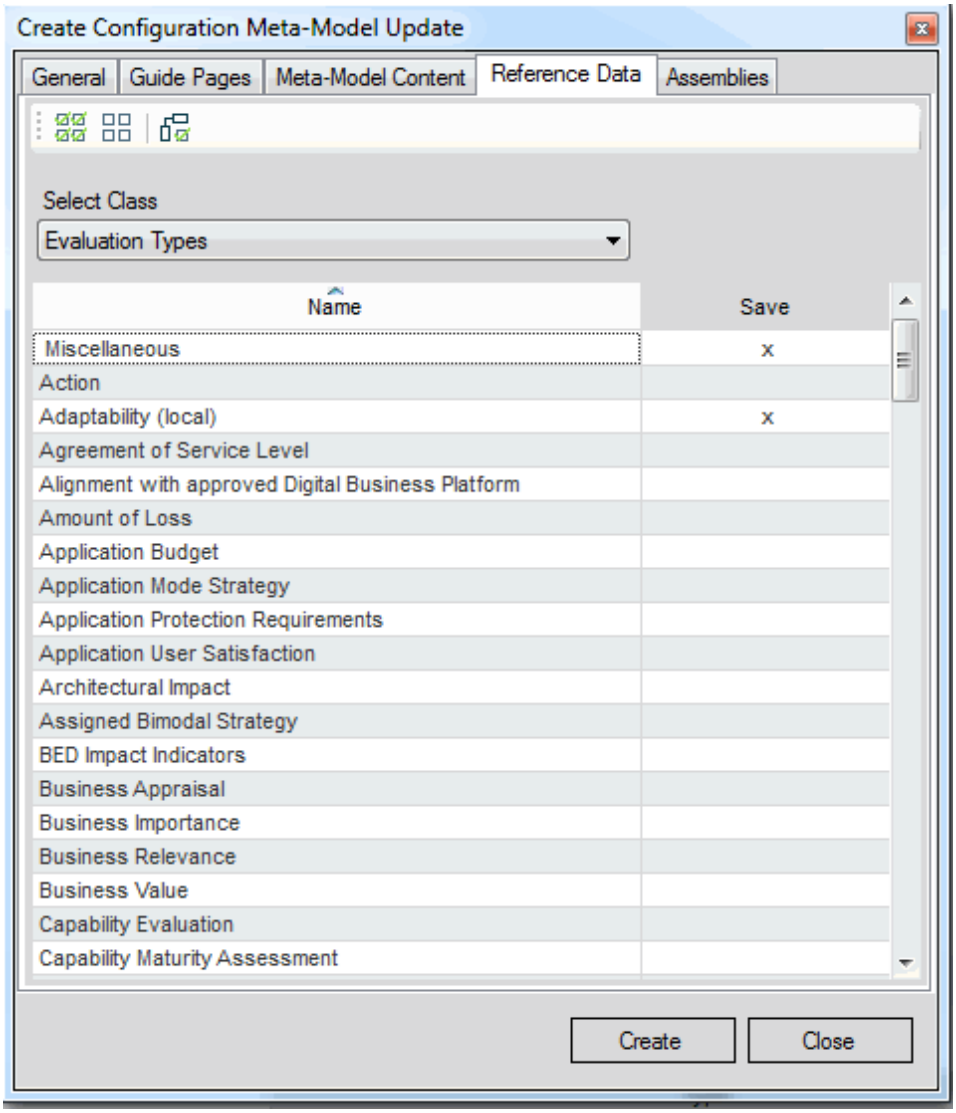
  

  If a guide page/guide view is defined as the start page for a user profile, you must explicitly include the guide page/guide view in the AMM update. If the guide page/guide view is not included, then the user will see an empty start page.

- **Configuration of reference data and evaluations**: Existing objects in the Alfabet database are overwritten if the key property for identification of the object is identical. The following table lists the configured objects that can be migrated via AMM, the key used to identify the objects, and whether the objects can be added to the AMM file by direct selection of objects or as sub-objects of a selectable parent object:

Object Class	Key	Selection
EvaluationType	Name	Directly
IndicatorType	Evaluation Type, Name	Included with selection of the evaluation type they are assigned to.
RoleType	Name	Directly
PrioritizationScheme	Name	Directly
ITPortfolio	Name	Directly
DiagramView	Name	Directly
DiagramViewItem	Name	Included with selection of the diagram view they are assigned to.
ColorRuleGroup	Name	Directly
ColorRule	Name	Directly or included with selection of the color rule group they are assigned to.
ClassConfiguration	Class Name	Directly

A table lists all configuration objects available for the type of configuration object selected in the **Select Class** field above the table. Select the type of configuration object in the **Select Class** field and click the cell in the **Save** column of the table for all configuration objects of the selected type that are to be saved to the AMM file:



To save all configuration objects or user profiles currently displayed in the table to the AMM file, click the **Check All** button.

When you select **Class Configuration** in the **Select Class** field and stereotypes are defined for an object class, each stereotype is listed in a separate row of the table with the **Name** defined as "Name (Stereotype)".

Color rules that are assigned to a color rule group cannot be included separately. Select **Color Rule Groups** in the **Select Class** field and select a color rule group to include the color rule group and all color rules that are assigned to the color rule group to the AMM update file. When you select Color Rules in the Select Class field, the table only displays color rules that are not assigned to a color rule group. These color rules can be selected separately.

Select the **Check Dependent Objects** button to select objects that depend on other objects that you have currently selected in the list. When you click the button, the dependent objects will be automatically selected:

- For each evaluation type currently selected in the list, the following dependent objects are also selected:

- all prioritization schemes to which the evaluation type or any of the indicator types assigned to the evaluation type are assigned
- all IT portfolios to which the evaluation type or any of the indicator types assigned to the evaluation type are assigned
- all diagram views to which any of the indicator types assigned to the evaluation type are assigned
- class configurations to which the evaluation type is assigned
- For each prioritization scheme currently selected in the list, the following dependent objects are also selected:
- all IT portfolios to which the prioritization scheme is assigned
- class configurations to which the prioritization scheme is assigned
- For each IT Portfolio currently selected in the list, the following dependent objects are also selected:
- class configurations to which the IT portfolio is assigned.

7) In the **Assemblies** tab, assemblies can be optionally uploaded to the AMM file if the configuration has been specified via a DLL file delivered by Software AG. If you need to include assemblies in the AMM file, see the section Managing Assemblies for detailed information.
8) Confirm the message by clicking **OK**. All connections to the Alfabet database are closed during update.

Checking and Repairing the Configuration Updates From a Master Database

A history is available for configuration updates from a master database. The history also provides access to log information for the update file and a summary of configuration objects updated.

The history only lists meta-model updates from a master database and data anonymization actions. File based updates of the meta-model are not included in the history.

Every entry in the history can serve as a restore point to re-establish the configuration prior to the selected update in the history.

If update from a master database is not enabled, the history is nevertheless displayed to inform about the anonymization actions. Restore of the configuration from a restore-point is then deactivated.

Do the following to check and optionally restore the configuration:

1) In the menu of Alfabet Expand, select **Meta-Model** > **Show Meta-Model Configuration History**. The history opens in the middle pane.
2) The history shows the following information:

You might need to scroll from left to right or enlarge the window to see all relevant information.

- **Name**: The name of the update defined during triggering of the update in the update dialog window.

- **Description**: The name of the update defined during triggering of the update in the update dialog window.
- **Update Time**: The date and time when the update was performed.
- **Executor**: The first name and name of the user that triggered the update process.
- **Product Version**: The version of the software that was imported from the source database. Please note that the version must match the current version of the target database. You can for example not restore the configuration from an update with a different version number than the current one.
- **Update Status**: The update status should be `Finished`. If it is `Error`, the update failed and you should check the log file for more information about the error that occurred. If the update process led to problems in your configuration, because only partial updates were performed, you can restore the configuration prior to the update by clicking the update in the table and clicking **Restore Configuration** in the toolbar. If the update was not performed at all, the log file is empty.

3) You can do any of the following:

- **To view the content summary of the AMM file** an update is based on, select the update in the table and click **Show Summary** in the toolbar.
- **To view the log file of the update process**, select the update in the table and click **Show Update Log** in the toolbar. The log file includes the content summary of the AMM file and informs about the success of the update steps.

Log messages are displayed in the language currently set for the master database.

- **To export the content of the history table** click **Export** in the toolbar. Select the output format from the drop-down list.
- `To restore the configuration prior to an update`, click the update that you want to undo, and click **Restore Configuration** in the toolbar. Confirm the warning by clicking **Yes**. The restore may take some time. All connections to the database are closed during update.

Please note the following:

- The current version of the Alfabet database must match the version number of the restore point to perform the restore.
- Reference data configuration in the instance store, like for example cost types, indicator types or user profiles, is not restored via this mechanism.

Correcting Issues that Occurred During Meta-Model Update

After update of the meta-model, check whether issues occurred during update. The following mechanism should be used to find and correct meta-model update issues:

- Checking the Success of Meta-Model Updates
- Securing and Checking Database Consistency with the Meta-Model

Checking the Success of Meta-Model Updates

If issues occurred during update of the meta-model via AMM file, a log file is created during update of the meta-model. The log file is written to the directory that contains the AMM file and has the name <Name of the AMM file>_<Time Stamp>.log. Consult the log file to view any issues that occurred during update.

Securing and Checking Database Consistency with the Meta-Model

The structure and content of the Alfabet database tables must be in accordance with the meta-model of the current Alfabet release.

To ensure database consistency with the meta-model, use only Alfabet software and interfaces for external access when performing changes to the Alfabet database. Any changes performed directly on the database with third-party mechanisms can lead to database corruption and data loss.

To make sure that the current database is in accordance with the current meta-model, Alfabet Expand provides a test mechanism that checks consistency issues.

To check the database consistency:

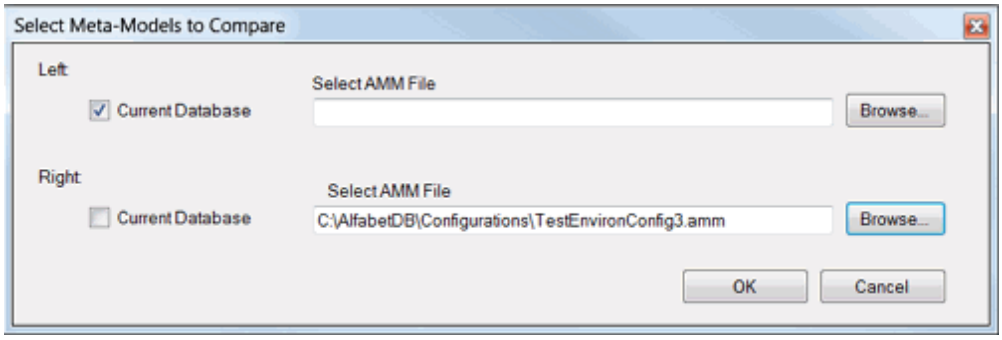
1) Open the tool Alfabet Expand with a server alias.
2) In the menu, select **Meta-Model** > **Check Meta-Model for Database Consistency**. The check will be performed, and a message will display information about the results. If an inconsistency is found (for example, a database table with an invalid name), an error message will be displayed that providing information about the error and advising you to contact Software AG Support.

Comparing Database Configurations

Alfabet Expand provides a mechanism to compare Alfabet configurations. You can either compare the configuration of the current Alfabet database with the configuration stored in an AMM file or the configuration stored in one AMM file with the configuration stored in another AMM file.

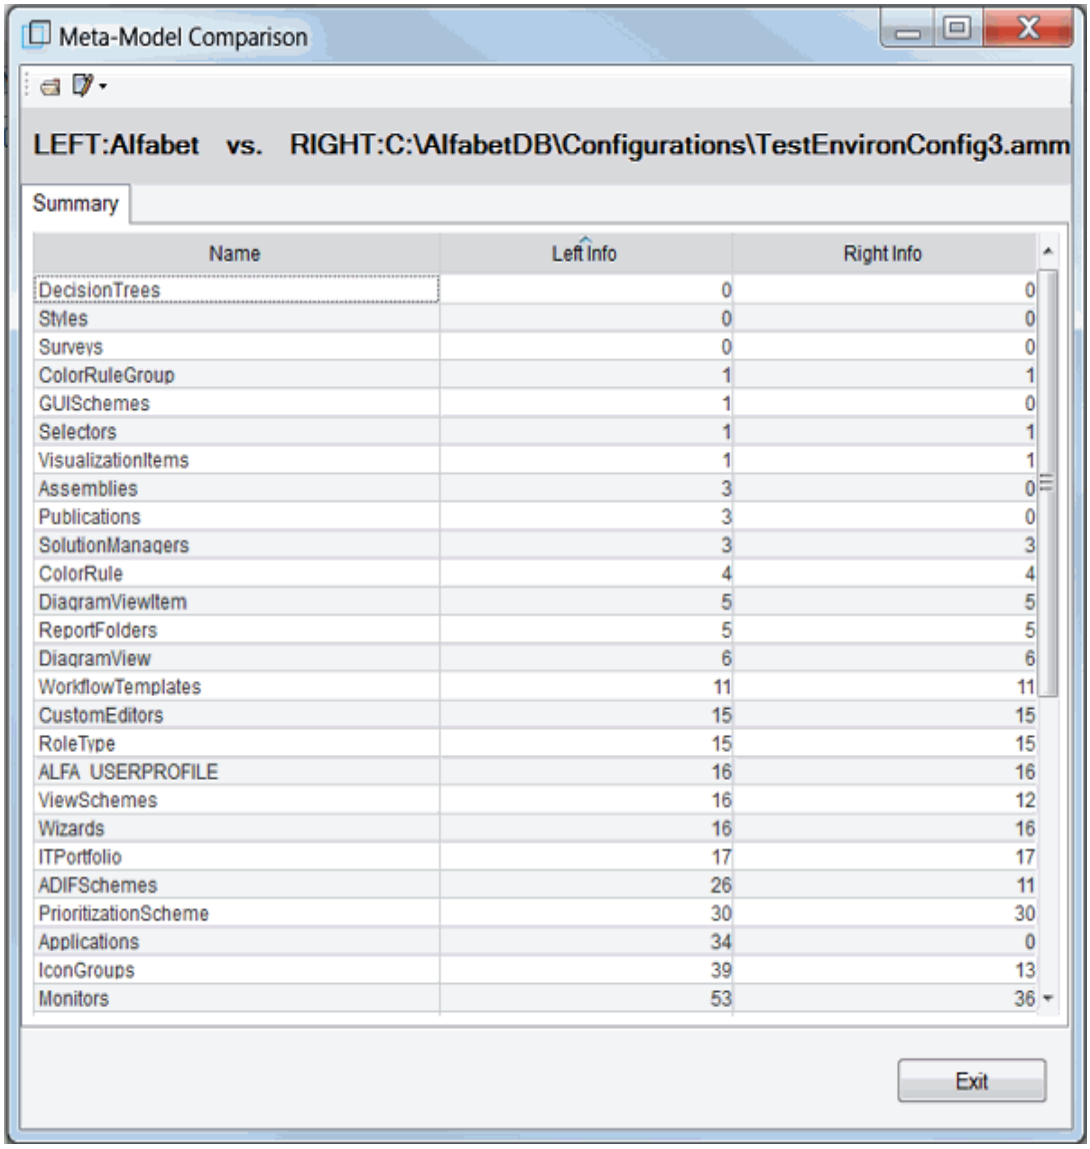
To compare two configurations:

1) In the menu of Alfabet Expand, select **Meta-Model** > **Compare Configurations**. The **Meta-Model Comparison** window opens.
2) In the toolbar of the **Meta-Model Comparison** window, click the **Select Meta-Models**  button to open the meta-model editor.
3) Select the meta-models that shall be displayed on the left side of the report and the right side of the report of the meta-model comparison:



- To select the meta-model configuration of the Alfabet database you are currently working with, activate the **Current Database** checkbox.
- To select a meta-model configuration stored in an AMM file, click the **Browse** button, and select the file from the local file system.

4) Click **OK**. The comparison is executed. This may take some time. The summary of the comparison is displayed in the **Meta-Model Comparison** window:

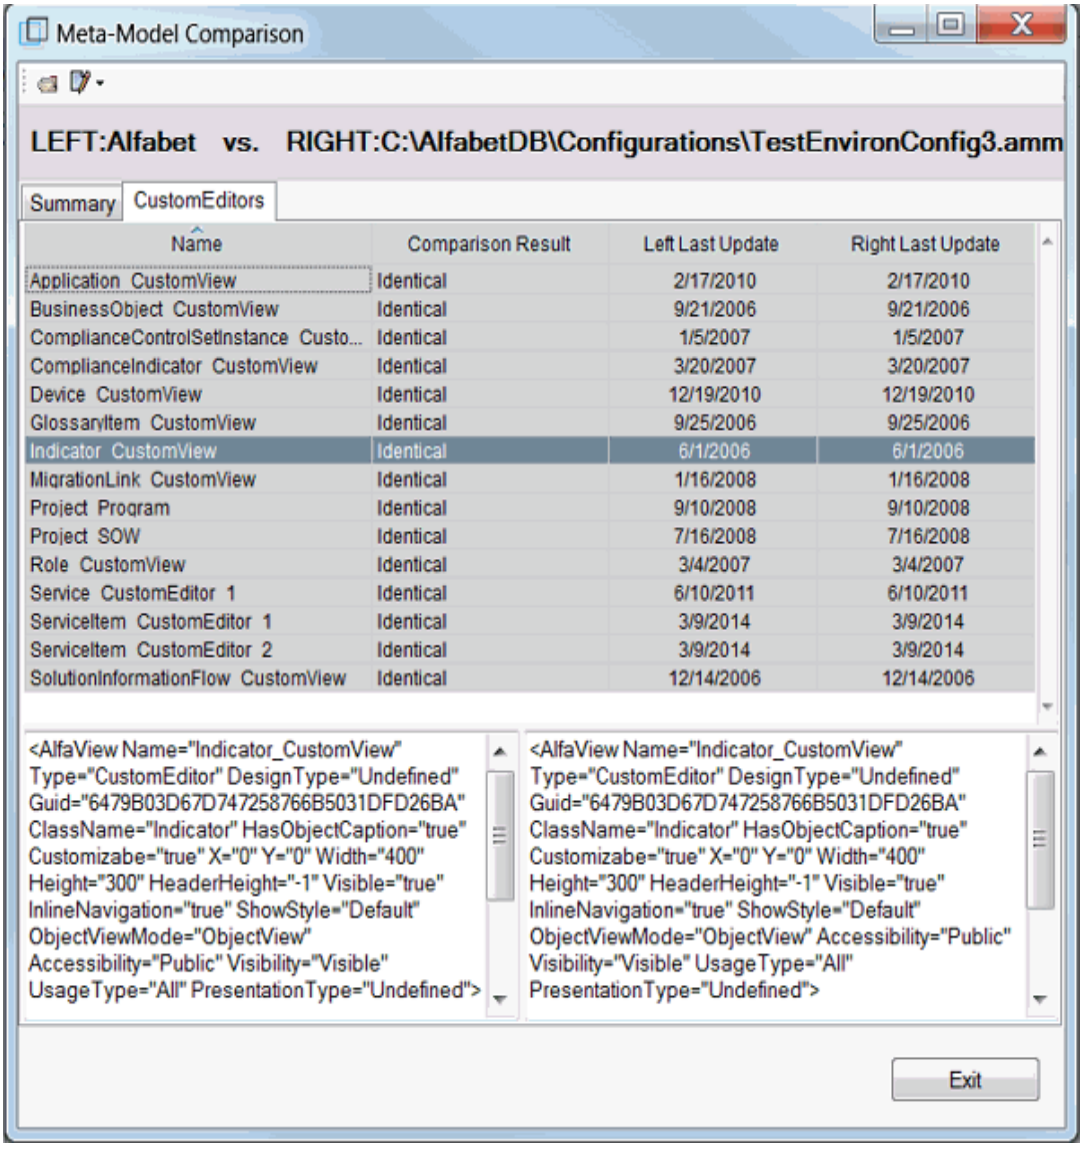


Name	Left Info	Right Info
DecisionTrees	0	0
Styles	0	0
Surveys	0	0
ColorRuleGroup	1	1
GUISchemes	1	0
Selectors	1	1
VisualizationItems	1	1
Assemblies	3	0
Publications	3	0
SolutionManagers	3	3
ColorRule	4	4
DiagramViewItem	5	5
ReportFolders	5	5
DiagramView	6	6
WorkflowTemplates	11	11
CustomEditors	15	15
RoleType	15	15
ALFA_USERPROFILE	16	16
ViewSchemes	16	12
Wizards	16	16
ITPortfolio	17	17
ADIFSchemes	26	11
PrioritizationScheme	30	30
Applications	34	0
IconGroups	39	13
Monitors	53	36

- On top of the **Summary** tab, you can see which meta-model configurations are selected for the left and right side of the comparison.
- The **Name** column lists the configuration object types that are part of the Alfabet meta-model.
- For each configuration object type, the number of configuration objects available in the respective meta-model is given in the **Left Info** and **Right Info** column.

  If the number of objects is identical in the **Left Info** and **Right Info** column, that does not indicate that the configurations are identical. If configuration objects are substituted by other configuration objects or changed, this does not change the overall number of configuration objects. To view the actual changes in the configuration, open a detail view:

5) Double-click a configuration object type in the table. A new tab opens that displays the differences between the two selected configurations for the selected configuration object type:



For each configuration object of the selected type that is part of either of the compared configurations, the following information is displayed

- **Name**: The name of the configuration object.

- **Comparison Result**: Indicates, whether the configuration object is identical or different for the compared meta-model configurations:
- **Identical**: The object exists in both configurations and is identical.
- **Different**: The object exists in both configurations and the configuration changed. The respective rows are displayed in red.
- **Left Only**: The object exists in the configuration represented by the left column only. The respective rows are displayed in yellow.
- **Right Only**: The object exists in the configuration represented by the right column only. The respective rows are displayed in yellow.
- **Left Last Update**: The date when the configuration of the object was last changed in the meta-model selected for the left column.
- **Right Last Update**: The date when the configuration of the object was last changed in the meta-model selected for the right column.

6) If you click a row in the table, the configuration of the object in the left and right column are displayed as XML. You can check in the XML which changes have been applied.
7) To limit the display to the relevant information about objects that have been changed, you can change the view by hiding objects with a selected comparison result value from the list. In the toolbar, click the **Hide** button and select one of the options in the sub menu to hide either objects identical in both databases or objects that are specific for one of the configurations and are not available in the other one. You can repeat the action to select another of the hide options. Both hide options are then applied. Clicking an already selected option will deselect the option.

Exporting Information About the Custom Configuration in an XML File

The **Meta-Model** > **Save Configuration** functionality in Alfabet Expand saves the customer configuration of the meta-model including custom properties, enumerations, culture settings, custom object views, custom explorers, data-set configurations, wizards, monitor settings, XML objects, text templates, workflow templates, configured reports, and custom translations to an XML file. This feature may be useful to generate reports about the configuration, compare different stages of configuration, archive different stages of configuration, or to be able to access the configuration information while the server is running and standalone access to Alfabet Expand is not available.

To save the configuration of the Alfabet solution environment:

1) Open the tool Alfabet Expand with a server alias.
2) In the menu, select **Meta-Model** > **Save Configuration**. A dialog window opens.
3) If necessary, you can change the location and/or file name of the default output file displayed in the dialog box.
4) Select that part of the configuration that you want to save. You can select all or some of the following options:

- **Save Entire Configuration** to save all customer specific configurations including, for example, view schemes, custom object views, and class settings.

Custom reports, publications, and workflow templates configured by your enterprise will not be saved by selecting this option!

- **Save All Reports** to save the custom reports configured by your enterprise.
- **Save All Workflow Templates** to save the workflow templates configured by your enterprise.
- **Save All Publications** to save the publication configuration of the Alfabet Publication Framework.

5) Click **Save**. The configuration XML file is saved.

Building Custom Reports that Inform About the Current Structure of the Standard And Custom Meta-Model

Importing Objects of Configuration Relevant Object Classes from a Master Database

Configurations may require the creation of objects for object classes in the Alfabet meta-model. For example:

- User profiles
- Mandates
- Reference data configured in the Configuration functionalities in the Alfabet user interface, for example, role types or cost types.
- Monitors
- Configured Reports

The AMM update mechanism only includes a subset of the objects stored in the instance store.

For import of other parts of the configuration objects stored as objects of object classes in the Alfabet meta-model, a unidirectional, direct connection can be established between two Alfabet database s for data update in the target database with data in the source database. Once the target database is configured to connect to the source database, a user can perform the import of new configuration relevant meta-model objects via the functionality **Import Data Search** of the Alfabet user interface. The import mechanism informs the user whether objects were added, and new objects can then be selected for import.

Optionally, the import mechanism can be configured to also detect changes to given configuration objects. This option is only available for a subset of the relevant classes.

The import mechanism has been developed for configuration objects only and shall not be used for import of any other object classes. The following limitations apply:

- The import mechanism matches the objects in the source and target database exclusively on basis of the **Image Properties** defined for the object class in the relevant class settings. Image properties must be carefully set to ensure that they can be used to unambiguously identify single objects. Source database objects with image properties not identical to the image properties of an object in the target database are regarded as new objects.

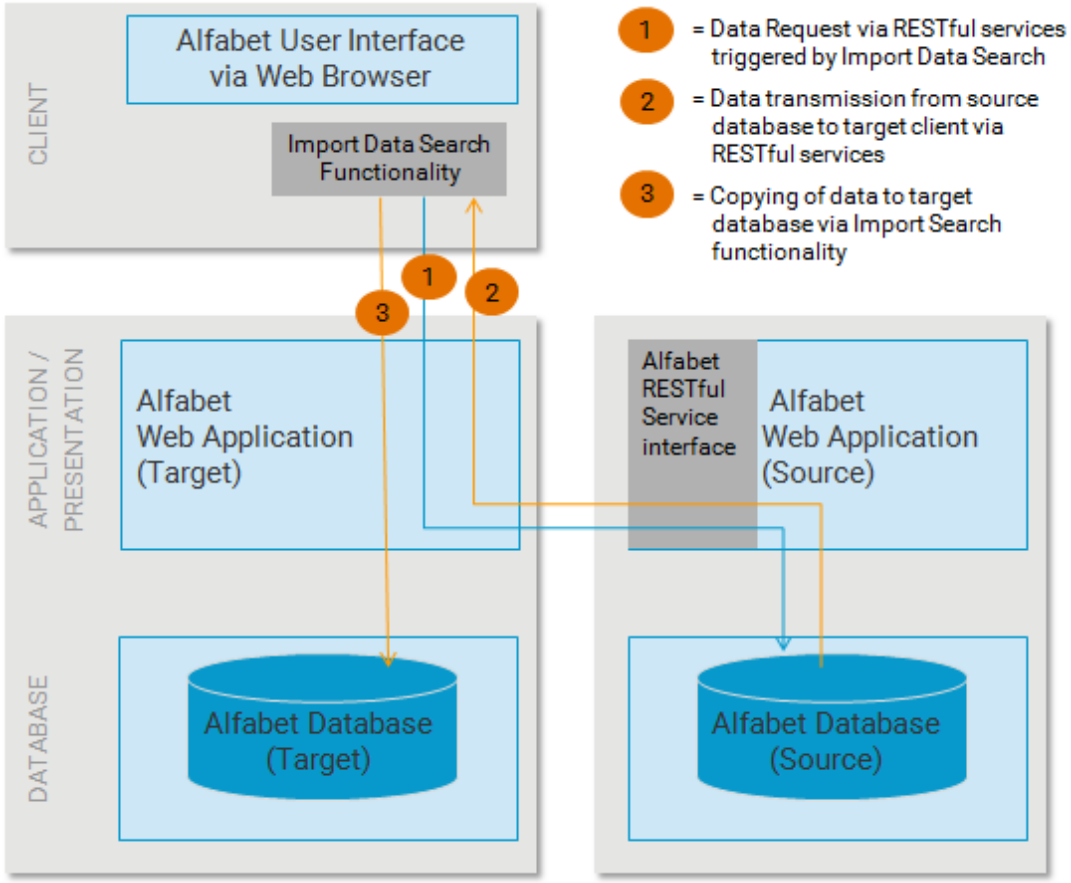
- The import mechanism optionally detects changed objects by comparing the `LAST_UPDATE` property of the object in the source and target database. If the `LAST_UPDATE` date of the object in the source database is younger than the `LAST_UPDATE` date of object in the target database, the object is marked as changed. Please note the following:
  - The comparison is based on the date without time. Therefore, if an object is for example imported and then changed in the source database on the same day, the object is not regarded as changed when performing the next update.
  - The way the object has been changed is not considered by this mechanism.
  - This feature is not available for all relevant object classes and may require additional configuration of the object class.
- During import, the object is created in the target database or, if an object with identical values for the image properties already exists in the target database, the object in the target database is overwritten. A merging process is not available.
- Values for object class properties of the type `ReferenceArray` are ignored during import.
- Values for object class properties of the type `Reference` are only imported if the referenced object already exists in the target database. If you would for example import a hierarchy of cost types, you must first import all root type cost types and then all cost types of the second level of the hierarchy followed by all cost types of the third level of the hierarchy. If you import a cost type on the second level of the hierarchy without prior import of the parent cost type, the cost type will become a root level cost type in the target database.
- Values for object class properties of the **Type** `String` that are based on an enumeration, that means that the **Type Info** attribute of the property is set to the name of an enumeration, are only imported if the specified enumeration item is available in the target database. It is recommended to import the enumeration configuration of the source database into the target database via AMM file based meta-model update prior to using **Import Data Search**.

The following information is available:

- Configuring the Connection Between the Source and Target Database
- Configuring the Source Database to Provide Access to the Relevant Data via the Alfabet RESTful Services
- Configuring the XML Object AlfabetIntegrationConfig of the Target Database
- Creating an Alfabet Database Connection in the Target Database
- Providing Access to the Import Data Search Functionality
- Optional Configuration for Detection of Changes to Configuration Object
- Importing Configuration Objects from a Source Database

Configuring the Connection Between the Source and Target Database

The connection to the source database is based on the Alfabet RESTful services. Establishing the connection requires that two Alfabet Web Application s are running, one with a connection to the source and one with a connection to the target database. The release version of the Alfabet components must be identical for source and target database. When a user triggers the data import mechanism on the Alfabet user interface, the Alfabet Web Application of the target database sends RESTful service requests to the Alfabet RESTful API of the Alfabet Web Application of the source database to request the data.



The configuration includes the following:

- Configuration of the Alfabet Web Application of the source database to activate the Alfabet RESTful API and set the required access permissions for access to the relevant data in the source database.
- Configuration of the Alfabet Web Application of the target database to act as a RESTful client. This configuration is done via Alfabet Expand in the XML object `AlfabetIntegrationConfig`. The configuration also includes a definition of the object classes that shall be imported.
- Configuration of the user access to the functionality in the target database. For this purpose, an object of the object class Alfabet Database Connection must be created via the Alfabet user interface and the access to the Alfabet database connection as well as to objects of the relevant object class must be granted to a user via the user profile assigned to the user.

The definition of object classes for that import is performed is typically further limited with each configuration step:

- Typically, only one database connection is configured in the XML object ***AlfabetIntegrationConfig*** for the connection to the source database. The configuration includes the definition of all object classes that shall be imported from the source database.
- Multiple different Alfabet database connections can then be configured for the same connection to the source database. For each Alfabet database connection, one or a subset of the object classes that can be imported via the connection can be selected as allowed object classes.
- In the **Import Data Search** functionality, the user first selects an Alfabet database connection. He/she then selects one of the object classes configured to be allowed object classes for the Alfabet database connection. Optionally, a full text search filter can be used to further restrict the import to a subset of the selected object class. As a result, import is limited to a subset of objects of one object class at a time. This is also relevant for performance, because the transmission of object data is limited to the objects found by the filtering.

The configuration includes a number of access permission settings to ensure that import can be restricted to a defined user for a defined object class.

The following configuration steps are required to activate the functionality:

- Configuring the Source Database to Provide Access to the Relevant Data via the Alfabet RESTful Services
- Configuring the XML Object AlfabetIntegrationConfig of the Target Database
- Creating an Alfabet Database Connection in the Target Database
- Providing Access to the Import Data Search Functionality
- Optional Configuration for Detection of Changes to Configuration Object

Configuring the Source Database to Provide Access to the Relevant Data via the Alfabet RESTful Services

The source database must be configured to allow access to the endpoint `objects` and `metamodel` of the Alfabet RESTful services. The required configuration is described below in a short overview. For a detailed description of the required configuration of the see the Alfabet RESTful API reference manual *Alfabet RESTful API*.

- A license for the Alfabet Data Integration Framework (ADIF) must be active.
- Configure the `web.config` file of the Alfabet Web Application to enable Alfabet RESTful services.
- Configure the Alfabet Web Application on the Web Server to enable access to the Alfabet RESTful services.
- Configure the server alias of the Alfabet Web Application to enable access to the Alfabet RESTful services.
- Create a user for access via the Alfabet RESTful services, with **Has GetObjectsByFilters Access** and **Has Meta-Model Access** permissions to the Alfabet RESTful services and generate a user password for the user.
- For each object class that shall be imported, define a class setting with the attribute **Allow Read via Rest API** set to `true`.

- Assign the relevant class settings to a user profile via a view scheme and assign the user profile to your access user.
- If your company is using Alfabet 's mandate concept, make sure that the mandate settings for your access user allow viewing all relevant objects.

In addition to the configuration relevant for the Alfabet RESTful services, the object classes that shall be imported into the target database may be configured to have an object class property `LAST_UPDATE` that enables to detect whether a configuration object that exists in both the source and target object has been changed in the source database after the last change to the object in the target database. For more information about the complete configuration to activate this feature, see Optional Configuration for Detection of Changes to Configuration Object.

Configuring the XML Object AlfabetIntegrationConfig of the Target Database

The Alfabet Web Application of the target database acts as RESTful client, connecting to the RESTful API of the Alfabet Web Application of the source database. The connection parameters must be configured in the configuration of the target database using Alfabet Expand:

1) Go the **Presentation** tab of Alfabet Expand and expand the explorer node **XML Objects** > **Integration Solutions**.
2) Right click the XML object `AlfabetIntegrationConfig` and select **Edit XML** from the context menu. The XML object opens in the middle pane.
3) Edit the XML as described below.
4) Click the **Save**button to save your changes.

The XML object must contain the following XML structure:

```
<AlfabetIntegrationConfig>
   <Connection
      name = "My Test Import"
      service="http://localhost/ALFABET1"
      active="true"
      data_portion="80"
      search_limit="500"
      emptyValues="true"
      user="DAME"
      psw="H7GLVUGZWQETKJFSX7HY6OK2CUB4WRGK"
      profile="MASTER">
         <ImplementedClass parent ="IncomeType" />
         <ImplementedClass parent ="ObjectMonitor" />
   </Connection>
</AlfabetIntegrationConfig>
```

The following XML elements and their attributes are part of the specification:

Element (Bold) / Attribute	Allowed Values	Mandatory/Optional	Configuration Requirements
Alfabet-Integration-Config		Mandatory	Root node of the configuration
Connection		Mandatory	The configuration parameters for sending the RESTful service call and request the data from the source database. This XML element can be added multiple times to define multiple source databases.
`name`	String	Mandatory	Enter a unique name for the connection configuration. The name is used to identify the connection configuration for example in editors on the Alfabet user interface.
`service`	URL	Mandatory	Enter the URL of the Alfabet Web Application for access to the source database.
`active`	`true`/`false`	Optional, the default is `true`	This attribute can be defined to deactivate (`false`) or activate (`true`) the connection. If the attribute is set to `false`, the connection will not be displayed in the drop-down list for the connection specification in the editor **Alfabet Database Connection** on the Alfabet user interface. In the **Import Data Search** functionality, all Alfabet database connections already defined for the connection definition are not available for triggering data import.
`data_portion`	Integer	Optional, the default is 100.	Enter the maximum number of results to be returned in a single request. If the maximum number of search results exceeds the `data_portion` value, multiple requests are sent to the Alfabet RESTful API of the Alfabet Web Application connected to the source database, each returning a subsequent subset of the data, until the maximum overall number of search results defined with the attribute `search_limit` is reached.
`search_limit`	Integer	Optional, the default is 300.	Enter the maximum number of objects for that the response of the call shall return data. This value may be set to limit data return from databases containing a high number of objects. **NOTE**: Import of a very high number of objects may lead to performance issues. It is recommended to restrict the maximum number of objects to be returned and use the filters on the **Import Data Search View** to limit the

Element (Bold) / Attribute	Allowed Values	Mandatory/Optional	Configuration Requirements
			number of imported data to a subset of the data available in the source database.
`emptyValues`	`true/false`	Optional	If set to `true`, all object class properties for an object are included into the response call, even if the property value is `NULL`. If set to `false`, only object class properties that are set in the source database are transmitted. It is recommended to set the parameter to `false` for transmission of high amounts of data. In the target database, values for a property are set to `NULL` for an object if the response call does not contain a value for a property or if it contains an empty field for the property.
`user`		Mandatory	Enter the user name of the user configured in the source database to grant access to the functionality. For more information about the configuration of the user, see .
`psw`		Mandatory	Enter the REST API password of the user configured in the source database to grant access to the functionality. For more information about the configuration of the user, see .
`profile`		Mandatory	Enter the user profile configured in the source database to grant the correct access permissions to the relevant object classes.
ImplementedClass		Mandatory	Defines which classes can be imported from the source database. Multiple XML elements `ImplementedClass` can be added to the XML object to define import from all relevant classes within one `Connection` definition.
`parent`		Mandatory	Enter the name of the object class to be imported or the name of the parent class in the class hierarchy of the Alfabet meta-model. Import will be allowed for the specified object class and all object classes that are subordinate of the specified object class in the Alfabet meta-model.

The definition of the object classes for import can be done via the parent object class to ease configuration. The hierarchy in the Alfabet meta-model is not visible in the Meta-Model tab in Alfabet Expand. If you have a valid license for ADIF, you can see the class hierarchy in the explorer of the ADIF tab in Alfabet Expand.

The following table lists all object classes that are relevant for import and the parent object class.

The table also informs whether the `LAST_UPDATE` property required for the optional data update functionality is available for the object class and whether it is available by default or requires configuration.

If the object class has standard object class properties of the type Reference or ReferenceArray, this information is also given in the list. Properties of the type ReferenceArray are ignored during import and properties of the type Reference are only imported if the target object for the reference is already available in the target database. If you import for example configured reports structured in report folders, you must allow import of both classes and report folders must be imported first.

If you define a parent object class, you might technically be able to import data for a high number of object classes. Nevertheless, object classes not listed here should not be imported via the **Import Data Search** functionality.

Class caption	Object class name	Parent object class name	Update functionality	Import restrictions
Currency	Currency	ITClass	No	Currencies are hierarchically structured. The currencies must be imported from top level first to the bottom level last.
Cost Type	CostType	ITClass	Requires configuration	Cost types are hierarchically structured. The cost types must be imported from top level first to the bottom level last.
Income Type	IncomeType	ITClass	Requires configuration	Income types are hierarchically structured. The income types must be imported from top level first to the bottom level last.
Connection Type	ConnectionType	ITClass	Requires configuration	
Connection Method	ConnectionMethod	ITClass	Requires configuration	
Connection Frequency	ConnectionFrequency	ITClass	Requires configuration	
Connection Data Format	ConnectionDataFormat	ITClass	Requires configuration	

Class caption	Object class name	Parent object class name	Update functionality	Import restrictions
Role Type	RoleType	ITClass	Requires configuration	
Skill	Skill	ITClass	Requires configuration	
Data Retention Policy	DataRetentionPolicy	ITClass	Requires configuration	
Indicator Time Series	IndicatorTimeSeries	ITClass	Requires configuration	
Generic Reference Data	GenericReferenceData	Artifact	Available by default	
Alfabet Database Connection	Alfabet_DBConnection	IntegrationConnection	Available by default	Assignment of authorized user groups is based on a ReferenceArray property and will not be included into the import. For security reasons, the development and production environment should use a different user configuration and authorized access shall not be imported but configured in the target database.
API Gateway Database Connection	APIGateway_DBConnection	IntegrationConnection	Available by default	Assignment of authorized user groups is based on a ReferenceArray property and will not be included into the import. For security reasons, the development and production environment should use a different user configuration and authorized access shall not be imported but configured in the target database.
API Portal Database Connection	APIPortal_DBConnection	IntegrationConnection	Available by default	Assignment of authorized user groups is based on a ReferenceArray property and will not be included into the import. For security reasons, the development and production environment should use a different user configuration and authorized

Class caption	Object class name	Parent object class name	Update functionality	Import restrictions
				access shall not be imported but configured in the target database.
ARIS Database Connection	ARIS_DBConnection	IntegrationConnection	Available by default	Assignment of authorized user groups is based on a ReferenceArray property and will not be included into the import. For security reasons, the development and production environment should use a different user configuration and authorized access shall not be imported but configured in the target database.
CentraSite Connection	CentraSite_DBConnection	IntegrationConnection	Available by default	Assignment of authorized user groups is based on a ReferenceArray property and will not be included into the import. For security reasons, the development and production environment should use a different user configuration and authorized access shall not be imported but configured in the target database.
Report Folder	ALFA_REPORTFOLDER	ALFA_REPORTBASE	Available by default	Assignment of authorized user groups is based on a ReferenceArray property and will not be included into the import. For security reasons, the development and production environment should use a different user configuration and authorized access shall not be imported but configured in the target database.
Configured Report	ALFA_REPORT	ALFA_REPORTBASE	Available by default	If configured reports are structured in report folders, the report folder must be imported prior to importing the configured reports. Access permission configuration will not be included into the import. For security reasons, the development and production environment should use a different user configuration and access permissions shall not be imported but configured in the target database.
Consistency Monitor	ConsistencyMonitor	ObjectMonitor	No	The listeners of the monitor are stored as ReferenceArray and are not included into the import. For security reasons, the development and production environment should use a different user configuration

Class caption	Object class name	Parent object class name	Update functionality	Import restrictions
				and listeners are then anyway not meaningful to import.
Notification Monitor	NotificationMonitor	ObjectMonitor	No	The listeners of the monitor are stored as ReferenceArray and are not included into the import. For security reasons, the development and production environment should use a different user configuration and listeners are then anyway not meaningful to import.
System Date Monitor	SystemDateMonitor	ObjectMonitor	No	The listeners of the monitor are stored as ReferenceArray and are not included into the import. For security reasons, the development and production environment should use a different user configuration and listeners are then anyway not meaningful to import.
Mandate	ALFA_MANDATE	SYSTEMCLASS	No	

Creating an Alfabet Database Connection in the Target Database

Configuration is done in the **Integration Solutions Configuration** functionality on the Alfabet user interface.

1) Go to the **Integration Solutions Configuration** functionality and click the **Alfabet Database Connection** node in the **Integration Solutions Configuration** explorer.
2) In the view, click **New** > **Create Alfabet Database Connection**.
3) In the **Alfabet Database Connection** editor, define the following fields as needed:

   Basic Data tab:

- **ID**: Alfabet assigns a unique identification number to each ARIS database connection. This number cannot be edited.
- **Name**: Enter a unique name for the Alfabet database connection. The name is displayed in the **Import Data Search** functionality in the drop-down list for selection of the master database for import of Alfabet configuration data.
- **Release Status**: Select the Alfabet database connection's current release status.

The set of release statuses available for an object class are configured by your solution designer in the configuration tool Alfabet Expand. For more information, see the section Configuring Release Status Definitions for Object Classes in the reference manual *Configuring Alfabet with Alfabet Expand*. For general information about release statuses, see the section *Understanding Release Statuses* in the reference manual *Getting Started with Alfabet*.

- **Description**: Enter a meaningful description that will clarify the purpose of the Alfabet database connection.

Authorized Access tab:

- **Authorized User**: Click the **Search** icon to assign an authorized user to the selected ARIS database connection. The authorized user will have Read/Write access permissions for the object and is responsible for the maintenance of the object.
- **Authorized User Groups**: Select one or more checkboxes to assign Read/Write access permissions to all users in the selected user group(s).

Connection tab:

- **Alfabet Connection**: Select the connection to the relevant Alfabet database that is configured in the XML element ***Connection*** in the XML object ***AlfabetIntegrationConfig*** in Alfabet Expand.
- **Allowed Classes**: Select one or multiple object classes for the users authorized to import data via this Alfabet database connection shall be able to import data via the **Import Data Search** functionality. All classes that may be imported according to the definition in the XML element ***Connection*** in the XML object ***AlfabetIntegrationConfig*** in Alfabet Expand are listed in the drop-down list of the field.

After you have selected object classes for import, you will see your selection in the field **Selected Classes**. The user will see the selected classes in the drop-down list of the object class filter in the **Import Data Search** functionality after having selected the Alfabet database connection.

4) Click **Test Alfabet Database Connection**. If your settings are correct, a message "The connection is valid" is displayed. Otherwise, an error message is displayed.

Providing Access to the Import Data Search Functionality

In the target database, the user that shall import the data via the **Import Data Search** functionality must log in with a user profile that is configured to grant access to the functionality per object class. The following must be configured for the user profile:

- The user must be able to access the **Import Data Search** functionality (`ImportDataSearch`) either via a menu item or a guide view or guide page.

For information about how to add a functionality to a user profile, see Making Functionalities Accessible to a User Profile.

- The attribute **Allow Update from External Reference Data Service** must be set to `true` for all class settings of all object classes for those objects shall be imported. The relevant class settings must be assigned via the view scheme configuration to the user profile the user logs in with.

For information about how to configure class settings for an object class, see Configuring Class Settings for Object Classes and Object Class Stereotypes.

For information about how to assign class settings to the view scheme of a user profile, see Configuring a View Scheme for a User Profile.

Optional Configuration for Detection of Changes to Configuration Object

Optionally, the import mechanism can be configured to detect whether a configuration object that exists in both the source and target object has been changed in the source database after the last change to the object in the target database. This mechanism is exclusively based on the value of the `LAST_UPDATE` property of the object.

Some of the configuration objects already have a standard property called `LAST_UPDATE`. For these object classes the functionality is available by default. For other object classes, the functionality can be implemented by adding a custom property `LAST_UPDATE` to the object class in both the source and the target database. A custom property with the Name attribute set to `LAST_UPDATE` will automatically be set to the current data by the system whenever the object is changed.

If a `LAST_UPDATE` property is available for the object class in both source and target database the search functionality of **Import Data Search** automatically compares the dates stores in the custom or standard properties `LAST_UPDATE` of the object if the source and the object with the same image property values in the target database. No further configuration is required.

If the `LAST_UPDATE` date of the target database is older than the one in the source database, the object is marked as changed. If the object in the source database is changed on the same day as the object in the target database, the change cannot be detected, because the LAST_UPDATE property only safes the date and not the date and time of the update.

For a subset of object classes relevant for import a `LAST_UPDATE` property is neither available by default nor can it be added via configuration. A complete overview of the availability of the `LAST_UPDATE` property is given in the list of relevant object classes provided in the section Configuring the XML Object AlfabetIntegrationConfig of the Target Database.

To create a custom `LAST_UPDATE` property, you must perform the following action in Alfabet Expand:

1) In the **Meta-Model** tab, expand the **Classes** node.
2) In the explorer, right-click on the object class for that you want to define a `LAST_UPDATE` property and select **Add New Property** from the context menu.
3) In the window that opens, enter `LAST_UPDATE` into both the **Property Name** and **Technical Name** field. `LAST_UPDATE` must be written in capital letters.
4) Click **OK**. The new property is added to the explorer tree and the attribute window shows the attributes of the new property.
5) In the **Property Type** attribute, select `Date` from the drop-down list.
6) Click the **Save** button to save your changes.

Importing Configuration Objects from a Source Database

The import of configuration relevant objects from a source to a target database can be performed under the following preconditions:

- The connection and data access permissions are fully configured as described in the section above.
- Both databases are currently available via a running Alfabet Web Application.

Import is done in the functionality **Import Data Search** and is a performed in two steps:

- First a comparison between the data in the source database and your current database is triggered. The result is displayed in a table.
- Import can then be performed by selecting one or multiple objects in the table and triggering import via a button in the toolbar.

Prior to starting an import, please carefully consider the restrictions that apply to data import that are listed in the section Importing Objects of Configuration Relevant Object Classes from a Master Database!

Do the following to import objects from the source database in the functionality **Import Data Search**:

1) Set the following filters:

- **Master Connection**: Select the Alfabet database connection that connects to the source database. You will see all Alfabet database connections that have been configured by your solution designer in the functionality **Integration Solutions Configuration**.
- **Search for**: Select the object class for that you want to import objects. The drop-down list contains all object classes that are configured in the Alfabet database connection as allowed object classes and for that you have import permissions granted via the user profile you are logged in with.
- **in**: After selection of an object class in the **Search for** field, the drop-down list of the field **in** is automatically filled with all searchable properties of the class. These are all object class properties with the **Property Type** set to `String` or `Text`. You can deselect properties from the drop-down list to search in a sub-set of the searchable properties only. Please note that for classes that are not visible in the **Classes** explorer in the **Meta-Model** tab of Alfabet Expand, search is limited to finding objects with a defined name.
- **Search Pattern**: Enter the string to find in the object class properties selected in the **in** field. The search finds objects in both source and target database. An asterisk can be user as wildcard in the search pattern.

2) Click the **Search** button. Results are listed in the table. The table lists all objects matching your filter definition with their name, description and, if applicable, their short name. The column **Data Source** and the color coding for the rows in the table informs whether the objects are found in the target database or in the source database only:

Object available in current (target) database	Object available in source database	Value for Data Source	Row color
yes	no	object is not included into the table	
yes	yes, LAST_UPDATE date identical or prior to LAST_UPDATE date of the object in target database or objects do not have a LAST_UPDATE property	Target	no background color
yes	yes, LAST_UPDATE data younger than LAST_UPDATE date of the object in the target database	Target to Update	blue
no	yes	Master	green

3) Select one or multiple new or changed objects in the table and click **Create as Copy** to copy the object into your database.

If the Alfabet user interface is rendered in a secondary language and data translation is enabled for the currently used interface language, the search results are displaying the translated object class properties, if provided. For objects for that no translation is provided, the string is displayed in the standard language (English, en-US). Please note the following for search and import of data:

- The search refers to the object class property values as displayed. That means if a translated value is displayed, the search finds the object by the translated value. If the English value is displayed, the user must enter the English string to find the object.
- The data import compares the values provided in the standard language, which is English (en-US). If for example objects are identified by name and the translation of the name changes while the name in the original language is not changed, the object is detected as changed (if this feature is implemented for the class) and not as a new object.
- If automated data translation capability is implemented, all automated translations for objects that have be imported are handled as automated translations in the target database.

Managing Assemblies

If a DLL file is developed by Software AG for your specific requirements, the file must be uploaded to the Alfabet database. This is typically done by a system administrator using the tool Alfabet Administrator. How the upload is performed will depend on how the file is delivered by Software AG:

- When the assemblies are delivered as files, they are uploaded via the assembly management functionality of the Alfabet Administrator. The upload of assemblies to a database using the Alfabet Administrator is described in the section *Managing Assemblies* in the reference manual *System Administration*.
- When the assemblies are delivered in a AMM file, the AMM file must be applied to the target database with the **Update Meta-Model** functionality. For more information, see the section *Uploading Assemblies via the *.amm Update File to Another Database* in the reference manual *System Administration*.

It is recommended that assemblies are uploaded first to a test environment to test the effects on the existing database before they are implemented in the production environment. If the assembly impacts the solution configuration, it typically must first be uploaded to the database of a development environment and then reviewed in the test environment before being applied to the production environment.

The tool Alfabet Expand provides a mechanism to upload both the customized configuration and the assembly files into an AMM updater file. This file can then be used to update the test and production environment to include both the DLL files and the required configuration changes. The AMM file can also trigger the execution of scripts during the upload of assemblies, if required.

The functionality to take over the configuration of a master database to a target database can be used in the test or production environment to take over the DLL files and the required configuration changes that have been made in the development environment. If the execution of a script is required, this must be performed separately by a system administrator.

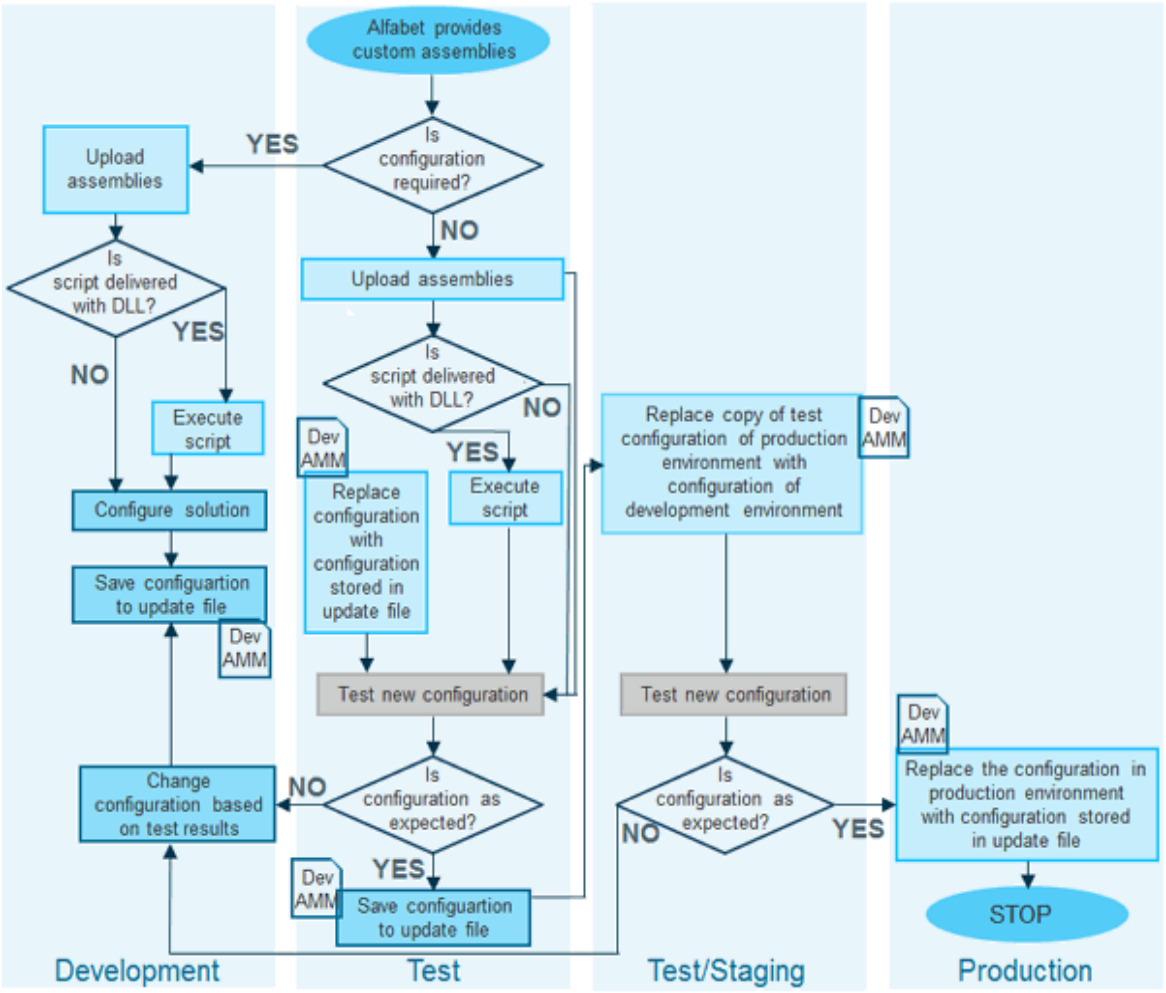


FIGURE: Example for a best practice workflow for the upload of custom assemblies to the database

Uploading Assemblies from One Database to Another Database via AMM File

The AMM based update mechanism that allows you to update the configuration of a Alfabet database with the configuration of another Alfabet database can also be used to streamline the upload of assemblies to a production database. The assemblies delivered by Software AG can be uploaded to an AMM file. Optionally, the execution of scripts and the merge or replace of the configuration of the target database with a configuration optimized for use of the assembly can be configured in the AMM file. The AMM file can then be used to upload the assemblies to a target database together with all scripting and configuration changes required for the assembly.

To save assemblies (and optionally, the custom configuration) to an AMM file.

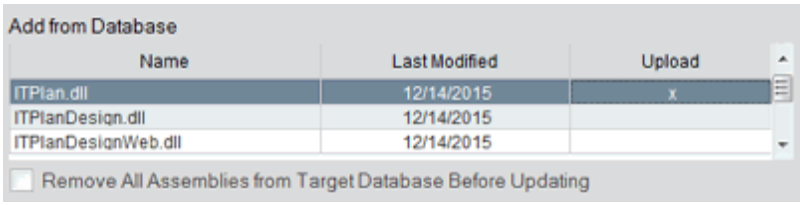
1) In the Alfabet Expand menu bar, select **Meta-Model** > **Create Configuration Meta-Model Update File**. An editor window opens:

2) Click the **Browse** button next to the **Select Output File** field and select the location and file name for storing the AMM file in the browser that opens.

3) In the **Name** field and **Description** field n the **General** tab, provide a meaningful name and description for the update performed by the AMM file when applied to the target database. The name and description are displayed in the **Update Meta-Model** dialog box when the AMM file is

used to update the configuration in a database. It allows the person performing the update to be informed about the content of the configuration in the AMM file.

4) In the **Assemblies** tab, all assemblies in the current database are listed in the **Add from File** table. Click the corresponding cell in the **Upload** column of the DLL to include the assembly in the AMM file. An X is displayed in the cell of each selected DLL. Click the cell again to remove the X and deselect the assembly.



5) In the **Assemblies** tab, select the following options related to the upload of the assembly, if applicable for your configuration:

- **Remove All Assemblies from Target Database Before Updating**: This button is deactivated. The functionality is currently not available.
- **Update Script**: This section allows to define the execution of a script during upload of an assembly. Instructions on how to fill in the fields in the section are provided by Software AG on delivery of the assembly.

> The execution of scripts is limited to scripts delivered by Software AG Support for various tasks such as maintenance procedures. Executing scripts that have not been provided by Software AG can cause severe damage to your Alfabet database.

6) Optionally, you can select all or part of the configuration of the current database to be uploaded to the AMM file together with the assembly by selecting the affected parts of the configuration in these **Meta-Model Content** tab and **Guide Pages** tab. For more information, see Saving Complete or Tagged Types of Configuration Objects or the Complete Configuration with Alfabet Expand.

> If you want to upload only single configured elements (for example, only one workflow instead of all of the workflows), you can define the AMM file with the **Find Meta-Model Objects for Deployment** functionality instead of using the **Create Configuration Meta-Model Update File** option. For more information, see Saving Selected Objects of the Configuration with Alfabet Expand.

7) Click the **Create** button. The AMM update file is created and an information about the successful creation is displayed.

To upload the assemblies stored in an AMM update file to a target database, follow the procedure described in the section Updating the Configuration of the Alfabet Solution Environment with Alfabet Expand.

Anonymizing Data

The data anonymization capability ensures data transparency and accountability across the enterprise as well as meet requirements of the General Data Protection Regulation (GDPR), and security requirements for business operations. For example, by means of pseudonymization, user data can be replaced with an artificial identifier to ensure anonymity if the user leaves the enterprise, or data about the architecture elements in IT can be used in the production environment but all sensitive data can be replaced with artificial identifiers in the development or test environment.

Anonymization can be performed on data of the type `String`, `Text`, `URL` and `Picture`. During anonymization, the original data can either be set to NULL, or be replaced with a random string or the REFSTR of the current object. Replacing the data with the REFSTR of the current object ensures that there is an unambiguous assignment of the data to the object. Therefore, the anonymization of key values, like the Name of an object, the User Name property for Alfabet users, or of object class properties defined as unique keys for a property is restricted to this method. Instead of the Name property of an object class, the solution administrator can decide during configuration of the feature to specify another property as key property that will then be restricted to being replaced with the REFSTR of the object during anonymization.

Anonymization requires configuration of individual object classes and properties thereof to be included into anonymization. Triggering anonymization via one of the available mechanisms then leads to anonymization of all data of all object classes for that anonymization is configured. The data is anonymized in the database table for the object class as well as in the audit history table for the object class. If user data is anonymized and the User Name of the user is included in anonymization, the User Name is also anonymized in all audit history tables of all object classes and in the information about the creation user and last update user available for configuration objects in Alfabet Expand.

For user data an additional method for anonymization is available. Data can be anonymized for individual users only. In addition, individual users can be excluded for anonymization. If data is anonymized in general, these users are not anonymized, which will for example ensure that administrators are still able to log in to Alfabet with their user name while all other user names were changed during anonymization.

Anonymization is performed via the Alfabet Server the Alfabet Web Application is configured to connect to. Prior to performing anonymization, a solution designer must pre-configure the anonymization capability as described in the following.

The following information is available:

- Activating Anonymization for Object Class Properties
- Changing Key Property Settings for Object Classes
- Configuring the Object Class to be Anonymized
- Configuring Anonymization of Data of Single Users Only
- Excluding Users from Anonymization
- Anonymizing Data
- Anonymizing All Relevant Data in the Alfabet database
- Anonymizing Data of Selected Users
- Creating a Database Archive File Containing Anonymized Data
- Checking Anonymization Actions

Activating Anonymization for Object Class Properties

The following steps are involved in the activation and configuration of anonymization:

- Changing Key Property Settings for Object Classes
- Configuring the Object Class to be Anonymized

Changing Key Property Settings for Object Classes

It is crucial to maintain data integrity during anonymization to be able to work with a database that contains anonymized data without any restrictions in usability.

A number of mechanisms are implemented that ensure data integrity:

- If an object class property of the type `String` is based on an enumeration, it is excluded from anonymization.
- The following object class properties are either based on values defined for example in an XML object or are crucial for implemented functionalities and are therefore excluded from anonymization:
- The object class properties `Stereotype`, `ObjectState`, `State`, `Status` and `Status History` for all object classes for which they are available.
- The object class properties `CheckInStatus` and `CheckInProtocol` of the object class `Project`.
- The object class properties `LevelID` and `LevelIDNum` of the object classes `Business Process` and `Domain`.
- For the object class `PERSON`, the object class property values of single objects can be excluded from anonymization. A new Boolean property `ExcludedFromAnonymization` has been added to the object class `PERSON`. A new option **Exclude From Anonymization** has been added to the **User** editor to set this property. If the checkbox is selected, the data for the user cannot be anonymized.
- If the object class property is mandatory, the anonymization method that sets the value to `NULL` is not available.
- If the object class property is included into the specification of a Class Key with a uniqueness constraint for the object class, the object class property can only be substituted with the REFSTR of the object during anonymization to ensure that the uniqueness constraint is observed.
- Independent from Class Key specifications for individual object classes, the `Name` property of an object class is by default regarded as key property and the object class property can only be substituted with the REFSTR of the object during anonymization. This rule can be overwritten by the solution designer in the XML object `AnonymizationKeyManager`. By default, the XML object `AnonymizationKeyManager` contains a definition for the object class `Person`. For the object class `Person`, the object class properties `USER_NAME` and `TECH_NAME` are set as key properties by default. This ensures that the audit history information and the information about the creator and last update user for configuration objects in Alfabet Expand, that is based on the `USER_NAME` or `TECH_NAME` property, is not corrupted.

  The server alias of the Alfabet Web Application can be configured with the attribute **Server Settings** > **General** > **Update History User Name** to use the `TECH_NAME` instead

of the `USER_NAME` of the user for writing information about the `CREATION_USER` and `LAST_UPDATE_USER` into the audit history tables.

If you would like to change the key property settings in the XML object `AnonymizationKeyManager` in Alfabet Expand, you should do the following prior to activating anonymization for object class properties in the Alfabet Expand meta-model:

1) In the **Presentation** tab, expand the node **XML Objects**.
2) Right-click the sub-node `AnonymizationKeyManager` and select **Edit XML** from the context menu. The XML object opens in the middle pane.
3) For each object class for that you want one or multiple object class properties to be used as key properties instead of the Name property only, add an XML element `ClassAnonymizationKeyDef` to the root XML element `AnonymizationKeyManager`.
4) Set the following XML attributes for the new XML element `ClassAnonymizationKeyDef`:

- `ClassName`: Write the name of the object class that the key shall be defined for into the attribute.
- `AnonymizationKeyProperties`: Write the name of the object class property that shall be the key property into the attribute. If multiple object class properties shall be defined as key, the object class property names must be written comma separated into the attribute.

5) Click the **Save**button to save your changes.

The following specification changes the key for the object class Business Function to both the Name and Level ID instead of the Name only:

```
<AnonymizationKeyManager>
   <ClassAnonymizationKeyDef ClassName="BusinessFunction"
   AnonymizationKeyProperties="Name,LevelID"/>
</AnonymizationKeyManager>
```

Configuring the Object Class to be Anonymized

Data of an object class is only anonymized if the object class is configured to be anonymized. By default, anonymization is deactivated in the configuration of all object classes.

The activation settings that are required can only be performed on a subset of classes and object class properties:

- Both the object class and the object class property must be protected or public.
- The object class property must be of the type:
- `String`, not based on an enumeration
- `Text`
- `URL`
- `Picture`
- The property is not explicitly excluded from anonymization. Currently, the following object class properties cannot be anonymized:

- The object class properties `Stereotype`, `ObjectState`, `State`, `Status` and `Status History` for all object classes for which they are available.
- The object class properties `CheckInStatus` and `CheckInProtocol` of the object class `Project`.
- The object class properties `LevelID` and `LevelIDNum` of the object classes `Business Process` and `Domain`.

Do the following to activate anonymization for an object class:

1) In the Meta-Model tab of Alfabet Expand, expand the node **Class Model** > **Classes**.
2) Click the object class that you want to activate anonymization for.

If the object class does not have any object class properties that can be anonymized, the attribute is deactivated.

3) Click into the attribute **Property Anonymization** to open the **Anonymization Rules for Class Properties** table. The table lists all object class properties of the current object class that might be anonymized. If the table does not open, the object class does not have any object class properties that can be anonymized.
4) In the column **Anonymization Type** of the table, select one of the following anonymization methods for each property to be anonymized:

- `ToBeLeftUnchanged`: The values for the object class property are not changed. Anonymization is not applied.
- `ToBeNullified`: The values for the object class property are set to `NULL`.
- `ToBeRandomized`: The values for the object class property are substituted with a random string. The length of the string is identical to the length of the original string. If auditing is activated, identical values are replaced with the same string in the audit tables. This method is only available for properties of the type `String` or `Text`.

The following randomization mechanisms are implemented for strings and texts:

- Properties of the type `String`: A random string is created using the Generate Random Password function of the .NET library with the length of the original string as input. Random strings do not contain special characters.
- Properties of the type `Text`: A random text is generated from the following base text:

```
lorem ipsum dolor sit amet consectetur adipisicing elit
sed do eiusmod tempor incididunt ut labore et dolore
magna aliqua ut enim ad minim veniam quis nostrud
exercitation ullamco laboris nisi ut aliquip ex ea
commodo consequat duis aute irure dolor in
reprehenderit in voluptate velit esse cillum dolore eu
fugiat nulla pariatur excepteur sint occaecat cupidatat
non proident sunt in culpa qui officia deserunt mollit
anim id est laborum
```

This randomization mechanism is creating random texts from this base text using the variable integer parameters `minWords`, `maxWords`, `minSentences`, `maxSentences`, `numLines`, and the variable boolean parameter `randomSize`. These parameters are a function of the data in the database that shall be randomized

2.000 random texts are created during an anonymization run and subsequently used to replacing the original text from the class property. This allows performance characteristics to be retained after anonymization of data.

- `ToBeReplacedByKey`: The values for the object class property are substituted with the `REFSTR` value of the current object. This method keeps the information about which object the anonymized data belongs to. This might be useful for example in case of user data. This method is only available for properties of the type `String`.

  The columns in the table provide information about the object class property that should be considered when choosing the anonymization method:

  - **Property Name**: The name of the object class property to identify the data that can be anonymized.
  - **Property Type**: The data type the object class property. The data type determines the availability of methods to be selected. Only strings can be replaced with a key and only string and text properties can be randomized.
  - **Is Mandatory**: Some protected object class properties are mandatory. A value must be provided for these properties to ensure operability of all features implemented in Alfabet. If `True` is displayed in this column, the object class property cannot be set to `NULL` during anonymization.
  - **Is Anonymization Key**: If `True` is displayed in this column, the object class property is either defined as key for the object class in the XML object `AnonymizationKeyManager` or there is no definition for the object class in the `AnonymizationKeyManager` and the object class property name is `Name`. This property can neither be set to NULL nor be randomized during anonymization.
  - **In Unique Index**: If `True` is displayed in this column, the object class property is part of a unique class key definition of the object class. This property can neither be set to NULL nor be randomized during anonymization.
  - **Has Validator**: If `True` is displayed, the values for this object class property are validated against a validator defined in the attribute **Validator** of the object class property. The availability of methods is not restricted if a validator is defined but depending on the selected anonymization methods the validation might fail after anonymization. You should check the object class property validator settings prior to selecting a validation method.

Configuring Anonymization of Data of Single Users Only

For the object class `PERSON`, anonymization cannot only be performed on a per class but also on a per object basis. That means that next to anonymizing data for all users that are currently stored in the Alfabet database, you can also anonymize data for one or multiple selected users. anonymization is triggered via Alfabet Expand Windows or on the Alfabet user interface and executed via the Alfabet Server. Prior to triggering user data anyonymization, anonymization must be configured for the object class `PERSON` as described in the section Configuring the Object Class to be Anonymized.

Excluding Users from Anonymization

The object class property values of single users can be excluded from anonymization. A new boolean property `ExcludedFromAnonymization` has been added to the object class `PERSON` for that purpose.

The property is set in the **Users Administration** functionality in the Alfabet user interface:

1) Navigate to the **Users Administration** functionality.
2) In the table, select the user that you want to exclude from anonymization.
3) In the toolbar, click **Edit**  . The **User** editor opens.
4) Select the checkbox **Exclude From Anonymization**.
5) Click **OK** to save your changes.

Anonymizing Data

If anonymization is triggered by one of the methods described below, the anonymization is applied to all data for an object class property if the object class is configured to be anonymized and an anonymization method is specified for the object class property.

For information about the required configuration to enable anonymization, see Activating Anonymization for Object Class Properties.

Anonymization changes the following object class property values in the database:

- Values stored in the object class table of the object class in the Alfabet meta-model. If data translation is enabled, translated values are also anonymized.
- Values stored in the history table <CLASSNAME>`_AU` of the object class.
- Anonymization will be applied to the values in the columns `AUDIT_USER`, `CREATION_USER`, `LAST_UPDATE_USER` and `DELETE_USER` of all audit history database tables (<CLASSNAME>`_AU` and `RELATIONS_AU`), if one of the following applies:
  - If the object class property `USER_NAME` of the object class `PERSON` is anonymized, and the server alias for connection to the Alfabet database is configured to use the `USER_NAME` for auditing.
  - If the object class property `TECH_NAME` of the object class `PERSON` is anonymized, and the server alias for connection to the Alfabet database is configured to use the `TECH_NAME` for auditing.
  - If the object class property `USER_NAME` of the object class `PERSON` is anonymized with the method `ToBeReplacedByKey`, anonymization will also be applied to the **Last Update User** and **Creator** attributes in the **Tech Info** section of the configuration objects in Alfabet Expand. For all other anonymization methods these attributes are left unchanged.

If the anonymized user is the **Last Update User** or **Creator** of any configuration object subordinate to the **Classes** explorer node, the connections of all currently running Alfabet components with the Alfabet database will be terminated and the database will be locked during the anonymization process. The Alfabet components need to be restarted afterwards.

There are three ways to anonymize data:

- The **Anonymize Data** functionality anonymizes all values for all object class properties configured to be anonymized in the Alfabet Meta-Model of the current Alfabet database.
- The **Anonymize User Data** functionality anonymizes data for one or multiple selected users, which means for one or multiple selected objects of the object class PERSON, if the configuration of the object class PERSON specifies that the respective object class property shall be anonymized.
- The **Archive Current Database with Anonymized Data** functionality anonymizes all values for all object class properties configured to be anonymized in the Alfabet Meta-Model in a database archive file (ADBZ) during creation of the archive file. The data in the original Alfabet database that is archived is not affected.

Anonymization can be triggered using other Alfabet components:

- All data anonymization methods are available via Alfabet Expand Windows.
- In Alfabet Expand Web, the method **Anonymize Data** is available in the context menu of **Utilities** > **Meta-Model Configuration**.
- In the Alfabet Administrator, all anonymization methods are available as options in the context menu of the server alias. For more information, see *Anonymizing Data* in the reference manual *System Administration*.
- In the **Users Administration** functionality on the Alfabet user interface, the user administrator can select one or multiple users in the table and select **Action** > **Anonymize User** in the toolbar to trigger anonymization for the selected user(s). For more information, see *Anonymizing User Data* in the reference manual *User and Solution Administration*.
- Anonymization can be triggered via a service call to the new endpoint `anonymizeuser` of the Alfabet RESTful service to anonymize data for users that are found via specification of the user's `REFSTR` in the REST API request. For more information, see *Anonymizing User Data For Selected Users* in the reference manual *Alfabet RESTful API*.
- The console application `AlfaAdministratorConsole.exe` can be used to anonymize all object class property values configured to be anonymized in an Alfabet database or data for one or multiple selected users. For more information, see *Anonymizing Data* in the reference manual *System Administration*.

The following information is available:

- Anonymizing All Relevant Data in the Alfabet database
- Anonymizing Data of Selected Users
- Creating a Database Archive File Containing Anonymized Data

Anonymizing All Relevant Data in the Alfabet database

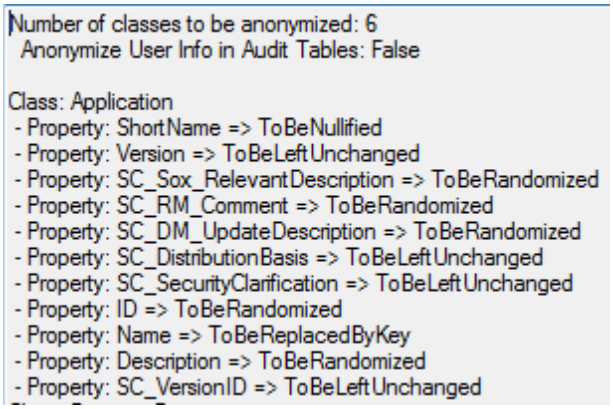
The **Anonymize Data** functionality anonymizes all values for all object class properties configured to be anonymized in the Alfabet Meta-Model of the current Alfabet database.

Anonymizing data is a sensible process that might disrupt database integrity. It cannot be reverted! **Always back up the Alfabet database prior to triggering data anonymization!**

Please note that the connection to the Alfabet database is closed during the anonymization process. Re-login of the current user is performed automatically with no need to fill in a login screen with the user name and password of the last login prior to anonymization. If the object class property `USER_NAME` is anonymized for the object class `PERSON`, a re-login to Alfabet Expand is not possible after anonymization. To avoid problems with re-login, the user performing anonymization can be excluded from anonymization. Alternatively, `ToBeReplacedByKey` may be used as anonymization method, which replaces the user name with the `REFSTR` of the respective user. Automatic re-login will then fail, but you can re-login via the login screen with the `REFSTR` as user name. The `REFSTR` can for example be written from a configured report prior to performing anonymization.

To trigger data anonymization in Alfabet Expand:

1) In the menu, select **Managers** > **Database Manager** > **Anonymize Data**.
2) In the window that opens, define the location for the log file that shall be used to log information about the anonymization process. If you select an already existing log file, the standard message of the selector window informs you that the file will be overwritten. Nevertheless, the log information is appended to the existing content of the selected file.
3) The following information is displayed:



- **Number of classes to be anonymized**: The overall number of object classes for that the attribute **Anonymize** is set to `True`.
- **Anonymize User Info in Audit Tables**: Informs about the anonymization in audit history tables (<CLASSNAME>`_AU` and `RELATIONS_AU`) in the Alfabet database and in the attributes **Creator** and **Last Update User** in the **Tech Info** section of the configuration objects in Alfabet Expand. The attribute **Anonymize** must be set to `True` for the object class `Person` and a method other than `ToBeLeftUnchanged` must be selected for the object class property `USER_NAME` and/or for the object class property `TECH_NAME` of the object class `Person`.
- `True`: The user name will then be anonymized in all audit history tables and in the attributes **Creator** and **Last Update User** in the **Tech Info** section of the configuration objects in Alfabet Expand.
- `True (Technical Info Not Anonymized)`: The user name will only be anonymized in the audit history tables. The attributes **Creator** and **Last Update User** in the **Tech Info** section of the configuration objects in Alfabet Expand is not anonymized. This means that the `TECH_NAME` is

anonymized, while the `USER_NAME` is left unchanged and the server alias configuration specifies that the `TECH_NAME` is written into the audit history.

- `False (Technical Info Anonymized)`: The user name will only be anonymized in the attributes **Creator** and **Last Update User** in the **Tech Info** section of the configuration objects in Alfabet Expand. The user information in the audit history tables is not anonymized. This means that the `USER_NAME` is anonymized, while the `TECH_NAME` is left unchanged and the server alias configuration specifies that the `TECH_NAME` is written into the audit history.
- `False`: Audit history tables and the attributes **Creator** and **Last Update User** in the **Tech Info** section of the configuration objects in Alfabet Expand are not anonymized.
- **Class**: For each object class for that data will be anonymized, all object class properties that may be subject to anonymization are listed with information about the configured anonymization method.

4) Click **Anonymize**.

Anonymizing Data of Selected Users

The **Anonymize User Data** functionality is available to anonymize data for one or multiple selected users, which means for one or multiple selected object of the object class `Person`.

Data for a selected user is only anonymized if anonymization is enabled in the configuration of the object class `Person` and if the user is not explicitly excluded from anonymization.

Anonymizing data is a sensible process that might disrupt database integrity. It cannot be reverted! **Always back up the Alfabet database prior to triggering data anonymization!**

If the anonymized user is the **Last Update User** or **Creator** of any configuration object subordinate to the **Classes** explorer node, the connections of all currently running Alfabet components with the Alfabet database will be terminated and the database will be locked during the anonymization process. The Alfabet components need to be restarted afterwards.

To trigger anonymization of the data of selected users in Alfabet Expand:

1) In the menu, select **Managers** > **Database Manager** > **Anonymize User Data**.
2) In the window that opens, select one or multiple users to be anonymized in the table. You can set the following filters and click **Update** to search for specific users:

- **Search Pattern**: Enter a search pattern to search for in either all standard attributes or in the attribute selected in the drop-down list of the field on the right of the **Search Pattern** field.
- **Profile**: Select a user profile in the drop-down list to limit the display in the table to users assigned to the selected user profile.
- **Show Alfabet-managed Users Without Password**: Select the checkbox to limit the display in the table to users that are logging in with a user name and password managed in Alfabet and that currently have no password assigned.

3) In the field **Log File**, define the location for the log file that shall be used to log information about the anonymization process. If you select an already existing log file, the standard message of the selector window informs you that the file will be overwritten. Nevertheless, the log information is appended to the existing content of the selected file.

4) Click **Anonymize**.

Creating a Database Archive File Containing Anonymized Data

The **Archive Current Database with Anonymized Data** functionality is available to anonymize all values for all object class properties configured to be anonymized in the Alfabet Meta-Model in a database archive file (ADBZ) during creation of the archive file. The data in the original Alfabet database that is archived is not affected. This method is useful to archive the content of a productive database in an anonymized form to implement it in a test or development environment without information about sensitive data.

To archive the non-anonymized data in the current database and apply anonymization to the data in the archive file, do the following in Alfabet Expand:

1) In the menu, select **Managers** > **Database Manager** > **Archive Current Database with Anonymized Data**. The **Alfabet Archive Manager (Anonymized Data)** opens.
2) In the window that opens, click the **Browse**  button on the right of the **The file in which you want to archive the Alfabet database** field to define the location for the database archive file on the local file system. The default name of database archive file contains the string `Anonymized` to distinguish between anonymized and non-anonymized archives which shall be used to log information about the anonymization process.
3) Select the checkbox **Squeeze Audit Tables** if you would like the audit tables to be cleaned prior to archiving the database. Any entries that were generated during, for example, a batch update of data via batch utilities without documenting any audit relevant changes will be deleted from the audit tables prior to archiving of the database.
4) Select the checkbox **Include User Settings** if you want user settings defined for the current database to be added to the archive.
5) Click **Archive**.

To overwrite the content of a database with the data from a database archive file, use the **Restore Database Archive** option in the context menu of the tool Alfabet Administrator. For more information, see *Using the Context Menu Available via the Alias Explorer Node* in the reference manual *System Administration*.

Anonymizing data is a sensible process that might disrupt database integrity. It cannot be reverted! **Always back up the Alfabet database prior to restoring it with an anonymized archive file!**

Checking Anonymization Actions

Anonymization actions on the current database are logged. Information is written into a log file that can be specified in a dialog that opens for triggering the anonymization from Alfabet Expand Windows, the Alfabet Administrator or the Alfabet user interface. When selecting an already existing log file, the log information in the file is appended, although a message in the file selector states that the file is overwritten.

The console applications write information into the standard log files for Alfabet console applications if defined in the command line.

The table provides information about the kind of anonymization action performed, the status of the anonymization, the user performing the anonymization and the update time. In addition, the version of the software that was implemented when the anonymization action was performed is displayed.

Configuring Default User Settings for the User Community

The XML object ***UserPersonalSettings*** allows you to define the default settings for various aspects of Alfabet including, for example, the default user profile displayed in the Login screen, the interface language that Alfabet opens with, or the automatic execution of validation rules for object definition.

The settings configuration in the XML object ***UserPersonalSettings*** will be applied to a named user upon activation in Alfabet. In other words, the default values you define here will be applied to any user that has not already defined his/her user settings.

The user can then modify the default values, as needed. Any changes you later make to the default values in the XML object ***UserPersonalSettings*** will not impact a user who has already defined his/her user settings.

To edit the XML object ***UserPersonalSettings***:

1) Go to the **Presentation** tab, expand the **XML Objects** folder, and expand the **Administration** folder.
2) Right-click the XML object ***UserPersonalSettings*** and select **Edit XML**. The XML editor is displayed in the center pane. For general information about editing XML objects in Alfabet Expand, see Working with XML Objects.
3) Edit the XML attributes, as needed. The table below displays the XML attributes that can be edited for the XML object ***UserPersonalSettings***:

XML Element (bold) / XML Attribute	Explanation
UserPersonalSettings	
`DefaultProfile`	Enter the default user profile that will be selected per default in the **User Profile** field in the Login screen. The user may select a different user profile, as needed.
`DefaultCulture`	Enter the culture code for the default language that should be displayed the first time a user logs in to Alfabet. The Alfabet interface is available in the following languages:

Language	Locale ID
Arabic (Saudi Arabia)	1025

XML Element (bold) / XML Attribute	Explanation
	German (Germany) 1031 English (United States) 1033 French (France) 1036 Portuguese (Brazil) 1046 Polish (Poland) 1045 Users can change the interface language via the < **UserName** > menu in the Alfabet interface. For more information about changing the interface language, see the section *Defining the Language of the User Interface* in the reference manual *Getting Started with Alfabet*. The default culture can also be defined in the server alias configuration. For more information, see the section *Creating a Server Alias for the Alfabet Web Application* in the reference manual *System Administration*.
`BookmarkLayout`	Define the default view for bookmarks available in the **My Bookmarks** functionality. Enter "`Details`" to display the bookmarks in a table structure. Enter "`Icons`" to display the bookmarks as icons on the desktop. For more information about working with bookmarks, see the section *Creating, Managing, and Accessing Your Bookmarks* in the reference manual *Getting Started with Alfabet*.
`ShowRetiredObjects`	Enter "`true`" to display objects that have reached a retired object state in search results as well as standard and configured reports. Enter "`false`" if objects that have reached a retired object state are not to be displayed in search results and standard and configured reports.
`ShowEmptyProfileValues`	Enter "`true`" to display properties that have no value in the **Attributes** section of the object profile. Enter "`false`" if properties must have a value defined to be displayed in the **Attributes** section of the object profile.
`ValidateObjectsByAccess`	Validation rules are based on the post-conditions defined for wizard steps. Any object in the object class that a post-condition is associated with may be validated when a user accesses the object in the object profile. Please note that executing validation rules based on

XML Element (bold) / XML Attribute	Explanation
	post-conditions for wizard steps may significantly impact performance since each time the object is visited and hence refreshed from the database this setting will trigger the execution of all validation rules pertaining to the associated wizard. If the validation of a property value is required, it is recommended that a check entry is configured for the property in the context of a custom object cockpit. Enter "`No`" if validation rules should not be executed. Enter "`Yes`" to execute all validation rules that have been configured via post-conditions on wizard steps. Violations will be displayed in the object profile.  Please note that users can individually decide whether to execute validation rules via the **Execute Object Validation on Access** field in the **User Settings** editor. The user setting in the **User Settings** editor will override the configuration in the XML attribute `ValidateObjectsByAccess` in the XML object ***UserPersonalSettings***. If the user selects **Default** in the **Execute Object Validation on Access** field in the **User Settings** editor, the definition configured in the XML attribute `ValidateObjectsByAccess` will be used. For more information about the definition of post-conditions for wizard steps, see the section Defining a Post-Condition for a Wizard Step. For more information about the configuration of a check entry in the custom object cockpit, see the section Adding a Check Entry to the Object Cockpit.
`IncludeFilter-Summary`	Define the default value for the **Include Filter Summary** field in the **User Settings** editor in Alfabet. The **Include Filter Summary** setting specifies whether a summary of the filter settings defined for a page view or configured report shall be exported to the relevant export file formats available in the page view or report. For more information, see the section *Exporting Data* in the reference manual *Getting Started with Alfabet*.
`WFGuiVersion`	Specify the view that opens when the **Workflow Activities** link defined in a navigation page is clicked or when the **Open Workflow Activities** link in an object profile is clicked. Enter "`Version_1`" if the standard **My Workflow Activities** views should open per default. Enter "`Version_2`" if the configured **Workflow Activities Explorer** view should open per default. For more information about the configuration of workflows, see the chapter Configuring Workflows.
`Collaboration`	Enter "`Yes`" if the collaboration functionality should be enabled. The **Show Collaboration Panel** button will be displayed in object views and page views. Enter "`No`" if the collaboration functionality should not be enabled. For more information about the working with

XML Element (bold) / XML Attribute	Explanation
	the collaboration capability, see the section *Communicating with Your Colleagues via the Alfabet Internal Collaboration Functionality* in the reference manual *Getting Started with Alfabet*.
`MaxDataset-CellTextLength`	Specify the number of characters to display in columns in datasets in order to improve the handling of data in columns in the Alfabet interface. Enter "`-1`" or leave the value empty to specify an unlimited number of characters, or enter an integer to limit the number of characters to display in columns. Any characters after the specified number will be truncated. Users can point to the cell to display a tooltip with the complete text or access the full information about the object by using the preview functionality.
`ValidateIFlowDates`	Specify whether information flows must be defined within the start and end dates of their source and target objects. Enter "`Yes`" if the start and end dates of information flows shall be validated. In this case, an error message will be displayed stating that information flows may not be created if their start and end dates are outside of the period of the start and end dates of the source and/or target objects. Enter "`No`" if the start and end dates of information flows shall not be validated based on the start and end dates of their source and target objects. In this case, information flows may be created with conflicting dates but they will be highlighted red in views to indicate that a confect exists. The XML attribute `ValidateIFlowDates` is set to "`Yes`" per default.
`ShowDialogWhen-PrintingDatasets`	Enter "`true`" if the user prompt " **Please use the Print capability in your browser to print this view** " should be displayed each time the user prints an Alfabet view. Enter "`false`" if the user prompt should be suppressed and not displayed each time the user prints an Alfabet view.
`PowerPoiontExport-Format`	Specify the slide size for export to Microsoft® PowerPoint®. The selected option corresponds to the slide size in the generated PowerPoint. Select `Default` if the slide size should be determined by the default settings specified by your enterprise. It is assumed Full HD resolution is supported. The following size formats are available: • **PPT Widescreen 16:9**: 720 x 405 Points • **PPT Standard 4:3**: 720 x 540 Point • **PPT Widescreen x4**: 1440 x 810 Points. This format is equal to the slide size for current Microsoft® PowerPoint® export features. • **Enable Splash Screen**: • **Enable Assistant**:

XML Element (bold) / XML Attribute	Explanation
`EnableSplashScreen`	Enter "`true`" if the **Edit Splash Screen** option should be available in the **Bookmark** menu. Enter "`false`" if the **Edit Splash Screen** option should not be available in the **Bookmark** menu. For more information about the splash screen capability, see the chapter *Creating a Splash Screen As Your Start Page* in the reference manual *Getting Started with Alfabet*.
`EnableAutoHelp`	Enter "`true`" if the configured automated assistants shall be available. Enter "`false`" to disable all configured automated assistants. For more information about the help provided by assistants, see the section *Using the Automated Help Assistant* in the reference manual *Getting Started with Alfabet*. For more information about configuring the automated assistant capability, see the section Providing Custom Online Help to the User Community.
`CaptureTranslatableContentInCurrentUILanguage`	Enter "`true`" if per default object data in editors and wizards shall be shown and edited in the current language of the user interface. Enter "`false`" if per default object data in editors and wizards shall be shown and edited in the primary language specified for the enterprise or for the object in the editor/wizard. This checkbox must be selected to capture data in a secondary language or statutory language. For more information about capturing data in a secondary language, see the sections Allowing Data To Be Captured in a Non-Primary Language and Specifying a Statutory Language for the Enterprise.
`AnimatedVisualizations`	Enter "`true`" if the graphics in standard views and configured reports displaying portfolios, Gantt charts, branching diagrams, sunray diagrams, circular roadmaps, etc. shall be built dynamically when the view is opened. Enter "`false`" if the graphics shall not be visualized dynamically when a relevant view is opened.
`EnableWebUIPolling`	Web polling allows the user interface to poll the server for the completion status of background processes for which completion shall be announced via an Event Feedback message. Enter "`true`" to enable user interface polling. Additional configuration is required to use the Web polling mechanism. For more information, see the section Configuring the Web Polling Mechanism.
`EnableFeedbackBot`	Enter "`true`" if the Feedback Bot should be displayed. The Feedback Bot allows users to provide feedback for a view, configured report, object cockpit, guide view, etc. For more information about the configuration of the Feedback Bot, see the section Configuring the Feedback Bot.
`EnableCheckFeedbackSameObject`	Select the checkbox to activate the **Feedback for Current View** capability. This is relevant for user profiles responsible for reviewing and

XML Element (bold) / XML Attribute	Explanation
	responding to feedback provided via the Feedback Bot. Feedback that has been provided for a view or report via the Feedback Bot can be displayed in the Alfabet user interface in a secondary view for those users responsible for reviewing and responding to the feedback. This allows the responsible users to navigate the Alfabet user interface and see the feedback for the relevant view where they currently are. A secondary view with the caption **Feedback for Current View** will be displayed with a link if feedback has been provided for the view, configured report, object cockpit, guide view, etc. Clicking the link will open the *Feedback Review Functionality* in a new browser tab which displays all feedback in detail for the view.
`EnableHelpBot`	Enter "`true`" if the FAQ Bot should be displayed.

4) In the toolbar, click the **Save** button to save the XML definition. You must completely close Alfabet Expand to activate any changes you have made to the XML object ***UserPersonalSettings***.

Configuring the Use of External Sources with Alfabet

External data access (for example, redirecting of object selectors) must be configured for your Alfabet solution by Software AG Support. You will be able to configure your individual interface settings only after the basic configuration of the Alfabet solution has been defined.

The configuration of external sources is a complex process and is described in detail in the section *Integrating Data from External Sources* in the reference manual *System Administration*. It is recommended that you edit the XML object ***ExternalSourceConfiguration*** via the assistant provided in the tool Alfabet Administrator only.

If synchronization with an external data source is to be performed on access of objects via the Alfabet interface, the relevant selectors must be configured to allow selection of data from the external source instead of from the Alfabet database. The interface must then be configured to use the external source selectors instead of the standard selectors.

The following must be carried out by Software AG Support in the tool Alfabet Expand in order to configure the redirection of object selectors:

- Create a selector definition to access the external data source. This requires the configuration of an XML object ***SelectorDef***.
- Configure Alfabet to use the external object selector instead of the default object selector in the XML object ***GeneralViewMap***.

The selector definitions in XML objects ***SelectorDef*** cannot be created by the customer, but the XML objects provided by Software AG are visible and editable in Alfabet Expand. Nevertheless, it is recommended that you NOT edit selector definitions or the XML object ***GeneralViewMap*** for external sources without support from Software AG Support.

The following information is available:

- Configuring Selectors for Data Synchronization with External Sources
- Configuring the Alfabet User Interface to Map Standard Configuration Objects to Custom Configuration Objects

Configuring Selectors for Data Synchronization with External Sources

If the data of a specific object class in the Alfabet database is synchronized with the data of an external source, the object selectors in the Alfabet interface will display the data from the external source instead of the data from the Alfabet database.

The following must be carried out by Software AG Support in the tool Alfabet Expand in order to configure the redirection of object selectors:

- Create a selector definition to access the external data source. This requires the configuration of an XML object ***SelectorDef***.

- Configure Alfabet to use the external object selector instead of the default object selector in the XML object ***GeneralViewMap***.

The selector definitions in XML objects ***SelectorDef*** cannot be created by the customer, but the XML objects provided by Software AG are visible and editable in Alfabet Expand. Nevertheless, it is recommended that you NOT edit selector definitions for external sources without support from Software AG Support.

To view the XML objects ***SelectorDef*** defined by Software AG Support for your external source configuration:

1) In Alfabet Expand, go to the **Presentation** tab, expand the **XML Objects** node, and then expand the **ObjectSelectors** folder.
2) Double-click the relevant selector definition. The XML object configuration opens in the center pane. The following table displays the XML elements and XML attributes of the XML object ***SelectorDef*** in order to help you to understand the predefined configuration:

XML Element (Bold) / XML Attribute	Description
ObjectSelectorDef	
`Name`	Specifies the name of the selector definition. This name is used in the XML object ***SelectorDef*** to identify the object selector.
`Pages`	For selector definitions in the scope of external source synchronization, the XML attribute `Pages` must be set to "`SimplePage`". "`Browse`" and "`FullTextSearch`" are not available for selection of data from an external source.
`ExternalSource`	Specifies the external data source from which data is provided in the selector. The external source is defined by the name of the external source configuration in the XML object ***ExternalSourceConfiguration*** that defines access to and data mapping for the external source.
Class	
`Name`	Specifies the object class the selector definition is valid for. The class is defined by the **Name** attribute of the object class in the Alfabet meta-model.

Configuring the Alfabet User Interface to Map Standard Configuration Objects to Custom Configuration Objects

The XML object ***GeneralViewMap*** allows you to map standard configuration objects (such as selectors, editors, and object class icons] to custom configuration objects. For example, you could map Alfabet object selectors to external data sources. If the data of a specific object class in the Alfabet database is synchronized with the data of an external source, the object selectors in the Alfabet interface will display the data from the external source instead of the data from the Alfabet database. For detailed information about the configuration of data synchronization with external sources, see the section *Integrating Data from External Sources* in the reference manual *System Administration*.

To view the XML object ***GeneralViewMap***:

1) Go to the ***Presentation*** tab and expand the node **XML Objects**.
2) Double-click the XML object ***GeneralViewMap***. The XML object configuration opens in the middle pane.
3) Right-click the XML object ***GeneralViewMap*** and select **Edit XML**. The XML editor is displayed in the center pane. For general information about editing XML objects in Alfabet Expand, see Working with XML Objects.
4) Define the XML attributes, as needed. The table below displays the XML elements and XML attributes that can be edited for the XML object ***GeneralViewMap***:

XML Element (Bold) / XML Attribute	Description
AlfaViewMap	
`Name`	Displays `Map`.
MapEntry	
`Type`	Enter the type of configuration object to map. For example: `Selector`, `Editor`, `Picture`.
`Source`	Enter the technical name of the source configuration object that shall be substituted.
`Target`	Enter the technical name of the target configuration object that shall substitute the source configuration object.

5) In the toolbar, click the **Save** button to save the XML definition.

Configuring the Visibility of Tabs in Alfabet Expand

You must ensure that Alfabet Expand is only accessible to those individuals in your company that make up the core team of solution designers who are authorized to make changes to the meta-model. Access to Alfabet Expand as well as the availability of specific functionalities in Alfabet Expand is controlled on a per-user basis. Each user must be explicitly specified to have access permission to Alfabet Expand as well as to the individual tabs and menus providing the various functionalities. This ensures that access to the functionalities in Alfabet Expand is explicitly differentiated based on the configuration tasks and responsibilities of the individual user.

The definition of user access permissions to Alfabet Expand is defined by the user administrator in the context of the **Users Administration** functionality that can be accessed in the user interface via an administrative user profile. For more information about specifying access permission for Alfabet Expand, see the section *Creating a User* in the reference manual *User and Solution Administration*.

Please note the following:

- Your licensing agreement with Software AG for Alfabet Expand functionalities will not impact which functionalities are listed in the **Expand Access Options** attribute in the **User** editor. All functionalities are displayed regardless of the content of license agreement. However, regardless the definition of **Expand Access Options** attribute, the licensing agreement will override. The definition of the **Expand Access Options** attribute specifies the visibility in both Alfabet Expand Web and Alfabet Expand Windows.
- If the XML object ***PlatformConfiguration*** is specified in Alfabet Expand, it will override the definition of the **Expand Access Options** attribute in the **User** editor in Alfabet Expand Windows.

To the XML object ***PlatformConfiguration***:

1) Go to the **Presentation** tab, expand the **XML Objects** folder, and expand the **Administration** folder.
2) Right-click the XML object ***PlatformConfiguration*** and select **Edit XML**. The XML editor is displayed in the center pane. For general information about editing XML objects in Alfabet Expand, see Working with XML Objects.
3) Define the following XML attributes:

- `ShowProfileMenu`: Set to "`true`" to display the **Change User Profile** option in the < **Alfabet User** r menu in the user interface Alfabet.
- `ShowProfileSelfAdminMenu`: Set to "`true`" to display the **Assign User Profile** option in the < **Alfabet User** r menu in the user interface Alfabet.
- `ShowPersonalInfoMenu`: Set to "`true`" to display the **Personal Info** option in the < **Alfabet User** r menu in the user interface Alfabet.
- `ShowUserSettingsMenu`: Set to "`true`" to display the **User Settings** option in the < **Alfabet User** > menu in the user interface Alfabet.
- `Expand_ClassModeel`: Set to "`true`" if users shall be allowed to access the **ClassModel** tab n the configuration tool Alfabet Expand.
- `Expand_Admin`: Set to "`true`" if users shall be allowed to access the **Admin** tab n the configuration tool Alfabet Expand.

- `Expand_Functions`: Set to "`true`" if users shall be allowed to access the **Functions** tab n the configuration tool Alfabet Expand.
- `Expand_Reports`: Set to "`true`" if users shall be allowed to access the **Reports** tab n the configuration tool Alfabet Expand.
- `Expand_Workflows`: Set to "`true`" if users shall be allowed to access the **Workflows** tab n the configuration tool Alfabet Expand.
- `Expand_ADIF`: Set to "`true`" if users shall be allowed to access the **ADIF** tab n the configuration tool Alfabet Expand.
- `Expand_Diagram`: Set to "`true`" if users shall be allowed to access the **Diagrams** tab in the configuration tool Alfabet Expand.

4) n the toolbar, click the **Save**  button to save the XML definition. You must completely close Alfabet Expand to activate any changes you have made to the XML object ***PlatformConfiguration***.

Chapter 3: Configuring Access Permissions for Alfabet

Alfabet offers various levels of access control:

- **Access permission for the Alfabet interface**

The access to the Alfabet interface requires login either by means of a user name and password, or by means of a Windows Sign-On mechanism. Windows Sign-On uses the user's Microsoft Windows domain login information as the Alfabet login and opens the interface automatically with the settings defined for the user without requiring the manual input of a user name and password.

It is also possible to configure the Interface with external login mechanisms for, for example, the login to a company portal or login triggered by data from an external LDAP server.

The login mechanism and additional login conditions such as an expiration period for user passwords can be specified in the configuration of the Alfabet Server and the Alfabet Windows Client with the tool Alfabet Administrator.

Which users are allowed to log in to Alfabet must be specified in the **User Administration** functionality that can be accessed in the Alfabet user interface via the `Admin` user profile.

For a detailed description of how to configure login to Alfabet, see the section *Configuring User Authentication* in the reference manual *System Administration*.

- **Access permission for Alfabet functionalities**

Alfabet allows the solution designer to configure the range of functionality that is visible to a user accessing the Alfabet interface. Functionalities are bundled in user profiles and the user profiles are assigned to Alfabet users. When a user logs in to Alfabet, the user profile that he/she logs in with will determine which functionalities are available. A user profile can be assigned to multiple users and one user can have multiple user profiles assigned, allowing him/her to work with different functionalities in different contexts.

For example, a user profile Data Maintenance displays an explorer with all applications that the user is responsible for. The functionality allows the user to view and edit data for the applications. Another user profile Project Planning bundles project planning functionalities and allows the user to create projects, define the architecture relevant for a project, and edit project data.

For a detailed description about configuring user profiles, see the section Configuring User Profiles for the User Community.

- **Access permissions for objects in the Alfabet database**

It is possible that a user logged in to the Alfabet interface may not be able to edit all objects in the database. Access permissions can be granted per object or per object class, depending on the definition of the various mechanisms available to control user access.

This chapter describes the mechanisms to configure access to object data in the Alfabet database and the configuration steps required to activate and customize access permissions. Access permissions can be controlled in different ways, depending on your enterprise's security policies and requirements. Access to objects can be controlled on the level of object classes or on the level of individual objects within object classes. It is possible to hide objects completely from the Alfabet interface or to restrict access permissions to ReadOnly access. Alfabet allows your enterprise to use multiple mechanisms in parallel to control access permissions. A predetermined hierarchy of access concepts specifies which access configuration has

precedence. An overview of the available mechanisms and the order of their execution is provided in order to help you configure access permissions to objects.

The following information is available about the configuration of access permissions to access objects:

- Overview of Access Permissions for Objects
- Access Modes for Objects
- Overview of Access Permission Concepts
- Rules Governing Access Permissions
- *Implementing the Mandate Capability for a Federated Architecture*
- *Creating Mandates for Your Enterprise*
- *Activating the Mandate Capability for the Enterprise*
- *Activating the Mandate Capability for Relevant Object Classes and Object Class Stereotypes*
- *Assigning Mandates to Users*
- Configuring Master Users and Master User Groups
- Configuring Permission Rules for Access to Objects
- Activating the Mandate Capability for the Enterprise

Overview of Access Permissions for Objects

This section provides an overview of the mechanisms available to control access to objects in the Alfabet database and the required configuration steps to implement the individual mechanisms. This overview is followed by an explanation of the interactions between the mechanisms.

The following overview distinguishes between access permissions to hide objects from view and access permissions that disable the editability of objects.

- Access Modes for Objects
- Overview of Access Permission Concepts
- Access Permissions for a User Profile
- Access Permissions in a Federated Architecture
- Access Permissions for Master Users
- Rule-Based Access Permissions
- Access Permissions for Authorized Users
- Access Permissions for Authorized User Groups
- Access Permissions for Deputies
- Access Permissions for Members of Discussion Groups

- Access Permissions for Users Responsible for Assignments
- Access Permissions for Users Responsible for a Workflow Step
- Access Permissions Based on an Object's Release Status
- Purpose of Roles
- Rules Governing Access Permissions

Access Modes for Objects

Access permissions in Alfabet can define whether data about an object:

- is not displayed at all
- is displayed but cannot be edited
- is displayed and can be edited.

Access Concepts Hiding Objects

By means of a federated architecture, it is possible to hide individual objects in an object class while other objects in the same object class are displayed in the Alfabet interface. For more information, see the section *Implementing the Mandate Capability for a Federated Architecture*.

Access Concepts Granting Read/Write Access

By means of user profiles, it is possible to define basic access permissions regarding visibility and editability for objects in Alfabet.

The  symbol is displayed in the object profile of an object that cannot be edited by the current user. If the user profile grants ReadOnly access permissions, the user can only view the visible objects when logging in to Alfabet. If the user profile grants Read/Write access permissions, the user can edit the objects if one of the following permission concepts applies:

- A configured rule-based access permission finds the object. For more information, see the section Rule-Based Access Permissions.
- A configured default permission rule finds the object. For more information, see the section Rule-Based Access Permissions.
- The user is the authorized user of the object. For more information, see the section Access Permissions for Authorized Users.
- The user is a member of an authorized user group defined for the object. For more information, see the section Access Permissions for Authorized User Groups.
- The user is a deputy of the object. For more information, see the section Access Permissions for Deputies.
- The user is a member of a discussion group about the object. For more information, see the section Access Permissions for Members of Discussion Groups.
- The user is responsible to process an assignment for the objects. For more information, see the section Access Permissions for Users Responsible for a Workflow Step.

- The user is responsible to perform a workflow activity for the object. For more information, see the section Access Permissions for Users Responsible for a Workflow Step.

AND

- The release status grants editing of the object. For more information, see the section Access Permissions Based on an Object's Release Status.

The various permission concepts available for Alfabet are evaluated in a given order and some permission concepts are configured to exclude other permission concepts from the evaluation of access permissions. The execution order of access permission concepts is described in the section Rules Governing Access Permissions.

If the user profile is marked as administrative user profile, the user has Read/Write access permissions to all objects that he/she can access in the functionalities available in the user profile. The visibility implemented by the federated architecture concept via mandates also applies in administrative user profiles.

Overview of Access Permission Concepts

This section describes the possibilities available in Alfabet to control access to objects. An overview of the configuration steps required is included in the description. The following information is available:

- Access Permissions for a User Profile
- Access Permissions in a Federated Architecture
- Access Permissions for Master Users
- Rule-Based Access Permissions
- Access Permissions for Authorized Users
- Access Permissions for Authorized User Groups
- Access Permissions for Deputies
- Access Permissions for Members of Discussion Groups
- Access Permissions for Users Responsible for Assignments
- Access Permissions for Users Responsible for a Workflow Step
- Access Permissions Based on an Object's Release Status
- Purpose of Roles

Access Permissions for a User Profile

User profiles are the basis of user administration in Alfabet. The user profile determines the functionalities available to a user. The user profile is the entry point when accessing Alfabet and every user must log in with a user profile that has been assigned to him/her, for example by a user administrator. Therefore, all users accessing Alfabet must be assigned at least one user profile. However, users may possess multiple user profiles in accordance with their responsibilities in the Alfabet user community and in the enterprise as a whole. A user can switch to another user profile at any point during a Alfabet session.

User profiles can be configured to grant either ReadOnly access permissions or Read/Write access permissions.

If the user profile is a ReadOnly profile:

- The user can view information about all objects that are available in the scope of the functionalities assigned to the user profile.
- The user may not edit or delete objects.
- Individual objects may be excluded from view if the mandate capability to manage a federated architecture has been implemented.
- The user will not be able to edit objects in the context of a workflow.

If the user profile is a Read/Write profile:

- The editability of an object will depend on all other access permission concepts described below. Therefore, some objects may be displayed in ReadOnly mode while the user may be able to edit or delete other objects. For an overview of the various concepts governing access, see the section Access Modes for Objects.

If the user profile is marked as administrative user profile, the user has Read/Write access permissions to all objects that he/she can access in the functionalities available in the user profile. The visibility implemented by the federated architecture concept via mandates also applies in administrative user profiles.

Access Permissions in a Federated Architecture

Some enterprises have a federated architecture. If this is the case in your enterprise, then mandates may be implemented to control the visibility of Alfabet objects.

A mandate is a means to organize and structure the federated architecture of a holding company. The assignment of mandates to objects allows the holding company to structure the objects in the enterprise architecture in order to regulate visibility to objects across some or all subsidiaries. Only users explicitly assigned to a mandate will see objects with that mandate definition. An object that has not been assigned to a mandate is considered not to be owned by a mandate and is thus visible throughout the holding company to users with relevant access permissions.

The use of mandates in the Alfabet solution is optional. If mandates are implemented in an enterprise, the visibility of an object with a mandate assignment will take precedence over other concepts of access permissions in Alfabet. For example, an authorized user of an object must be assigned the relevant mandate to access the object that he/she is the owner of.

Within the context of mandates, the conventional rules governing access permissions apply. Thus, a user assigned to a mandate will only have Read/Write access permission to the objects made visible by the mandate if he/she has authorized access to the object as an authorized user, deputy, member of an authorized user group or discussion group or via rule-based access permissions, workflow contributor or assignee of an assignment.

Keep the following in mind when working with mandates:

- The object classes for which mandates are available are preconfigured by Software AG. For more information about whether mandates are available for a particular object class, see *Overview of*

Configurable Features for Object Classes in the reference manual *Configuring Alfabet with Alfabet Expand - Appendix*.

- A user will typically have only one mandate associated with his/her user name. When the user is logged in with a mandate, he/she will have access only to those objects that are assigned to that mandate as well as to all objects that are not assigned to a mandate. In other words, the user will not see objects that have a different mandate assigned.
- Objects that do not have a mandate assigned are visible to anyone with relevant access permissions.
- If an object has a mandate assignment different than the user's mandate assignment, the user will still be able to view basic preview information as well as the reference information about the dependent objects associated with the object.
- If objects at the root level in an explorer structure are controlled by a mandate, then they will only be visible to users logged in with that mandate. Any root object in the explorer structure that has a different mandate than the mandate that the user is logged in with will not be visible in the explorer. If the user has accessibility to an object at the root level in the explorer structure, then all subordinate objects will be displayed in the explorer even if the subordinate objects have a different mandate than the mandate assigned to the user. However, the user will only see the basic preview information for such objects if he/she attempts to select the object.
- Dependent objects that are not controlled by a mandate are accessible to anyone that has access permission to the ascendant object. For example, a business support is a dependent object associated with an application, organization/market product, or business process/domain. Therefore, the business support can be viewed and possibly edited by anyone with a mandate owning the associated application, organization/market product, or business process/domain. Likewise, an information flow can be viewed and possibly edited by anyone with a mandate owning the source or target application.
- When a user with a mandate creates an object, the object is automatically assigned to the user's mandate.

  Please note that the assignment of mandates to information flows deviates from this rule. Mandates for information flows are implicitly derived from the source and target applications/components that they connect. Information flows are assigned to all mandates that the source and target objects are assigned to.

- The mandate owning an object may change over the lifecycle of an object. For example, an application may be owned by one mandate during the pilot phase, but another mandate may become the owning mandate once the application is in a productive status.
- If a user receives an assignment associated with an object owned by a mandate different than the mandate that the user is logged in with, then, in order to view or edit the object, the user must re-login with the mandate that matches the mandate owning the object.

The following steps are necessary in order to implement the mandate capability:

- Mandates must be created.
- The mandate capability must be generally activated.
- The mandate capability must be activated for each object class that will be included in the federated architecture.

These procedures are carried out in Alfabet Expand. For more information, see the section *Implementing the Mandate Capability for a Federated Architecture*.

- Each user must be assigned a mandate. Mandates can be assigned to users in the **User Management** functionality accessible via the `Admin` user profile. For more information, see either the section *Assigning a Mandate to a User* in the chapter *Defining and Managing Users* in the reference manual *User and Solution Administration*.
- When configuring the interface for the user community, you should consider whether the *Mandates Page View* (`ObjectMandates`) must be accessible to the relevant user profile configuration. When an object is created, it will automatically inherit the mandate of the user creating the object. The mandate assignment for an object can later be changed in the *Mandates Page View* for the relevant object.

Access Permissions for Master Users

A master user is a named user specified to have access permissions to all Alfabet objects regardless of the access permissions defined for the object. Likewise, a master user group can also be specified so that all users in the master user group have access permissions to all objects regardless of the access permissions defined for the object. Please note the following:

- The access permissions defined for a master user or users in the master user group will have precedence over access established via the authorized user and authorized user group definition as well as query-based access permission rules.
- The access permissions defined for a master user or users in the master user group do not have precedence over access denied due to a non-editable release status or mandate definitions.

Master users and master user groups are defined in the XML object ***RightsManager*** in Alfabet Expand. For more information, see the section Configuring Master Users and Master User Groups.

Rule-Based Access Permissions

Rule-based access permissions are a form of permission rules based on an Alfabet query or native SQL query that finds an object. Read/Write access to objects as well as the permission to delete objects can be granted by query-based permission rules.

For example, a permission rule can define that a user has Read/Write access to all information flows that have a source or target application for which he/she is the authorized user.

Or

A permission rule can define that a user has Read/Write access to all ICT objects for which he/she has the role Architect defined.

There are two types of permission rules that differ in execution mode and time:

- **Global permission rules** are executed when the user logs in to Alfabet and on first access of an object of a defined class. The evaluation is then repeated in regular intervals. The user has Read/Write access permissions for all objects returned by the query defined for the rule.

Additionally, default permission rules can be defined. Default permission rules can specify Read/Write or ReadOnly access permissions. Default permission rules are not based on an Alfabet query or native SQL query but rather are explicitly defined for an object class. If a default permission rule is defined for an object class and an object of the object class is not found via a query-based permission rule of the type `Global`, the access permission defined in the default permission rule will apply.

If no default permission rule is specified for the object class and an object of the object class is not found via a query-based permission rule, access permissions will be regulated via the concept of authorized user/authorized user groups.

- **Local permission rules** are executed whenever the user accesses an object. The resulting dataset from the query defined for the rule is executed in combination with the XML attribute `ResultType` which can be either `Positive` or `Negative`. When the query returns a dataset with at least one result and the XML attribute `ResultType` is `Positive`, or when the query returns an empty dataset and the XML attribute `ResultType` is `Negative`, Read/Write access permissions will be granted. If the conditions for granting the defined access permissions are not met, the XML attribute `ExecutionType` of the permission rule defines the further processing of the access conditions. If theXML attribute `ExecutionType` is set to `Exclusive`, the user will have ReadOnly access to the object. If the XML attribute `ExecutionType` is set to `Standard`, the access permission concepts defined in addition to the local permission rule (such as conventional access permissions) will be evaluated.

Global permission rules can be applied to one object class and local permission rules can be applied to a different object class, but only one type of permission rule can be defined per object class.

Permission rules are defined in the XML object ***RightsManager*** in Alfabet Expand. For more information, see the section Configuring Permission Rules for Access to Objects.

Access Permissions for Authorized Users

When an object is created, the creator of the object is automatically designated the authorized user. The authorized user is assigned to an object in the **Authorized Access** tab in the respective object's editor. The authorized user has Read/Write access to the object. After an object is created, the authorized user may be changed at any time. Every object can have at most one authorized user. However, it is also possible that no authorized user is defined for an object.

Access permissions for authorized users, deputies and authorized user groups are only valid if:

- global permission rules are defined for the object class, whereby no default permission rule is defined and the object is not included in the dataset returned by any of the global permission rules.

or

- the local permission rules defined for the object class do not grant Read/Write access permission to the object and the XML attribute `ExecutionType` of the local permission rule is set to `Standard`.

If permission rules are defined that do not include the authorized user as a permitted user, the authorized user may only edit the object in the context of the user session in which the object is being created. Once the user session ends, the authorized user will no longer be able to edit the object.

To guarantee that authorized users, deputies and authorized user groups can access objects they are responsible for even if permission rules are specified, a permission rule should be specified for the relevant object class that specifies Read/Write access permissions for users that are authorized user, deputy or member of an authorized user group for the object.

Please note that some functionalities use explorers that are based on the concept of authorized access and therefore display only objects that the current user is the authorized user of or objects that are available to the current user via an authorized user group affiliation. Such explorer nodes are typically named "My <ObjectClassName>" (For example, the **Document Application** functionality has an explorer with the caption **My Applications**). Because a permission rule may be configured so that a user may not have ReadWrite access permission to objects for which he/she is the authorized user, it is recommended that these functionalities are not implemented when permission rules are specified.

You should carefully consider whether the **Authorized User Objects** page view (`USER_PersonalItems`) in the **Personal Info** functionality, which displays all objects that a user is responsible for, should be included in the user profile configuration.

Access Permissions for Authorized User Groups

A user can also be assigned authorized access to an object via his/her membership in a user group if this user group is defined as the authorized user group for the object. In this case, all members of the user group will automatically have Read/Write access to the object. The authorized user group is assigned to an object in the **Authorized Access** tab in the respective object's editor.

The solution designer can also configure rules for the inheritance and/or propagation of a user group's access permissions to all ascendant and/or descendant user groups in the XML object ***RightsManager***. The following can be configured regarding inheritance and propagation:

- Propagation: All user groups in the user group hierarchy that are ascendant to a user group with permissions to an object should also have the same permissions to that object.
- Inheritance: All user groups in the user group hierarchy that are descendant to a user group with permissions to an object should also have the same permissions to that object.

Access permissions for authorized users, deputies and authorized user groups are only valid if:

- global permission rules are defined for the object class, whereby no default permission rule is defined and the object is not included in the dataset returned by any of the global permission rules.

or

- the local permission rules defined for the object class do not grant Read/Write access permission to the object and the XML attribute `ExecutionType` of the local permission rule is set to `Standard`.

If permission rules are defined that do not include the authorized user as a permitted user, the authorized user may only edit the object in the context of the user session in which the object is

being created. Once the user session ends, the authorized user will no longer be able to edit the object.

To guarantee that authorized users, deputies and authorized user groups can access objects they are responsible for even if permission rules are specified, a permission rule should be specified for the relevant object class that specifies Read/Write access permissions for users that are authorized user, deputy or member of an authorized user group for the object.

Please note that some functionalities use explorers that are based on the concept of authorized access and therefore display only objects that the current user is the authorized user of or objects that are available to the current user via an authorized user group affiliation. Such explorer nodes are typically named "My <ObjectClassName>" (For example, the **Document Application** functionality has an explorer with the caption **My Applications**). Because a permission rule may be configured so that a user may not have ReadWrite access permission to objects for which he/she is the authorized user, it is recommended that these functionalities are not implemented when permission rules are specified.

The following configuration is necessary in order to implement the authorized user group concept:

- User groups must be created in the **User Group Administration** functionality that can be accessed in the Alfabet user interface via the `Admin` user profile and users must be assigned to the user group. For more information, see the section *Defining and Managing User Groups* in the reference manual *User and Solution Administration*.
- Rules of inheritance and/or propagation can be defined in the XML object ***RightsManager*** in Alfabet Expand. For more information, see the section Configuring the Propagation/Inheritance of User Group Rights.
- You should consider whether the *Authorized User Groups Page View* (`ObjectUserGrousOnly`), which allows authorized user groups to be assigned to an object, should be included in the **Personal Info** functionality in the user profile configuration.

Access Permissions for Deputies

The authorized user of an object can assign one or more deputies to an object. Each deputy has Read/Write access permissions to the object and thus can capture, edit, and delete the data for the object when the authorized user is unable to.

Access permissions for authorized users, deputies and authorized user groups are only valid if:

- global permission rules are defined for the object class, whereby no default permission rule is defined and the object is not included in the dataset returned by any of the global permission rules.

or

- the local permission rules defined for the object class do not grant Read/Write access permission to the object and the XML attribute `ExecutionType` of the local permission rule is set to `Standard`.

If permission rules are defined that do not include the authorized user as a permitted user, the authorized user may only edit the object in the context of the user session in which the object is

being created. Once the user session ends, the authorized user will no longer be able to edit the object.

To guarantee that authorized users, deputies, and authorized user groups can access objects they are responsible for even if permission rules are specified, a permission rule should be specified for the relevant object class that specifies Read/Write access permissions for users that are authorized user, deputy or member of an authorized user group for the object.

Please note that some functionalities use explorers that are based on the concept of authorized access and therefore display only objects that the current user is the authorized user of or objects that are available to the current user via an authorized user group affiliation. Such explorer nodes are typically named "My <ObjectClassName>" (For example, the **Document Application** functionality has an explorer with the caption **My Applications**). Because a permission rule may be configured so that a user may not have ReadWrite access permission to objects for which he/she is the authorized user, it is recommended that these functionalities are not implemented when permission rules are specified.

When configuring the interface for the user community, you must take into account that the following functionalities may be necessary and must therefore be accessible to users:

- The **Authorized Deputies** page view (`ObjectDeputiesOnly`) should be available in the object views where users with Read/Write access permissions to an object may define a deputy for respective object.
- You should consider whether the **Deputy Objects** page view (`USER_DeputyItems`), which allows persons to be assigned as deputes to an authorized user's object, should be included in the **Personal Info** functionality in the user profile configuration.

Access Permissions for Members of Discussion Groups

Alfabet provides a discussion functionality that supports collaborative discussions about an object by discussion groups that have been configured for your enterprise. If Read/Write access has been configured for a discussion group, the members of that discussion group will also be able to access and edit the object that is under discussion.

Discussion groups and the access permissions of their members are configured in the **Discussion Groups** functionality that can be accessed in the Alfabet user interface via the `Admin` user profile. For more information, see the section *Defining Discussion Groups for Collaborative Discussions* in the reference manual *User and Solution Administration*.

When configuring the interface for the user community, you must take into account that the following functionalities may be necessary and must therefore be accessible to users:

- The **My Discussions** (`DSC_PersonDiscussions`) functionality should be available so that members of a discussion group can access the objects that are under discussion. For a detailed description about the discussion process, see the section *Initiating, Contributing to, and Managing a Discussion About Objects* in the reference manual *Getting Started with Alfabet*.
- The **Discussions** page view (`DSC_Items`) should be available in the object views where users can initiate a discussion about an object as well as contribute to and track the discussion about that object.

Access Permissions for Users Responsible for Assignments

Alfabet provides an assignment capability that allows users to define tasks for objects and assign the tasks to users that are responsible to perform that task.

Any user that has been assigned an assignment associated with an object has Read/Write access to that object for the period of the assignment.

When configuring the interface for the user community, you must take into account that the following functionalities may be necessary and must therefore be accessible to users:

- The **Assignments** page view (`ObjectAssignments`) should be available int he object views where users with edit permissions to an object can create assignments for the object.
- The **My Assignments** (`Home_Assignments`) functionality should be available so that a user can see all assignments that he/she is responsible for.
- The **Sent Assignments** (`Home_SentAssignments`) functionality should be available so that a user can see all assignments that he/she has created. For a detailed description about the assignment process, see the section *Sending and Receiving Assignments for Alfabet Objects* in the reference manual *Getting Started with Alfabet*.

Access Permissions for Users Responsible for a Workflow Step

A workflow is a collaborative process of workflow steps that are typically carried out by one or more users. One or more user(s) that are currently responsible for a workflow step associated with an object will have Read/Write access to that object in the context of the workflow step for as long as he/she is responsible for the workflow step.

If an object targeted has ReadOnly access permissions, the user(s) responsible for performing the workflow step will nevertheless have Read/Write permissions to the targeted object. All other users (including authorized users) will continue to have ReadOnly access permissions to the object for the period that the workflow step is active.

For more information about the configuration required to use the workflow capability, see the chapter Configuring Workflows in this reference manual.

Access Permissions Based on an Object's Release Status

Release status definitions are customizable and can be configured for a preconfigured set of object classes and, if applicable, object class stereotypes. Typical statuses could be Draft, Approved, Retired, etc. The release status is assigned to an object via the object editor when creating or editing the object or via the **Change Status** button in the toolbar of the object profile.

As part of the configuration of release statuses, it is possible to specify which release statues are non-editable. For all objects with release statuses that are configured as non-editable, users will neither be able to edit the attributes in the object's editor nor edit the object's relationships via the page views available in the object view.

Release status definitions are configured in the XML object ***ReleaseStatusDefs*** in Alfabet Expand. For information about configuring release statuses for object classes, see the section Configuring Release Status Definitions for Object Classes in the chapter Configuring the Class Model.

Purpose of Roles

In Alfabet, you may associate roles with a user or organization. A role describes a functional relationship that the user or organization has to an object (for example, as a Controller, Stakeholder, or Manager). The definition of a role does not affect access permissions in any way unless specifically implemented through a configured access permission rule. Roles are for the purpose of documentation and analysis only and do not have any impact on the access permissions associated with the object.

- It is possible to grant Read/Write access permissions to users with a specific role for the object by defining an access permission rule. For more information, see Configuring Permission Rules for Access to Objects.
- Roles are based on configured role types. Role types must first be created in the **Reference Data** functionality and assigned to the relevant object class in the **Class Configuration** module. For more information, see the chapter *Configuring Role Types to Define Roles in the Responsibilities Page View* in the reference manual *Configuring Evaluation and Reference Data in Alfabet*.

Rules Governing Access Permissions

Access permissions defined for objects are evaluated in a specified order.

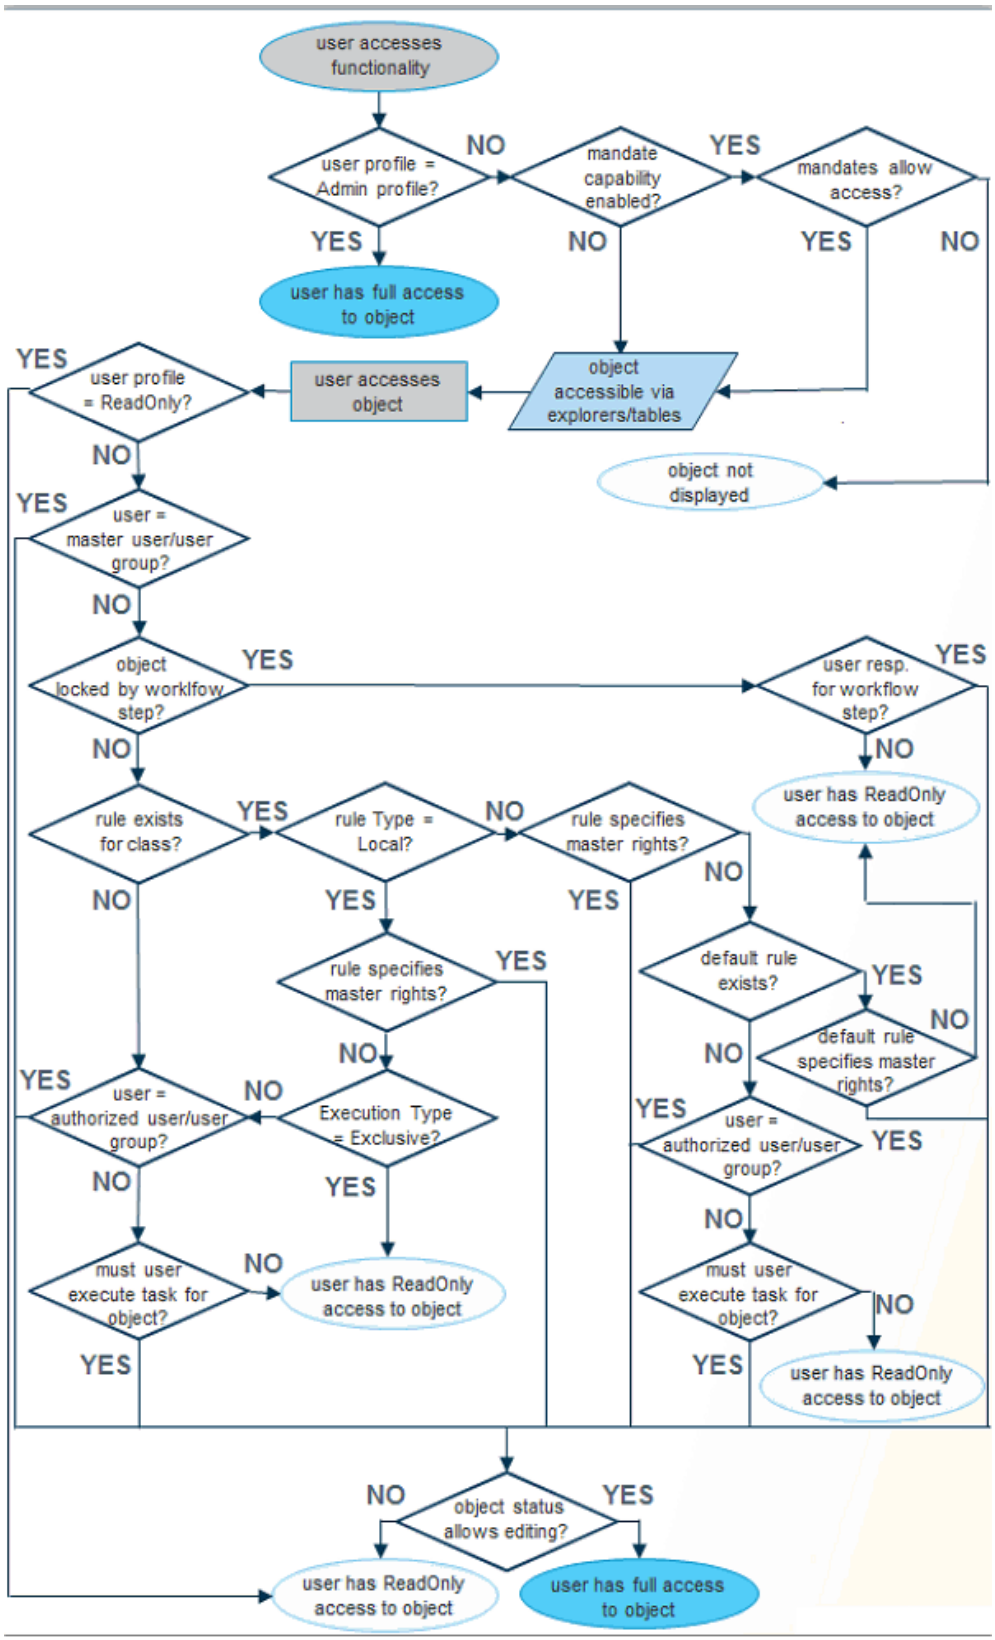


FIGURE: Order of evaluation of access permissions

- Access permissions are not evaluated at all if the user logs in with the `Admin` user profile. Users logged in with the `Admin` user profile can edit any object in the Alfabet database independent of the access permission concepts described below.
- Access permissions governing general visibility of objects take precedence over all other access permission concepts.

If your enterprise has a federated architecture and implements mandates, then users may potentially view and access only those objects that are owned by a mandate that matches the mandate the user is currently logged in with. Other objects will not be visible to the user in explorers and views. However, a preview of an object with a different mandate will be displayed if the object is referenced by an object accessible to the user's mandate.

An object that is not owned by a mandate is visible to anyone, regardless of the mandate assignment.

- For visible objects, the editability of objects is then evaluated as follows:

- If the user profile is a ReadOnly user profile, the user cannot edit any object regardless of the access permissions granted by other access permission concepts.
- If the user is a master user, Read/Write access permissions are granted regardless of the following access concepts if the release status is configured to grant Read/Write access.
- If the object is targeted by an active workflow step that restricts editing of the target object, only the user responsible for performing the workflow step may edit the object. All other users including authorized users will have ReadOnly access permissions to the object for the period that the workflow step is active. This ensures that other users not involved in the current workflow step do not edit the data of the object that is being currently processed in the workflow step.
- If the user profile is a Read/Write user profile, objects will be editable if the user has Read/Write access to the object due to a configured permission rule. A configured permission rule is a query-based rule specified by your enterprise to define the conditions to find the objects that a user may access with Read/Write access conditions.
- Permission rules have not been specified for the object class stereotype or object class.
- If global permission rules are defined for the object class and no default permission rule is defined for the object class, and the object does not match any of the defined permission rules.
- If local permission rules are defined and the XML attribute `ExecutionType` of the last defined rule for the object class is set to Standard.
- The authorized user and members of the relevant authorized user groups can edit the object if the permission rule configuration allows evaluation of other access permission concepts.
- If the user is responsible to perform a task for that object in the context of an assignment, workflow step, or discussion, the user will be able to edit the object as long as he/she is the responsible for the task. The user will be able to edit the object even if no access permissions are granted via the authorized user concept. Configured permission rules supersede the concept of task-based access permissions.
- If the object has a release status that is configured as a non-editable status, the user will have ReadOnly access permissions to the object regardless of the access permissions described above.

For some objects, special conditions apply independent of the general permission concepts:

- When a user creates an object, he/she has access permissions to that object during the active session, even if a configured permission rule based on attributes of the object does not allow the user to edit the object. The same applies when the user changes the properties of the object that define access permissions (for example, the object's mandate setting or authorized use is changed in such a way that would prevent him from seeing or editing the object). Changes to the access permissions are only taken into account for new sessions.
- Although you may have Read/Write permissions to objects that are considered reference data (for example, cost types, user groups, evaluation types), these objects can only be edited in the context of the **Configuration** module or, as the case may be, by accessing Alfabet with the `Admin` user profile.
- In a few cases, access permissions are not directly defined for objects that belong to a few object classes (for example, object classes like Master Plan Folder). These object classes automatically inherit the access information from their ascendant object (for example, the master plan folder inherits the access information from the ascendant master plan).

For an overview of which object classes inherit permission permissions, see *Overview of Configurable Features for Object Classes* in the reference manual *Configuring Alfabet with Alfabet Expand - Appendix*.

Implementing the Mandate Capability for a Federated Architecture

Some enterprises have a federated architecture. If this is the case in your enterprise, mandates may be implemented to control the visibility of Alfabet objects.

A mandate is a means to organize and structure the federated architecture of a holding company. The assignment of mandates to objects allows the holding company to structure the objects in the enterprise architecture in order to regulate visibility to objects across some or all subsidiaries. Only users explicitly assigned to a mandate will see objects with that mandate definition. An object that has not been assigned to a mandate is considered not to be owned by a mandate and is thus visible throughout the holding company to users with relevant access permissions.

The use of mandates in the Alfabet solution is optional. If mandates are implemented in an enterprise, the visibility of an object with a mandate assignment will take precedence over other concepts of access permissions in Alfabet. For example, an authorized user of an object must be assigned the relevant mandate to access the object that he/she is the owner of.

Within the context of mandates, the conventional rules governing access permissions apply. Thus, a user assigned to a mandate will only have Read/Write access permission to the objects made visible by the mandate if he/she has authorized access to the object as an authorized user, deputy, member of an authorized user group or discussion group or via rule-based access permissions, workflow contributor or assignee of an assignment.

For information about which object classes support the mandate capability, see *Overview of Configurable Features for Object Classes* in the reference manual *Configuring Alfabet with Alfabet Expand - Appendix*.

Keep the following in mind when working with mandates:

- A user will typically have only one mandate associated with his/her user name. When the user is logged in with a mandate, he/she will have access only to those objects that are assigned to that mandate as well as to all objects that are not assigned to a mandate. In other words, the user will not see objects that have a different mandate assigned.
- Objects that do not have a mandate assigned are visible to anyone with relevant access permissions.
- If an object has a mandate assignment different than the user's mandate assignment, the user will still be able to view basic preview information as well as the reference information about the dependent objects associated with the object. However, any custom object class properties defined for the object are not visible in the object's preview or object profile to the user with the mandate different than the object's mandate.
- If objects at the root level in an explorer structure are controlled by a mandate, then they will only be visible to users logged in with that mandate. Any root object in the explorer structure that has a different mandate than the mandate that the user is logged in with will not be visible in the explorer. If the user has accessibility to an object at the root level in the explorer structure, then all subordinate objects will be displayed in the explorer even if the subordinate objects have a different mandate than the mandate assigned to the user. However, the user will only see the basic preview information for such objects if he/she attempts to select the object.
- Dependent objects that are not controlled by a mandate are accessible to anyone that has access permission to the ascendant object. For example, a business support is a dependent object associated with an application, organization/market product, or business process/domain. Therefore, the business support can be viewed and possibly edited by anyone with a mandate owning the associated application, organization/market product, or business process/domain. Likewise, an information flow can be viewed and possibly edited by anyone with a mandate owning the source or target application.
- When a user with a mandate creates an object, the object is automatically assigned to the user's mandate.

  Please note that the assignment of mandates to information flows deviates from this rule. Mandates for information flows are implicitly derived from the source and target applications/components that they connect. Information flows are assigned to all mandates that the source and target objects are assigned to.

- When a user switches to another mandate, the access permission of the new mandate is immediately applied, and the user is redirected to the start page.
- The mandate owning an object may change over the lifecycle of an object. For example, an application may be owned by one mandate during the pilot phase, but another mandate may become the owning mandate once the application is in a productive status.
- If a user receives an assignment associated with an object owned by a mandate different than the mandate that the user is logged in with, then, in order to view or edit the object, the user must re-login with the mandate that matches the mandate owning the object.
- The object classes for which mandates are available are configured by Software AG. For an overview of the object classes that support the mandate capability, see *Overview of Configurable Features for Object Classes* in the reference manual *Configuring Alfabet with Alfabet Expand - Appendix*.

Mandates are ignored in the context of workflows. Regardless of the mandate assignments to the user and the object managed in a workflow step, the user assigned responsibility for a workflow step has all access permissions required to execute the workflow step within the context of the

My Workflow Activities functionalities (`WF_UserWorkflowActivities`, `WF_UserWorkflowActivitiesExt`, and `WF_UserWorkflowActivitiesCommon`) and/or the **Workflow Activities Explorer** (`WFS_Explorer`).

Therefore, if only users with a specific mandate should be permitted to perform a workflow step, the workflow designer must ensure that mandate assignment is taken into consideration via a query configured for the workflow step.

The following steps are required to implement the mandate capability:

- You must first create mandates. For more information, see *Creating Mandates for Your Enterprise*.
- You must activate the mandate capability in order to implement it. The mandate capability must be activated in the XML object ***RightsManager*** in order for the activation on the level of the object class to take effect. For more information, see *Activating the Mandate Capability for the Enterprise*
- You must ensure that the mandate capability is activated for each relevant object class. For more information, see *Activating the Mandate Capability for Relevant Object Classes and Object Class Stereotypes*.
- If the object class has object class stereotypes defined, you must configure the mandate capability for the object class stereotypes. For more information, see the section *Activating the Mandate Capability for Relevant Object Classes and Object Class Stereotypes*. For the special case of the implementation of the mandate capability for a domain model, see the section Implementing Mandates for the Domain Model.
- Assign the mandates to users. For more information, see *Assigning Mandates to Users*.

Creating Mandates for Your Enterprise

An enterprise may configure up to 30 mandates. The implementation of the mandate capability and the definition of mandates should only be done with the support of a consultant from Alfabet.

To create mandates:

1) Go to the **Admin** tab and right-click the **Mandates** node  and select **Show All Mandates**. The **Mandate Management** editor opens in the center pane.
2) In the toolbar, click the **New**  button and select **Create Mandate**. A dialog box opens.
3) Define the name and, if necessary, provide a description clarifying the purpose of the mandate.
4) Click **OK** to save the mandate. The new mandate  is displayed below the **Mandates** node in the explorer.

Activating the Mandate Capability for the Enterprise

The XML object ***RightsManager*** allows you to configure whether the mandate capability should be implemented in your enterprise's Alfabet software. The XML object ***RightsManager*** allows you to activate or deactivate the mandate capability as a whole.

To implement the mandate capability, you must activate the mandate capability in the XML object ***RightsManager*** AND explicitly define the mandate capability for the relevant object classes that should be controlled in your enterprise's federated architecture as described in the section Activating the Mandate Capability for Relevant Object Classes and Object Class Stereotypes.

To edit the XML object ***RightsManager***:

1) Go to the **Presentation** tab, expand the **XML Objects** folder, and then expand the **Administration** folder by clicking the + symbol. You will see all XML objects that can be edited.
2) Right-click the XML object ***RightsManager*** and select **Edit XML...**. The XML editor is displayed in the center pane.

For general information about editing XML objects in Alfabet Expand, see Working with XML Objects. All attributes that are described in the following are permissible attributes in the XML object. If they are not automatically displayed in the XML editor with a default value when opening the XML object, you can write them to the appropriate position in the editor. The example provided with this documentation shows the correct position of the attribute within the XML code.

3) In the XML attribute `MandateMode`, enter "`true`" to activate the mandates defined for the relevant object classes. Any objects that do not have a mandate assigned are visible to any user that has relevant access permissions. Enter "`false`" if the mandate capability should not be activated. In this case, the mandate definitions will not be applied to the objects.

The following example shows an XML object ***RightsManager*** for which the XML attribute `MandateMode` is set to "`true`":

```
<?xml version="1.0" encoding="utf-8" ?>
<AlfaRightsManager
    Inheritance="false"
    Propagation="true"
    MandateMode="true"
    AssemblyName="ITPlan"
    AssemblyClass="ITPlanSolution.SolutionRightsManager"
>
<AlfaMethod Type="OnGetObjectRights" Name =
"OnGetObjectRights" />
</AlfaRightsManager>
```

4) In the toolbar, click the **Save**  button to save the XML definition.

Activating the Mandate Capability for Relevant Object Classes and Object Class Stereotypes

To implement the mandate capability, you must ensure that the mandate capability is explicitly activated for each object class that should be controlled in your enterprise's federated architecture. The implementation of the mandate capability for an object class is defined via the **Can Have Mandates** attribute available for the object class. If the object class has object class stereotypes configured, you can implement the mandate capability for one, some, or all of the object class stereotypes. The mandate configuration may differ for each object class stereotype defined for an object class via the XML attribute `HasMandates` that can be defined for the **Stereotypes** attribute for the object class.

Please note however that this is not the case for the object class `Domain`. The object class `Domain` requires that the configuration of the XML attribute `HasMandates` that can be defined for the **Stereotypes** attribute for the object class `Domain` is the same for all domain stereotypes in a domain hierarchy. For more information about the configuration of the mandate capability for the object class `Domain`, see the section Implementing Mandates for the Domain Model.

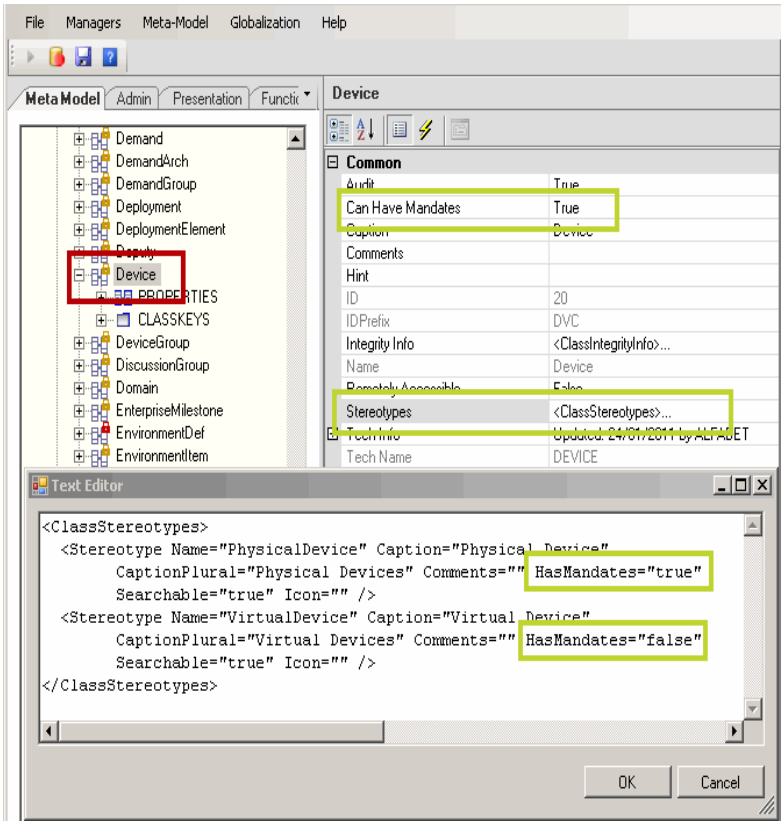
Per default, the XML attribute `HasMandates` is defined as "`false`" for all object class stereotypes. This means that the default setting specifies that objects based on a stereotype will be visible to users with any mandate implemented in your enterprise. Therefore, you must explicitly define the mandate capability for each object class stereotype if visibility should be controlled for the objects of an object class stereotype.

To implement the mandate capability for your Alfabet implementation, you must activate the mandate capability in the XML object ***RightsManager*** as described in the section Activating the Mandate Capability for the Enterprise AND explicitly define the mandate capability for the relevant object classes that should be controlled in your enterprise's federated architecture.

To make the mandate capability active for an object class:

1) Go to the **Meta-Model** tab, expand the **Class Model** folder, then expand and the **Classes** node and navigate to the relevant object class.

2) Click the relevant object class  to open the attribute window.



3) In the attribute window, select `True` in the **Can Have Mandates** field if the mandate capability should be available for the selected class. Select `False` if the mandate capability should not be available.

4) If object class stereotypes have been defined for the object class, you can explicitly define the mandates capability for each stereotype. In the **Stereotypes** field, click the **Browse** button to open the editor and specify the XML definition.

5) To implement the mandate capability for an object class stereotype, the XML attribute `HasMandates` must be defined as "`true`". If you do not want to implement the mandate capability for an object class stereotype, the XML attribute `HasMandates` must be defined as "`false`". If the XML attribute `HasMandates` is defined as "`false`" for an object class stereotype, objects based on the stereotype will be visible to permissible users with any mandate implemented in your enterprise.

6) Close the editor by clicking **OK**.

7) In the toolbar, click the **Save** button to save your changes.

Assigning Mandates to Users

Mandates can be assigned to users via the **User Management** functionality accessible in the Alfabet interface via the `Admin` user profile or via the tool Alfabet Administrator. One or more mandates can be assigned to a user although typically a user will be assigned only one mandate. The user will be able to access any objects that have been assigned to his/her mandate. The access to objects via the assignment of a mandate overrides any other assignment of access permissions.

Please note that a user can be specified as a mandate master in the **User** editor accessible via the **User Management** functionality in the Alfabet interface. The mandate master can log in to Alfabet and view any object regardless of its mandate. The visibility of objects will be based on the user profile that the mandate master is logged in with. For more information, see either the section *Assigning a Mandate to a User* in the reference manual *User and Solution Administration*.

Configuring Permission Rules for Access to Objects

The XML object ***RightsManager*** allows you to configure permission rules that define access permissions to objects in the Alfabet database.

Permission rules identify objects in the Alfabet database by means of an Alfabet query or SQL query and assign Read/Write access permissions to the user for these objects. The user can then edit and delete the object.

There are two types of permission rules that differ in the execution mode and execution time:

Permission Rule Type	Execution Time	Permission Evaluation Mode	Permission Evaluation If Rule Does not Apply
Global	The permission rule is executed when the user logs in and on first access of an object of a class. Execution is repeated in a regular interval configurable in the XML object ***RightsManager*** to consider changes performed to database objects during a user session.	A query is defined for the rule that returns a dataset of objects for that the user shall have Read/Write access permissions. The user can access all objects that are included in the result data set until the next evaluation of the permission rule.	Default permission rules can be defined per object class or object class stereotype that specify the access permissions for objects of a class or stereotype that do not apply to a query based global permission rule. If no default permission rule is defined for the object class, all other access permissions, like access for authorized users or due to an assignment for the object apply.
Local	The permission rule is executed each time a user accesses an object. Please note that this may lower the performance because queries must be executed whenever the user accesses an object.	Access permissions depend on the query defined for the permission rule and the setting of the XML attribute `ResultType`. If the query returns a dataset with at least one result and the XML attribute `ResultType` is set to `Positive`, or if the query returns an empty dataset and the XML attribute `ResultType` is set to `Negative`, Read/Write access permissions will be granted.	The XML attribute `ExecutionType` defines further processing. If the XML attribute `ExecutionType` is set to `Exclusive`, access will be ReadOnly if the rule does not apply. If the XML attribute `ExecutionType` is set to `Standard`, all other access permissions will apply (such as access for authorized users or access due to an assignment for the object).

Local and global permission rules cannot be defined in parallel for an object class. You can define local permission rules for objects of one object class and global permission rules for objects of another object class, but you must make sure that only one type of permission rules is defined per object class.

Access permissions for authorized users, deputies and authorized user groups are only valid if:

- global permission rules are defined for the object class, whereby no default permission rule is defined and the object is not included in the dataset returned by any of the global permission rules.

or

- the local permission rules defined for the object class do not grant Read/Write access permission to the object and the XML attribute `ExecutionType` of the local permission rule is set to `Standard`.

If permission rules are defined that do not include the authorized user as a permitted user, the authorized user may only edit the object in the context of the user session in which the object is being created. Once the user session ends, the authorized user will no longer be able to edit the object.

To guarantee that authorized users, deputies and authorized user groups can access objects they are responsible for even if permission rules are specified, a permission rule should be specified for the relevant object class that specifies Read/Write access permissions for users that are authorized user, deputy or member of an authorized user group for the object.

Please note that some functionalities use explorers that are based on the concept of authorized access and therefore display only objects that the current user is the authorized user of or objects that are available to the current user via an authorized user group affiliation. Such explorer nodes are typically named "My <ObjectClassName>" (For example, the **Document Application** functionality has an explorer with the caption **My Applications**). Because a permission rule may be configured so that a user may not have ReadWrite access permission to objects for which he/she is the authorized user, it is recommended that these functionalities are not implemented when permission rules are specified.

Configuring Global Permission Rules

Global permission rules are query based. A user has ReadWrite access to an object if the query of any of the defined global permission rules for the object class returns that object.

The global permission rules are evaluated whenever a user logs in and on first access of an object of an object class during the current user session. Access permissions for the object class are then stored in the memory and read from the memory when the user accesses another object of the same class. The evaluation of permission rules is repeated during the user session in regular intervals of typically 300 seconds to ensure that changes in the database (such as the creation of new objects or new relations between objects) are taken into account. The interval to evaluate permission rules is configurable in Alfabet Expand.

For example, if a rule specifies that a user can edit all objects for which he/she has the role Architect defined, and the authorized user changes the person that is responsible for the role Architect to another user, the user who formerly had the role Architect assigned will have

ReadOnly permissions to the object as soon as the permission rules are re-executed during the active user session.

Independent of the evaluation of permission rules, the user will have Read/Write access to an object that he/she has created in a session as long as the session is active.

Please note that changes to the database or the user settings during the current session are only evaluated in the given time interval. For example, if a permission rule is based on the user profile the user is currently logged in with and the user session starts with a user profile granting Read/Write access to an object, the user will still have Read/Write access permissions to the object even if he/she changes to another user profile granting ReadOnly access to the object as long as the permission rules are not re-executed.

Additionally, default permission rules can be defined per object class or object class stereotype. These permission rules do not have a query specified. The default permission rule defines the access permissions for objects in a specified object class that are not found via a query-based permission rule.

If no default permission rule is defined for an object class or object class stereotype and the object does not match any of the global permission rules defined, the alternative permission concepts like access-based on authorized user permissions will be evaluated.

Global permission rules are defined in the XML object ***RightsManager***:

1) Go to the **Presentation** tab, expand the **XML Objects** folder, and then expand the **Administration** folder by clicking the + symbol. You will see all XML objects that can be edited.
2) Right-click the XML object ***RightsManager*** and select **Edit XML**. The XML editor is displayed in the center pane.

For general information about editing XML objects in Alfabet Expand, see Working with XML Objects. All attributes that are described in the following are permissible attributes in the XML object. If they are not automatically displayed in the XML editor with a default value when opening the XML object, you can write them to the appropriate position in the editor. The example provided with this documentation shows the correct position of the attribute within the XML code.

3) Optionally, specify the interval to evaluate permission rules. The configured permission rules will be evaluated whenever a user logs in or tries to access an object. The evaluation of permission rules is then repeated during the user session in regular intervals of typically 300 seconds to ensure that changes in the database (such as the creation of new objects or new relations between objects) are taken into account.

   To change the interval, the XML attribute `UpdatePeriod` must be added to the XML element ***AlfaRightsManager***. The value of the XML attribute specifies the update interval in seconds.

The following example shows the configuration of permission rule evaluation every 120 seconds in the XML attribute `UpdatePeriod`. The element includes other settings for the configuration of other access permission concepts:

```
<AlfaRightsManager
Inheritance="false"
Propagation="false"
MandateMode="true"
AssemblyName="ITPlan"
```

```
AssemblyClass="ITPlanSolution.SolutionRightsManager"
UpdatePeriod="120"
>
    [.....]
</AlfaRightsManager>
```

4) Define the permission rules and default permission rules as specified below.

5) In the toolbar, click the **Save**  button to save the XML definition.

A global permission rule is specified in the XML element ***RightsRule***, which is a child element of the XML element ***AlfaRightsManager***. The XML element ***AlfaRightsManager*** may contain multiple ***RightsRule*** elements.

The following example shows the complete configuration for permission rules including the definition of one permission rule that allows the user to access all market products for which the user is assigned to the object via the role Architect:

```
<AlfaRightsManager
[...]
AssemblyName="ITPlan"
AssemblyClass="ITPlanSolution.SolutionRightsManager"
UpdatePeriod="120"
></AlfaRightsManager>
   <AlfaMethod Type="OnGetObjectRights" Name = "OnGetObjectRights"
   />
   <RightsRule Name="Market Product Access for Architects"
   ClassName="MarketProduct"
   Rights="Master"
   Query="ALFABET_QUERY_500 FIND MarketProduct
   InnerJoin Role ON Role.Object = MarketProduct.REFSTR
   InnerJoin RoleType ON RoleType.REFSTR = Role.RoleType
   InnerJoin Person ON Role.Responsible = Person.REFSTR
   WHERE (AND RoleType.Name = 'Architect' Person.REFSTR
   =:CURRENT_USER)"/>
```

The following attributes can be defined for the XML element ***RightsRule*** to configure a global permission rule:

XML Attribute	Allowed Value Types or Allowed Values	Mandatory/Optional	Purpose
`Name`	`String`	Mandatory	Defines a name for the permission rule. The name can be any string and is for internal XML element identification by the editor of the rules.
`Rights`	`Master` `Read`	Mandatory	The XML attribute `Rights` must be set to `Master` to specify a valid permission rule. For default permission rules, the XML attribute `Rights` can be set to `Master` to grant Read/Write access permissions, or to `Read` to grant ReadOnly access permissions.
`Query`	`Alfabet query` `SQL query`	Optional	Defines the objects that the user shall be able to edit. Objects are specified by an Alfabet query in Alfabet query language 500 or by an SQL-based query. If no query is defined, the permission rule is a default permission rule and defines the default access permissions for the object class. **NOTE**: The query must find objects of the object class defined with the XML attribute `ClassName`.
`ClassName`	`String`	Mandatory for stereotype specific rules	If the permission rule is defined for an object class stereotype, the object class and object class stereotype for which the permission is specified must be defined with the XML attribute `ClassName`. The XML attribute `ClassName` must be defined as `<class name>:<stereotype name>`, for example: `Application:BusinessApplication`

A permission rule assigns edit permissions to the objects of the object class defined in the XML attribute `ClassName` that match the conditions of the query defined in the XML attribute `Query`. Default permission rules define access permissions for objects of the object class defined in the XML attribute `ClassName` that do not match the conditions of any query defined in the permission rule for the object class.

Permission rules can be defined per object class or per object class stereotype. To define a permission rule for an object class stereotype, you must define the `RightsRule` attribute as follows:

- The XML attribute `ClassName` must be defined as `<class name>:<stereotype name>`
- The query defined in the XML attribute `Query` must return only objects of the selected stereotype.

It is possible to specify more than one permission rule for an object class. The user will then have edit permissions for all objects for which one of the specified rules apply.

When permission rules are defined for both an object class and stereotypes of that object class, the access permissions for an object of a given stereotype are evaluated by first applying the rules for the stereotype and, if the object does not match the criteria defined in any of these rules, the rules for the object class.

When a user creates an object, he/she has access permissions to that object during the active session, even if a permission rule based on attributes of the objects does not allow editing of the object by the user.

Please consider the following when specifying an Alfabet query for a permission rule:

- Edit permissions are specified for the base object class of the Alfabet query only. Object classes can be added with a `JOIN` to add attributes of other classes to `WHERE` statements. The access permissions of the object classes added with a `JOIN` are not affected by the permission rule.
- `SHOW` and `SORT` property specifications are not allowed in a permission rule.
- Alfabet query language parameters can be used to refer to the current environment. For example, the parameter `CURRENT_USER` can be used to refer to the user that is currently logged in to the Alfabet user interface. The parameter `BASE` that refers to the current object cannot be used for global permission rules because the permission rule is not evaluated for a single base object.

Please note that changes to the database or the user settings during the current session are only evaluated in the given time interval. For example if a permission rule refers to the user profile the user is currently logged in with with the parameter `CURRENT_PROFILE`, and the user session starts with a user profile granting Read/Write access to an object, the user will still have Read/Write access permissions to the object even if he/she changes to another user profile granting ReadOnly access to the object as long as the permission rules are not re-executed.

For more information about Alfabet query language parameters, see Referring to the Current Alfabet Context in a WHERE Condition in the chapter Defining Queries.

- If the Alfabet query contains special characters (for example, a greater then (>) or lesser then (<) symbol) in the `WHERE` clause, you must replace it with the HTML compatible strings:

- `>` for >
- `<` for <
- `&quot;` for "
- `&#091;` for [
- `&#093;` for]

- For basic information about the Alfabet query language, see the chapter Defining Queries.

Please consider the following when specifying an SQL-based query for a permission rule:

- To define an SQL-based query for a permission rule, native SQL can be written directly into the XML attribute `Query`.
- Edit permission are specified for objects of the object class specified with the XML attribute `ClassName` of the permission rule. The SQL-based query is only used to define conditions that an object of the object class specified with the XML attribute `ClassName` must meet in order for the permission rule to apply.

- The SQL-based query must return the values of the `REFSTR` property of the relevant objects.
- Alfabet query language parameters can be used to refer to the current environment. For example, the parameter `CURRENT_USER` can be used to refer to the user that is currently logged in to the Alfabet user interface. The parameter `BASE` that refers to the current object cannot be used for global permission rules, because the permission rule is not evaluated for a single base object. For more information about Alfabet query language parameters, see Referring to the Current Alfabet Context in a WHERE Condition and Using Alfabet Parameters in the chapter Defining Queries.
- If the SQL-based query contains special characters (for example, a greater then (>) or lesser then (<) symbol), you must replace it with the HTML compatible strings:

- `>` for >
- `<` for <
- `&quot;` for "
- `&#091;` for [
- `&#093;` for]

Configuring Local Permission Rules

Independent of the evaluation of permission rules, the user will have Read/Write access to an object that he/she has created in a session as long as the session is active.

Local permission rules are defined in the XML object ***RightsManager***:

1) Go to the **Presentation** tab, expand the **XML Objects** folder, and then expand the **Administration** folder by clicking the + symbol. You will see all XML objects that can be edited.
2) Right-click the XML object ***RightsManager*** and select **Edit XML**. The XML editor is displayed in the center pane.

   For general information about editing XML objects in Alfabet Expand, see Working with XML Objects. All attributes that are described in the following are permissible attributes in the XML object. If they are not automatically displayed in the XML editor with a default value when opening the XML object, you can write them to the appropriate position in the editor. The example provided with this documentation shows the correct position of the attribute within the XML code.

3) Define the XML elements and XML attributes for the permission rules and default permission rules as specified below.
4) In the toolbar, click the **Save**  button to save the XML definition.

A local permission rule is specified in the XML element ***RightsRule***, which is a child element of the XML element ***AlfaRightsManager***. The XML element ***AlfaRightsManager*** may contain multiple ***RightsRule*** XML elements.

The following example shows the configuration of a local permission rule that allows the user to access all market products for which the user is assigned to the object via the role Architect:

```
<AlfaRightsManager
[...]
AssemblyName="ITPlan"
AssemblyClass="ITPlanSolution.SolutionRightsManager"
UpdatePeriod="120"
></AlfaRightsManager>
    <AlfaMethod Type="OnGetObjectRights" Name = "OnGetObjectRights"
    />
    <RightsRule Name="Local Market Product Access for Architects"
    Rights="Master"
    RuleType="Local"
    ExecutionType="Standard"
    ResultType="Positive"
    ClassName="MarketProduct"
    Query="ALFABET_QUERY_500 FIND MarketProduct
    InnerJoin Role ON Role.Object = MarketProduct.REFSTR
    InnerJoin RoleType ON RoleType.REFSTR = Role.RoleType
    InnerJoin Person ON Role.Responsible = Person.REFSTR
    WHERE (AND RoleType.Name = 'Architect' Person.REFSTR
    =:CURRENT_USER MarketProduct.REFSTR =:BASE)"/>
```

The following attributes can be defined for the XML element ***RightsRule*** to configure a global permission rule:

Attribute	Allowed Value Types or Allowed Values	Mandatory/Optional	Purpose
`Name`	`String`	Mandatory	Defines a name for the permission rule. The name can be any string and is for internal identification by the editor of the rules.
`RuleType`	`Local`	Mandatory	The XML attribute `RuleType` must be set to `Local` to specify a local permission rule.
`Rights`	`Master`	Mandatory	The XML attribute `Rights` must be set to `Master` to specify a valid permission rule.

Attribute	Allowed Value Types or Allowed Values	Mandatory/Optional	Purpose
ClassName	String	Mandatory for stereotype-specific rules	If the permission rule is defined for an object class stereotype, the object class and object class stereotype for which the permission is specified must be defined with the XML attribute ClassName The XML attribute ClassName must be defined as <class name>:<stereotype name>, for example: Application.BusinessApplication
Query	Alfabet query SQL query	Mandatory	Defines a query that refers to the current object and may or may not return a dataset. The user has Read/Write access to an object if the query returns a dataset and the XML attribute ResultType is set to Positive or if the query returns no dataset and the XML attribute ResultType is set to Negative.
ResultType	Positive Negative	Mandatory	The user has Read/Write access to an object if the query defined with the attribute Query returns a dataset and the XML attribute ResultType is set to Positive or if the query returns no dataset and the XML attribute ResultType is set to Negative.
ExecutionType	Standard Exclusive	Mandatory	Defines whether other access permission concepts are evaluated when the condition defined via the XML attributes ResultType and Query are not fulfilled. If the XML attribute ExecutionType is set to Exclusive, the user has ReadOnly access when the permission rule does not grant ReadWrite access permissions. If the XML attribute ExecutionType is set to Standard, the access permissions for the object are evaluated according to other configured permission concepts, like the authorized user concept.

It is possible to specify more than one permission rule for an object class. The user will then have edit permissions for an object if one of the specified rules apply.

Note the following when defining more than one local permission rule:

- The permission rules are evaluated in the order they are written in the XML object ***RightsManager*** until the object matches one of the defined criteria.
- When the XML attribute ExecutionType of a rule is set to Exclusive, the following rules will not be evaluated. The XML attribute ExecutionType of the last defined rule specifies, whether other access concepts are evaluated when the object does not apply to any of the defined local rules.
- When permission rules are defined for both an object class and stereotypes of that object class, the access permissions for an object of a given stereotype are evaluated by first applying the rules for the stereotype and, if the object does not match the criteria defined in any of these rules, the rules for the object class.

- When a user creates an object, he has access permissions to that object during the active session, even if a permission rule based on attributes of the objects does not allow editing of the object by the user.

Please consider the following when specifying an Alfabet query for a permission rule:

- Edit permissions are specified for the base object class of the Alfabet query only. Object classes can be added with a `JOIN` to add attributes of other object classes to `WHERE` statements. The access permissions of the object classes added with a `JOIN` are not affected be the permission rule.
- `SHOW` and `SORT` property specifications are not allowed in a permission rule.
- The query must refer to the current object with the Alfabet query language parameter `BASE` that returns the `REFSTR` value of the object the user currently accesses. Other Alfabet query language parameters can also be used to refer to the current environment. For example the parameter `CURRENT_USER` can be used to refer to the user that is currently logged in to the Alfabet user interface.

For more information about Alfabet query language parameters, see Referring to the Current Alfabet Context in a WHERE Condition in the chapter Defining Queries.

- If the Alfabet query contains special characters (for example, a greater then (>) or lesser then (<) symbol) in the `WHERE` clause, you have to replace it with the HTML compatible strings:

- `>` for >
- `<` for <
- `&quot;` for "
- `&#091;` for [
- `&#093;` for]

- For basic information about the Alfabet query language, see the chapter Defining Queries.

Please consider the following when specifying an SQL-based query for a permission rule:

- To define an SQL-based query for a permission rule, native SQL can be written directly into the attribute `Query`.
- Edit permissions are specified for objects of the object class specified with the attribute `ClassName` of the permission rule. The SQL-based query is only used to define conditions that an object of the object class specified with the attribute `ClassName` must meet in order for the permission rule to apply.
- The SQL-based query must return the values of the `REFSTR` property of the relevant objects.
- The query must refer to the current object with the Alfabet query language parameter `BASE` that returns the `REFSTR` value of the object the user currently accesses. Other Alfabet query language parameters can also be used to refer to the current environment. For example, the parameter `CURRENT_USER` can be used to refer to the user that is currently logged in to the Alfabet user interface.

For more information about Alfabet query language parameters, see Referring to the Current Alfabet Context in a WHERE Condition and Using Alfabet Parameters in the chapter Defining Queries.

- If the SQL-based query contains special characters (for example, a greater then (>) or lesser then (<) symbol), you have to replace it with the HTML compatible strings:

- `>` for >
- `<` for <
- `&quot;` for "
- `&#091;` for [
- `&#093;` for]

Configuring Master Users and Master User Groups

In the XML object ***RightsManager***, the XML elements ***MasterUser*** and ***MasterUserGroup*** allow a named user or user group to have access permissions to all Alfabet objects regardless of the access permissions defined for the object.

Please note the following:

- The access permissions defined for a master user or users in the master user group will have precedence over access established via the authorized user and authorized user group definition as well as query-based access permission rules.
- The access permissions defined for a master user or users in the master user group do not have precedence over access denied due to a non-editable release status or mandate definitions.
- The named user or users in the user group must access Alfabet with a user profile that has ReadWrite access permissions defined.
- The XML object ***RightsManager*** is handed over to the server process at start of the application. Any changes to the XML object ***RightsManager*** only become valid after server restart. If you want to test your configuration by accessing the Alfabet user interface via Alfabet Expand, you must restart Alfabet Expand after making any change to the XML object ***RightsManager*** and prior to opening the Alfabet user interface.

To edit the XML object ***RightsManager***:

1) Go to the **Presentation** tab, expand the **XML Objects** folder, and then expand the **Administration** folder by clicking the + symbol. You will see all XML objects that can be edited.
2) Right-click the XML object ***RightsManager*** and select **Edit XML**. The XML editor is displayed in the center pane.

   For general information about editing XML objects in Alfabet Expand, see Working with XML Objects. All attributes that are described in the following are permissible attributes in the XML object. If they are not automatically displayed in the XML editor with a default value when opening the XML object, you can write them to the appropriate position in the editor. The example provided with this documentation shows the correct position of the attribute within the XML code.

3) To define a master user, add a child XML element ***MasterUser*** to the XML element ***AlfaRightsManager***. TheXML element ***MasterUser*** must have an XML attribute `Name` that defines the user name of the master user.

The name entered in theXML attribute `Name` of the XML elements ***MasterUser*** and ***MasterUserGroup*** must be capitalized as it is in the Alfabet database table. Any user name defined in the **User** editor (`USER_Editor`) in the context of the **Users Administration** functionality is saved to the Alfabet database in all capital letters, regardless of how it is entered in the editor. For more information about defining users in Alfabet, see the section *Defining and Managing Users* in the reference manual *User and Solution Administration*.

4) To define a master user group, add a child XML element ***MasterUserGroup*** to the XML element ***AlfaRightsManager***. The XML element ***MasterUserGroup***t must have an XML attribute `Name` that defines the name of the user group.

Below is an example of the definition of a master user and a master user group in the XML object ***RightsManager***:

```
<AlfaRightsManager
[...]
AssemblyName="ITPlan"
AssemblyClass="ITPlanSolution.SolutionRightsManager"
UpdatePeriod="120"
></AlfaRightsManager>
    <AlfaMethod Type="OnGetObjectRights" Name = "OnGetObjectRights"
    />
    <MasterUser Name='CLIENTE' />
    <MasterUserGroup Name='Object Owners' />
    <RightsRule Name="Market Product Access for Architects" [...]/>
```

Configuring the Propagation/Inheritance of User Group Rights

The XML object ***RightsManager*** allows you to configure rules for propagation or inheritance for user group permissions. The concept of access permissions for user groups is described in the section Access Permissions for Authorized User Groups. The following is determined via the configuration of inheritance and propagation in the XML object ***RightsManager***:

- **Propagation**: All user groups in the user group hierarchy that are ascendant to a user group should have the same access permissions to that object.
- **Inheritance**: All user groups in the user group hierarchy that are descendant to a user group should have the same access permissions to that object.

This XML object should be defined as part of the initial configuration of the Alfabet solution. These definitions should not be changed once the Alfabet database is in use.

To edit the XML object ***RightsManager***:

1) Go to the **Presentation** tab, expand the **XML Objects** folder, and then expand the **Administration** folder by clicking the + symbol. You will see all XML objects that can be edited.

2) Right-click the XML object ***RightsManager*** and select **Edit XML**. The XML editor is displayed in the center pane.

For general information about editing XML objects in Alfabet Expand, see Working with XML Objects. All attributes that are described in the following are permissible attributes in the XML object. If they are not automatically displayed in the XML editor with a default value when opening the XML object, you can write them to the appropriate position in the editor. The example provided with this documentation shows the correct position of the attribute within the XML code.

3) In the XML attribute `Inheritance` of the XML element ***AlfaRightsManager***, enter "`true`" if a user group's access permissions to a specific object should be automatically inherited by all descendant groups in the user group hierarchy. Enter "`false`" if access permissions should not be inherited by all descendant groups in the user group hierarchy.

4) In the XML attribute `Propagation` of the XML element ***AlfaRightsManager*** enter "`true`" if a user group's permissions to a specific object should be automatically propagated to all ascendant groups in the user group hierarchy. Enter "`false`" if access permissions should not be propagated to the ascendant groups in the user group hierarchy.

The following example shows an XML object ***RightsManager*** in which the XML attribute `Inheritance` is set to "`false`" and the XML attribute `Propagation` is set to "`true`":

```
<?xml version="1.0" encoding="utf-8" ?>
<AlfaRightsManager
    Inheritance="false"
    Propagation="true"
    MandateMode="true"
    AssemblyName="ITPlan"
    AssemblyClass="ITPlanSolution.SolutionRightsManager" >
<AlfaMethod Type="OnGetObjectRights" Name =
"OnGetObjectRights" />
</AlfaRightsManager>
```

5) In the toolbar, click the **Save**  button to save the XML definition.

Chapter 4: Localization and Multi-Language Support for the Alfabet Interface

Software AG provides localization possibilities as well as multi-language support in order to adapt the Alfabet interface to suit the needs and expectations of the various locales in which your enterprise operates. All Alfabet components are delivered with the default interface in `English (United States)` as well as a translated interface for the supported secondary languages. A vocabulary, which constitutes the set of standard original and translated strings for a language, is available for each supported language.

The Alfabet interface is available in the following languages:

Language	Locale ID
Arabic (Saudi Arabia)	1025
German (Germany)	1031
English (United States)	1033
French (France)	1036
Portuguese (Brazil)	1046
Polish (Poland)	1045

Custom strings for configuration objects (such as custom properties, custom editors, configured reports, etc.) must be captured in English, regardless of the primary culture definition. All strings for captions for configuration objects and guide page/guide view content will be displayed in the `Original` column in the **Translation Editor** or XLSX files of the relevant vocabulary.

The following is possible in order to localize the Alfabet interface for your enterprise's needs:

- Specify cultures that capture the locale ID, the interface language, and the date, time, and number formats. Users can select the relevant culture to display on the user interface via the **Language** option in the < **Alfabet User** > menu.
- Modify the standard English strings and provide alternative terminology that is relevant for your enterprise. For example, if the English term `Software` is used instead of `Application` in your enterprise, you can customize all strings for the `Original` vocabulary in which the term `Application` is used so that the word `Software` is used instead. Likewise, if the German term `Anwendung` is used instead of `Applikation` in your enterprise, you can customize all translated strings for the `German` vocabulary in which the term `Applikation` is used so that the word `Anwendung` is used instead.

- Manually or automatically translate the custom strings that your enterprise has created when configuring the class model, custom editors, selectors, object views/object cockpits, workflows, wizards, configured reports, guide pages/guide views, etc. to the languages supported by Software AG.
- Specify whether manual or automated translation is allowed for the translation of object data by users in the Alfabet user interface. You can specify the object classes and properties for which data translation is allowed. The translation of object data typically includes the captions, descriptions, and other custom properties of the type `String` defined for objects that users create in the Alfabet user interface.
- Specify a statutory language to address regulatory requirements that mandate that objects are captured in a specific language. When a user creates an object based on the object class/object class stereotype, a statutory language selector will open in which the language can be selected. In the object editor that opens, the user can capture all attributes that support automated translation in the statutory language.
- Provide a custom online help.
- Translate the online help files `(HTML)` provided with Alfabet.

The following information is available:

Specifying the Cultures Relevant to Your Enterprise

A culture constitutes the base configuration of the default primary language displayed on the user interface when the user first logs in as well as the date, time, and number formats, etc. used to capture and render dates, times and numbers in the Alfabet user interface.

The Alfabet interface is available in the following languages:

Language	Locale ID
Arabic (Saudi Arabia)	1025
German (Germany)	1031
English (United States)	1033
French (France)	1036

Language	Locale ID
Portuguese (Brazil)	1046
Polish (Poland)	1045

A base culture must be specified for each culture you define. The base culture is associated with a culture code which is the equivalent of a locale code assigned by Microsoft® Windows®. The culture code determines which vocabulary (the set of original and translated strings) to display in the Alfabet user interface - in other words, the base culture determines the language displayed on the Alfabet user interface. In addition to the base culture, you can also specify date and time patterns used to capture dates and timestamps, whether a point or comma is used as the decimal symbol in numbers, or whether measurements for printing are in the metric or imperial system, etc. A base culture may be defined for only one culture.

You may define multiple cultures associated with the supported languages. If only one culture is defined for your enterprise, then the automated and manual data translation functionalities will be disabled in the Alfabet user interface.

If your enterprise has various corporate locations around the world that all use the same corporate language but require different date patterns, time patterns, measurement units, you can create two cultures, each that reference the same language but with different date and time patterns and measurement units. For example, if you have a subsidiary in the United States and one in Ireland, you could create an additional English language culture setting such as English (Ireland) and specify the date pattern, time pattern, and measurement units for the cultures English (United States) and English (Ireland) as needed.

To specify a new or existing culture:

1) In the **Meta-Model** tab, right-click the **Cultures** node and select **Add New Culture** . The new culture is displayed below the **Cultures** node and is labelled **Invariant Language**.
2) Click the new culture to display the attribute window and define the following attributes:

- **Base Culture**: Select the locale that you are defining. The primary language displayed in the user interface is determined by the **Base Culture** attribute. Therefore, if you specify `French (France)`, then the `French (France)` vocabulary will be called when the base culture `French (France)` is displayed in the user interface. If a base culture is selected for which no vocabulary has been created, the default `English (United States)` will be displayed in the Alfabet interface.
- **Language Culture Name**: Displays the name of the language associated with the base culture. This information may be relevant for the specification of REST API calls.
- **Current Machine Date Pattern**, **Current Machine Date Separator**, and **Current Machine Time Pattern**: Displays the local settings of the server machine. These default settings will be used if the **Date Pattern**, **Date Separator**, and **Time Pattern** attributes are not explicitly set. In order to ensure that the user has consistent date and number formating, the following attributes should be defined.

  Please note that the dates in editor fields are always displayed as a numeric value, regardless of the date format. For example, whereas the date format dddd, dd MMMM yyyy will be displayed as Tuesday, 22 August 2006 in the object profile, it will

be displayed as 22/08/2006 in the editor field. For more information about the syntax and possible output values defined for date/separator/time specification, see the section Permissible Date and Time Formats in Alfabet .

- **Date Format**: Select the locale of the date and time format to be displayed in the solution interface. An error message will be displayed in the user interface if the user attempts to enter a date that has a different date format. Please note the following:
- If no locale is selected in the **Date Format** field, the default date and time formats defined for the server machine will be displayed. These are displayed in the **Current Machine Date Pattern**, **Current Machine Date Separator**, and **Current Machine Time Pattern** fields.
- The date format determines the representation of the date pattern, date separator and time pattern. If a different date pattern, date separator, or time pattern is required than that specified by the locale selected in the **Date Format** field, you must explicitly define the **Date Pattern**, **Date Separator**, and /or **Time Pattern** attribute.
- **Date Pattern**: If the date pattern should deviate from the date pattern specified in the **Date Format** attribute or the **Current Machine Date Pattern** attribute, enter the date pattern to implement for the culture setting.

  Please note that users will typically define dates in editor and filter fields using the **Calendar** button available for the field. However, if you would like to enable users to define dates manually, you must ensure that the **Date Separator** attribute is also defined.

- **Date Separator**: If the date separator should deviate from the date separator associated with the **Date Format** attribute or the **Current Machine Date Separator** attribute, enter the date separator to implement for the culture setting. This definition supersedes the value in the **Current Machine Date Pattern** field. Please note that if both the **Date Separator** and the **Date Pattern** attribute are specified, the "/" character must be used as the separator when specifying the **Date Pattern** attribute.
- **Time Pattern**: If the time pattern should deviate from the time pattern associated with the **Date Format** attribute or the **Current Machine Time Pattern** attribute, enter the time pattern to implement for the culture setting.
- **Number Format**: If the number format should deviate from the locale associated with the **Base Culture** attribute, select the locale of the number format to be displayed in the solution interface. An error message will be displayed if a user attempts to enter a number with a different number format.
- **Decimal Symbol**: If the decimal symbol should deviate from the decimal symbol associated with the **Number Format** attribute or the **Base Culture** attribute, enter the decimal symbol that should be used for integers and real numbers. (For example, the English language decimal symbol typically uses a period (10.50) and the German language decimal symbol typically uses a comma (10,50).
- **Digit Grouping Symbol**: If the digit grouping symbol should deviate from the digit grouping symbol associated with the **Number Format** attribute or the **Base Culture** attribute, enter the digit grouping symbol that should be used for integers and real numbers defined for standard and custom attributes. (For example, the English language digit grouping symbol typically uses a comma (100,000,000) and the German language digit grouping symbol typically uses a period (100.000.000).
- **Icon**: Typically, an icon of the national flag associated with the base culture is displayed in the Alfabet user interface for the currently selected culture. If a different icon should be displayed, select the icon in the **Icon** field. For more information about adding custom icons, see Uploading Custom Icons to the Icon Gallery.

- **Is Primary Culture**: Select `True` if this culture is the base culture. The primary culture is the culture displayed in the Alfabet user interface upon login. It is also the language that is considered the primary language when users create or modify objects in editors and wizards in the Alfabet user interface. To change the **Is Primary Culture** definition, see the section Specifying the Primary Culture for Your Enterprise.
- **Help Culture**: Select the locale of the context-sensitive online help that shall be available for the culture. A standard online help is provided only for `English (United States)1033` and `German (Germany)1031`. If the **Base Culture** attribute is set to a language other than `English (United States)` or `German (Germany)`, an online help will not be available unless you explicitly provide one. For more information about translating the online help, see the section Creating a New Language Version of the Online Help
- **Measurement Units**: Select the measurement unit relevant for the printing functionality (margin settings, etc.).
- **Support Data Translation**: Specifies whether instance translation of object data is allowed for the selected culture. Data translation constitutes the translation of the values defined for properties of the type `String` or `Text`defined for objects. The data captured may be translated to any of the languages supported by the enterprise. If the **Support Data Translation** attribute is set to `False`, then the automated and manual data translation functionalities will be disabled and the language code will not be displayed in the language field in all object editors. If the **Support Data Translation** attribute is set to `True` for the culture, data translation will be possible per default for all object classes for predefined protected properties and custom properties of the type `String` or `Text`. However, you can restrict data translation to specified classes and specified custom properties. For more information about configuring the data translation capability, see the section Configuring the Translation of Object Data.

  To change the data translation definition, right-click the culture  and select:

- **Activate Support for Data Translation** to specify that data translation is allowed for the culture. The **Support Data Translation** attribute will be set to `True` of you select this option.
- **Deactivate Support for Data Translation** to specify that data translation is not allowed for the culture. The **Support Data Translation** attribute will be set to `False` of you select this option.
- **Automated Assistant Parameter**: If your enterprise provides translations of the content specified for automated help assistants, the translated content may be displayed when the user interface is rendered in a secondary language. The URL defined for the automated help assistant should include a {CURRENT_LANGUAGE} parameter whereby {CURRENT_LANGUAGE} is replaced with the language of the user interface at the time of the call. For example:
  `http://autohelp.alfabet.com/\{CURRENT_LANGUAGE}/showcase/user_profile/Full_Access.html`

In the **Automated Assistant Parameter** attribute, specify the replacement value for the {CURRENT_LANGUAGE} parameter. This could be, for example, DE or Deutsch or 1031 or DE-de. If no parameter is specified, the four-digit ISO code will be used (for example 1031). For more information about configuring automated help assistants, see the section Understanding the Automated Help Assistant.

3) In the toolbar, click the **Save**  button to save the culture definition.

Permissible Date and Time Formats in Alfabet

Please note that the dates in editor fields are always displayed as a numeric value, regardless of the date format. For example, whereas the date format dddd, dd MMMM yyyy will be displayed as Tuesday, 22 August 2006 in the object profile, it will be displayed as 22/08/2006 in the editor field.

Please consider the following syntax for the specification of date and time formats.

- To specify the 24-hour clock system, use "H" or "HH" for hours.
- To specify the 12-hour clock system, use "h" or "hh". Users will need to specify AM or PM.
- To specify a time format, use "M" for month and "m" for minute.

The following formats can be specified:

Date/Time/Separator Syntax	Date/Time/Separator Output
MM/dd/yyyy	08/22/2006
dddd, dd MMMM yyyy	Tuesday, 22 August 2006
dddd, dd MMMM yyyy HH:mm	Tuesday, 22 August 2006 06:30
dddd, dd MMMM yyyy hh:mm tt	Tuesday, 22 August 2006 06:30 AM
dddd, dd MMMM yyyy H:mm	Tuesday, 22 August 2006 6:30
dddd, dd MMMM yyyy h:mm tt	Tuesday, 22 August 2006 6:30 AM
dddd, dd MMMM yyyy HH:mm:ss	Tuesday, 22 August 2006 06:30:07
MM/dd/yyyy HH:mm	08/22/2006 06:30
MM/dd/yyyy hh:mm tt	08/22/2006 06:30 AM
MM/dd/yyyy H:mm	08/22/2006 6:30
MM/dd/yyyy h:mm tt	08/22/2006 6:30 AM

Date/Time/Separator Syntax	Date/Time/Separator Output
MM/dd/yyyy h:mm tt	08/22/2006 6:30 AM
MM/dd/yyyy h:mm tt	08/22/2006 6:30 AM
MM/dd/yyyy HH:mm:ss	08/22/2006 06:30:07
MMMM dd	August 22
MMMM dd	August 22
yyyy'-'MM'-'dd'T'HH':'mm':'ss.fffffffK	2006-08-22T06:30:07.7199222-04:00
yyyy'-'MM'-'dd'T'HH':'mm':'ss.fffffffK	2006-08-22T06:30:07.7199222-04:00
ddd, dd MMM yyyy HH':'mm':'ss 'GMT'	Tue, 22 Aug 2006 06:30:07 GMT
ddd, dd MMM yyyy HH':'mm':'ss 'GMT'	Tue, 22 Aug 2006 06:30:07 GMT

Date/Time/Separator Syntax	Date/Time/Separator Output
`yyyy MMMM`	`2006 August`
`yyyy MMMM`	`2006 August`

Specifying the Primary Culture for Your Enterprise

As part of the configuration of the Alfabet solution, you must specify which culture is the base culture for the enterprise. The primary culture constitutes the culture code, primary language, and date and time formats specified for the culture. Only one culture can be defined as the primary culture.

Custom strings for configuration objects (such as custom properties, custom editors, configured reports, etc.) must be captured in English, regardless of the primary culture definition. All strings for captions for configuration objects and guide page/guide view content will be displayed in the `Original` column in the **Translation Editor** or XLSX files of the relevant vocabulary.

The primary culture will be displayed when users open the Alfabet user interface upon first login. After the user has accessed Alfabet for the first time, the user can then change the language displayed in the Alfabet user interface via the **Language** button in the upper-right corner of the Alfabet interface. The language used for the user's last session will be automatically displayed when the user opens a new user session.

To define the primary culture that is automatically displayed in the Alfabet user interface when a user first logs in to Alfabet, click the relevant culture below the **Cultures** node and in the attribute window, select `True` in the **Is Primary Culture** attribute. Click the **Save**  button to save the culture definition.

Please consider the following:

- The **Support Data Translation** attribute must be set to `False` for the culture that you want define as the primary culture.
- In order to set a different culture as the primary culture, you must first set the **Is Primary Culture** attribute of the original primary culture to `False` and then set the **Is Primary Culture** attribute for the new primary culture to `True`.

Modifying, Translating and Managing the Vocabularies

A vocabulary is the set of original and translated strings that are implemented in the Alfabet interface. Each vocabulary is associated with a base culture via the locale ID.

The Alfabet interface is available in the following languages:

Language	Locale ID
Arabic (Saudi Arabia)	1025
German (Germany)	1031
English (United States)	1033
French (France)	1036
Portuguese (Brazil)	1046
Polish (Poland)	1045

For technical reasons, the translatable strings are divided into four separate vocabularies which constitute terminology sets based on their source of origin in the software. These are `METAMODEL`, `ITPlan`, `Platform`, `Extensions`, and `GUIDEPAGES`. The vocabularies are displayed as columns in the **Translation Editor**. If you choose to export the vocabularies for translation, each terminology set will be exported as a separate vocabulary file (as either a VOC or XLSX file). The file names include the locale ID of the translated language as well as the name of the specific vocabulary set. For example, the following file syntax would be displayed for the meta-model file containing the English strings and any existing German translations: `AlfaVoc_127_METAMODEL_`<date>`_`<timestamp>.xlsx.

An automated translation that leverages a translation service is available to provide a translation of terms in the standard vocabularies as well as the object data defined by users. For more information, see the section Configuring the Translation of Object Data.

The following explains the content in each of the vocabularies:

- `METAMODEL`: Strings derived from the meta-model. This includes strings for the following:
- Standard configuration objects. These strings are protected strings and are typically already translated by Software AG. They include, for example, the caption of standard object classes, object class properties, page view names and descriptions, toolbar buttons, menu options, and the captions and tooltips available for editor and filter fields. The standard English terminology as well as the translated terms may be changed, if needed.
- Custom configuration objects. These are public strings and may be translated. They include, for example, captions of object class stereotypes and custom properties, the captions and tooltips defined for custom editor and filter fields, the captions of custom object views and object cockpits, the

captions of explorer names in custom selectors, and the text defined in the context of guide views and splash screens. These strings will be added to the vocabulary after the configuration has been saved. Translation to any language other than `English (United States)` must be provided by the customer.

Custom strings for configuration objects (such as custom properties, custom editors, configured reports, etc.) must be captured in English, regardless of the primary culture definition. All strings for captions for configuration objects and guide page/guide view content will be displayed in the `Original` column in the **Translation Editor** or XLSX files of the relevant vocabulary.

- The strings for the following configuration objects require additional configuration steps in order to make the relevant strings available in the `METAMODEL` vocabulary:
- Enumerations. For more information, see the section below Understanding the Configuration Required to Translate Enumerations.
- Object states. For more information, see the section below Understanding the Configuration Required to Translate Object States.
- Release statuses. For more information, see the section below Understanding the Configuration Required to Translate Release Statuses.
- Lifecycle phases. For more information, see the section below Understanding the Configuration Required to Translate Lifecycle Phases.
- Indicators (of type `Text`). For more information, see the section below Understanding the Configuration Required to Translate Semantic Indicators.
- User profiles: The translated user profile name will be displayed in the masthead of the Alfabet user interface as well as in the **Change User Profile** menu in the <Alfabet User Name> menu in the main toolbar. Please note however that the translation of the user profile name will not be displayed in the **User Profiles Administration** and **User Administration** functionalities in the Alfabet user interface as well as the **User Profiles** node in Alfabet Expand.
- Workflows and wizards: The captions, comments, and user messages configured for workflows, workflow steps, wizards, and wizard steps are public strings and may be translated. For more information about the additional step required to translate workflows, see the section Understanding the Configuration Required to Translate Workflows and Wizards.
- HTML in custom editors and object cockpits. For more information, see the section below Translating HTML Defined in Custom Editors and Object Cockpits.
- Configured reports: The caption and description configured for custom reports are public strings and may be translated. For more information about the additional configuration required to translate configured reports, see the section Understanding the Additional Configuration Required to Translate Configured Reports.
- Text templates. For more information, see the section below Translating Text Templates Configured for Email Notifications.
- `ITPlan`: Strings derived from the standard solution code. These strings are protected strings and may be modified, if necessary. Please note that only a subset of strings derived from code-triggered functions are available in the vocabulary and may be translated.
- `Platform`: Strings from the platform code. This includes underlaying functionality and error messages. These strings are protected strings and may be modified, if necessary. Please note that

only a subset of strings derived from code-triggered functions are available in the vocabulary and may be translated.

Some error messages such as those sourced by Microsoft® .NET Framework are not part of the standard translation and will typically be displayed in English regardless of the language selected to display the Alfabet user interface.

- `GUIDEPAGES`: Strings defined in the context of guide page configured by the solution designer. These strings are public strings and may be translated. Please note that the translation of guide pages requires additional configuration steps in order to make the relevant strings available in the vocabulary. For more information, see the section below Translating Guide Pages and Guide Views. For detailed information about the configuration of guide pages, see the reference manual *Designing Guide Pages for Alfabet*.

Please note that the strings specified for guide pages will be extracted to the `GUIDEPAGES` vocabulary and the strings specified for guide views will be extracted to the `METAMODEL` vocabulary.

Custom strings for guide pages and guide views must be captured in English, regardless of the primary culture definition. All strings for captions for configuration objects and guide page/guide view content will be displayed in the `Original` column in the **Translation Editor** or XLSX files of the relevant vocabulary.

Modifying the Original Strings Provided by Software AG

You can modify the standard strings provided for English or a supported secondary language and provide alternative terminology that is relevant for your enterprise. A custom term may be provided for any public or protected string vocabulary, allowing you to redefine terms in the vocabulary to match the specific terminology used in your company. For example, if the English term `software` is used instead of `application` in your enterprise, you can customize all strings in the `Original` vocabulary and replace the term `application` with the word `software`. Likewise, you could modify messages or strings displayed in the user interface in order to customize the information.

The changes to the vocabularies must be saved to the database. If an entry is not made for a string in the custom terminology, the term in the standard `English (United States)` vocabulary will be used. In this way, you only need to modify those terms that deviate from the standard Alfabet terminology. If you change a string, your text will be displayed instead of the original Alfabet term on the Alfabet interface. If you do not modify a term, the original English terminology will be used.

The changes can be made directly in the **Translation Editor** of Alfabet Expand or in an exported XLSX or XML (*VOC) file. In this case, you would export the vocabulary, edit the terminology in the XLSX file, and import the altered file to the Alfabet database. For more information about using the **Translation Editor**, see the section XXXTranslationInCustomEditor. For more information about exporting the vocabulary and translating the strings in an XLSX or XML file, see the section Translating Strings via XLSX files, XML (*VOC), or Simple Text Files.

To define alternative terms in English, you would need to do one of the following:

- Create a new culture with a base culture that references the same language as the culture with the terms you are modifying. For example, to replace the English term `application` with the term `software`, you could create a new culture with a base culture that uses English such as `English (Australia)` or `English (Zimbabwe)`. Other than the **Base Culture** attribute, all other culture attributes should be identical to the standard `English (United States)` culture (with the exception of the **Icon** attribute, which will allow you to specify a custom icon to display for the custom terminology in the Alfabet interface).

- Search for all instances of the term `application` in the new vocabulary and modify the term as needed. Please note that if an entry is not made for a string in the custom terminology, the term in the standard `English (United States)` vocabulary will be used.
- Save the modified vocabulary to the database and review the translated strings in the Alfabet interface.

To create new terms in any supported secondary language, you would need to do one of the following:

- Modify the translated strings directly in the vocabulary for the secondary language (for example, for `German (Germany)`. Any modified terms will be displayed as custom translations in the **Translation Editor**. Save the modified vocabulary to the database and review the translated strings in the Alfabet interface.
- Create a new culture and modify strings with the new terminology. The following steps are required to do this:

- Create a new culture for the language you want to modify. For example, to alter the vocabulary for `German (Germany)`, you could create a new culture for `German (Schweiz)`.
- Export the vocubularies to an XLSX files for the supported secondary language. For example, export the `MetaModel` vocabulary for `German (Germany)`.
- In the Excel file, copy all strings from the `Translation` column to the `Custom Translation` column.
- In the name of the XLSX file, replace the locale ID with the locale ID of the new culture. For the culture `German (Schweiz)`. For example, you want to change the file name the exported `MetaModel` vocabulary for `German (Germany)`, which is `AlfaVoc_1031_METAMODEL` to `AlfaVoc_2055_METAMODEL`.
- Import the modified XLSX file to Alfabet.
- In the **Translation Editor**, check that the new strings are available in the secondary language. Modify the translated strings as needed to.
- Save the modified vocabulary to the database and review the translated strings in the Alfabet interface.

Translation can be performed during runtime of the Alfabet Web Application with an Alfabet Expand instance directly connecting to the Alfabet database with a server alias in parallel to the Alfabet Web Application.

Updates to the translation table require the Web server to be restarted or the meta-model to be reread if the server is running in Design mode (if in the `web.config` file the key attribute "`appmode`" is set to `Design`).

Manually Translating Custom Strings from Your Solution Configuration

The custom strings that your enterprise has created when configuring the class mode may be manually translated for any of the languages supported by Software AG. If only one culture is defined for your enterprise, then the manual data translation functionality will be disabled in the Alfabet user interface. Translations can be created for the custom strings defined for custom editors, custom selectors, custom object views/object cockpits, workflows, custom wizards, configured reports, guide pages/guide views, etc. Most

of the terminology displayed in the Alfabet interface is translated in the vocabularies available with your Alfabet product.

Custom strings for configuration objects (such as custom properties, custom editors, configured reports, etc.) must be captured in English, regardless of the primary culture definition. All strings for captions for configuration objects and guide page/guide view content will be displayed in the `Original` column in the **Translation Editor** or XLSX files of the relevant vocabulary.

The vocabularies can either be translated in the **Translation Editor** in Alfabet Expand or exported and translated XLSX files or XML (*VOC) files. A translated string will be displayed instead of the original Alfabet string in the Alfabet interface. If a translation does not exist for a string, the original English string will be used.

The strings for the following configuration objects are NOT added to the vocabularies and therefore require separate treatment in order to be made available in a secondary language:

- Text templates: Text templates used in the context of the email capability. For more information about providing translated text templates, see the section Translating Text Templates Configured for Email Notifications.
- HTML templates: HTML templates used in the context of workflow and wizard configuration. For more information about providing translated HTML templates, see the section Understanding the Configuration Required to Translate Workflows and Wizards.
- Publications: Publications of data in Microsoft® Word® format. For more information about provided translated publications, see the section Configuring Alfabet Functionalities Implemented in the Solution Environment in the chapter Publishing Data In Microsoft® Word Format.
- Object data: The translation of the **Name** and **Description** properties of Alfabet objects are created and maintained in Alfabet. The translation of the name and description of such objects like applications, components, etc. is made by users in the context of the editors where these objects are edited. For more information about the translation of names and descriptions of Alfabet objects, see the section Configuring the Translation of Object Data.

Updates to the translation table require the Web server to be restarted or the meta-model to be reread if the server is running in Design mode (if in the `web.config` file the key attribute "`appmode`" is set to `Design`).

The following information is available:

- Understanding the Configuration Required to Translate Enumerations
- Understanding the Configuration Required to Translate Object States
- Understanding the Configuration Required to Translate Release Statuses
- Understanding the Configuration Required to Translate Lifecycle Phases
- Understanding the Configuration Required to Translate Semantic Indicators
- Understanding the Configuration Required to Translate Workflows and Wizards
- Updating the Translation of Workflow Templates

Understanding the Configuration Required to Translate Enumerations

An enumerations is a set of preconfigured enumeration items available to users when defining an object class property in Alfabet. An enumeration is associated with a standard or custom property. Each enumeration will have multiple enumerations items which represent the values that can be selected by users to define the custom property. The enumeration items can be translated as needed. For more information about the definition of custom and protected enumerations, see the section Defining Protected and Custom Enumerations section in the chapter Configuring the Class Model

Translation support is available for the preconfigured values available for enumeration items, which can be modified, as well as for the enumeration items created in the context of custom properties. Please note that the **Translatable in Meta-Model Vocabulary** for the custom property that the enumeration is assigned to must be set to `True` so that the strings defined for the enumeration items will be available in the `METAMODEL` vocabulary for translation.

The translated enumeration values will only be displayed on the Alfabet interface if the following requirements are met.

- The **Extract for Translation** attribute for the enumeration must be set to `True` and the **Enable Data Translation** attribute for the custom or protected property that the enumeration is assigned to must also be set for to `True`. This mechanism allows the enumeration to be translated for one object class property of the type `String` and displayed in the original language for another object class property.
- For object profiles: For an enumeration based on a custom or protected property displayed in an object profile, the attribute **Enable Data Translation** must be set to `True` for the property that has been added to the **Attributes** section of the object profile.

- For object cockpits: For an enumeration based on a custom or protected property displayed in an object cockpit, the attribute **Enable Data Translation** must be set to `True` for the Value Control interface control associated with the object class property.
- For configured reports: Instructions must be specified in order to display the translated enumeration values. This is described in detail in the section below Translating Enumerations, Object States, Release Statuses, and Indicator Values in a Configured Report.

Please note that properties of the type `StringArray` cannot be translated.

Translations of strings for enumeration items are NOT used in the standard history tracking information: In the standard history tracking report provided by Software AG, enumerations are not translated. In order to view history tracking information with translated enumerations, you should create a configured report displaying the history tracking information. For more information about configuring history tracking-related configured reports, see Defining Audit Management Related Configured Reports in the chapter Configuring Reports.

Understanding the Configuration Required to Translate Object States

The captions of the standard values available for object states and their hints can be modified by the solution designer in the XML object ***ObjectStateManager***. For more information about the configuration of the values available for object states, see the section Configuring Object State Definitions for Object Classes in the chapter Configuring the Class Model.

Translation support is available for the values defined in the XML element `ObjectStateDef` in the XML object ***ObjectStateManager*** and the strings will be available in the `METAMODEL` vocabulary for translation. However, please note that the translated strings for object state values will only be displayed on the Alfabet interface if the following requirements are met.

- For object profiles: The attribute **Enable Data Translation** must be set to `True` for the `ObjectState` property that has been added to the **Attributes** section of the object profile.
- For object cockpits: The attribute **Enable Data Translation** must be set to `True` for the Value Control interface control associated with the `ObjectState` property.
- For configured reports: Instructions must be specified in order to display the translated enumeration values. This is described in detail in the section below Translating Enumerations, Object States, Release Statuses, and Indicator Values in a Configured Report.

For a small subset of standard selectors used in the context of the editor search fields as well as the **Simple Search** functionality, the translated strings for the values for object state values cannot be entered in the secondary language rendered in the Alfabet interface but must rather be entered in the English original. These search selectors include: `COM_SelectorDef`, `ICTO_SelectorDef`, `ICTO_ICTOV_SelectorDef`. Similarly, the search for object class stereotypes must be entered in English in the following selectors: `DOM_SelectorDef`, `DVC_SelectorDef`, `ICTO_SelectorDef`, `SRVPRD_SelectorDef`, `VMND_SelectorDef`.

Translations of strings for values defined in the XML element `ObjectStateDef` in the XML object ***ObjectStateManager*** are NOT used in the standard history tracking information: In the standard history tracking report provided by Software AG. In order to view history tracking information with translated values for `ObjectState` properties, you should create a configured report

displaying the history tracking information. For more information about configuring history tracking-related configured reports, see Defining Audit Management Related Configured Reports in the chapter Configuring Reports.

Understanding the Configuration Required to Translate Release Statuses

Translation support is available for the values configured for release statuses. The captions and the hints specified for release statuses can be configured by the solution designer in the XML object ***ReleaseStatusDefs***. For more information about the configuration of release statuses, see the section Configuring Release Status Definitions for Object Classes in the chapter Configuring the Class Model.

Translation support is available for the values defined in the XML element `ReleaseStatusDef` in the XML object ***ReleaseStatusDefs*** and the strings will be available in the `METAMODEL` vocabulary for translation. However, please note that the translated strings for release status values will only be displayed on the Alfabet interface if the following requirements are met.

- For object profiles: The attribute **Enable Data Translation** must be set to `True` for the `Status` property that has been added to the **Attributes** section of the object profile.
- For object cockpits: The attribute **Enable Data Translation** must be set to `True` for the Value Control interface control associated with the `Status` property.
- For configured reports: Instructions must be specified in order to display the translated enumeration values. This is described in detail in the section below Translating Enumerations, Object States, Release Statuses, and Indicator Values in a Configured Report.

For a small subset of standard selectors used in the context of the editor search fields as well as the **Simple Search** functionality, the translated strings for the values for release status values cannot be entered in the secondary language rendered in the Alfabet interface but must rather be entered in the English original. These search selectors include: `COM_SelectorDef`, `ICTO_SelectorDef`, `ICTO_ICTOV_SelectorDef`. Similarly, the search for object class stereotypes must be entered in English in the following selectors: `DOM_SelectorDef`, `DVC_SelectorDef`, `ICTO_SelectorDef`, `SRVPRD_SelectorDef`, `VMND_SelectorDef`.

Translations of strings for values defined in the XML element `ReleaseStatusDef` in the XML object ***ReleaseStatusDefs*** are NOT used in the standard history tracking information: In the standard history tracking report provided by Software AG. In order to view history tracking information with translated values for `Status` properties, you should create a configured report displaying the history tracking information. For more information about configuring history tracking-related configured reports, see Defining Audit Management Related Configured Reports in the chapter Configuring Reports.

Understanding the Configuration Required to Translate Lifecycle Phases

Translation support is available for the preconfigured values available for lifecycle definitions. The captions and the hints specified for lifecycle phases can be configured by the solution designer in the XML object ***ObjectLifeCycleManager***. For more information about the configuration of object lifecycles, see the section Configuring Lifecycle Definitions for Object Classes in the chapter Configuring the Class Model.

Translation support is available for the values defined in the XML element `ObjectLifecycle` in the XML object ***ObjectLifeCycleManager*** and the strings will be available in the `METAMODEL` vocabulary for translation. However, please note that the translated strings for lifecycle phases will only be displayed on the Alfabet interface if the following requirements are met.

- For object profiles: The attribute **Enable Data Translation** must be set to `True` for the relevant `TimeStatus` property that has been added to the **Attributes** section of the object profile.
- For object cockpits: The attribute **Enable Data Translation** must be set to `True` for the Value Control interface control associated with the relevant `TimeStatus` property.
- For configured reports: Instructions must be specified in order to display the translated enumeration values. This is described in detail in the section below Translating Enumerations, Object States, Release Statuses, and Indicator Values in a Configured Report.

Translations of strings for values defined in the XML element `ObjectLifecycle` in the XML object ***ObjectStateManager*** are NOT used in the standard history tracking information: In the standard history tracking report provided by Software AG. In order to view history tracking information with translated values for `TimeStatus` properties, you should create a configured report displaying the history tracking information. For more information about configuring history tracking-related configured reports, see Defining Audit Management Related Configured Reports in the chapter Configuring Reports.

Understanding the Configuration Required to Translate Semantic Indicators

An indicator is the value defined for an indicator type in the context of an object in the IT landscape. In some cases, your company may configure a range of permissible indicator values that may be defined for each indicator type. These are semantic indicators that users will manually enter values for. These values are configured in the **Range** property in the **Indicator Type** editor.

All valid values for manually-entered indicators for an indicator type must be written in accordance with the following convention: <NumericalValue>-<SemanticValue> (for example, `1-low, 2-medium, 3-high`). For more information about the configuration of a range of indicators for an indicator type, see the section *Configuring Evaluations, Prioritization Schemes, and Portfolios* in the reference manual *Configuring Evaluation and Reference Data in Alfabet*.

Translation support is available for the preconfigured values available for the semantic values configured for the **Range** property for indicator types and the strings will be available in the `METAMODEL` vocabulary for translation. The text specified for the semantic indicators and defined in the **Range** property for an indicator type will be available in the `METAMODEL` vocabulary for translation. Please note the following:

- The translation of the range values may not exceed 128 characters.
- The numerical value and the hyphen are not added to the vocabulary.
- If icons are specified to visualize the range values for an indicator type, the captions of the icons will be added to the vocabulary and can be translated.

However, please note that the translated strings for semantic indicators will only be displayed on the Alfabet interface if the following requirements are met.

- For object profiles: The attribute **Enable Data Translation** must be set to `True` for the `IndicatorType` property that has been added to the **Attributes** section of the object profile.

- For object cockpits: The attribute **Enable Data Translation** must be set to `True` for the Value Control interface control associated with the `IndicatorType` property.
- For configured reports: Instructions must be specified in order to display the translated enumeration values. This is described in detail in the section below Translating Enumerations, Object States, Release Statuses, and Indicator Values in a Configured Report.

Translations of strings for indicators are NOT used in the standard history tracking information: In the standard history tracking report provided by Software AG, enumerations are not translated. In order to view history tracking information with translated indicators, you should create a configured report displaying the history tracking information. For more information about configuring history tracking-related configured reports, see Defining Audit Management Related Configured Reports in the chapter Configuring Reports.

Understanding the Configuration Required to Translate Workflows and Wizards

The captions, descriptions, technical comments, and user messages configured for workflows, workflow steps, workflow step actions, and pre- and post-conditions can be made available in the vocabularies and translated to a secondary language for the user community. In the case of workflows, an explicit update of the strings associated with workflow templates must be carried out in order to update the relevant strings to the vocabulary.

If HTML templates are configured for either workflows or wizards, these well not be added to the vocabulary but must be explicitly translated in the context of the HTML template.

The following information is available:

- Updating the Translation of Workflow Templates
- Translating HTML Used in Workflows and Wizards

Updating the Translation of Workflow Templates

Captions, descriptions, technical comments, and user messages configured for workflows, workflow steps, workflow step actions, and pre- and post-conditions can be translated to a secondary language for the user community. In the case of workflows, an explicit update of the strings associated with workflow templates must be carried out regardless of the value of the **Workflow State** attribute for the workflow template.

To update the translated strings available in the vocabularies for all workflow templates, click **Globalization** > **Update Workflow Translation** in the menu bar of Alfabet Expand. A message will be displayed stating that the translated strings available for workflow templates, workflow steps, workflow step actions, and pre- and post-conditions have been updated for all workflow templates.

It is also possible to update individual workflow templates for which the **Workflow State** attribute of the workflow template is set to `Active`. In this case, right-click the workflow template and select **Update Translation**. A message will be displayed stating that the translated strings available for the selected workflow template and its workflow steps, workflow step actions, and pre- and post-conditions have been updated.

Please note that the workflow step states (`Confirmed`, `Pending`, `Running`, `Finished`, etc.) cannot be translated.

Translating HTML Used in Workflows and Wizards

Configurable HTML templates based on XHTML using HTML5 standards may be implemented in the context of workflows. The HTML templates contain basic elements to capture information about a workflow step and are used to render the specified data in the **Workflow Activities Explorer** functionality (`WFS_Explorer`) as well as in custom explorers configured for workflow activities. For more information about the configuration of the **Workflow Activities Explorer** functionality, see the section Specifying the Customized Workflow Activities Explorer (WFS_Explorer) or a Custom Explorer in the chapter Configuring Workflows.

In the case of wizards, HTML text based on XHTML using HTML5 standards may be used to display information in the header of a wizard step. The HTML may contain basic elements to capture information about the wizard step as well as the object targeted by the wizard step and specify the layout and visualization of the data. For more information about the configuration of the header for a wizard step, see the section Configuring the Header Text of a Wizard Step in the chapter Configuring Wizards.

If the text defined in the HTML implemented for workflows and wizards is to be translated, you must provide the translation directly in the HTML specification.

For example:

```
<!DOCTYPE HTML>
<xhtml>
    <culture_1031 >
        <html>
        ..
        </html>
    <culture_1031>
    <culture_1033>
        <html>
        ..
        </html>
    </culture_1033>
</xhtml>
```

Please note the following:

- The element `<culture_xxx>` must be specified as a child element of the root element `<xhtml>`, whereby the `_XXX` specifies the Alfabet locale ID.
- A element `<culture_xxx>` should be created for each language for which a translation should be available.

- Each <culture_xxx> contains the <html> element with the HTML specification in the relevant language.

Translating HTML Defined in Custom Editors and Object Cockpits

An HTML Control interface element can also be added to a custom editor to display text with HTML formatting (font and color). The code must start with an <html> tag and end with </html>. The definition of <head> and <body> specification is optional. The HTML code can include CSS style definitions and links to external URLs. The inclusion of images is not supported.

If multiple languages are used in the Alfabet interface, a language version must be defined directly in the HTML defined in HTML control of the custom editors with an element <Culture_xxx> whereby the_XXX specifies the Alfabet locale ID. No root element is required. Each <culture_xxx> contains the <html> element with the HTML specification in the relevant language. The translated text can be captured in the relevant locale ID element <culture_xxx>.

Understanding the Additional Configuration Required to Translate Configured Reports

If your enterprise requires the Alfabet interface to be displayed in any of the secondary supported languages, then you must explicitly ensure that the data displayed in configured reports is also translated to the relevant language. The following must be carried out in order to translate the content of a configured report:

- For each report configured in Alfabet Expand, the **Caption** and **Description** attributes will be displayed in the Alfabet interface. These attributes can be translated as described below in the section Translating the Caption and Description of a Configured Report.
- For relevant configured reports configured in Alfabet Expand, the column headers of tabular reports are created based on either the alias definitions in the Show properties of the Alfabet query, the SELECT clause of the native SQL query, or the instructions defined for the query. The column headers can be translated as described in the section Translating Column Headers or Captions of a Configured Report.
- String values in a graphic report that have been defined directly in an attribute of the report assistant are usually added automatically to the vocabulary files. This includes, for example, the captions for lanes in lane reports, the names of color rules and indicator rules that are used as legend headers, static text definitions in widget reports, or the graphic title, X-axis title, and Y-axis title of business chart reports or portfolio reports. For gauge and map chart reports, this also includes the captions defined for color range members. For general information about vocabulary translation, see Modifying, Translating and Managing the Vocabularies.
- Text defined for the cell tooltip in the LinkAssignment_Edit instruction as well as text defined as legend text in the Alfabet query language instructions ColorAssignment, PictureAssignment, RowColorAssignment, FontStyleAssignment, FontStyleColorAssignment are added automatically to the vocabulary files. For general information about vocabulary translation, see Modifying, Translating and Managing the Vocabularies.
- In the case of configured portfolio, lane, and grid reports, the graphic title, X-axis title, and Y-axis will not be added automatically to the vocabulary files. Texts provided for the calculation of a total value for pie charts will also not be added automatically to vocabulary files. These values can be translated as described in the section Translating Column Headers or Captions of a Configured Report.

Please note that the labels displayed in configured portfolio charts and gauge reports and the labels for enterprise milestones in configured Gantt chart reports cannot be translated.

If configured reports are translated to Arabic, you should be aware that the text is right-aligned instead of left-aligned in user interface elements. For example, for the display of a **Caption** defined for a **Lane** in a lane report, you will see the text above the lanes instead of above the object boxes because the space for the caption spans both object boxes and lanes. To display a caption above the object boxes, you must define the caption in the **Caption** attribute of the **Node** element below the **Lane** element.

If the Alfabet user interface is rendered in Arabic language, the order of columns and display of graphic elements in graphic reports is changed to right to left instead of left to right, as for all other supported languages. Only configured reports based on the template `MatrixMapReport` that have the subtype `Diagram` and Pivot Grids rendered with the embedded DevExpress® component are still displayed left to right.

- For Alfabet objects displayed in a configured report, the translation of relevant object properties is read from the database tables. The following object class properties are translatable and can be displayed in a secondary language:

- Predefined protected properties such as the object's **Name** and **Description** properties as well as custom properties of the type `String` and `Text`. These properties will be displayed in the target language if the **Support Data Translation** attribute of the relevant culture is set to `True`, and a translation has been made in the relevant object class editor in the Alfabet user interface. The translated values for object data will be displayed automatically in configured reports based on Alfabet query language. For native SQL queries, however, a special code triggering the translation must be added to native SQL queries in order to enable the display of translation values for object data. For more information, see Displaying Translated Object Data In the Current Language of the User Interface in the chapter Defining Queries. For more information about object data translation, see the section Configuring the Translation of Object Data.

- The caption of the object class and object class stereotype. These captions can be added to a configured report via instructions. If this is the case, the captions of the object class and object class stereotype can be displayed in a target language if they are translated in the vocabularies available in Alfabet Expand. For general information about vocabulary translation, see Configuring the Translation of Object Data.

- Values defined for object states, release statuses, indicator values, enterprise releases, project milestones, and enumerations. These values can be displayed in a target language if the following applies:

- The **Enable Data Translation** attribute of the relevant object class property (properties of the type `String` or `Text`) is set to `Manual` or `ManualAndAutomated`.

- Translations are provided in the vocabularies available in Alfabet Expand. For more information about vocabulary translation, see Configuring the Translation of Object Data.

- The values are not automatically displayed translated in configured reports. An instruction triggering the translation must be added to queries to enable the display of translation values. For more information, see Translating Enumerations, Object States, Release Statuses, and Indicator Values in a Configured Report.

Status values that are editable in the **Report** editor in the **Reports Administration** functionality available in the Alfabet interface is neither a release status, object state, nor based on an enumeration and therefore cannot be translated in the **Report** editor.

Translating the Caption and Description of a Configured Report

The **Caption** and **Description** attributes will be displayed in the Alfabet interface for each report configured in Alfabet Expand. These attributes can be translated to the languages supported by your enterprise.

Once the **Caption** and **Description** attributes have been specified for a configured report, they will be automatically added to the vocabularies available in Alfabet Expand. Once they are available in the vocabularies, they can be translated like any other string in the **Translation Editor** or exported to a Microsoft Excel file and translated there. For more information about this process, see the section Modifying, Translating and Managing the Vocabularies.

For technical reasons, the translation of report captions and descriptions is coupled with the mechanisms of object data translation. Therefore, the translation provided via the vocabularies is only displayed in the Alfabet interface if the following applies:

- The **Support Data Translation** attribute must be set to `True` for the respective culture.
- The translation must be updated in the data translation columns of the database table of the object class `Report`. To write the translated **Caption** and **Description** attributes to the database table of the object class `Report`:
  1) Set the **Report State** attribute for the configured report to `Plan`.
  2) Right-click the configured report and select **Update Translation**.

     To batch update the translation of multiple configured reports, right-click the **Reports** node and select **Update Translation**. The captions and descriptions for all configured reports for which the **Report State** attribute is set to **Plan** will be updated.

  3) Set the **Report State** attribute for the configured report to `Active`.

Translating Enumerations, Object States, Release Statuses, and Indicator Values in a Configured Report

Configured reports require the specification of instructions to display the translated values. Two new Alfabet instructions are available that trigger the display of translated values for indicator ranges, enumerations, object states, and status definition values:

- To display enumeration, object state, and release status values in the translated language, the following Alfabet instruction must be added to the query. The `ColumnName` is the name of the column containing the information that shall be translated:

  ```
  TranslateEnums("ColumnName,ColumnName,..");
  ```

- To display indicator range values in the translated language, the following Alfabet instruction must be added to the query. The `ColumnName` is the name of the column containing the information that shall be translated:

```
TranslateIndicators("ColumnName,ColumnName,..");
```

For detailed information about the definition of the Alfabet instructions see Displaying Translated Values of Enumerations, Object States, Statuses, Milestones and Indicators in Configured Reports in the section Using Instructions to Format the Results of an Alfabet or Native SQL Query.

Translating Column Headers or Captions of a Configured Report

The definition of column header or graphic report elements in a native SQL query or Alfabet query is typically a complex process. This is the case, for example, for a native SQL query containing a `WITH` statement or if instructions are used for renaming and restructuring the results of the query. In such cases, it is not possible to automatically scan the query definitions for strings that need to be translated.

Therefore, if you want to translate column headers, you must write the column header strings in the XML object ***VocXML***. The strings defined in the XML object ***VocXML*** are automatically added to the meta-model section of the vocabularies and can be translated to a defined target language as described in the section Modifying, Translating and Managing the Vocabularies.

Strings that are defined directly in report assistants such as the caption of lane reports or strings that are explicit in the query definition such as column headers defined in `SetColumnShowName` instructions are automatically added to the translation tables. You can check the vocabularies prior to adding strings to the XML object ***VocXML*** to evaluate which strings have already been added automatically to the vocabulary.

To add column headers to the translation table of the Alfabet vocabularies:

1) In the **Presentation** tab of Alfabet Expand, expand the **XML Objects** node and double click the XML object ***VocXML***. The XML object ***VocXML*** opens in the center pane. The editor automatically displays the root XML element `VocXml` of the XML object.
2) For each column header, enter a child element `Entry` to the `VocXml` root element. In the `Entry` element, write the string of the column header in the original language.

Alfabet vocabularies are string-based. Therefore, if two configured report have the same column header, you must only add the string once to the XML object t ***VocXML***. If the header column string is identical to a string that is used somewhere else in the configuration of the Alfabet meta-model (for example, if the header column is identical to the caption of an object class property), the string will already exist in the vocabulary and does not need to be entered in the XML object t ***VocXML***. If you enter a duplicate string in the XML object ***VocXML*** it will be ignored.

3) In the toolbar, click the **Save**  button to save your changes.

For example, a configured report is based on the following native SQL query:

```
SELECT proj.REFSTR, proj.NAME AS 'Project Name',proj.STEREOTYPE
FROM PROJECT proj
```

The query is combined with the following Alfabet instructions:

```
InsertColumn("1","StereotypeCaption");
SetColumnShowName("StereotypeCaption","Project Stereotype");
```

```
SetStereotypeCaption("REFSTR","STEREOTYPE", "StereotypeCaption");
RemoveColumns("STEREOTYPE");
```

The resulting configured report will have two column headers:

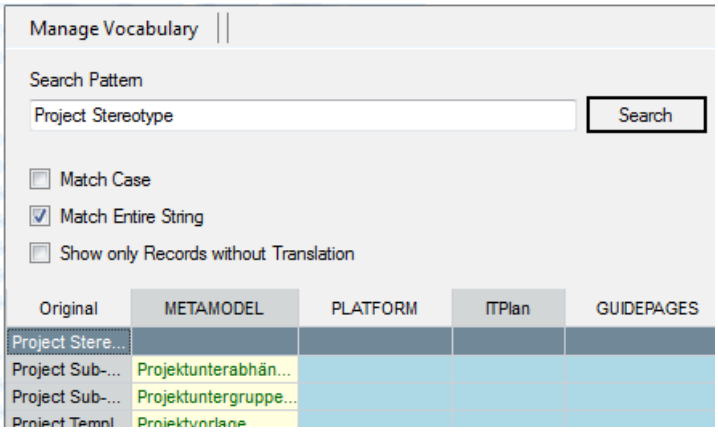
- "Project Name", derived from the alias definition in the `SELECT` clause of the native SQL query
- "Project Stereotype" defined via the `SetColumnShowName` instruction.

	Project Name	Project Stereotype
1	Consolidate Trading Applications	Program
2	Retire GL Applications	Project
3	Upgrade GenLManager	Project
4	Reshape Core Trading Applications	Project
5	Enhance TradeNet	Project
6	Implement Unified Trade Solution	Project
7	UTS phase 1	Project Step
8	UTS phase 2	Project Step
9	UTS phase 3	Project Step
10	Streamline CRM Applications	Program
11	Migrate CRM Opti Retail to CRM CSS	Project
12	Integrate CRM with SAP	Project
13	Retire GL Applications Solution	Project

To translate the headers of the configured report, the two definitions must be written in the XML object ***VocXML***:

```
<VocXml>
    <Entry>Project Name</Entry>
    <Entry>Project Stereotype</Entry>
</VocXml>
```

The terms are then translated to the target language (in this case, German) in the **Translation Editor** of Alfabet Expand:



The translations will be displayed if German is selected as the base culture for th---e culture displayed in the Alfabet interface.

	Projektname	Projekt-Stereotyp
1	Consolidate Trading Applications	Programm
2	Retire GL Applications	Projekt
3	Upgrade GenLManager	Projekt
4	Reshape Core Trading Applications	Projekt
5	Enhance TradeNet	Projekt
6	Implement Unified Trade Solution	Projekt
7	UTS phase 1	Projektschritt
8	UTS phase 2	Projektschritt

Please note: You can see from the example that the content of the configured report is also only partially translated. The project names are displayed in English because data translation has not yet been activated. The stereotype captions are automatically added to the vocabulary and have been translated. Therefore, the translated values are displayed in the configured report. For more information about data translation, see the section Configuring the Translation of Object Data.

Translating Text Templates Configured for Email Notifications

A text template is the predefined text in an email that is automatically generated as the result of an action triggered by a user. The text template defines the email text in English, the relevant references to objects and object class properties in Alfabet, and hyperlinks to the relevant objects in Alfabet.

The text defined in a text template will not be added to the vocabulary but must be explicitly translated in the context of the text template. For this purpose, locale text templates can be created in order to translate the content of the text template to the secondary languages implemented in your solution interface. It is possible to create one or more locale text templates for each text template implemented in the enterprise. In other words, each text template required by the user community can be translated to all non-English languages that you will use in the Alfabet interface. The translation of the text template occurs directly in the locale text template configuration object.

The language displayed for a user's email notifications is specified by a user administrator in the **Email Notification Language** attribute for the relevant user in the **User Administration** functionality accessible via the `Admin` user profile. For more information, see the section *Defining and Managing Users* in the reference manual *User and Solution Administration*.

To create and translate a locale text template:

1) Go to the **Presentation** tab and expand the **Text Templates** node. Expand the relevant text template folder.
2) Right-click the text template that you want to create a language version for and select **Create Locale Text**. You will see a copy of the text template appear in the explorer tree below the original English-language text template.

   The locale text template must be stored in the appropriate folder with its parent text template. For example, all text templates for workflows must be stored in the `WF` folder, all text templates for consistency monitors must be stored in the `M_CON` folder, etc.

3) Click the new locale text template to open the attribute window and define the following attributes:

- **Locale Name**: Select the base culture specified in the culture that this local text template is translated for.
- **Text**: Edit the text of the email message as you would for any protected text template. Please note the following:
- The text displayed in the templates can be translated, as needed.
- Predefined variables as well as configurable object variables can be moved via copy and paste within a text template.
- The expression in curly brackets `{XXX}` in predefined variables may not be edited.
- For detailed information about specifying a text template, see the section *Editing a Protected Text Template*.

4) In the toolbar, click the **Save**  button to save your changes.

Translating Guide Pages and Guide Views

Guide page projects allow an enterprise to configure start pages with links and information for the enterprise's users in order to efficiently guide them to specific functionalities in the Alfabet interface. Both guide pages and guide views are HTML files that are created in the Guide Pages Designer. Once they have been configured, the guide page project must be uploaded to the Alfabet database. Once the guide pages and guide views have been uploaded to the Alfabet database, their strings will be available in the English original vocabularies and can be translated to the secondary languages implemented in your company.

Please note that the strings specified for guide pages will be extracted to the `GUIDEPAGES` vocabulary and the strings specified for guide views will be extracted to the `METAMODEL` vocabulary.

Custom strings for guide pages and guide views must be captured in English, regardless of the primary culture definition. All strings for captions for configuration objects and guide page/guide view content will be displayed in the `Original` column in the **Translation Editor** or XLSX files of the relevant vocabulary.

The translation of the guide pages can be carried out in the **Translation Editor** or in an XLSX file as described in the section Translating Strings via XLSX files, XML (*VOC), or Simple Text Files. For more information about creating and uploading guide page projects, see the reference manual *Designing Guide Pages for Alfabet*.

To delete all translated strings for all guide page vocabularies, click **Globalization** > **Delete Guide Pages Translation** in the menu bar of Alfabet Expand and confirm the message box.

Translating Strings via the Translation Editor

A **Translation Editor** is available in Alfabet Expand in which you can translate your custom strings or modify the standard strings that are displayed in the Alfabet interface. Before you can begin to translate, the culture must already be created, and the base culture must be specified with the correct locale. For more information about creating a culture setting, see the section Specifying the Cultures Relevant to Your Enterprise.

Alternative to modifying the strings in the context of the **Translation Editor**, the vocabulary file (.voc) for a translated language can be exported to an XML file or to a Microsoft Excel format. In this way, you could edit the vocabularies in the translation tools used in your company.

Translation can be performed during runtime of the Alfabet Web Application with an Alfabet Expand instance directly connecting to the Alfabet database with a server alias in parallel to the Alfabet Web Application.

All terminology displayed in the **Translation Editor** can be translated for the various cultures implemented by your enterprise. Translation and modification of the strings is done on a string-by-string basis. You can modify the strings in the vocabularies available for any of the supported languages.

The translation of languages not provided with the Alfabet product is not supported. The initial translation for a specific language must be provided by Software AG. Custom translations can only be created for existing vocabularies.

Extreme caution should be used when translating vocabularies: Please note the following important issues regarding the Alfabet vocabularies:

- Strings may not be longer than 600 characters. If a text is longer than 600 characters, it will NOT be stored in the Alfabet database.
- Do NOT edit or translate the following when found in the vocabularies:
- Variables enclosed in curly brackets: {ExampleVariable}. The text in curly brackets will be automatically generated by the system. Variables MUST remain untranslated and in curly brackets {..} so that they can be read by the software. Changing curly brackets or the variable inside the curly brackets may cause an error in the system.
- Compound words that have no empty spaces. For example: `CentraSiteManager`, `SearchManager`, `SolutionOptions`.
- Words written in all capital letters. For example: `WHERE` or `SELECT`.
- Terms enclosed in single quotes (‘arg’, property of the type ‘String’)
- Special characters used in the source language such as square brackets [ ], angle brackets < >, ampersand &, and backslash \ . For example, "`Application|Component`" can be customized to "`Program|Software`" but not to "`Program` and `Software`" and "save as *.html" can be customized to "format *.html" but not to "save as html file".
- If configuration objects created by your enterprise are deleted, their translations will NOT be automatically deleted from the vocabularies. However, during the meta-model update process, any translation entries that cannot be matched to an original will be deleted from the Alfabet database. An XLSX file will be generated during the meta-model update process that lists all orphaned translations that have been removed from the Alfabet database. Solution administrators should analyze this list to determine whether any of the orphaned translations require the creation of new (custom) translations.

To translate strings in the **Translation Editor**:

1) In the menu bar, click **Globalization** > **Edit Translation**. The **Translation Editor** opens.
2) A message is displayed asking you whether a scan for new originals shall be executed. If you click **Yes**, new original strings that are available due to changes to the solution configuration will be

scanned, updated in the `ALFA_SYS_VOCABULARY` database table, and available for translation. The **Translation Editor** will open once the scan has been completed. If you click **No**, the **Translation Editor** will open immediately but the original strings will not be updated.

3) In the **Translation Editor** toolbar, click **Manage Vocabulary** > **Open** and select the culture for which you want to translate the vocabularies. The target language for translation is displayed in the header of the **Translation Editor**. You will see the following in the **Translation Editor**:

- The `Original` column displays the English terms.
- For technical reasons, the translatable strings are divided into four separate vocabularies which constitute terminology sets based on their source of origin in the software. These are `METAMODEL`, `ITPlan`, `Platform`, `Extensions`, and `GUIDEPAGES`. The following columns are displayed:
- `METAMODEL`: Strings derived from the meta-model. This includes the following:
    - Protected strings from the standard configuration objects.
    - Custom strings resulting from the customization of the meta-model via Alfabet Expand.
- `ITPlan`: Strings derived from the standard solution code.
- `Platform`: Strings from the platform code.
- `Extensions`: Strings derived from the extensions code.
- `GUIDEPAGES`: Strings from the guide pages designed by the solution designer with the tool Guide Pages Designer provided by Software AG.

For a more detailed description of the content of the terminology sets, see the section Manually Translating Custom Strings from Your Solution Configuration.

- A legend is displayed at the bottom of the **Translation Editor** explaining the color-coding for the standard translation and the custom translation. Please note the following:
- White cells indicate that the `Original` string can be translated for the corresponding vocabulary. In some cases, the same `Original` string may be available in multiple vocabularies (`METAMODEL`, `ITPlan`, `Platform`, `Extensions`, and `GUIDEPAGES`.). Each entry may have a different translated string. Typically, translations will be available with the standard Alfabet product. The standard translation can be modified but not deleted, but it should not be overwritten unless there is an explicit reason. If you attempt to delete these terms, they will remain in the Alfabet database and will continue to be available in the **Translation Editor**. The standard translation will be reinstantiated if a custom string that replaced it is deleted.
- Yellow cells indicate that the string is a custom string. The cell will only be colored yellow if the string has been saved to the database. The custom translations defined for configuration objects that have been created for your solution (custom properties, custom editors, etc) can be modified or deleted from the vocabularies.
- Blue cells indicate that no translation is required for the `Original` string for the corresponding vocabulary.
- To sort the terminology alphabetically in each column, click the column caption. The sort can be either a descending or ascending alphabetical order. Undefined terminology is displayed before terms starting with "A". To change the sort order, re-click the column caption. The translatable term will be displayed in a white cell in the column displaying the terminology set from which it originates.

- To find a specific term, enter the complete term in the **Search Pattern** field. You can use the star symbol * as a wildcard. Define the following filters as needed and click the **Search** button:
- **Match Case**: Select the checkbox if only strings with matching capitalization should be displayed
- **Match Entire String**: Select the checkbox if only strings containing the entire string should be displayed.
- **Show Only Strings with No Translation**: Select the checkbox to display all strings that have no translation defined. All strings with empty cells in the vocabulary columns will be displayed.
- **Show Only Strings with Automated Translation**: Select the checkbox to display all strings that have a translation that has been generated via the automated translation capability. These are the strings that are imported when the **Get Low-Confidence Translations** functionality is executed. For more information, see the section Translating Custom Strings via the Automated Translation Capability.
- The first entry matching the search criteria will be highlighted. Click the **Search** button to highlight the next match.

4) Translate the `Original` strings to the targeted culture, as needed. To translate a term, click the relevant cell displaying either a standard translation or custom translation and enter your translation of the term. Please note that if you edit a translation in a field in the **Translation Editor**, it will not be automatically saved. You must move the focus from the last edited field in the **Translation Editor** to any other field and then save the vocabulary.
5) After you have translated all necessary terms, click **Manage Vocabulary** > **Save to Database** to save the translation.
6) Click the **Close** button to close the **Translation Editor**.

Updates to the translation table require the Web server to be restarted or the meta-model to be reread if the server is running in Design mode (if in the `web.config` file the key attribute "`appmode`" is set to `Design`).

Translating Strings via XLSX files, XML (*VOC), or Simple Text Files

You might want to define your terminology in XLSX or XML (*VOC) files rather than directly in the **Translation Editor**. (*VOC files are Alfabet proprietary files in XML language used for the explicit purpose of importing and exporting vocabulary strings.) This would allow you, for example, to translate the terminology in the translation tools used by your company. In this case, you can export the vocabularies for a selected target language as either XLSX or XML (*VOC) files, translate the strings to the target language, and import the edited XLSX or XML (*VOC) files to Alfabet. A separate file will be generated for each terminology set (`METAMODEL`, `ITPlan`, and `Platform`, and `GUIDEPAGES`).

As an alternative to manually translating the empty strings in the vocabularies, you can configure a translation service such as Google Translate®, Amazon Translate®, or DeepL® Translator to automatically translate the empty strings. This is described in more detail in the section Translating Custom Strings via the Automated Translation Capability.

All terminology displayed in the **Translation Editor** can be translated for the various culture settings implemented by your enterprise. Translation and modification of terminology is done on a term-by-term basis. You can modify the terms in the vocabularies available for any of the supported languages.

Extreme caution should be used when translating vocabularies: Please note the following important issues regarding the Alfabet vocabularies:

- Strings may not be longer than 600 characters. If a text is longer than 600 characters, it will NOT be stored in the Alfabet database.
- Do NOT edit or translate the following when found in the vocabularies:
  - Variables enclosed in curly brackets: {ExampleVariable}. The text in curly brackets will be automatically generated by the system. Variables MUST remain untranslated and in curly brackets {..} so that they can be read by the software. Changing curly brackets or the variable inside the curly brackets may cause an error in the system.
  - Compound words that have no empty spaces. For example: `CentraSiteManager`, `SearchManager`, `SolutionOptions`.
  - Words written in all capital letters. For example: `WHERE` or `SELECT`.
  - Terms enclosed in single quotes ('arg', property of the type 'String')
  - Special characters used in the source language such as square brackets [ ], angle brackets < >, ampersand &, and backslash \ . For example, "`Application|Component`" can be customized to "`Program|Software`" but not to "`Program` and `Software`" and "save as *.html" can be customized to "format *.html" but not to "save as html file".
- If configuration objects created by your enterprise are deleted, their translations will NOT be automatically deleted from the vocabularies. However, during the meta-model update process, any translation entries that cannot be matched to an original will be deleted from the Alfabet database. An XLSX file will be generated during the meta-model update process that lists all orphaned translations that have been removed from the Alfabet database. Solution administrators should analyze this list to determine whether any of the orphaned translations require the creation of new (custom) translations.

The following information is available:

- Exporting the Vocabulary Files
- Translating the Vocabulary Files
- Importing the Vocabulary Files

Exporting the Vocabulary Files

To export Alfabet vocabularies to XLSX or XML (*VOC) files:

1) In the menu bar, click **Globalization** > **Open Vocabulary Manager**.

   To import and export simple text files displaying the unique identifier and the string (ID=Value), click **Globalization** > **Export Vocabularies with Unique Identifiers**. Once the strings have been modified, you can import them via **Globalization** > **Import Vocabularies with Unique Identifiers**.

2) A message is displayed asking you whether a scan for new originals shall be executed. If you click **Yes**, new original strings that are available due to changes to the solution configuration will be

scanned, updated in the `ALFA_SYS_VOCABULARY` database table, and available for translation. The **Vocabulary Manager** will open once the scan has been completed. If you click **No**, the **Vocabulary Manager** will open immediately but the original strings will not be updated.

3) In the **Vocabulary Manager**, select the source language and terminology set that you want to customize. You can select multiple terminology sets by holding down the SHIFT key while selecting.

All existing vocabularies are listed in the **Vocabulary Manager**. The **Source** column displays where the vocabulary string is stored. A `METAMODEL`, `ITPlan`, `Platform`, `Extensions`, and `GUIDEPAGES`. file is typically available for each culture supported by Software AG. The entry `Original` in the **Vocabulary** column contains the `English (United States)` vocabularies with no translated strings.

4) In the toolbar, click the **Export Vocabularies**  button. The **Translation Export** dialog box opens.

For more information about the **Get Low-Confidence Translations** menu, see the section Translating Custom Strings via the Automated Translation Capability.

5) Click the **Browse** button next to the **Target Folder** field and select the target directory for the export.

6) In the **Export Type** drop-down list, select `Excel` to export the selected terminology sets to XLSX files or select `Voc` to export the selected terminology sets to XML files.

The XML files will have the extension VOC.

7) Click **OK** to start the export of terminology. A message will be displayed indicating how many files were created. Click **OK** to confirm the message.

Translating the Vocabulary Files

You can translate the vocabulary in XLSX or XML (*VOC) files which are Alfabet proprietary files in XML language used for the explicit purpose of importing and exporting vocabulary strings. A separate file will be generated for each terminology set (`METAMODEL`, `ITPlan`, and `Platform`, and `GUIDEPAGES`).

Extreme caution should be used when translating vocabularies: Please note the following important issues regarding the Alfabet vocabularies:

- Strings may not be longer than 600 characters. If a text is longer than 600 characters, it will NOT be stored in the Alfabet database.
- Do NOT edit or translate the following when found in the vocabularies:
- Variables enclosed in curly brackets: {ExampleVariable}. The text in curly brackets will be automatically generated by the system. Variables MUST remain untranslated and in curly brackets {..} so that they can be read by the software. Changing curly brackets or the variable inside the curly brackets may cause an error in the system.

- Compound words that have no empty spaces. For example: `CentraSiteManager`, `SearchManager`, `SolutionOptions`.
- Words written in all capital letters. For example: `WHERE` or `SELECT`.
- Terms enclosed in single quotes (‘arg’, property of the type ‘String’)
- Special characters used in the source language such as square brackets [ ], angle brackets < >, ampersand &, and backslash \ . For example, "`Application|Component`" can be customized to "`Program|Software`" but not to "`Program` and `Software`" and "save as *.html" can be customized to "format *.html" but not to "save as html file".

- If configuration objects created by your enterprise are deleted, their translations will NOT be automatically deleted from the vocabularies. However, during the meta-model update process, any translation entries that cannot be matched to an original will be deleted from the Alfabet database. An XLSX file will be generated during the meta-model update process that lists all orphaned translations that have been removed from the Alfabet database. Solution administrators should analyze this list to determine whether any of the orphaned translations require the creation of new (custom) translations.

Please note the following regarding the different file formats:

- XLSX files: The following columns are relevant for translation:

- ***Original***: The original string from the `English (UnitedStates)` vocabulary provided by Software AG. This column must not be edited.
- ***Translation***: The standard translation provided by Software AG. This column is empty for all exported vocabulary files except for files exported for the `German (Germany)` vocabulary. This column must not be edited. Translations added to a vocabulary in the `Translation` column are ignored during update of vocabulary by the vocabulary file import mechanisms of the **Vocabulary Manager** editor.
- ***CustomTranslation***: The customized terminology added by the customer. Enter the translated or modified terms in the column `CustomTranslation`.

- XML (*VOC) files: The XML file contains one XML element `Entry` for each term. The following XML attributes are relevant for translation:

- ***Original***: The original string from the `English (UnitedStates)`) vocabulary provided by Software AG. This column must not be edited.
- ***Translation***: The standard translation provided by Software AG. This column is empty for all exported vocabulary files except for files exported for the `German (Germany)` vocabulary. This column must not be edited. Translations added to a vocabulary in the `Translation` column are ignored during update of vocabulary by the vocabulary file import mechanisms of the **Vocabulary Manager** editor.
- ***CustomTranslation***: The translation of the original string. Enter a translation for the string in the XML attribute `Original`.

Importing the Vocabulary Files

To import the customized terminology from Microsoft Excel files or XML files:

1) In the menu bar, click **Globalization** > **Open Vocabulary Manager.**

If you have exported simple text files via the **Export Vocabularies with Unique Identifiers** functionality, then you must import the files via **Globalization** > **Import Vocabularies with Unique Identifiers**.

2) In the **Vocabulary** toolbar, click the **Import Vocabularies** button. The **Translation Import** editor opens.

3) In the **Translation Import** editor, click the **Add Vocabulary** button and select the relevant files to import.

The XML files for the export of terminology have the extension VOC.

4) The selected files are displayed in the **Translation Import** dialog box. The column **File** displays the file that you have selected to import.

- If the column **Translation Source** is empty, select the type of terminology set that you are importing in the drop-down list.
- If the column **Culture** is empty, select the locale that you are importing in the drop-down list.

5) Click **OK** to import the terminology.

Updates to the translation table require the Web server to be restarted or the meta-model to be reread if the server is running in Design mode (if in the `web.config` file the key attribute "`appmode`" is set to `Design`).

Optionally you can select the checkbox **Clear All Translations** to remove all translations from the terminology set and vocabulary that were imported from the import file.

Make sure that the import file contains all required translations prior to import with a selected **Clear All Translations** checkbox. For example, a terminology set already includes a translation of both standard and configuration terms. You have exported **Standard** terms only without exporting the **Configuration** part of the terminology. After changing the terminology in the exported file, you import the translations and select the **Clear All Translations** checkbox. All custom translations will be deleted from the terminology set and then the translations from the import file are added to the custom translation in the terminology set. The import file only contains standard terminology, which results in all configuration related translations to be irrevocably deleted from the terminology set during import.

Translating Custom Strings via the Automated Translation Capability

An automated translation capability is available that supports interoperability with a translation service. This capability allows the enterprise to provide a translated user interface for the supported secondary languages quickly, with a minimal amount of effort and cost.

The custom strings that your enterprise has created when configuring the class model may be automatically translated via the automated translation capability for any of the languages supported by Software AG. If only one culture is defined for your enterprise, then the automated data translation functionality will be disabled in the Alfabet user interface. Translations can be fetched via a configured translation service such as Google Translate® for the custom strings defined for custom editors, custom selectors, custom

object views/object cockpits, workflows, custom wizards, configured reports, guide pages/guide views, etc. Any English string that does not have a translated string available will be translated to the target language that you select. Via the **Get Low-Confidence Translations** functionality, you can automatically translate the custom strings to any of the languages supported by Software AG.

The following translation services are supported for the automated translation capability:

- Google Translate®
- AWS Translate®
- DeepL® Translator

For more information about using the automated translation capability to translate object data to the languages supported by your enterprise, see the section Configuring the Translation of Object Data.

Please note the following:

- The automated translations will be saved to the `Custom Translation` column in the vocabulary for the relevant language.
- If a string is used in multiple vocabularies (for example, in both `MetaModel` and `GuidePages`), the same translation string will be used for all occurrences of the string.
- The translation service will not overwrite existing custom translations that have been either manually or automatically translated.
- The translation service will not overwrite standard strings provided by Software AG.
- The enterprise must have a valid license to one of the following translation services:
- Google Translate®
- AWS Translate®
- DeepL® Translator
- Microsoft® Azure® Translate Text
- The XML object ***AlfaTranslationServicesConfig*** must be configured and the connection to the translation service must be activated. For more information about the configuration of the XML object ***AlfaTranslationServicesConfig***, see the section *Configuring Interoperability with a Translation Service* in the reference manual *API Integration with Third-Party Components*.
- The pre-conditions for activating the Rest API must be fulfilled. For more information, see the reference manual *Alfabet RESTful API*.
- One user in the enterprise must be specified to execute self-reflective events and must start the Alfabet Server. For more information, see the chapter *Setting a User as a Self-Reflective User to Execute Events* in the reference manual *Configuring Alfabet with Alfabet Expand*.
- The Alfabet Server must be running and able to connect to the Internet.

To provide automated translations for empty strings in the vocabularies:

1) In the menu bar, click **Globalization** > **Edit Translation**. You will see the **Translation Editor**

2) Click **Manage Vocabulary** > **Open** and select the culture for which you want to automatically translate the vocabularies. The target language for translation is displayed in the header of the **Translation Editor**.

3) In the header, click **Get Low-Confidence Translations** > **Meta-Model Configuration**. An message dialog is displayed asking confirmation to start the automated translation process. Click **OK** to confirm the message and start the automated translation process.

The **Get Low-Confidence Translations** functionality may not be displayed in Alfabet Expand if the XML object ***AlfaTransltionServicesConfig*** is not correctly configured.

4) When the automated translation process has been completed, a message will be displayed with the number of automated translations that have been uploaded. Confirm the information message by clicking **OK**. The strings added to the vocabularies via the automated translation capability will be displayed as custom translations in the **Translation Editor**.

5) Click the **Close** button to close the **Vocabularies** editor.

Managing Imported Vocabularies

It is possible to track the vocabularies that have been updated via imported Microsoft Excel or XML files. To do so, click **Globalization** > **Show Vocabulary Update History** in the menu bar. The following information is displayed:

- **Culture**:The locale ID of the language.
- **Source**: The name of the vocabulary that has been updated.
- **Update File**: The name of the file imported for the translation update.
- **Update Time**: The timestamp when the file was imported for the translation update.
- **Standard Translation Count**: The number of strings updated in the standard translation.
- **Custom Translation Count**: The number of strings updated in the custom translation.

Deleting Vocabularies

You can delete a vocabulary because, for example, the culture that the vocabulary is associated with is no longer supported in the enterprise. Please note the following about deleting a vocabulary:

- After deleting a vocabulary, the vocabulary file no longer exists, and the strings cannot be imported and exported using the **Vocabulary Manager**.
- Nevertheless, the vocabulary of a language culture can be opened and edited via the translation editor as long as the vocabulary is defined as **Base Culture** in a culture setting defined in Alfabet Expand. If you open the **Translation Editor** and add a string to a terminology set of a vocabulary that was formerly deleted, the terminology set is re-created and can then be exported via the vocabulary manager.

If you delete the vocabularies for a culture, the custom strings will be irrevocably deleted from the Alfabet database. In order to restore standard strings provided by Software AG, see the section Restoring Deleted Vocabularies.

To delete a vocabulary:

1) In the menu bar, click **Globalization** > **Open Vocabulary Manager**. You will see the **Vocabularies** editor.
2) In the table, select one or multiple vocabularies that you want to delete.
3) In the toolbar of the **Vocabularies** editor, click the **Delete** button. The vocabularies are removed for the selected vocabulary. No translation will be available for the strings in the **Translation Editor**:

You can alternatively remove vocabularies by means of the **Translation Editor**:

1) In the menu bar, click **Globalization** > **Edit Translation.** The **Translation Editor** opens.
2) In the **Translation Editor** toolbar, click **Manage Vocabulary** > **Open** and select the culture for which you want to delete the vocabularies.
3) In the **Translation Editor** toolbar, click **Manage Vocabulary** > **Remove Vocabulary**. Confirm the warning message by clicking **OK**. No translation will be available for the strings in the **Translation Editor**:

Restoring Deleted Vocabularies

If the standard Alfabet vocabularies have been accidentally deleted, it is possible to restore them by means of the option **Globalization** > **Restore All Vocabularies**. Please contact Software AG Support to attain the necessary binary file required to restore the standard Alfabet vocabularies.

Transferring the Custom Translation to the Alfabet Administrator

If you have changed some standard translation strings that are displayed in the Alfabet Administrator, you must explicitly transfer the custom translation to the Alfabet Administrator if you want the custom translation displayed in the interface of the Alfabet Administrator. This must be done after the custom translation has been imported to the Alfabet database. The `LocTr.bin` file that is created will be stored in the Alfabet `Programs` directory. Please note that the `Programs` directory must have Write permissions at run time.

To implement the custom translation in the interface of the Alfabet Administrator, click **Globalization** > **Transfer Translation to Alfabet Administrator**. Click **OK** to confirm the message.

Configuring the Translation of Object Data

Depending on the configuration of your Alfabet solution, object data such as names, descriptions, and other relevant custom properties may be captured in the enterprise's primary language, any of its secondary languages, or in a statutory language that is mandated for relevant object classes. If the enterprise supports multiple languages, the data captured for protected and custom properties of the type `String` and `Text` may be translated to the other languages implemented in your Alfabet solution. When the user interface is rendered in a one of the languages for which translations are available, the translated names of objects will be displayed in explorers, object profiles, page views, previews, etc. Objects with names defined in a secondary language will be ordered accordingly in explorer trees and page views.

If data translation is supported for the class **Business Process**, a user could capture the **Name** and **Description** of their business processes in the primary language. The same user or other users with access to the business processes could then either manually provide a translation for the names and descriptions of the business processes in the editor/wiazárd or, if the automated translation capability is configured, the data can be translated via a translation service to the languages supported by the enterprise.

As solution designer, you can configure on a per-class basis whether the translation of object data is possible and which properties may be manually translated or translated via the automated translation capability. The following scenarios to capture and translate object data are supported:

- Data can be captured in the primary language only. If only one culture is defined for the enterprise, then the **Manual Translation** and **Automated Translation** icons will be disabled in the editor/wizard.
- Data can be captured in the primary language and may be translated either manually and/or automatically to one or more secondary languages. It is possible to configure on a per-class basis the object classes where only manual translation is possible, where only automated translation is possible, or where an automated translation is provided if no manual translation has been entered.
- The manual translation can be captured by changing the language selector in the editor/wizard and entering the translation in the relevant field.
- The automated translation will be triggered when the **OK** button in the editor or **Next** button in the wizard is clicked.

In some cases, a new object will inherit the translated name, description, etc. of its parent object. This is the case, for example, for information flows, local components, or business services. If translations are available for the name of the parent object, the new

information flow, local component, or business service will inherit the translated name of its parent object. For example, a business service will inherit the translated name of the business function it is based on and an information flow will inherit the name of its source and target applications.

- Data can be captured in a secondary language. The Alfabet user interface must be rendered in the secondary language to capture data in that language. In this case, it is recommended that the automated translation capability is configured in order to provide a translation of the name for the object in the primary language. For more information about capturing data in a secondary language, see the section *Capturing Data in a Secondary Language*.
- Data can be captured in a statutory language, which can be the primary language or a secondary language. The Alfabet user interface should be rendered in the statutory language to capture data in that language. If the statutory language is a secondary language, it is recommended that the automated translation capability is configured in order to provide a translation of the name for the object in the primary language. For more information about capturing data in a statutory language, see the section *Capturing Data in a Statutory Language*.
- Data can be captured via XLSX files based on data capture templates configured in the **Extended Data Capture Templates** functionality. In this case, data can also be captured in a primary, secondary, or statutory language. For more information about configuring and using data capture templates to import object data, see the chapter *Capturing Data with Data Capture Templates* in the reference manual *User and Solution Administration*.

The following configuration is required to specify data translation:

- Specify which cultures support object data translation.
- Specify which object classes allow object data translation. For each object class, you must consider the following:
  - Which protected and custom properties of the type `String` and `Text` shall be translated. The protected properties that may be translated are predefined by Software AG.
  - Which properties shall be translated manually by users when they create a new object in the editor/wizard.
  - Which properties shall be translated via the automated translation capability in the editor/wizard.
  - You can specify that the data for an object class must be captured in a statutory language.
  - Specify whether users may initially capture object data in a secondary language.
  - Specify whether users should capture object data in a statutory language.

  The configuration of the object classes and their properties is applicable to all cultures for which object data translation is permissible.

- In addition, if the automated translation capability shall be implemented, the following must be configured:
  - The enterprise must have a valid licence to one of the following translation services:
  - Google Translate®
  - AWS Translate®

- DeepL® Translator
- Microsoft® Azure® Translate Text
- The XML object ***AlfaTranslationServicesConfig*** must be configured and the connection to the translation service must be activated. For more information about the configuration of the XML object ***AlfaTranslationServicesConfig***, see the section *Configuring Interoperability with a Translation Service* in the reference manual *API Integration with Third-Party Components*.
- The pre-conditions for activating the Rest API must be fulfilled. For more information, see the reference manual *Alfabet RESTful API*.
- One user in the enterprise must be specified to execute self-reflective events and must start the Alfabet Server. For more information, see the chapter *Setting a User as a Self-Reflective User to Execute Events* in the reference manual *Configuring Alfabet with Alfabet Expand*.
- The Alfabet Server must be running and able to connect to the Internet.

Translated values for object data will be displayed automatically in configured reports that are based on the Alfabet query language. For configured reports based on native SQL queries, however, a special syntax triggering the translation must be added to the native SQL query in order to enable the display of translation values for object data. For more information, see Displaying Translated Object Data In the Current Language of the User Interface in the section Defining Native SQL Queries in the chapter Defining Queries.

The following information is available:

- Enabling Object Data Translation for a Culture
- Enabling the Manual Translation of Object Data
- Configuring Automated Translation of Object Data
- Specifying Object Classes and Properties for Automated Translation
- Configuring the Connection to the Translation Service
- Allowing Data To Be Captured in a Non-Primary Language
- Specifying a Statutory Language for the Enterprise

Enabling Object Data Translation for a Culture

The **Support Data Translation** attribute of a culture determines whether object data translation is possible for the culture. In order for users to be able to either manually or automatically translate object data to a language available in the Alfabet solution, the **Support Data Translation** attribute must be set to `True` for the respective culture. If the **Support Data Translation** attribute is set to `True` for the culture, manual and automatic data translation is permissible for all classes per default. You can refine this and configure the permissibility of data translation for specified object classes as well as their protected and custom properties. This is described in the sections Enabling the Manual Translation of Object Data and Configuring Automated Translation of Object Data.

The configuration of the object classes and their properties is applicable to all cultures for which object data translation is permissible. For more information about configuring cultures, see the section Specifying the Cultures Relevant to Your Enterprise.

If the **Support Data Translation** attribute is set to `True` for a culture, the database tables will include the necessary columns needed for translation purposes for the permissible object classes. Please note that the translations are stored in separate columns in the database tables with the column name having the following syntax: < **Tech Name** attribute of object class property>_<locale ID>. For example, the `Name` property of the object class `Application` can be translated to German. The number 1031 is the locale ID for German. Therefore, the column ***NAME_1031*** will be available in the `Application` database table.

To specify the permissibility of manual or automatic data translation on object classes:

- If the **Support Data Translation** attribute is set to `True` in the attribute grid of the relevant the culture , data translation will be possible per default for predefined protected properties and custom properties of the type `String` or `Text` for all object classes. The language associated with the culture will be available for selection in the language selector in the relevant editors/wizards in the Alfabet user interface.
- If the **Support Data Translation** attribute is set to `False`, data translation will not be possible at all for the culture and the language will not be displayed in the language selector in object editors/wizards.

To change the data translation definition for a culture, right-click the culture node in the **Class Model** explorer and select:

- **Activate Support for Data Translation** to specify that data translation is allowed for the culture. The **Support Data Translation** attribute will be set to `True` if you select this option. In the toolbar, click the **Save** button to save the culture definition.
- **Deactivate Support for Data Translation** to specify that data translation is not allowed for the culture. The **Support Data Translation** attribute will be set to `False` if you select this option. In the toolbar, click the **Save** button to save the culture definition.

Enabling the Manual Translation of Object Data

In order to allow users to manually translate object data, you must ensure that the relevant object classes and properties are enabled for data translation. The translation of object data typically includes the captions, descriptions, and other custom properties of the type `String` and `Text` defined for objects that users create in the Alfabet user interface. For each object class for which object data may be translated, you should review which standard and custom properties of the type `String` and `Text` shall be manually translated.

For an overview of how users can translate object data in editors and wizards, see the section *Multi-Language Support in Editors and Wizards* in the reference manual *Getting Started with Alfabet*.

The following configuration must be carried out in order to ensure that the values defined for standard and custom properties may be manually translated:

- For all cultures for which object data translation should be possible: Set the **Support Data Translation** attribute to `True` for the culture. For more information about specifying a culture, see the section Specifying the Cultures Relevant to Your Enterprise.

  It is important to note that the configuration regarding the permissibility of manual translation and automated translation for object classes and/or properties is relevant for all cultures for which the **Support Data Translation** attribute is set to `True`.

- For all object classes for which object data translation should be possible:
  - Set the **Enable Data Translation** attribute to `True` for the object class to ensure that the object class may be translated. For more information about configuring object classes, see the section Editing a Protected Object Class in the chapter Configuring the Class Model. Please consider the following:
  - The **Enable Data Translation** attribute is set to `True` per default for all object classes that are visible in Alfabet Expand. Therefore, if specific object classes shall not support object data translation, you must set the **Enable Data Translation** attribute to `False` for these object classes.
  - If you set the **Enable Data Translation** attribute to `False`, then the translation of object data for that object class will not be permissible for all cultures.
  - If you change the **Enable Data Translation** attribute setting for an object class from `True` to `False`, any existing automated translations will be deleted from the Alfabet database for that class.
  - Set the **Enable Automated Data Translation** attribute to `False` for the object class to ensure that the automated translation capability is disabled per default for the object class.
- For custom properties of the type `String` and `Text`: Set the **Enable Data Translation** attribute to either `Manual` if the custom property may be only manually translated or `ManualAndAutomated` if the custom property may be manually translated or translated via the automated translation capability. For more information about specifying a custom property, see the section Configuring Custom Properties for Protected or Public Object Classes in the chapter Configuring the Class Model. Please consider the following:
  - If the **Enable Data Translation** attribute is set to `ManualAndAutomated`, the **Enable Automated Data Translation** attribute for the object class must be set to `True` to ensure that the automated translation capability is enabled.
  - If you change the **Enable Data Translation** attribute setting for an object class property from `ManualAndAutomated` to `Manual`, any existing automated translations will be deleted from the Alfabet database for that property.

Configuring Automated Translation of Object Data

In order to allow users to translate object data via the automated translation capability, you must ensure that the relevant object classes and properties are enabled for data translation. The translation of object data typically includes the captions, descriptions, and other custom properties of the type `String` and `Text` defined for objects that users create in the Alfabet user interface. For each object class for which object data may be translated, you should review which standard and custom properties of the type `String` and `Text` shall be translated via the automated translation capability.

If users shall capture data in a secondary language or a statutory language, then the automated translation capability should be implemented in order to ensure that the data captured in a secondary language will also have values in the primary language. For more information about capturing data in a secondary language, see the sections Allowing Data To Be Captured in a Non-Primary Language and Specifying a Statutory Language for the Enterprise.

In addition to configuring the permissibility of object classes and properties for automated translation, the following must be configured in order to implement the automated translation capability:

- The enterprise must have a valid license to one of the following translation services:
- Google Translate®
- AWS Translate®
- DeepL® Translator
- Microsoft® Azure® Translate Text
- The XML object ***AlfaTranslationServicesConfig*** must be configured and the connection to the translation service must be activated. For more information about the configuration of the XML object ***AlfaTranslationServicesConfig***, see the section *Configuring Interoperability with a Translation Service* in the reference manual *API Integration with Third-Party Components*.
- The pre-conditions for activating the Rest API must be fulfilled. For more information, see the reference manual *Alfabet RESTful API*.
- One user in the enterprise must be specified to execute self-reflective events and must start the Alfabet Server. For more information, see the chapter *Setting a User as a Self-Reflective User to Execute Events* in the reference manual *Configuring Alfabet with Alfabet Expand*.
- The Alfabet Server must be running and able to connect to the Internet.

In the Alfabet user interface, the user will define a value for a relevant property in an editor field displaying the **Automated Translation**  icon. Upon clicking the **OK** button in the editor/the **Next** button in the wizard, a private event template `GetAutomatedTranslation_For_Instance` will be triggered that sends a Rest API call. The Rest API call then triggers the execution of an ADIF import scheme that fetches the translation strings from the configured translation service for all relevant languages. Please note the following:

- The translated string will not be immediately displayed. A few minutes may be needed to fetch the translations.
- If an object is created as a copy of an object, then the automated translation will be copied to the new object. For example, if an application variant is created based on an application or if a local component is created for an application, the translation of the application's description will be

copied to the respective application variant or local component. The translation string can be changed as needed.

- If the original string is used for multiple object data, the same translation string will be used for all occurrences of the original string in the Alfabet database.
- If the original string is changed in the editor/wizard after translation strings have been fetched, the automated translation will be triggered again when the **OK** button in the editor/the **Next** button in the wizard is clicked and new translation strings will be fetched from the translation service.
- If an existing translation string has already been translated manually or via the automated translation capability, it will not be retranslated if the automated translation capability is triggered for other fields in the editor/wizard.
- If an existing translation string has been translated via the automatic translation capability, it may be manually revised in the editor/wizard or in the *Automated Data Translation Functionality*. If the original string is used for multiple object data, then only the explicit translation string that is being revised will be changed in the Alfabet database. Other instances of the translation string will remain unchanged and will not be impacted by the revised translation string. In this way, you can revise the translation string for a specific context.
- A user with an administrative profile may review the translation strings fetched via the automated translation capability and modify them as needed in the *Automated Data Translation Functionality*. For more information, see the chapter *Managing Automated Translation Strings* in the reference manual *User and Solution Administration*.
- A user with an administrative profile may review whether the event has been successfully triggered in the *Events Administration Functionality*. If the event is not displayed or has an `Error` status, then the prerequisites should be reviewed. For more information about events administration, see the chapter *Managing Events* in the reference manual *User and Solution Administration*.
- A user with an administrative profile may view the status of the ADIF import schemes (`Get Automated Instance Translations from Service Provider` or `Get Automated Translations for an Instance from Service Provider`) that are executed for the automated translations in the *ADIF Jobs Administration Functionality*.
- If automated translations have not been fetched due to Internet connection outages, a solution designer can trigger the ADIF import scheme `Get_Instance_Automated_Translations_For_Empty_Texts` or similar ADIF jobs to retrieve the automated data translations that have been missed as a result of the Internet connection outages.

Furthermore, several private ADIF import scheme are also available in Alfabet Expand to support the automated translation capability. For more information about the predefined ADIF schemes for the automated translation capability, see the chapter *Predefined ADIF Schemes* and for more information about executing the ADIF job based on an ADIF scheme, see the chapter *Configuring ADIF Schemes* in the reference manual *Alfabet Data Integration Framework*.

For an overview of how users can translate object data in editors and wizards, see the section *Multi-Language Support in Editors and Wizards* in the reference manual *Getting Started with Alfabet*.

A **Get Low-Confidence Translations** functionality is available to automatically translate the custom strings defined for custom editors, custom selectors, custom object views/object cockpits, workflows, custom wizards, configured reports, guide pages/guide views, etc. to any of the

languages supported by Software AG. For more information, see the section Translating Custom Strings via the Automated Translation Capability.

- Specifying Object Classes and Properties for Automated Translation
- Configuring the Connection to the Translation Service

Specifying Object Classes and Properties for Automated Translation

In order to allow users to translate object data with the automated translation capability, you must ensure that the relevant object class is enabled for data translation and for automated data translation. For each object class for which object data may be translated, you must specify which protected and custom properties of the type `String` and `Text` may be translated via the automated translation capability. The protected properties that are permissible for data translation are predefined by Software AG.

You should carefully review whether it is meaningful for a particular property to be translated. For example, it may not be appropriate to translate the name of applications or components as these are typically product names whereas it would be meaningful to translate business process names as these tend to be descriptive texts.

If you specify that a particular property may be translated via the automated data translation capability, users can disable the automated data translation capability for the property for in the context of the object's editor. For example, in the case of the object class **Location**, you may specify that the automated translation capability shall fetch the translations for the names of locations. Whereas it may be meaningful for a city name to be translated (for example, `Berlin` would be translated to `Berlino` in Italian, `Berlim` in Portuguese, and `Berlina` in Polish), it may make no sense for the names of small towns to be translated because no actual translation of the town's name exists. The user can click the **Automated Translation** icon next to a field in the editor to disable it. The **Disable Automated Translation** icon will then be displayed in the editor and will be ignored by the automated translation capability.

The following configuration must be carried out in order to ensure that the values defined for standard and custom properties may be translated via the automated translation capability:

- For all cultures for which object data translation should be possible: Set the **Support Data Translation** attribute to `True` for the culture. For more information about specifying a culture, see the section Specifying the Cultures Relevant to Your Enterprise.

  It is important to note that the configuration regarding the permissibility of manual translation and automated translation for object classes and/or properties is relevant for all cultures for which the **Support Data Translation** attribute is set to `True`. In other words, it is not possible to

- For all object classes for which object data translation should be possible:

- Set the **Enable Data Translation** attribute to `True` for the object class. For more information about configuring object classes, see the section Editing a Protected Object Class in the chapter Configuring the Class Model.
-
-

-

Please consider the following:

- The **Enable Data Translation** attribute is set to `True` per default for all object classes that are visible in Alfabet Expand. Therefore, if specific object classes shall not support object data translation, you must set the **Enable Data Translation** attribute to `False` for these object classes.
- If you set the **Enable Data Translation** attribute to `False`, then the translation of object data for that object class will not be permissible for all cultures.
- If you change the **Enable Data Translation** attribute setting for an object class from `True` to `False`, any existing automated translations will be deleted from the Alfabet database for that class.

- Set the **Enable Automated Data Translation** attribute to `True` for the object class to ensure that the automated translation capability is enabled for the object class. Please consider the following:
- The specification of the **Enable Data Translation** attribute applies to all cultures defined for your enterprise. Therefore, if you specify that a data translation is not permissible for an object class property, then object data cannot be specified for that object class for all defined cultures. Please note that regardless of the specification of the **Enable Data Translation** attribute for an object class/object class property, if the **Support Data Translation** attribute is set to `False` for a culture, data translation will not be possible at all for the culture and the language code will not be displayed in the language field in all object editors.
- The specification of the **Enable Data Translation** attribute for an object class property will have precedence over the specification made in the **Automated Translation Rules for Class Properties** attribute for the object class. In other words, if the **Enable Data Translation** attribute for the property is set to `None` or `Manual` and the property is set to `True` in the **Automated Translation Rules for Class Properties** attribute for the object class, the property will not be automatically translated.
- Specify the **Automated Translation Rules for Class Properties** attribute for the object class. Click the **Browse** button to open the editor to specify which protected and custom properties may be translated automatically. For each property listed in the **Automated Translation Rules for Class Properties** editor, select `True` in the **Automated Translation Enabled** column to permit the property to be automatically translated. Please consider the following:
- The `Name` property for the following object classes has been set to `False` per default for the automated translation capability. This too can be changed as needed via the **Automated Translation Rules for Class Properties** attribute in the attribute grid of the object class:
  - Application
  - Component
  - Component Catalog Element
  - Connection Data Format
  - Platform Catalog Element
  - Platform Element
  - Platform Information Flow
  - Platform Layer
  - Platform Tier
  - Solution Platform Element
  - Solution Platform Information Flow
  - Solution Standard Platform
  - Standard Platform

- Connection Frequency
- Connection Method
- Connection Type
- Device
- Information Flow
- Interface System
- Local Component
- Peripheral
- Platform Template
- Solution Application
- Solution Component
- Solution Device
- Solution Information Flow
- Solution Local Component
- Solution Peripheral
- Stack
- Stack Element
- Stack Item
- Technology
- Technology Group
- Threat
- Threat Group
- Vendor
- Vendor Product

- For many classes, the `Name` property may be automatically translated per default. In some cases, a new object such as an information flow, local component, or business service will inherit the translated name of its parent object. For example, a business service will inherit the translated name of the business function it is based on and an information flow will inherit the name of its source and target applications. If translations are available for the name of the parent object, the new information flow, local component, or business service will inherit the translated name of its parent object.
- The specification of the **Enable Data Translation** attribute for an object class property will have precedence over the specification made in the **Automated Translation Rules for Class Properties** field for the object class. If the **Enable Data Translation** attribute is changed to `Manual` or `None` for a property, then the respective property will not be displayed in the **Automated Translation Rules for Class Properties** editor for the object class.
- If the **Enable Data Translation** attribute is set to `None` or `Manual` for a custom property, the value in the **Automated Translation Enabled** column will be set to `False` per default and cannot be automatically translated.
- For custom properties  of the type `String` and `Text`: Set the **Enable Data Translation** attribute to `ManualAndAutomated` to enable the automated translation capability for the custom property. All custom properties for which the **Enable Data Translation** attribute is set to `ManualAndAutomated` will be added to the **Automated Translation Rules for Class Properties** editor for the object class. Users will be able to either provide a manual translation or translate the custom property's value via the automated translation capability. For more information about specifying a custom property, see the section Configuring Custom Properties for Protected or Public Object Classes in the chapter Configuring the Class Model. Please consider the following:
- If you change the **Enable Data Translation** attribute setting for an object class property from `ManualAndAutomated` to `Manual`, any existing automated translations will be deleted from the Alfabet database for that property.

Configuring the Connection to the Translation Service

The XML object ***AlfaTranslationServicesConfig*** allows you to specify interoperability with a translation service for the purposes of providing an automated translation for custom strings in the vocabularies that have been defined in the context of the solution configuration as well as for object data translation may be

users in the context of editors and wizards in the Alfabet user interface. For more information, see the section *Configuring Interoperability with a Translation Service* in the reference manual *API Integration with Third-Party Components*.

The following translation services are supported for the automated translation capability:

- Google Translate®
- AWS Translate®
- DeepL® Translator

The XML object usually includes an example definition. In addition, a template is available via the **XML Template** in the attribute grid of the XML object ***AlfaTranslationServicesConfig***. The template can be copied to the XML object to avoid manually writing the configuration. In this case, you would edit the XML elements described below. The following information describes a configuration from scratch.

To edit the XML object ***AlfaTranslationServicesConfig***:

1) Go to the **Presentation** tab, expand the **XML Objects** folder, and expand by the **Integration Solutions** folder.
2) Right-click ***AlfaTranslationServicesConfig*** and select **Edit XML.** . The XML object ***AlfaTranslationServicesConfig*** opens.
3) Optionally, you can configure the integration interface to send requests to a translation service instance via a proxy server. To define a proxy server, add a child XML element `Proxy` to the XML element ***AlfaTranslationServicesConfig*** and define the following XML attributes for the XML element `Proxy`:

- `url`: Define the URL of the proxy server.
- `user`: If required, enter the user name for access to the proxy server. The domain name for authentication is defined separately with the XML attribute domain and must not be specified as part of the user name.
- `password`: If required, enter the password for access to the proxy server.
- `domain`: If required, define the domain name that shall be used as part of the user name for authentication at the proxy server

Please note that server variables read the value of the XML attribute at runtime from the server alias configuration of the Alfabet Web Application when a connection to the integration solution is established. For information about configuration the server variables in the server alias, see *Configuring Server Variables for Integration and Interoperability Solutions*.

4) For each translation service that you want to define in the XML object, create a child XML element `TranslationServiceInfo`.
5) Define the following XML attributes for each XML element `TranslationServiceInfo`:

- `Name`: Enter a name for the translation service connection.

- `IsActive`: Enter "`true`" to activate interoperability with the translation service. One translation service may be active at any given time. If multiple connections are set to `IsActive` = `true`, then the first active connection will be used.
- `Type`: Enter one of the following, depending on the translation service that you will connect to and for which you have a valid license:
- `Google`
- `AWS`
- `DeepL`
- `Azure`
- `ServiceType`: You must specify `AzureCognitive` if the XML element `Type` is set to `Azure`. Failure to specify this XML attribute will result in an error if interoperability is specified with Microsoft® Azure® Translate Text.
- `Timeout`: Define the HTTP request timeout for the data connection.
- `AccessKey`: The access key for connection to the translation service.
- `SecretKey`: The secret key for connection to the translation service.

6) Automated translation is available for HTML texts including embedded tables if the **Enable Data Translation** attribute is set to `True` for the custom property. Because most translation engines impose a limitation on the maximum number of translated characters, any HTML that exceeds 5000 characters will not be translated. In order to specify how the translation mechanism in Alfabet shall deal with HTML that exceeds 5000 characters, the XML attribute `TranslateContentExceedingHTMLLengthLimit` should be specified. If set to `False`, automated translation will not be performed if the text in HTML or ASCII format exceeds 5000 characters. If set to `True`, the text in HTML format will be translated and displayed as ASCII format in the relevant translated languages.

Columns will be added to the relevant class table in the database for properties for which the **Can Have HTML Content** attribute has been set to `True`. This ensures that texts will be stored in the database in ASCII format as well as HTML format. The column name for the text with HTML format will consist of Class.Property.TechName, the ISO-code of the translated language, and the suffix _RT (rich text). Due to the implementation of _RT columns in the database tables, the number of characters that may be used for the technical name of a property that supports HTML and shall be translated is restricted to 23 characters.

7) In the toolbar, click the **Save**  button to save the XML definition.

Allowing Data To Be Captured in a Non-Primary Language

The possibility to capture data in a secondary language provides end users with the means to capture and maintain IT portfolio information in their preferred language and ensures high data quality in multi-language organizations.

The Alfabet user interface must be rendered in the secondary language that the user wants to capture the original data for. For details regarding how to capture data in a secondary language in the user interface, see the section *Capturing Data in a Secondary Language* in the reference manual *Getting Started with Alfabet*.

The following configuration is required in order to allow users to capture data in a secondary language:

- The automated translation capability as described in the section Configuring Automated Translation of Object Data must be configured and all requirements to successfully fetch translations from the configured translation service must be fulfilled.

  Every new object that is created requires a value in the **Name** attribute for the primary language. If the data is originally captured in a secondary language, then the **Name** attribute must be specified in the primary language either via a manual translation or via the translation capability.

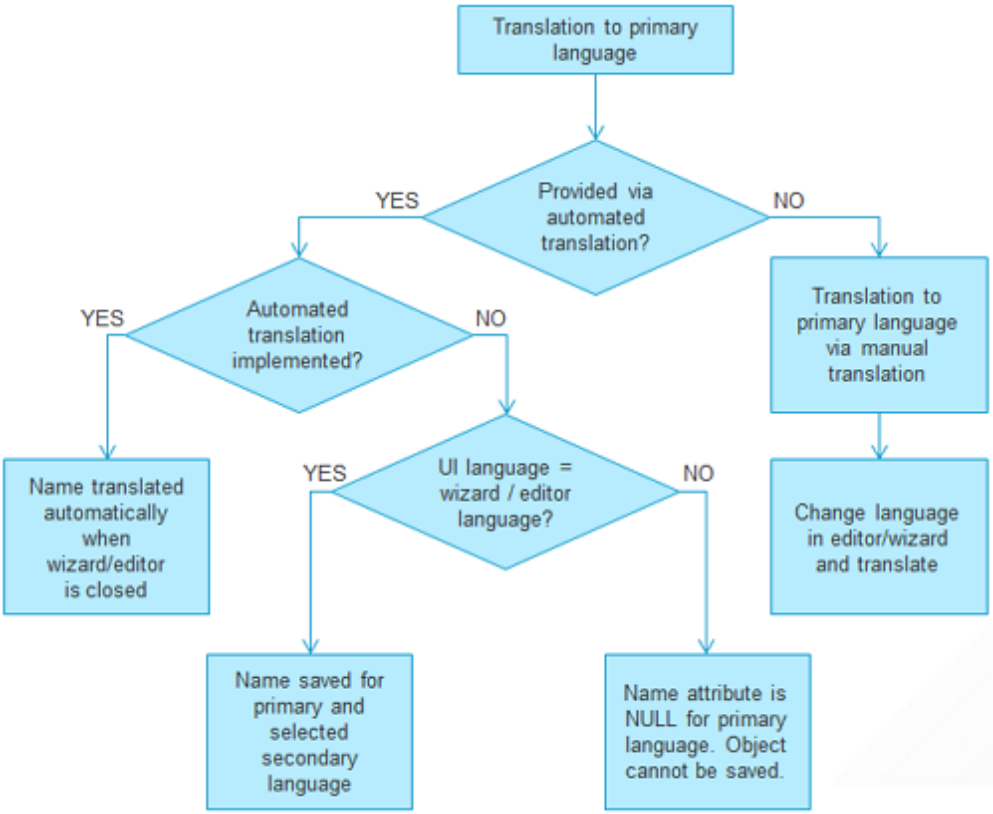


FIGURE: Translation to primary language

Please note the following:

- If the translation to the primary language is provided via the automated translation capability:
  - If the automated translation capability is implemented, the name will be automatically translated to the primary language when the editor/wizard is closed.
  - If the automated translation capability is **not** implemented, please consider the following:
  - If the language of the user interface is the same as the language selected in the editor/wizard, the value entered in the **Name** field will be saved for both the selected secondary language as well as the primary language. The language can be manually translated to the primary language in the editor after the new object has been saved.
  - If the language of the user interface is not the same as the language selected in the editor/wizard, the object cannot be saved because the **Name** attribute is NULL for the primary language. In this case, you must change the language of the user interface to the language that you want to capture the data in.
  - If a translated string is changed, the automated translation will be triggered again for all languages. The original string captured in the secondary or statutory language will not be changed via the automated translation.
- If the translation to the primary language shall be defined via a manual translation:
  - Enter the value in the editor field, change the language selector at the bottom of the editor to the primary language, and enter the translated value in the relevant editor. Click the **OK** button in the editor/the **Next** button in the wizard to save the definitions.
  - If no manual translation is defined for the primary language, the original string defined in the secondary language will be displayed for the **Name** when the user interface is rendered in the primary language. This may be revised at any time in the editor/wizard.
  - If no manual translation is defined for any of the other secondary languages, the value displayed for the **Name** when the user interface is rendered in the primary language will also be displayed when the user interface is rendered in the secondary language.

- The XML attribute `EnableTranslationToPrimaryLanguage` in the XML object ***SolutionOptions*** must be set to `True`. For more information, see the section Configuring Automated Translation of Object Data.
- In order for users to be able to capture language in a secondary language, they must select the checkbox for the **Capture Translations in Language of User Interface** field in their **User Settings** editor. For more information, see the section *Defining Your User Settings in Alfabet*. For more information about the configuration requirements to capture data in a secondary language, see the section Allowing Data To Be Captured in a Non-Primary Language in the reference manual *Configuring Alfabet with Alfabet Expand*.
- A user with an administrative profile may review the translation strings fetched via the automated translation capability and modify them as needed in the *Automated Data Translation Functionality*.

For more information, see the chapter *Managing Automated Translation Strings* in the reference manual *User and Solution Administration*.

Specifying a Statutory Language for the Enterprise

A statutory language capability is available in order to address regulatory requirements that mandate that objects are captured in a specific language. For example, if an enterprise has English as its primary language, but an organization in the enterprise is located in Germany and is required to capture data in German, than users can capture the data in the statutory language of German.

When a user creates an object based on a relevant object class/object class stereotype, a statutory language selector will open in which the statutory language can be selected. All languages supported by the enterprise will be available for selection. In the object editor that opens, the user can capture all attributes that support data translation in the statutory language. The automated translation capability will then translate the data to the primary language as well as other relevant secondary languages.

Please note the following:

- If the **Enable Statutory Language** attribute for the relevant object class is set to `True`, all languages will be available in the statutory language selector.
- There is no enforcement mechanism that requires users to capture data in a statutory language.
- The Alfabet user interface must be rendered in the statutory language that the user wants to capture the original data for.
- The value defined for the selected statutory language will never be replaced by an automated translation string.

Please note that if the user interface is rendered in a language that is different than the selected statutory language, a warning will be displayed in the editor. If the user nevertheless proceeds to capture data in the non-statutory user interface, an automated translation string will not be fetched for the statutory language and the value for the statutory language will be empty.

- For details regarding how to capture data in a statutory language in the Alfabet user interface, see the section *Capturing Data in a Statutory Language* in the reference manual *Getting Started with Alfabet*.

The following configuration is required to implement the statutory language capability:

- For all object classes  for which object data translation should be possible: Set the **Enable Statutory Language** attribute for the relevant object class to `True`. For more information about specifying a statutory language for an object class, see the section Configuring Custom Properties for Protected or Public Object Classes in the chapter Configuring the Class Model.
- For all object class stereotypes for which object data translation should be possible: Set the XML attribute `StatutoryLanguage` in the **Stereotypes** attribute of the object class to "`true`". If the XML attribute `EnableStatutoryLanguage` is not set for an object class stereotype in the Stereotypes attribute, the object class stereotype will inherit the definition of the **Enable Statutory Language** attribute specified for the object class. For more information about specifying a statutory language for an object class stereotype, see the section Configuring Object Class Stereotypes for Object Classes in the chapter Configuring the Class Model.

- The automated translation capability as described in the section Configuring Automated Translation of Object Data must be configured and all requirements to successfully fetch translations from the configured translation service must be fulfilled.

  Every new object that is created requires a value in the **Name** attribute for the primary language. If the data is originally captured in a secondary language, then the **Name** attribute must be specified in the primary language either via a manual translation or via the translation capability.

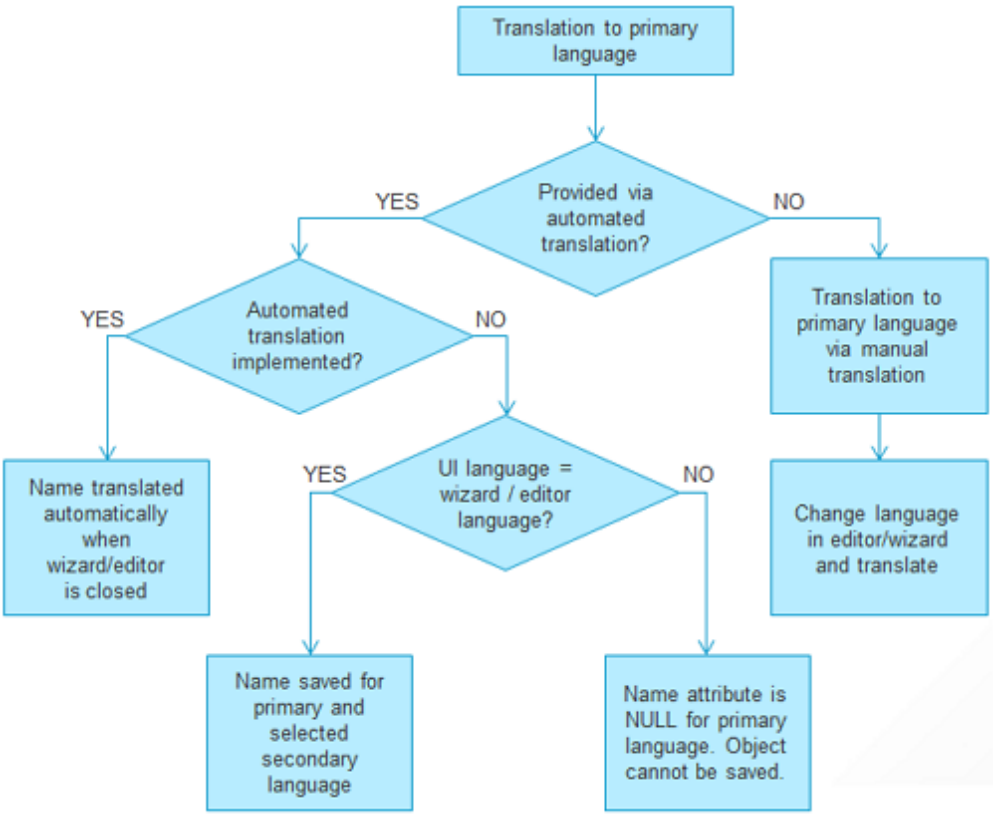

FIGURE: Translation to primary language

Please note the following:

- If the translation to the primary language is provided via the automated translation capability:
  - If the automated translation capability is implemented, the name will be automatically translated to the primary language when the editor/wizard is closed.
  - If the automated translation capability is **not** implemented, please consider the following:
    - If the language of the user interface is the same as the language selected in the editor/wizard, the value entered in the **Name** field will be saved for both the selected secondary language as well as the primary language. The language can be manually translated to the primary language in the editor after the new object has been saved.
    - If the language of the user interface is not the same as the language selected in the editor/wizard, the object cannot be saved because the **Name** attribute is NULL for

the primary language. In this case, you must change the language of the user interface to the language that you want to capture the data in.

- If a translated string is changed, the automated translation will be triggered again for all languages. The original string captured in the secondary or statutory language will not be changed via the automated translation.

- If the translation to the primary language shall be defined via a manual translation:

- Enter the value in the editor field, change the language selector at the bottom of the editor to the primary language, and enter the translated value in the relevant editor. Click the **OK** button in the editor/the **Next** button in the wizard to save the definitions.

- If no manual translation is defined for the primary language, the original string defined in the secondary language will be displayed for the **Name** when the user interface is rendered in the primary language. This may be revised at any time in the editor/wizard.

- If no manual translation is defined for any of the other secondary languages, the value displayed for the **Name** when the user interface is rendered in the primary language will also be displayed when the user interface is rendered in the secondary language.

- The XML attribute `EnableTranslationToPrimaryLanguage` in the XML object ***SolutionOptions*** must be set to `True`. For more information, see the section Configuring Automated Translation of Object Data. Please note that the XML attribute `EnableTranslationToPrimaryLanguage` must be set to `True` and the **Capture Translations in Language of User Interface** field in the user's **User Settings** editor must be selected (=True) so that the statutory language selected by the user in the statutory language selector will also be selected per default in the editor/wizard.

- In order for users to be able to capture language in a secondary language, they must select the checkbox for the **Capture Translations in Language of User Interface** field in their **User Settings** editor. For more information, see the section *Defining Your User Settings in Alfabet*. For more information about the configuration requirements to capture data in a secondary language, see the section Allowing Data To Be Captured in a Non-Primary Language in the reference manual *Configuring Alfabet with Alfabet Expand*.

- A user with an administrative profile may review the values defined for the **Name** attribute of the objects with a statutory language definition and change them as needed in the *Statutory Language Review for Data Translations* functionality. Furthermore, the administrative user can change the statutory language or remove the statutory language definition if needed For more information, see the chapter *Managing the Translations for the Enterprise's Statutory Language* in the reference manual *User and Solution Administration*.

- A user with an administrative profile may review the translation strings fetched via the automated translation capability and modify them as needed in the *Automated Data Translation Functionality*. For more information, see the chapter *Managing Automated Translation Strings* in the reference manual *User and Solution Administration*.

Translating the Standard Online Help Provided with Your Solution

After translating the Alfabet interface to a new language or after adapting the Alfabet terminology to you company's terminology, you may want to translate or modify the context-sensitive online help of the Alfabet interface. Software AG provides a context-sensitive online help for the Alfabet software. The online help delivered with your Alfabet software contains documentation for all functionalities in the software, including those that may not be part of your company's Alfabet configuration.

A standard online help is provided for `English (United States)1033` and `German (Germany)1031`. If the **Base Culture** attribute is set to a language other than `English (United States)` or `German (Germany)`, an online help will not be available unless you explicitly specify one. You can either copy the existing online help for `English (United States)1033` or `German (Germany)1031` or provide a translated version of the copied help files.

Context-sensitive custom online help can be made available for a standard business function/custom explorer, custom object profile and object cockpit, standard page view, or configured report included in the Alfabet user interface. Additionally, a custom help link may be made available for a user profile, thus allowing information to be available to relevant users regardless of the view that they are currently looking at. This type of custom help is independent of the help files specified in the Help folder as well as the culture setting definition. The custom online help is configured on a per-view basis and is based on the URL configured for that view. The custom help is viewed in a browser. For more information, see the chapter Providing Custom Online Help to the User Community.

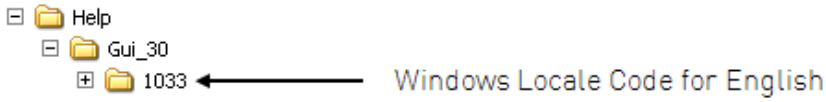
For more information about using the Alfabet online Help, see the section *Using the Context-Sensitive Help* in the reference manual *Getting Started with Alfabet*.

The following information is available:

- Finding the Online Help Files for Alfabet
- Adapting the Online Help Files to Include Custom Terminology
- Creating a New Language Version of the Online Help

Finding the Online Help Files for Alfabet

The Alfabet online Help files are located in the sub-directory `Help` of the Alfabet Web Application. The directory `Help` contains the sub-directory `Gui_30`, which contains a sub-folder for each language version of the online help. By default, Software AG provides an `English (United States)` and `German (Germany)` version of the online help.



The name of the folder containing the help files for a language version is identical to the name of the Microsoft® locale ID (LCID) of the language that the online help is used for

The Alfabet interface is available in the following languages:

Language	Locale ID
Arabic (Saudi Arabia)	1025
German (Germany)	1031
English (United States)	1033
French (France)	1036
Portuguese (Brazil)	1046
Polish (Poland)	1045

Therefore, if a user opens the Alfabet interface with a culture setting where the **Base Culture** attribute is set to `German (Germany)`, for example, the online help will be called from the folder with the locale identifier 1031. Within each language folder, four sub-folders are available:

- `images`: This folder contains images for all parts of the help in GIF or PNG format.
- `Alfabet`: This folder contains the context-sensitive HTML files for the Alfabet online Help
- `eXpand`: This folder contains the HTML files for the reference manual *Configuring Alfabet with Alfabet Expand*. The files are accessible via hyperlinks from both the Alfabet online Help and the `eXpandTech` help files. Please note that the German language folder contains English HTML files because the documentation of the configuration tool Alfabet Expand is not translated.
- `eXpandTech`: This folder contains the context-sensitive HTML files for the configuration tool Alfabet Expand. Please note that the German language folder contains English HTML files because the documentation of the configuration tool Alfabet Expand is not translated.

Adapting the Online Help Files to Include Custom Terminology

An HTML file provided by Software AG for the online help can be opened and changed with any HTML compliant editor. If, for example, your company uses a different term for the phrase "application variant", you could change the terms in the online Help file describing the Alfabet functionality for creating and maintaining application variants.

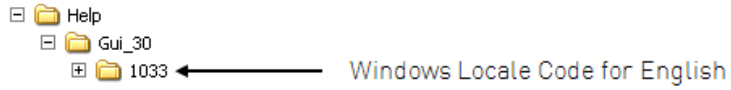
The name of each HTML file reflects the technical name of the view. If you do not know the technical name of the relevant view, you could call up the context-sensitive Help for that view in Alfabet. The technical name of the view is displayed in the path information when opening the context-sensitive help for the view. For example, the address bar displays the following path information for the **Application Variants** page view: `http://pc-customer/ALFABET_HELP/Gui_30/1033/OpenHelp.html?Path=Alfabet,APP_Variants.html`

The name of the HTML file for this view is `APP_Variants.html`. You could either access this HTML file in the `Alfabet` folder or edit the HTML file directly via an HTML compliant editor.

Changes applied to the HTML files located in the `Alfabet` folder will be automatically displayed to the users opening the help via the Alfabet interface.

Creating a New Language Version of the Online Help

You can create new language versions of the online help. The new online help requires the same folder structure as the standard online help and the names of the HTML files may not be changed.



The translated online help files must be placed in a sub-folder of the `Gui_30` folder. The sub-folder containing the translated HTML files must be named with the relevant Microsoft® locale ID (LCID) relevant for the culture specified in the **Base Culture** attribute of the relevant culture setting.

The full-text search available for the standard online help will not work for the new version because no help index is available for the online help. A help index can only be created by Software AG Support.

To create a new language version of the online Help:

1) In the sub-folder `Gui_30` of the online help, create a new folder with the locale identifier (LCID) associated with the language that online help will be translated to.
2) Copy the folder labelled `1033` containing the English help, paste it to a new folder below the `Gui_30` node labeled with the standard locale ID for the language you want to provide. For example, for a `Portuguese (Brazil)` culture setting, you would label the folder `1046`. The folder containing the custom help should correspond to the locale ID for the locale specified in the **Base Culture** attribute.
3) Translate the content of the HTML files. The online help files are written in standard compliant HTML. The online help can be translated with any standard translation tool or opened and modified with any standard HTML editor. Please note that the online help is context-sensitive and the file names of the HTML files may not be changed.

   Custom help can be made available for a standard business function/custom explorer, custom object profile and object cockpit, standard page view, or configured report included in the Alfabet user interface. Additionally, a custom help link may be made available for a user profile, thus allowing information to be available to relevant users regardless of the view that they are currently looking at. This type of custom help must be available via a URL that can be viewed in a browser. For more information, see the chapter Providing Custom Online Help to the User Community.
4) Replace the original language files with the translated files.
5) Ensure that the culture associated with the LCID is specified in the **Base Culture** attribute of the relevant culture.

Chapter 5: Configuring the Class Model

The standard Alfabet meta-model includes a class model that is made up of object classes used in the Alfabet solution, the properties of the object classes, and the relationships between object classes. The following chapter describes information important to understanding the standard meta-model as well how to customize it to meet the needs of your enterprise.

The **Meta-Model** tab allows you to view and edit the class model including the creation and definition of new custom object class properties required to meet the specific data input needs of your organization as well as the creation of object class stereotypes for a specified set of object classes. In the context of class model configuration, information is also provided about the creation of enumerations, which are necessary for the configuration of some types of custom object class properties as well as the configuration of class keys which determine uniqueness constraints for specified properties when users create a new object.

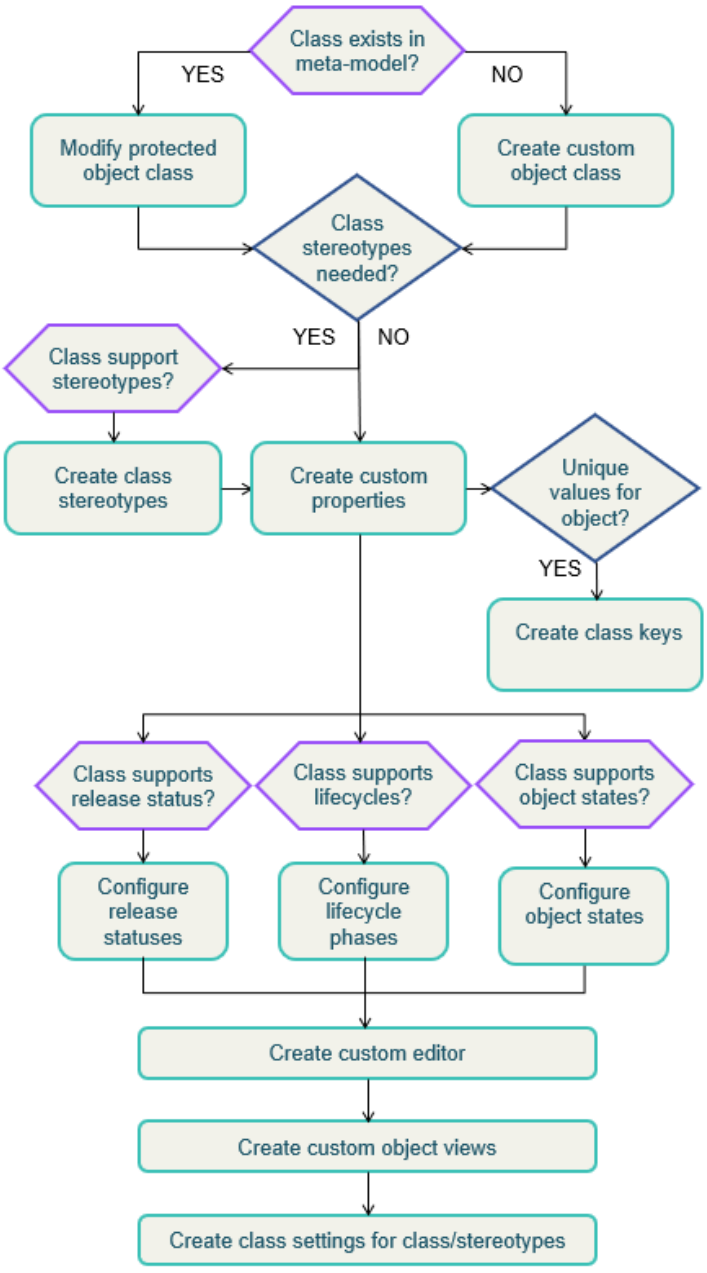


FIGURE: Steps to configure a standard or custom object class

Please note that the reference manual *Alfabet Meta-Model* provides detailed information about all standard object classes and their standard object class properties.

Furthermore, this chapter includes the specification of the release status, object state, and lifecycle definition for those object classes that support these concepts. For an overview of the object classes that implement the release status, object state, and lifecycle concepts, see the chapter *Overview of Configurable Features for Object Classes* in the reference manual *Configuring Alfabet with Alfabet Expand - Appendix*

Any changes made to the meta-model will impact both the relevant class table and audit table in the Alfabet database. For example, if a custom object class property is deleted from the class model, it will also be deleted from the audit table and thus will no longer be displayed in the *Object Audit Page View* available in your Alfabet solution.

It is highly recommended that you do not change the meta-model once the auditing capability is implemented, otherwise errors may occur in the audit information.

A custom object class can be created for special circumstances. For example, some companies may require a custom object class that represents an interface to support data migration. A custom object class is a public class and can be deleted at any time. Custom object classes should only be created with the assistance of Software AG Support.

The following information is available:

- Configuring the XML Object ReleaseStatusDefs
- Configuring Object State Definitions for Object Classes
- Configuring Lifecycle Definitions for Object Classes
- Configuring Class Keys for Object Classes
- Specifying History Tracking for an Object Class

Understanding the Class Model

The Alfabet class model is based on object classes, some of which are visible in the configuration tool Alfabet Expand. Each object class has a set of preconfigured object class properties and attributes.

The class model can be grouped into three different categories of object classes:

- The extendable meta-model that represents artifact object classes. Artifact object classes represent any object class for which object classes can be created in the Alfabet solution. These classes are typically protected object classes  for which protected object class properties can be modified and custom object class properties can be created. These classes are used to persistently store data about the customer's IT landscape in the Alfabet database. Most of these classes are customizable and customers can add custom object class properties to the classes to store company specific data that is not reflected in the standard properties of the object class. These object classes are visible in the **Class Model** explorer in Alfabet Expand.
- Object classes that represent objects designed to support functionality. These classes are used to persistently store data about object classes supporting functionality. This includes, for example, the object class `TimeStatus` that is used to store the lifecycle of objects or the object class `RoleTypeConfig` that is used to store information about which roles a user can have with regard to an object. Only the most important object classes for the storage of functionality-related data are visible in the explorer in Alfabet Expand.
- Auxiliary constructs required for Alfabet functionality. Some of the auxiliary object classes are persistently stored in Alfabet database tables, whereas others are not persistently stored. These object classes are not visible in Alfabet Expand and are not explicitly relevant to tasks of the solution designer.

An Alfabet database table exists for each object class displayed in the Alfabet Expand interface (as well as those that are not visible). Each class property displayed below its object class node corresponds to a column in the Alfabet database table.

The object classes that are displayed are relevant to the configuration of the Alfabet solution. Please note that the **Class Model** explorer displays the object classes as a flat list. Each object class in the meta-model has a preconfigured set of object class properties that serve to semantically describe the object class. These are nested below the object classes.

The following information is available:

- Overview of the Classes Node in the Class Model Explorer
- About Object Class Names and IDs
- About the Stereotypes Attribute for an Object Class

- About the Inheritance of Access Permissions
- About the Dependencies of an Object Class
- About the Tracking of Object Changes for an Object Class
- About XML-Based Configurations Relevant to Object Classes
- About the Configuration of Reference and Evaluation Data for an Object Class
- About Mandatory Object Class Properties

Overview of the Classes Node in the Class Model Explorer

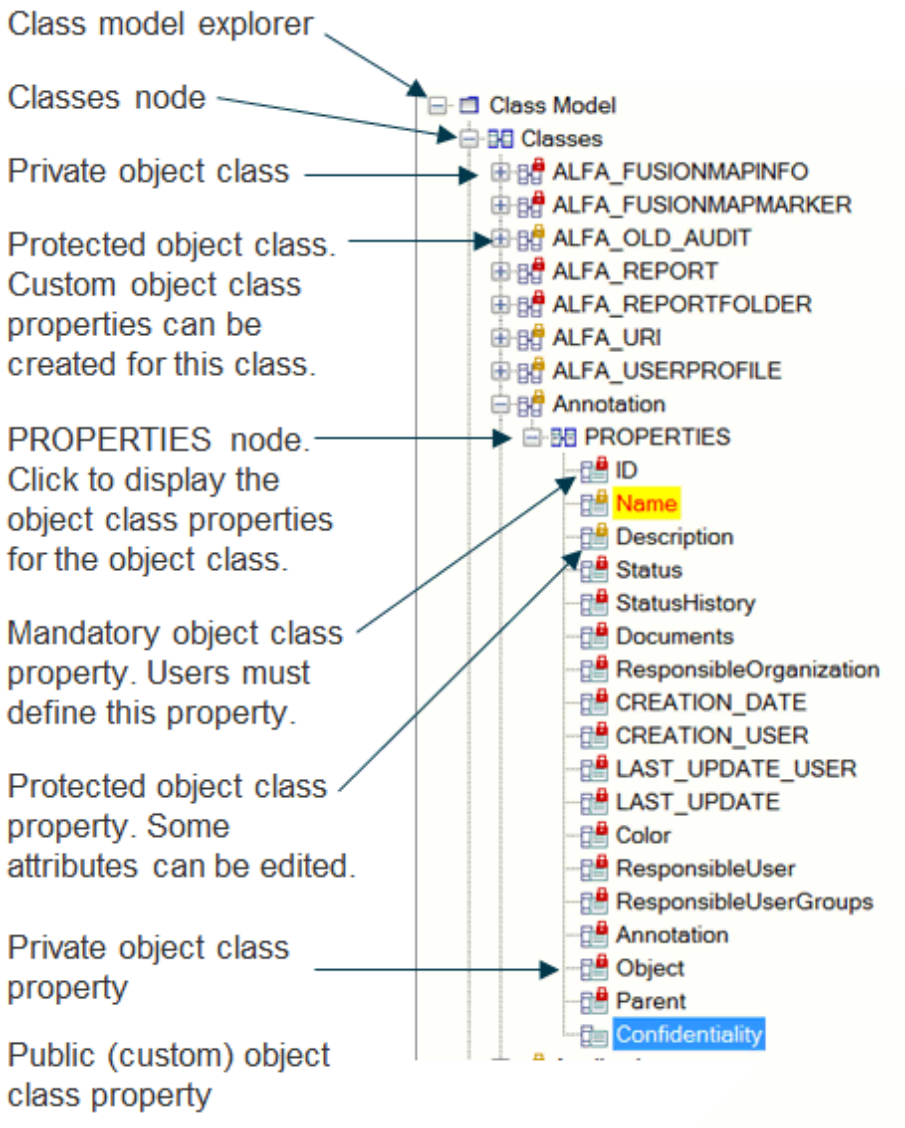

FIGURE: Class Model explorer in the Meta-Model tab

When you expand the **Classes** node, you may see any of the following:

- A private object class cannot be modified. Custom object class properties cannot be configured for private object classes. Private object classes are displayed for informational purposes and can be configured in Alfabet queries.
- A protected object class can be edited in a limited way. A protected object class typically has private object class properties that cannot be edited, protected object class properties that may be edited (for example, `ResponsibleUser`, `Documents`, `CREATION_DATE`, etc.) but allows for custom object class properties to be created and configured for a protected object class.
- A public object class is a custom class that has typically been created by your enterprise with the help of Software AG Support. All relevant object class properties may be edited and the custom class may be deleted. The attribute **Tech Name** must be explicitly defined for call custom object classes. Custom object class properties can be created and configured for a public object class.
- Some private and protected object class properties are highlighted yellow in the **Class Model** explorer. These are standard object class properties that are recommended by Software AG to be mandatory properties. No enforcement mechanism is implemented if the object class property is undefined. However, if the object class property is included in a class key definition, an error will occur if the object class property is not defined. Therefore, if you include a mandatory object class property in a class key, the object class property may not be hidden in the editor or wizard used to create new objects of the relevant property class.

In Alfabet Expand, object classes are displayed with their names, which means the value of the **Name** attribute of the object class. In some cases, this may differ from the caption used in the standard Alfabet user interface.

When you expand the **Properties** node below an object class, you may see any of the following:

- A private object class property cannot be modified. Private object class properties are displayed to provide guidance in defining new objects.

  Please note that the **Hint** attribute cannot be defined for private object class properties . If you need to provide custom tooltips for private object class properties, you can either:

  - Display the object class property in an object cockpit and configure a hint for the interface control. In this way, you can define a customized tooltip for the specific context that the object class property is displayed in each relevant object cockpit. For more information, see the section Configuring Object Cockpits for a Custom Object View.
  - Define a custom translation to replace the standard tooltip via the translation capability available in Alfabet. The translation of the standard tooltip will be displayed in all instances in Alfabet in which it appears. For inherited object class properties such as `Name` and `ID` which are used in most protected object classes in Alfabet, the custom translations will be displayed for all `Name` and `ID` properties for all relevant object classes. For more information, see the chapter Localization and Multi-Language Support for the Alfabet Interface.

- A protected object class property  is a standard property that allows some attributes for the object class property to be edited including, for example, the **Caption** attribute, which is displayed for the object class property in the Alfabet interface, and the **Hint** attribute, which is the text for the tooltip that is displayed in the **Attributes** section of an object view and the editor. Both the **Caption** attribute and **Hint** attribute can be translated for the Alfabet interface. A protected object class property may not be deleted.
- A public object class property  is a custom object class property that has typically been created by your enterprise. All relevant attributes may be edited and the custom object class property may be deleted.

Click any object class node in the **Class Model** explorer to display its attributes in the attribute window. These attributes specify the technical data about the object class property. The attributes displayed in the attribute window will depend on the object class property type definition in the **Type** attribute. For more information about configuring object classes and object class properties, see the chapter Configuring the Class Model.

Some object classes have a **Class Key Group** node below the object class which will display any existing class keys. A class key  allows for the specification of a unique combination of values for a specified set of standard or custom object class properties. This may be implemented to specify uniqueness constraints for the definition of an object in the object class as well as to create indexes to improve performance. For more information about the configuration of class keys, see the section Configuring Class Keys for Object Classes.

Below the **Class Model** node, you will also see a node labelled **Enums**, which may contain private, protected, and public enumerations. Enumerations allow you to define values that can be selected in combo-box or checked list box interface controls. Once an enumeration is defined, you may assign it to any custom object class property of the type `String`, `Real`, or `Integer` associated with a protected object class. An enumeration can be reused for numerous object class properties for multiple object classes. For more information about the configuration of enumerations, see the section Defining Protected and Custom Enumerations.

You may see any of the following under the **Enums** node:

- Private enumerations  are for reference purposes only and cannot be edited.
- Protected enumerations  are created by Software AG. The enumeration name cannot be changed but you can edit the values specified in the **Sort Enumeration Items** attribute in order to determine which values should be displayed to users in the Alfabet interface.
- Public enumerations  are custom enumerations. All attributes can be edited.

About Object Class Names and IDs

Select an object class in the **Class Model** explore to display its attribute window in the right pane. The attribute window displays the attributes that can be defined for the object class. The following attributes are relevant to the identification of the object class:

- **Caption**: Specifies the name of the object class or object class property displayed in the Alfabet user interface.

- **Name**: Used to identify the object class in Alfabet Expand and to specify the object class in Alfabet queries and when defining configuration objects such as XML objects. This attribute is unique for each object class in the meta-model as well as for each property in the object class. In some cases, the **Name** may differ from the caption used in the standard Alfabet interface.

  A validation mechanism checks for correct syntax when defining a technical name. The technical name of a configuration object may not begin with an empty space nor include any of the following special characters: **\ / * ? " > < | ':**

  Furthermore, please note that names may not begin with an empty space nor include special characters. For a list of the special characters that are not allowed, see the section Defining Attributes for Configuration Objects in the chapter Getting Started with Alfabet Expand.

  Furthermore, if the technical name of a configuration object is changed, the name will be correctly updated in other configuration objects referencing the changed object during design time. Please note that the name of a changed configuration object will not be updated in guide pages nor if the guide pages reference a configuration object listed in the **Show Usage** functionality. If you plan to change the name of a configuration object, the reference in the guide page should be changed prior to changing the configuration object name.

- **Tech Name**: Specifies the name of the Alfabet database table column for the object class property. This attribute is unique for each object class. The **Tech Name** attribute is used in native SQL queries to identify the object class.
- **ID Prefix**: The automatically-generated abbreviation of typically 2 or 3 letters to identify the object class (for example, `APP` for `Application` or `BD` for `BusinessData`). The prefix is used to generate the ID for a new object. The object identification number will include the prefix of the object class, followed by an automatically-generated identification number (for example: `APP-378`, whereby `APP` is the value for the **ID Prefix** attribute and `378` is the value for the **ID** attribute). Users can search and identify objects in Alfabet based on their object ID.
- **ID**: The automatically-generated identification number for the object class (for example: `APP-378`, whereby `APP` is the value for the **ID Prefix** attribute and `378` is the value for the **ID** attribute). This attribute cannot be edited and is not visible in the Alfabet interface.
- **Validator**: This attribute is only available for some object class properties of the type String, such as the object class property `Name`, `ShortName`, or `Version`. This attribute allows regular expressions according to Microsoft® syntax conventions to be specified that enforce that the values defined for the attribute have a specific structure. For example, on the object class property `Version`, the **Validator** attribute could specify that version numbers should always be defined as two digits made up of a period and another digit. The validator is enforced on all editors where the object class property can be edited for the relevant object class. Users will be prompted with an error message if the value provided does not match the specified validator. The error message will state that the input value has an invalid format and will display the informational text about the validator that your enterprise has specified in the **Comments** attribute for the custom object property. It is your responsibility to inform users about custom validators configured for object class properties in your enterprise's solution configuration. Please note that specific enforcement mechanisms must be implemented for existing records or records that are imported to Alfabet from external systems. For more information about the syntax conventions for regular expressions, see http://msdn.microsoft.com/en-us/library/hs600312(VS.71).aspx.

About the Stereotypes Attribute for an Object Class

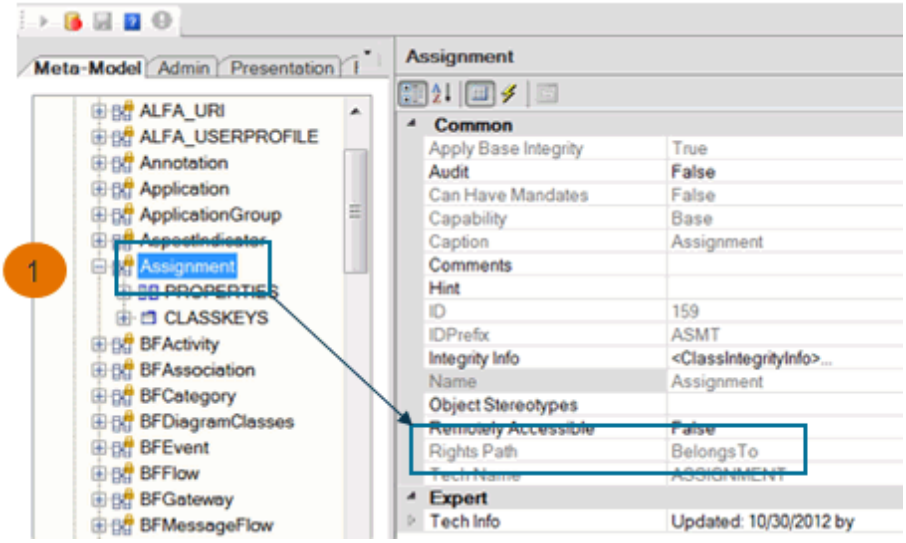
An object class stereotype is a sub-classification of an object class. A permissible object class can have multiple object class stereotypes, each of which captures a specified set of attributes, reference data, and class configurations. For example, the object class Application that may have the object class stereotypes Business Applications and Technical Applications.

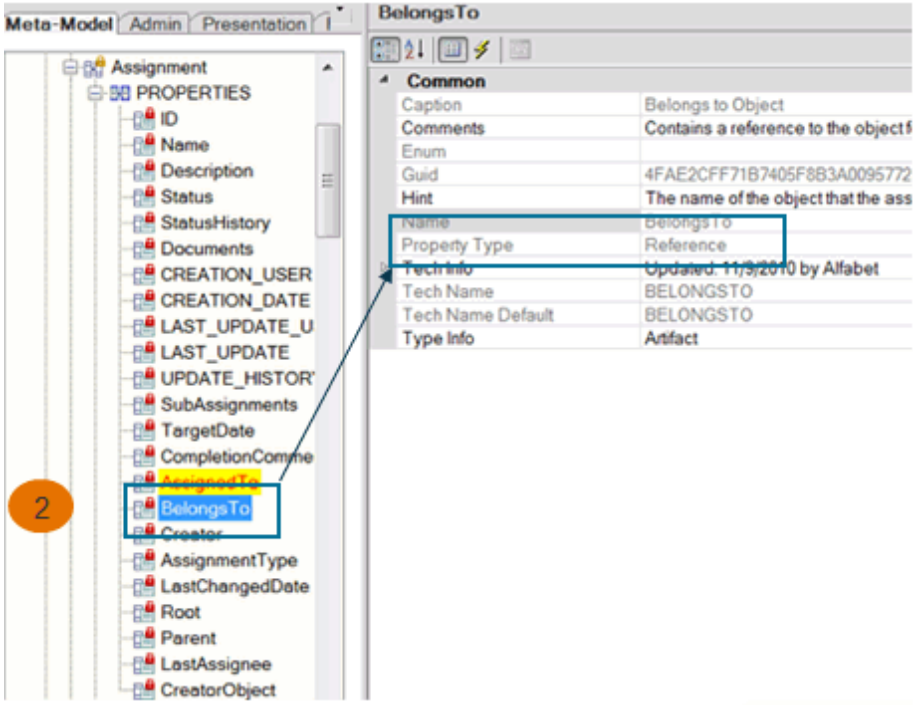
Only a limited number of object classes support the configuration of object class stereotypes.

For an overview of the object classes that support the object class stereotype concept, see the chapter *Overview of Configurable Features for Object Classes* in the reference manual *Configuring Alfabet with Alfabet Expand - Appendix*. For detailed information about how to configure object class stereotypes, see the section Configuring Object Class Stereotypes for Object Classes.

About the Inheritance of Access Permissions

In the Alfabet meta-model, objects in an object class may inherit the access permissions from another object class. The **Rights Path** attribute for an object class indicates if access permissions are inherited and which object class determines the access permissions for the object of that object class. If the **Rights Path** attribute is empty, access permissions are not inherited from another object class. If access permissions are inherited, the **Rights Path** attribute will indicate which object class property determines the access permission.





For example, for the object class `Assignment`, the **Rights Path** attribute is set to `BelongsTo`. The object class property `BelongsTo` is of the type `Reference`. Thus, the object that the assignment belongs to also determines the access permissions for the assignment. In other words, only the owner of an application, for example, has access permissions to its assignment.

Or for example, for the object class `BusinessProcessVariant`, the **Rights Path** attribute is set to `Object`. The object class property `Object` is set to `BusinessProcess`. Thus, the business process variant inherits its access permissions from the business process that it is derived from.

About the Dependencies of an Object Class

In the Alfabet meta-model, objects in an object class may have a dependent relationship to objects in other object classes. The **Integrity Info** attribute defined for an object class (considered the base object class) specifies the object classes that are dependent on that base object class. If an object in the base object class is deleted, all dependent objects will also be deleted. For example, if an application is deleted, all information flows for which the base application is either the owner application (if **Integrity Info** attribute = `Owner`) or the referenced incoming or outgoing application (if **Integrity Info** attribute = `To` or `From`) will also be deleted.

The dependencies between private and protected object classes are part of the standard configuration and should not be customized. An error message will be displayed if syntax errors are written in the XML definition of the **Integrity Info** attribute. For an overview of the objects that are impacted by the deletion of an object in Alfabet, see the description of the relevant object class in the reference manual *Alfabet Meta-Model*.

A service is offered by Software AG that allows the integrity information to be defined on the slave object classes in a master/slave class relationship if a custom class has been introduced to the meta-model. This service ensures that if an object in a custom object class is deleted, the

referenced Alfabet objects will also be deleted. For more information about the definition of the **Integrity Info** attribute for slave object classes, please contact Software AG Support.

About the Tracking of Object Changes for an Object Class

Software AG provides a history tracking functionality that documents the changes made to an object in the context of the Alfabet solution. All changes made to an object's standard and custom object class properties and relations are documented.

The history tracking functionality is implemented on a class-by-class basis. History tracking is available for all protected classes  and public classes  . Please keep the following in mind:

- The **Audit** attribute is set to `True` per default for relevant IT object classes so that the history tracking functionality activated. Please be aware that tracking the history of a significant number of object classes may lead to a decrease in performance. It is recommended that your enterprise consider whether some object classes do not require the history tracking functionality to be activated.
- The history tracking functionality tracks only the change history of objects in the Alfabet solution. A deleted object cannot be restored via the history tracking functionality. If an object has been erroneously deleted, the object must be recreated and redefined in the Alfabet solution.

For more information about configuring history tracking, see the section Specifying History Tracking for an Object Class.

About XML-Based Configurations Relevant to Object Classes

Many functionalities relevant to the implementation of object classes in the Alfabet solution are controlled via an XML object definition. For example, multiple object classes have an object class property **Status** that allows the release status of the object in the approval process to be defined; the possible values for release status definitions must be configured in the XML object ***ReleaseStatusDefs***.

For information about some of the typical configurations required for an object class, see the following sections:

- Configuring Release Status Definitions for Object Classes
- Configuring Object State Definitions for Object Classes
- Configuring Lifecycle Definitions for Object Classes

About the Configuration of Reference and Evaluation Data for an Object Class

The data that can be captured for some object class properties may be determined by the configurations made for the associated object class. Evaluation types and their indicator types, cost types and income types, role types, and diagram views are examples of some of the configured objects that may be assigned to a set of object classes used in your enterprise.

The configuration of evaluation types, indicator types, cost types, income types, role types and diagram types is carried out in the **Configuration** module of Alfabet. The configuration objects are created independent of an object class. For example, an evaluation type may be created for the enterprise and then assigned to many different object classes in the context of the **Class Configuration** functionality in the **Configuration** module. The configuration objects must explicitly be assigned to each object class that they are relevant for. This allows you to create reference or evaluation data that is relevant to a specific object class context. For example, indicators required to evaluate applications typically differ from the indicators required to evaluate devices.

The `TechnicalName` property for the object classes `EvaluationType`, `IndicatorType`, and `RoleType` has been set to protected. It is recommended that you specify the **Validator** attribute of the **Name** property for these classes to indicate that only letters, numbers, blank spaces, underscores, and slashes are allowed as characters for the technical name. To do so, you should enter the following for the **Validator** attribute of the **Name** property for these classes: ^[A-Za-z_0-9\s\/]+$

The validator is enforced on all editors where the object class property is editable. Users will be prompted with an error message if the value provided does not match the validator specified. The error message will state that the input value has an invalid format and will display the text defined in the **Comments** attribute for the custom object class property. It is your responsibility to inform users about custom validators configured for object class properties in your enterprise's solution configuration. Please note that specific enforcement mechanisms must be implemented for existing records or records that are imported into Alfabet from external systems. For more information about the syntax conventions for regular expressions, see http://msdn.microsoft.com/en-us/library/hs600312(VS.71).aspx.

For detailed information about the configuration of reference and evaluation data, see the reference manual *Configuring Evaluation and Reference Data in Alfabet*.

About Mandatory Object Class Properties

Private and protected object class properties that are preconfigured to be mandatory are highlighted yellow in the **Class Model** explorer. These are standard object class properties that are recommended by Software AG to be mandatory properties. No enforcement mechanism is implemented if the object class property is undefined. Mandatory properties may be hidden from editors and wizards as long as they are not included in a class key definition. If the mandatory property is hidden in an editor or wizard, the user is not required to enter a value for the object class property

However, if the object class property is included in a class key definition, an error will occur if the object class property is not defined and users will be prompted to enter a value for the mandatory property. Therefore, if you include a mandatory object class property in a class key, the object class property may not be hidden in the editor or wizard used to create new objects of the relevant property class. For information about the definition of class keys, see the section Specifying History Tracking for an Object Class.

For more information about hiding object class properties in editors or wizards, see the section Refining Visibility Issues in the View Scheme in the chapter Configuring User Profiles for the User Community.

Custom properties may be configured to be mandatory in the context of the custom editor that they are implemented in. In this case, the custom object class property itself is not mandatory but rather the interface control associated with the object class property. For more information, see the section Specifying the Interface Control To Be Mandatory in the chapter Configuring Custom Editors.

Editing a Protected Object Class

A protected object class can be edited in a limited way. A protected object class typically has private object class properties that cannot be edited, protected object class properties that may be edited (for example, `ResponsibleUser`, `Documents`, `CREATION_DATE`, etc.). New object class properties (referred to as custom or public object class properties) can also be created for a protected object class. If custom properties are created for a protected object class, you will typically require a custom appropriate editor in order to allow data to be captured for the custom properties. The creation of custom properties is described in detail in the section Configuring Custom Properties for Protected or Public Object Classes. In addition to creating custom properties for the protected object class or modifying its protected properties, some attributes of the protected object class can be changed.

The **Anonymize** and **Property Anonymization** attributes are relevant for the data anonymization capability, which ensures data transparency and accountability across the enterprise. This capability requires multiple configuration steps and therefore the **Anonymize** and **Property Anonymization** attributes are not described here. For more information about configuring data anonymization, see the section Anonymizing Data in the chapter Executing Administrative Tasks in Alfabet Expand.

To edit the attributes of a projected object class:

1) Expand the **Classes** node and click the protected object class that you want to edit. The attribute grid is displayed.
2) Edit the following attributes, as needed:

- **Can Have Mandates**: Select `True` if the mandate capability should be available for the selected class. Select `False` if the mandate capability should not be available. For detailed information about the implementation and configuration of a federated architecture and mandates, see the section Implementing the Mandate Capability for a Federated Architecture in the chapter Configuring Access Permissions for Alfabet .
- **Audit**: Select `True` if an audit table should be generated in the Alfabet database. Select `False` if an audit table should not be generated in the Alfabet database. Please be aware that tracking the history of a significant number of object classes may lead to a decrease in performance. Furthermore, changes to some properties for some classes may also produce an excessive number of entries in the Alfabet database table. For more information about configuring the history capability, see the section Specifying History Tracking for an Object Class.
- **Comments**: Specify comments relevant to the configuration of the object class. The comments will not be displayed in the Alfabet user interface.
- **Enable for Data Capture Templates**: Select `True` if the object class may be captured via data capture templates. Select `False` if the object class may not be captured via data capture templates. For each object class for which the **Enable for Data Capture Templates** attribute is set to `True`, you must enable the individual properties that shall be captured for the object class by setting the **Enable for Data Capture Templates** attribute for each object class property to `True`. For information about specifying the **Enable for Data Capture Templates** attribute for an object class property, see the section Editing a Protected Property.

  Data capture is limited to `Artifact` object classes only and the **Enable for Data Capture Templates** attribute may only be specified for those classes for which data

capture is permissible. If data capture is not permissible for a class, the attribute will be greyed out.

For more information about data collection via data capture templates, see the section *Capturing Data with Data Capture Templates* in the reference manual *User and Solution Administration*.

- **Integrity Info**: In the Alfabet meta-model, objects in an object class may have a dependent relationship to objects in other object classes. The **Integrity Info** attribute defined for an object class (considered the base object class) specifies the object classes that are dependent on that base object class. If an object in the base object class is deleted, all dependent objects will also be deleted. For example, if an application is deleted, all information flows for which the base application is either the owner application (if **Integrity Info** attribute = `Owner`) or the referenced incoming or outgoing application (if **Integrity Info** attribute = `To` or `From`) will also be deleted. For an overview of the consequences of deleting an object in Alfabet, see the class descriptions in the reference manual *Alfabet Meta-Model*.
- **Stereotypes**: If necessary, specify object class stereotypes for the public object class. For more information about specifying object class stereotypes, see the section Configuring Object Class Stereotypes for Object Classes.
- **Enable Data Translation**: If the **Support Data Translation** attribute is set to `True` for a culture, data translation will be permissible for all classes per default. The **Enable Data Translation** attribute allows you to refine the culture definition and specify the permissibility of data translation for some but not all object classes as well as selected object class properties of the permissible object classes. You can refine permissibility of data translation as follows:

  Please consider the following:

  - Data translation is possible for some protected properties and all public properties of the type `Text` and `String`. You can further refine the permissibility to translate data for selected protected object class properties as well as public properties configured for the object classes for which the **Enable Data Translation** attribute is set to `True`. The specification of data translation for a protected property is defined in defined via the **Automated Translation Rules for Class Properties** attribute described below. For more information about the definition of the data translation for a custom property, see the section Configuring Custom Properties for Protected or Public Object Classes.
  - The specification of the **Enable Data Translation** attribute applies to all cultures defined for your enterprise. Therefore, if you specify that a data translation is not permissible for an object class, then object data cannot be specified for that object class for all defined cultures. Please note that regardless of the specification of the **Enable Data Translation** attribute for an object class, if the **Support Data Translation** attribute is set to `False` for a culture, data translation will not be possible at all for that culture and the language code will not be displayed in the language field in all object editors.If the **Support Data Translation** attribute is set to `False`, then the automated and manual data translation functionalities will be disabled and the language code will not be displayed in the language field in all object editors available for the class.

- The **Enable Data Translation** attribute must be set to `True` in order to enable the object class for either manual data translation or automatic data translation.
- If the **Enable Data Translation** attribute is set to `False`, then the automated and manual data translation functionalities will be disabled, and the language code will not be displayed in the language field in all object editors available for the class.
- For more information about the configuration of object data translation, see the section Configuring the Translation of Object Data in the chapter Localization and Multi-Language Support for the Alfabet Interface.

- To enable an object class for data translation, navigate to the relevant object class and set the **Enable Data Translation** attribute to `True`.
- To disable an object class for data translation, navigate to the relevant object class and set the **Enable Data Translation** attribute to `False`.
- **Enable Automated Data Translation**: Set to `True` if the object class may be translated automatically by the translation service specified in the XML object `AlfaTranslationServicesConfig`. For more information about the configuration of object data translation, see the section Configuring the Translation of Object Data in the chapter Localization and Multi-Language Support for the Alfabet Interface.
- **Automated Translation Rules for Class Properties**: If the **Enable Automated Data Translation** attribute is set to `True`: Click the **Browse** button to open the editor to specify which protected and custom properties may be translated automatically. For each property listed in the **Automated Translation Rules for Class Properties** editor, select True in the **Automated Translation Enabled** column to permit the property to be automatically translated.

  Please note that if the **Enable Data Translation** attribute is set to `None` or `Manual` for a custom property, the value in the **Automated Translation Enabled** column will be set to `False` per default and cannot be automatically translated.

- **Enable Statutory Language**: Set to `True` if the statutory language capability shall be available for the object class. The statutory language capability is available in order to address regulatory requirements that mandate that objects are captured in a specific language. When a user creates an object based on a relevant object class/object class stereotype, a statutory language selector will open in which the language can be selected. In the object editor that opens, the user can capture all attributes that support automated translation in the statutory language. If the XML attribute `EnableStatutoryLanguage` is not set for an object class stereotype in the Stereotypes attribute, the object class stereotype will inherit the definition of the **Enable Statutory Language** attribute specified for the object class. For more information about specifying a statutory language, see the section Specifying a Statutory Language for the Enterprise in the chapter Localization and Multi-Language Support for the Alfabet Interface.
- Attributes in the section **AlfaBot Support**: The attribute in this section are only editable for custom object class. They define if and how the AlfaBot can be used with respect to this object class. Each object class in the meta-model has an **AlfaBot Support** attribute section with four attributes. For standard private and protected object classes, the attributes are visible but not editable. The attributes can only be set for public, customer-defined object classes. The attributes **Creation Mode**, **Editing Mode**, and **Navigation Mode** specify whether and how creation of object, editing of objects or navigation to objects is supported for the object class. The attribute **Analysis Intent Mode** specifies

whether the object class is included into the search in configured reports that can be performed via the `Analyze` intent of the AlfaBot. The attributes can be set to one of the following:

- `None`: The functionality is not supported for the AlfaBot.
- `ContextDependent`: The functionality is supported by the AlfaBot and will take a required context into account. For example information flows can only meaningfully be created in the context of a source or target object. If the user wants to create an information flow via the AlfaBot, the relevant view for creation of the information flow will open, like for example the **Information Flows** page view of an application.
- `Full`: The functionality is supported by the AlfaBot context free. For the creation of objects with the **Creation Mode** attribute set to `Full`, the relevant editor or wizard will open.

> For an overview of the AlfaBot capability, see the section *Using the AlfaBot Capability* in the reference manual *Getting Started with Alfabet*. For information about how to implement the AlfaBot capability, see the section Implementing the AlfaBot for Navigation via a Full-Text Command.

- **Alias**: If the **Analysis Intent Mode** attribute of th object class is set to `Full`, a list of synonyms for the object class can be defined in this attribute. If a user searches for one of the synonyms in the `Analyze` intent of the AlfaBot, the AlfaBot will provide search results for the object class that the synonym is defined for.

3) In the toolbar, click the **Save** button to save the new custom object class.

Creating a Public Object Class

A public object class can be created for special circumstances. For example, some companies may require a custom object class to support setup interoperability to external repositories. In this case, a new object class must be created to capture the reference information to objects in the external repository. The new object class may have multiple properties, one of which typically references an object class/object class stereotype in Alfabet and another property that typically captures the ID of object in the linked repository. For example, the custom object class Application Incident would have a custom property referencing the Alfabet object class Application and a custom property to capture the ID of the linked object in the external incident management repository. Other custom properties can be specified that allow some of the data about the object from the external repository to be captured in Alfabet while other properties may be used to further describe the reference context in Alfabet. The latter would require an appropriate editor to be defined for the reference class (for example, Application Incidents).

Please note the following:

- A custom object class can be deleted at any time. Custom object classes should only be created with the assistance of Software AG Support.
- It is highly recommended that you do not change the technical name of an object class. if you do changed the technical name of an existing public class, the name of the associated database table must also be changed. Otherwise, an error will occur if an attempt is made to update the meta-model and the update of the meta-model will be aborted.

The **Anonymize** and **Property Anonymization** attributes are relevant for the data anonymization capability, which ensures data transparency and accountability across the enterprise. This capability requires multiple configuration steps and therefore the **Anonymize** and **Property Anonymization** attributes are not described here. For more information about configuring data anonymization, see the section Anonymizing Data in the chapter Executing Administrative Tasks in Alfabet Expand.

To create a public object class:

1) Right-click the **Classes** node and select **Add New Class**. The **Create New Class** editor opens. Define the following fields:

- **Class Name**: Enter a unique name for the custom object class. This value is displayed in the solution interface if the **Caption** attribute is not defined.
- **Tech Name**: Enter a unique technical name for the custom object class that will be used in the Alfabet database table. Click **OK** to save the definition.

Please note that the `Tech Name` is the name of the database table that will be created in the Alfabet database for storing object property data of objects of the custom object class. The following rules apply:

- The technical name may not begin with an empty space nor include special characters. For a list of the special characters that are not allowed, see the section Defining Attributes for Configuration Objects in the chapter Getting Started with Alfabet Expand.
- The technical name should only contain standard `ASCII` characters.
- The technical name should consist of upper-case letters only.
- The maximum length of a technical name may not exceed 30 characters.
- The technical name may not coincide with any of the reserved key words of the relational database management system.

A validation mechanism checks for correct syntax when defining a technical name.

2) The public object class is added to the explorer. Click the public object class and define the following attributes in the attribute grid:

- **Name**: This is the technical name of the object class. It is highly recommended that you do not change the technical name of an object class. if you do changed the technical name of an existing public class, the name of the associated database table must also be changed. Otherwise, an error will occur if an attempt is made to update the meta-model and the update of the meta-model will be aborted.
- **Caption**: Specify the caption of the object class that displayed in the Alfabet user interface. If no caption is defined, then no caption will be displayed in the Alfabet user interface.
- **Caption Plural**: Specify the plural form of the caption of the object class.
- **ID Prefix**: Enter the automatically-generated abbreviation of typically 2 or 3 letters to identify the object class (for example, `APP` is used for `Application` or `BD` is used for `BusinessData`). The prefix is used to generate the ID for a new object. The object identification number will include the prefix of the object class, followed by an automatically-generated identification number (for example: `APP-378`,

whereby `APP` is the value for the **ID Prefix** attribute and `378` is the value for the **ID** attribute). Users can search and identify objects in Alfabet based on their object ID.

- **Hint**: Enter informational text about the custom object class. Please note that the **Hint** attribute defined for the custom object class will not be displayed in the Alfabet user interface.
- **Rights Path**: In the Alfabet meta-model, objects in an object class may inherit the access permissions from another object class. The **Rights Path** attribute for an object class indicates if access permissions are inherited and which object class determines the access permissions for the object of that object class. Before you can specify the **Rights Path** attribute you must create the custom property that determines the access permissions for the object class. Once this has been done, enter the name of the custom property in the **Rights Path** attribute. If the **Rights Path** attribute is empty, access permissions will not be inherited from another object class. For more information about creating a custom property, see the section Configuring Custom Properties for Protected or Public Object Classes.

  For example, for the object class `Assignment`, the **Rights Path** attribute is set to `BelongsTo`. The object class property `BelongsTo` is defined for the object class `Assignment` and is of the type `Reference`. Thus, the object that the assignment has been created for (`BelongsTo`) also determines the access permissions for the assignment. In other words, only the owner of an application, for example, has access permissions to its assignment. Or for example, for the object class `BusinessProcessVariant`, the **Rights Path** attribute is set to `Object`. The object class property `Object` is set to `BusinessProcess`. Thus, the business process variant inherits its access permissions from the business process that it is derived from.

- **Apply Base Integrity**: Select `True` if all references to the deleted object should also be deleted if an object of the object class is deleted. The references are specified in the **Integrity Info** attribute. Select `False` if no integrity management should be performed for the object class. In order to improve performance, the value `False` may be set for some custom object classes if no object classes references the custom object class. However, it is highly recommended that you contact Software AG Support if you want to set the value to `False` for a custom object class. Setting the **Apply Base Integrity** attribute to `False` may result in serious inconsistency problems in the database.
- **Audit**: Select `True` if an audit table should be generated in the Alfabet database. Select `False` if an audit table should not be generated in the Alfabet database. Please be aware that tracking the history of a significant number of object classes may lead to a decrease in performance. Furthermore, changes to some properties for some classes may also produce an excessive number of entries in the Alfabet database table. For more information about configuring the history capability, see the section Specifying History Tracking for an Object Class.
- **Comments**: Specify comments relevant to the configuration of the object class. The comments will not be displayed in the Alfabet user interface.
- **Enable for Data Capture Templates**: Select `True` if the object class may be captured via data capture templates. Select `False` if the object class may not be captured via data capture templates. For each object class for which the **Enable for Data Capture Templates** attribute is set to `True`, you must enable the individual properties that shall be captured for the object class by setting the **Enable for Data Capture Templates** attribute for each object class property to `True`. For information about specifying the **Enable for Data Capture Templates** attribute for an object class property, see the section Editing a Protected Property.

  Data capture is limited to `Artifact` object classes only and the **Enable for Data Capture Templates** attribute may only be specified for those classes for which data

capture is permissible. If data capture is not permissible for a class, the attribute will be greyed out.

For more information about data collection via data capture templates, see the section *Capturing Data with Data Capture Templates* in the reference manual *User and Solution Administration*.

- **Integrity Info**: In the Alfabet meta-model, objects in an object class may have a dependent relationship to objects in other object classes. The **Integrity Info** attribute defined for an object class (considered the base object class) specifies the object classes that are dependent on that base object class. If an object in the base object class is deleted, all dependent objects will also be deleted. For example, if an application is deleted, all information flows for which the base application is either the owner application (if **Integrity Info** attribute = `Owner`) or the referenced incoming or outgoing application (if **Integrity Info** attribute = `To` or `From`) will also be deleted. For an overview of the consequences of deleting an object in Alfabet, see the class descriptions in the reference manual *Alfabet Meta-Model*.
- **Stereotypes**: If necessary, specify object class stereotypes for the public object class. For more information about specifying object class stereotypes, see the section Configuring Object Class Stereotypes for Object Classes.
- **Enable Data Translation**: If the **Support Data Translation** attribute is set to `True` for a culture, data translation will be permissible for all classes per default. The **Enable Data Translation** attribute allows you to refine the culture definition and specify the permissibility of data translation for some but not all object classes as well as selected object class properties of the permissible object classes. You can refine permissibility of data translation as follows:

  Please consider the following:

  - Data translation is possible for some protected properties and all public properties of the type `Text` and `String`. You can further refine the permissibility to translate data for selected protected object class properties as well as public properties configured for the object classes for which the **Enable Data Translation** attribute is set to `True`. The specification of data translation for a protected property is defined in defined via the **Automated Translation Rules for Class Properties** attribute described below. For more information about the definition of the data translation for a custom property, see the section Configuring Custom Properties for Protected or Public Object Classes.
  - The specification of the **Enable Data Translation** attribute applies to all cultures defined for your enterprise. Therefore, if you specify that a data translation is not permissible for an object class, then object data cannot be specified for that object class for all defined cultures. Please note that regardless of the specification of the **Enable Data Translation** attribute for an object class, if the **Support Data Translation** attribute is set to `False` for a culture, data translation will not be possible at all for that culture and the language code will not be displayed in the language field in all object editors. If the **Support Data Translation** attribute is set to `False`, then the automated and manual data translation functionalities will be disabled and the language code will not be displayed in the language field in all object editors available for the class.

- The **Enable Data Translation** attribute must be set to `True` in order to enable the object class for either manual data translation or automatic data translation.
- If the **Enable Data Translation** attribute is set to `False`, then the automated and manual data translation functionalities will be disabled and the language code will not be displayed in the language field in all object editors available for the class.
- For more information about the configuration of object data translation, see the section Configuring the Translation of Object Data in the chapter Localization and Multi-Language Support for the Alfabet Interface.

- To enable an object class for data translation, navigate to the relevant object class and set the **Enable Data Translation** attribute to `True`.
- To disable an object class for data translation, navigate to the relevant object class and set the **Enable Data Translation** attribute to `False`.
- **Enable Automated Data Translation**: Set to `True` if the object class may be translated automatically by the translation service specified in the XML object `AlfaTranslationServicesConfig`. For more information about the configuration of object data translation, see the section Configuring the Translation of Object Data in the chapter Localization and Multi-Language Support for the Alfabet Interface.
- **Automated Translation Rules for Class Properties**: If the **Enable Automated Data Translation** attribute is set to `True`: Click the **Browse** button to open the editor to specify which protected and custom properties may be translated automatically. For each property listed in the **Automated Translation Rules for Class Properties** editor, select True in the **Automated Translation Enabled** column to permit the property to be automatically translated.

  Please note that if the **Enable Data Translation** attribute is set to `None` or `Manual` for a custom property, the value in the **Automated Translation Enabled** column will be set to `False` per default and cannot be automatically translated.

- **Enable Statutory Language**: Set to `True` if the statutory language capability shall be available for the object class. The statutory language capability is available in order to address regulatory requirements that mandate that objects are captured in a specific language. When a user creates an object based on a relevant object class/object class stereotype, a statutory language selector will open in which the language can be selected. In the object editor that opens, the user can capture all attributes that support automated translation in the statutory language. If the XML attribute `EnableStatutoryLanguage` is not set for an object class stereotype in the Stereotypes attribute, the object class stereotype will inherit the definition of the **Enable Statutory Language** attribute specified for the object class. For more information about specifying a statutory language, see the section Specifying a Statutory Language for the Enterprise in the chapter Localization and Multi-Language Support for the Alfabet Interface.
- Attributes in the section **AlfaBot Support**: The attribute in this section are only editable for custom object class. They define if and how the AlfaBot can be used with respect to this object class. Each object class in the meta-model has an **AlfaBot Support** attribute section with four attributes. For standard private and protected object classes, the attributes are visible but not editable. The attributes can only be set for public, customer-defined object classes. The attributes **Creation Mode**, **Editing Mode**, and **Navigation Mode** specify whether and how creation of object, editing of objects or navigation to objects is supported for the object class. The attribute **Analysis Intent Mode** specifies

whether the object class is included into the search in configured reports that can be performed via the `Analyze` intent of the AlfaBot. The attributes can be set to one of the following:

- `None`: The functionality is not supported for the AlfaBot.
- `ContextDependent`: The functionality is supported by the AlfaBot and will take a required context into account. For example information flows can only meaningfully be created in the context of a source or target object. If the user wants to create an information flow via the AlfaBot, the relevant view for creation of the information flow will open, like for example the **Information Flows** page view of an application.
- `Full`: The functionality is supported by the AlfaBot context free. For the creation of objects with the **Creation Mode** attribute set to `Full`, the relevant editor or wizard will open.

> For an overview of the AlfaBot capability, see the section *Using the AlfaBot Capability* in the reference manual *Getting Started with Alfabet*. For information about how to implement the AlfaBot capability, see the section Implementing the AlfaBot for Navigation via a Full-Text Command.

- **Alias**: If the **Analysis Intent Mode** attribute of th object class is set to `Full`, a list of synonyms for the object class can be defined in this attribute. If a user searches for one of the synonyms in the `Analyze` intent of the AlfaBot, the AlfaBot will provide search results for the object class that the synonym is defined for.

3) In the toolbar, click the **Save** button to save the new custom object class.

Configuring Object Class Stereotypes for Object Classes

An object class stereotype is a sub-classification of an object class. A permissible object class can have multiple object class stereotypes, each of which captures a specified set of attributes, reference data, and class configurations. For example, the object class Application that may have the object class stereotypes Business Applications and Technical Applications.

Only a limited number of object classes support the configuration of object class stereotypes.

> For an overview of the object classes that support the object class stereotype concept, see the chapter *Overview of Configurable Features for Object Classes* in the reference manual *Configuring Alfabet with Alfabet Expand - Appendix*.

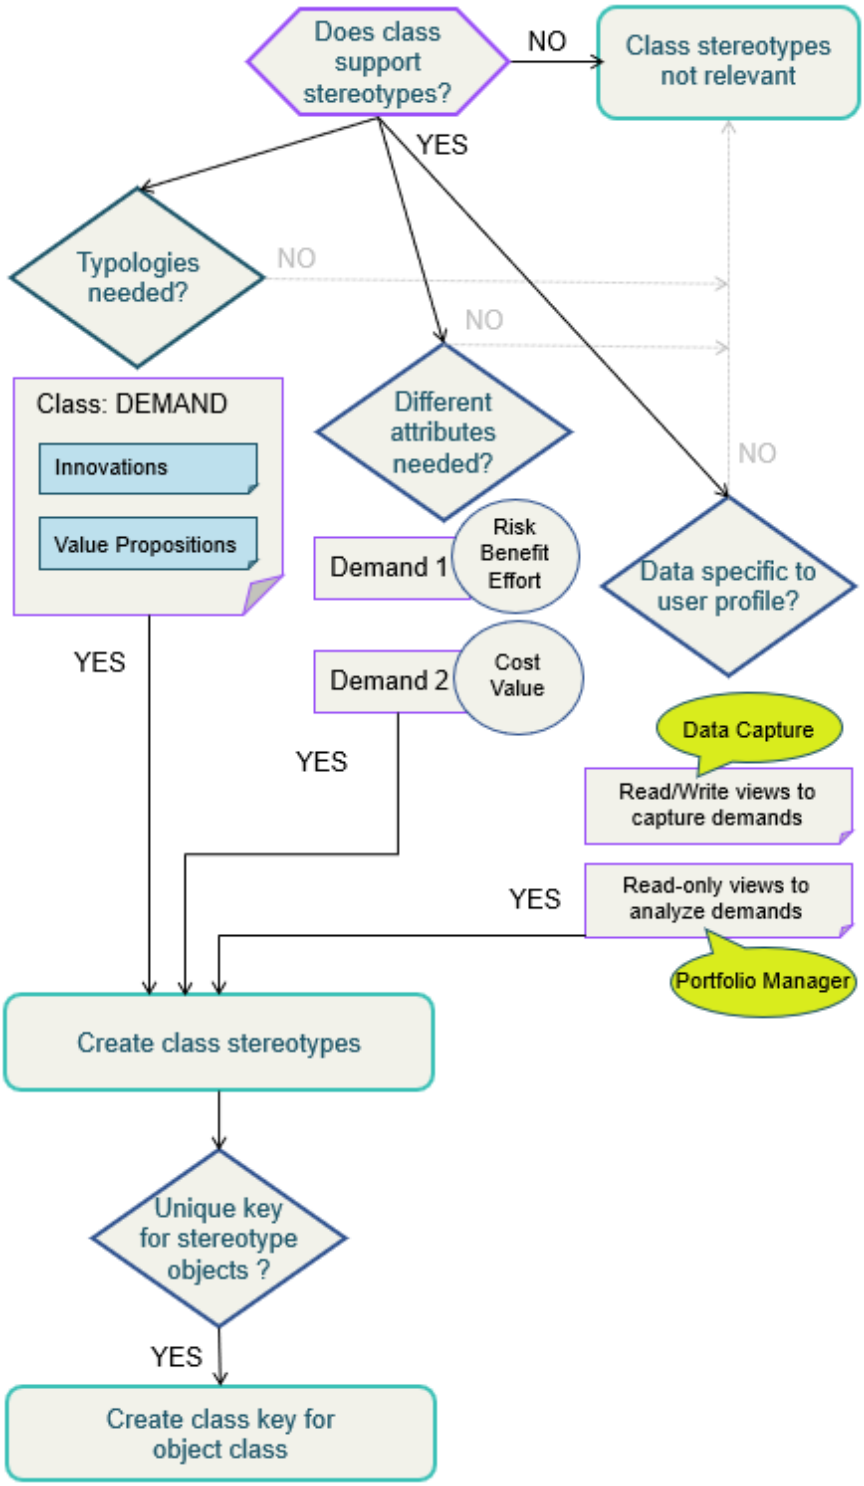


FIGURE: Determining whether to configure class stereotypes

The following can be configured for each object class stereotype created for an object class:

Configuration Option	Explanation
Statuses and Release Statuses	Release statuses can be configured for object class stereotypes in the XML object ***ReleaseStatusDef***. For more information, see the section Configuring Release Status Definitions for Object Classes.
Object States	Object states cannot be configured for individual object class stereotypes in the XML object ***ObjectStateManager***. If the concept of object states is available for the object class that the object class stereotype is based on, then it will also be available to the object class stereotype. For more information, see the section Configuring Object State Definitions for Object Classes.
Lifecycles	Lifecycle definitions cannot be configured for individual object class stereotypes in the XML object ***ObjectLifeCycleManager***. The object class stereotype will inherit the lifecycle concept of the object class that it is based on. For more information, see the section Configuring Lifecycle Definitions for Object Classes.
Searchability	If object class stereotypes have been defined for an object class, the solution designer can specify searchability on the level of the object class and/or object class stereotype. The searchability of object classes/object class stereotypes is defined by means of the **Searchable** attribute for class settings: • If the entire class is to be searchable the **Searchable** attribute for the relevant class settings defined for the object class must be set to `True`. The name of the object class will be displayed in the **Search for** filter in the search functionality. This setting will override the specification of the **Searchable** attribute for the relevant class settings defined for the object class stereotype(s). • If one or more specific object class stereotypes are to be searchable, the **Searchable** attribute for the relevant class settings defined for the object class stereotype(s) must be set to `True`. For more information, see the section Configuring Class Settings for Object Classes and Object Class Stereotypes in the chapter Configuring User Profiles for the User Community.
Mandates	Defined via the XML attribute `HasMandates` in the XML definition of the **Stereotypes** attribute for the relevant object class. If the XML attribute `HasMandates` is set to "`true`", the objects based on the object class stereotype can be defined to have mandates in a federated architecture. For detailed information about the implementation and configuration of a federated architecture and mandates, see the section Implementing the Mandate Capability for a Federated Architecture in the chapter Configuring Access Permissions for Alfabet.
Custom online Help	A custom help can be specified for the object class stereotype via the object view configured for the object class stereotype. For information about the

Configuration Option	Explanation
	syntax of the path, see the chapter Providing Custom Online Help to the User Community.
Custom properties	Custom properties are defined for the base object class that the object class stereotypes are configured for and then assigned to the relevant custom editor and custom object view that they are relevant for. Configure as for a conventional object class. For more information, see the section Configuring Custom Properties for Protected or Public Object Classes.
Custom editors	One or more custom editors must be created to capture data for an object class stereotype. Configure as for a conventional object class. For more information, see the chapter Configuring Custom Editors.
Wizard	Multiple wizards may be created to capture data for an object class stereotype. Configure as for a conventional object class. For more information, see the chapter Configuring Wizards.
Custom object view	One or more custom object views must be created for an object class stereotype to make the information available in the Alfabet user interface. Configure as for a conventional object class. For more information, see the chapter Configuring Object Views.
Class settings	One or more class settings must be created per object class stereotype. Class settings for stereotypes are configured as for a conventional object class. For more information, see the section Configuring Class Settings for Object Classes and Object Class Stereotypes in the chapter Configuring User Profiles for the User Community.
Workflows	Multiple workflows may be created per object class stereotype. Configure as for a conventional object class. For more information, see the chapter Configuring Workflows.
Reference data including, for example, cost types, evaluation types, portfolios, and role types.	Configure as for a conventional object class in the **Configuration** module. The object class stereotypes will be displayed in the explorer of the **Class Configuration** functionality. For more information, see the reference manual *Configuring Evaluation and Reference Data in Alfabet*. **NOTE**: If reference data, evaluation types, etc. are NOT assigned to an object class stereotype in the **Class Configuration** functionality, the reference data, evaluation types, etc. assigned to the base object class of the object class stereotype will be implemented. For example, if no evaluation types are assigned to `Application:<ApplicationStereotype>`, then the evaluations types assigned to the class `Application` will be available for objects based on `<ApplicationStereotype>`

Configuration Option	Explanation
	For some types of configurations, the specifications for the object class stereotype will be ignored. In this case, the configuration specified for the base object class of the object class stereotype will apply. This is the case for: • Prioritization Schemes • Portfolios (but not configured report portfolio views) • Diagram View Items • Aspect Evaluation Types • Aspect Prioritization Schemes • Aspect Portfolios

If object class stereotypes are defined for an object class, then a user creating a new object will be required to first define the object class stereotype that the new object is to be based on in the **Stereotype Selector** that will automatically open when the **Create New <ObjectClass>** action is selected. The **Stereotype Selector** lists the possible object class stereotypes for the selected object class. The **Stereotypes** attribute is thus specified for the object via the selection in the **Stereotype Selector**. Once the selector is closed, the relevant editor will open and the user can continue to define the new object. The defined object can then be viewed in the relevant custom object view configured for the object class stereotype. The **Stereotypes** attribute must be specified whenever an object is created that is based on an object class for which object class stereotypes are configured.

A **Change Stereotype** button is available in the toolbar of object profiles for which object class stereotypes have been configured thus allowing the user to easily change the stereotype that an object is based on. The menu of the **Change Stereotype** button will display all stereotypes configured for the object class. If the **Change Stereotype** button should not be used by users with a specific user profile, the button can be hidden for that user profile. For more information, see the section Hiding Functionalities in an Object View in the chapter Configuring User Profiles for the User Community.

Please note that the **Change Stereotype** button will only be available for object classes that are not relevant in the configuration of an XML object available in the **SolutionManagers** folder in Alfabet Expand. The following classes do not support the **Change Stereotype** button: **Application**, **Component**, **Demand**, **Demand Group**, **Domain**, **Feature**, **ICT Object**, **Organization**, **Policy**, **Policy Group**, **Project**, **Resource**, **Service Product**, **Service Product Item**, **Standard Platform**, **Technical Service**, **Technical Service Operation**, **Technical Service Operation Method**, and **Value Node**, and **Vendor Product**.

If object class stereotypes have been configured for an object class, the **Stereotype** attribute must be specified for every object of that object class. This is particularly important to take into consideration if objects are to be created by means of the **Extended Data Capture** functionality. Once the object class stereotype has been defined for a new object, it can be changed via the **Change Stereotype** button in the toolbar of object profile (unless it is based one of the object classes listed above that do not support the **Change Stereotype** button. For more information about the **Extended Data Capture** functionality, see the chapter *Capturing Data with Data Capture Templates* in the reference manual *User and Solution Administration*.

The following information is available:

- Creating Object Class Stereotypes for an Object Class
- Configuring Uniqueness Constraints for an Object Class Stereotype
- Providing Custom Online Help for an Object Class Stereotype

Creating Object Class Stereotypes for an Object Class

Object class stereotypes must be created for the relevant object class via the **Stereotypes** attribute. By means of the **Stereotypes** attribute, the solution designer creates the object class stereotypes by defining a stereotype name, the singular and plural form of the object class stereotype's caption, and whether the object class stereotype may have mandates assigned. Once the object class stereotype has been created, class settings can be configured to specify whether the object class stereotype is searchable in the search functionalities and which icon and preview properties to display for the object class stereotype. For more information, see the section Configuring Class Settings for Object Classes and Object Class Stereotypes in the chapter Configuring User Profiles for the User Community.

The configuration of object class stereotypes should not be changed once the object class stereotype is implemented. It is important that all relevant object class stereotypes that you plan to implement in your enterprise are well-considered at the stage of configuration.

The following information describes the general procedure to configure object class stereotypes for all object classes that allow stereotype configuration. The specification object class stereotypes is made in an XML definition in the **Stereotypes** attribute for the relevant object class. For an overview of the object classes that support the object class stereotype concept, see the chapter *Overview of Configurable Features for Object Classes* in the reference manual *Configuring Alfabet with Alfabet Expand - Appendix*.

Example of the XML definition in the **Stereotypes** attribute for the object class `Domain`:

```
<ClassStereotypes>
   <Stereotype Name="Area" Caption="Area" CaptionPlural="Areas"
   Comments="" HasMandates="false" IDPrefix="AR" />
   <Stereotype Name="SubArea" Caption="Sub-Area" CaptionPlural="Sub-
   Areas" Comments="" HasMandates="false" IDPrefix="SAR"/>
   <Stereotype Name="BusinessDomain" Caption="Business Domain"
   CaptionPlural="Business Domains" Comments="" HasMandates="false"
   IDPrefix="BDOM"/>
   <Stereotype Name="TechnologyDomain" Caption="Technology Domain"
   CaptionPlural="Technology Domains" Comments=""
   HasMandates="false" IDPrefix="TDOM"/>
</ClassStereotypes>
```

For some object classes, a hierarchy is typically configured for the object class stereotypes of these object classes and thus additional configuration is required. This is described in detail in the following sections of the chapter Configuring Alfabet Functionalities Implemented in the Solution Environment.

- For the object class `Domain`, see Configuring Domain Models and Domain Planning.

Please note that the mandate capability may be differently configured for the individual object class stereotypes defined for an object class, with the exception of the object class `Domain`. The object class `Domain` requires that the configuration of the `HasMandates` attribute is the same for all domain stereotypes. For more information about the configuration of the mandate capability for the object class `Domain`, see the section Implementing Mandates for the Domain Model in the chapter Configuring Domain Models and Domain Planning.

- For the object class `Project`, see Configuring the Project Management Capability.
- For the object class `ValueNode`; see Configuring the Strategy Deduction Capability.
- For the object class `OrgaUnit`, see Configuring the Organizational Hierarchy.
- For the object class `ICTObject`, see Configuring the ICT Object Hierarchy.
- For the object class `Demand`, see Configuring the Demand Hierarchy.
- For the object class `Feature`, see Configuring the Feature Capability.
- For the object class `ITPolicy`, see Configuring the Policy Hierachy.
- If object class stereotypes are configured for an object class that can be defined in the *To-Be Architecture Page View* (such as `Application`, `Component`, `Device`, or `StandardPlatform`) then you must create an identical configuration for the corresponding solution object class (for example, for `SolutionApplication` or `SolutionComponent`, `SolutionDevice`, or `SolutionStandardPlatform`). For example, the configuration defined in the **Stereotypes** attribute for the object class `Application` should be copied and pasted to the **Stereotypes** attribute for the object class `SolutionApplication`. If the configuration is not the same, errors may occur when solution objects are checked in to the Alfabet inventory in the context of project and solution planning. For more information about configuration requirements for solution Alfabet, see the section Making the As-Is Architecture and To-Be Architecture Capabilities Available.

To configure object class stereotypes for a relevant object class:

1) Expand the **Classes** node and click the relevant protected object class for which it is permissible to configure object class stereotypes.
2) In the attribute window, define the **Stereotypes** attribute in the text editor available for the XML definition. For each object class stereotype, define the following XML attributes:

An error message will be displayed upon closing the text editor if syntax errors are written in the XML definition of the **Stereotypes** attribute.

- `Stereotype Name`: Enter the technical name for each object class stereotype. You may define a name of up to 64 characters. This name should not be changed once the object class stereotypes are implemented.

Changing the technical name after objects have been created based on the object class stereotype requires such objects to be updated by means of an ADIF scheme.

For more information, see the reference manual *Alfabet Data Integration Framework*.

- `Caption`: Enter the caption for the object class stereotype. This is the name that users will see in the Alfabet user interface.

  Please note that the following:

  - The caption of the object class stereotype should be different than the caption of its object class. This is particularly important for the implementation of the search functionality for the object class stereotype. For more information, see the section Configuring Class Settings for Object Classes and Object Class Stereotypes in the chapter Configuring User Profiles for the User Community.
  - The values defined for the XML attribute `Caption` can be translated whereas the values defined for the XML attribute `Stereotype Name` cannot be translated. However, in the table of the **Simple Search** functionality as well as other search selectors, the values defined for the XML attribute `Stereotype Name` of the object class stereotype are displayed in the **Stereotypes** column. If the values defined for the XML attribute `Caption` should be displayed, a custom selector should be defined. For more information, see the section Configuring a Custom Selector for Search Functionalities.
  - If you want to enter a caption (`Caption`) or plural form for the caption (`CaptionPlural`) that contains special characters (for example, a greater then (>) or lesser then (<) symbol), you must replace the special characters with respective XML compliant code, for example:
    - > for >
    - < for <
    - " for "
    - [for [
    -] for]
  - The caption will be available in the vocabularies and can be translated to the secondary languages implemented in your enterprise.

- `Description`: Provide a brief description about the object class stereotype. The description will be displayed in the **Stereotype Selector** that opens when the user must select which stereotype a new object is to be based on. The description should help the user to understand which stereotype the new object should be based on. The description will be available in the vocabularies and can be translated to the secondary languages implemented in your enterprise.
- `CaptionPlural`: Enter a plural form for the caption. This is the name in plural that users will see in the Alfabet user interface.
- `IDPrefix`: Enter no more than 5 characters for the ID prefix used to generate the unique identification number for new objects based on the object stereotype. If the XML attribute `IDPrefix` is not specified, the ID prefix of the object class that the object class stereotype is based on will be used to generate the unique ID. Please note that the integer generated for the unique ID is based on the number of instances

created for the object class that the object class stereotype is based on, and includes all instances of all object class stereotypes created for the object class.

The prefix ID of existing objects based on an object class stereotype can be updated via the ADIF import scheme `SetStereotypeID` available in the `Alfabet Standard Jobs` folder. For more information, see the section *Predefined ADIF Schemes* in the reference manual *Configuring Alfabet with Alfabet Expand*.

- `Comments`: Enter text in order to provide information about the object class stereotype. This information is only for the purposes of configuration. It is not displayed in the Alfabet user interface.
- `HasMandates`: Enter "`true`" if the mandate capability should be available for the object class stereotype. Enter "`false`" if the mandate capability should not be available for the object class stereotype. If the XML attribute `HasMandates` is defined as "`false`" for an object class stereotype, objects based on the object class stereotype will be visible to users with any mandate implemented in your enterprise. For information about additional configuration requirements necessary to implement the mandate capability, see the section *Implementing the Mandate Capability for a Federated Architecture* in the chapter Configuring Access Permissions for Alfabet .
- `EnableStatutoryLanguage`: Set to `True` if the statutory language capability shall be available for the object class stereotype. The statutory language capability is available in order to address regulatory requirements that mandate that objects are captured in a specific language. When a user creates an object based on a relevant object class/object class stereotype, a statutory language selector will open in which the language can be selected. In the object editor that opens, the user can capture all attributes that support automated translation in the statutory language. If the XML attribute `EnableStatutoryLanguage` is not set, the object class stereotype will inherit the definition of the **Enable Statutory Language** attribute specified for the object class. Specifying a Statutory Language for the Enterprise

3) In the toolbar, click the **Save** button to save your changes.

Configuring Uniqueness Constraints for an Object Class Stereotype

Uniqueness constraints cannot be explicitly defined for a specific object class stereotype. Uniqueness constraints are configured in the class key on the level of the base object class. The class key configuration is thus inherited by all object class stereotypes configured for the object class. For example, a class key defined for the object class `Application` will inherently be applied to all object class stereotypes configured for the object class `Application`. For more information about configuring class keys, see the section Configuring Class Keys for Object Classes.

Providing Custom Online Help for an Object Class Stereotype

You can provide a custom online Help for the object class stereotypes that you configure in order to help your user community understand the content of the object class stereotype. The path to the custom help must be defined in the **Custom Context-Sensitive Help URL** attribute for the object view configured for the object class stereotype. Please note that the hyperlinked caption displayed in the Help window will display the name of the object class that the object class stereotype is defined for and not the caption of the object class stereotype. For example, the help link will display **Help on Applications** (and not, for example, **Help on Technical Applications**).

In the **Custom Context-Sensitive Help URL** attribute for the object view configured for the object class stereotype, enter the URL or server variable that targets the custom context-sensitive help.

For more information about configuring an object view for an object class stereotype, see the chapter Configuring Object Views. For detailed information about the various options for configuring custom help, see the chapter Providing Custom Online Help to the User Community.

Configuring Custom Properties for Protected or Public Object Classes

You can create multiple custom object class properties for an object class. For reasons of performance, it is recommended that you do not create more than 30 custom object class properties per object class. All standard and custom object class properties are listed in the **Class Model** explorer below the relevant object class node. The properties are listed in the order of their creation. To organize the object class properties in alphabetical order, right-click the **Classes** node in the **Meta-Model** tab and select **Sort Properties by Name**. All properties will be sorted for all classes for the current user session.

The number of object class properties that may be created for an object class is limited to 255. If a user attempts to create more than 255 object class properties, a warning will be displayed and the property exceeding the limit will be discarded. If more than 255 properties exist and a meta-model update is executed, a warning will be added to the log file that the class properties for the specific class exceeds the limit. The limit of 255 applies only to the properties displayed in Alfabet Expand and does not include database properties such as RefStr, INSTGUID, etc.

Any changes made to the meta-model will impact both the relevant class table and audit table in the Alfabet database. For example, if a custom object class property is deleted from the class model, it will also be deleted from the audit table and thus will no longer be displayed in the *Object Audit Page View* available in your Alfabet solution.

It is highly recommended that you do not change the meta-model once the auditing capability is implemented, otherwise errors may occur in the audit information.

- Configuring Custom Properties of the Type Text
- Configuring Custom Properties of the Type Real
- Configuring Custom Properties of the Type Integer

- Configuring Custom Properties of the Type URL
- Configuring Custom Properties of the Type Reference
- Configuring Custom Properties of the Type ReferenceArray
- Configuring Custom Properties of the Type Email
- Changing an Existing Custom Property

What to Consider When Creating Custom Properties

You can define custom object class properties  for any protected object class  that you see displayed in the **Classes** node in the **Meta-Model** tab of Alfabet Expand.

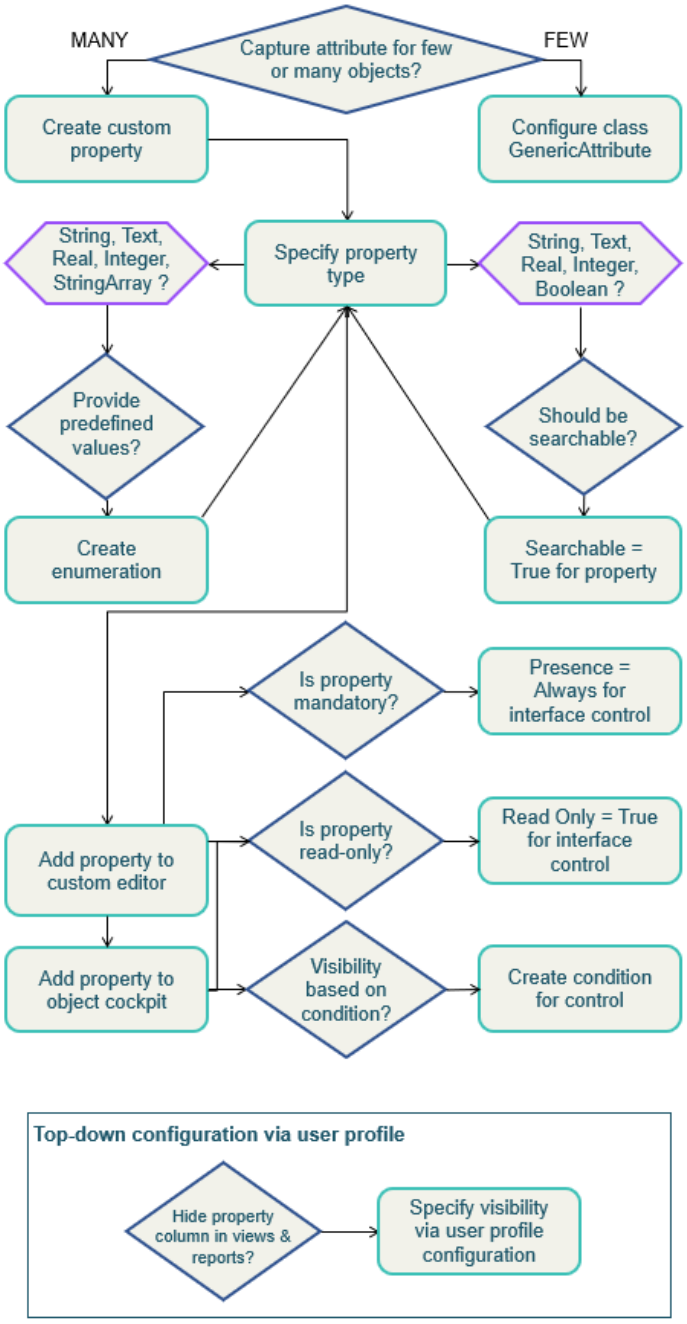

FIGURE: Steps to configure object class properties

The following issues should be taken into consideration when you configure custom object class properties for your Alfabet solution:

- What kind of data must the user enter for the custom object class property? This will determine the property type that you define for the custom object class property. For example, will the user enter a `True/False` value (`Boolean`), a number (`Real` or `Integer`), or text (`String` or `Description`)? For an overview of the available property types, see the section Overview of Data Types Available for Custom Properties.
- Will the data generally be captured for most objects or only in rare cases. A generic attribute can be used if one or more attributes are required for informational purposes only and each attribute is only used for a small subset of objects rather than for all objects in an object class. A generic attribute is

an alternative to configuring a custom property for an object class. For more information about working with generic attributes, see the section Implementing the Generic Attribute Concept Instead of Custom Properties.

- Can the user enter a value of his/her choice or must he/she select a value from a drop-down list displaying predefined values? If a drop-down list with pre-defined values is needed, you will first need to create an enumeration, which is the set of values that are to be displayed in the drop-down list. An enumeration can only be assigned to custom object class properties of the type `String`, `Text`, `Real`, `Integer`, or `StringArray`. For more information about configuring enumerations for a custom object class property, see the section Defining Protected and Custom Enumerations

- How many custom object class properties will be required for an object class? How many custom tabs will be required for the custom object class properties in the custom editor that you will later create? For more information about the types of interface controls available for custom editors, see the section Overview of the Interface Controls Available for Custom Editors in the chapter Configuring Custom Editors.

- Are rules (class keys) required so that users must enter a unique set of values for a combination of standard and/or custom object class properties? If this is the case, you must ensure that the custom object class properties that are to be included in the class key definition are of the object class property types `Date`, `Integer`, `Real`, or `String`. For more information about configuring class key for a custom object class property, see the section Configuring Class Keys for Object Classes.

- Do the captions for custom object class properties need to be translated for other interface languages used in your Alfabet solution? For general information about translating captions, see the section Modifying, Translating and Managing the Vocabularies in the chapter Localization and Multi-Language Support for the Alfabet Interface.

- Should the custom object class property be displayed in relevant page views or configured reports. If this is the case, you should specify it to be visible as a column in the relevant page view/configured report. For more information, see the section Refining Visibility Issues in the View Scheme in the chapter Configuring User Profiles for the User Community.

Keep the following in mind when defining custom object class properties:

- When you define a custom object class property, you can choose from a limited number of property types. For an overview of all data types and the possible visualization of these data types in a custom editor, see the section Overview of Data Types Available for Custom Properties.

- A custom editor can display multiple custom object class properties distributed across multiple tabs. For the sake of usability and performance, however, it is recommended that you do not create more than a total of 30 custom object class properties per object class nor design more than three tabs per custom editor.

- Each property type is automatically associated per default with a specific interface control. Once the custom object class properties are defined, you can automatically generate the custom editor. The custom object class properties are assigned to the default interface controls and automatically placed in the custom editor. If more than ten custom object class properties are defined for the object class, additional tabbed pages will be generated. You can later modify the visualization of the custom editor, add additional tabbed pages, and opt for a different interface control for a specific custom object class property.

- The searchability of private properties is predefined by Software AG, but the searchability of protected properties as well as public properties may be specified by the solution designer via the **Searchable** attribute available for the protected/public property. Therefore, private properties that are preconfigured by Alfabet as well as all public and protected properties of the type `String`,

`Integer`, `Real`, `Date`, and `Boolean` for which the **Searchable** attribute has been set to `True` will be available in the **Search Attributes** field. Keep the following in mind:

- Any protected or custom object class properties that you configured to be searchable can be defined by users as search criteria in the **Search Attributes** field in the **Simple Search** tab of the object selector or **Search** functionality when searching for objects in the relevant class.
- Any protected or custom object class properties that you configured to be searchable and that are either 1) of the type `String` and have an enumeration assigned or 2) of the type `Boolean` can be selected in multiple selection combo box filters (such as the **Object Filter** fields typically available in diagrams. In this way, users can filter the results shown in a diagram based on the object class properties. The multiple selection combo box displays searchable standard and custom object class properties using the following nomenclature: `<ClassName>.<CustomPropertyName> = <CustomPropertyValue>`.For more information about the use of object filters in diagrams and other views, see the section *Defining Multiple Selection Combo Box Fields* in the reference manual *Getting Started with Alfabet*

Implementing the Generic Attribute Concept Instead of Custom Properties

The object class **Generic Attribute** (`GenericAttribute`) has the following object class properties.

- `Name`: The name of the generic attribute. This attribute corresponds to the caption of a custom object class property.
- `Type`: The data type defined for the generic attribute. Generic attributes can have the type `String`, `Boolean`, `Integer`, `Date`, `Real`, `Color` or `Icon`. Alternatively, an existing enumeration can be specified as the type and an enumeration item can be selected as the value for the generic attribute. Please note that the attribute **Enabled for Generic Attribute** must be set to `True` for the enumeration if it is to be available in the context of a generic attribute. Only enumerations set to **True** will be displayed in the relevant **Type** field in the **Generic Attribute** editor.
- `Owner`: The object that the generic attribute is defined for. Generic attributes can be created for objects of the object classes `Application`, `Component`, `Deployment`, `Deployment Element`, `Standard Platform`, `Standard Platform Element`, `Stack`, `Stack Element`, and `Stack Item` (**Stack Configuration Item**).
- `Value`: The value for the generic attribute. The possible value that can be defined will depend on the data type specified for the **Type** attribute.
- `Group`: Generic attributes can be structured in generic attribute groups. Generic attributes with identical string values for the property `Group` belong to the same group.

Please note the following regarding the implementation of generic attributes:

- Generic attributes can be configured for an object class or object class stereotype in the *Generic Attributes Page View* (`SET_GenericAttributes`) available in the **Class Configuration** functionality. Generic attributes can be created here with a predefined value and reused in the *Generic Attributes Page View* (`ObjectGenericAttributes`) available for objects of the relevant object classes/object class stereotypes. The value can be changed for an object as needed.
- The *Generic Attributes Page View* (`ObjectGenericAttributes`) is available per default in the **Structure** workspace of the standard object views for the object classes `Application`, `Component`, `Deployment`, `Deployment Element`, `Standard Platform`, `Standard Platform Element`, `Stack`, `Stack Element`, and `Stack Item` (**Stack Configuration Item**). The *Generic*

Attributes Page View (`ObjectGenericAttributes`) allows new generic attributes to be created or existing generic attributes created for an object of the same object class or in the context of the **Class Configuration** functionality to be created for a selected object. The value of the generic attribute can be changed, as needed.

- To display generic attributes in object profiles or object cockpits, see the sections Adding a Generic Attribute to the Attributes Section and Adding a Generic Attribute to the Object Cockpit in the chapter Configuring Object Views.
- Properties that are stored as objects of the class `GenericAttribute` can be imported or exported via the Alfabet RESTful API v2. For more information, see the reference manual *Alfabet RESTful API*

Overview of Data Types Available for Custom Properties

When you define a custom object class property, you can choose from a limited number of property types. The attributes that are available for an object class property type will vary. The table also indicates whether it is possible to specify a default value for the custom object class property, the searchability of the custom object class property, or an enumeration providing preconfigured values for user to define for the custom object class property.

Please note that a `NULL` value will be stored in the Alfabet database for a data type if no value is defined for the custom object class property. In the case of custom object class properties of the type `Boolean`, it is highly recommended that a default value is configured to ensure that the value `False` (rather than `NULL`) is stored for a custom object class property if the associated checkbox that is not selected.

The following data types can be selected in the **Property Type** attribute for a custom object class property.

Custom Property Data Types	Description	Default Value	Is Searchable	Enumeration	Interface Control
`String`	An object class property of the type `String` may have between 1-1999 characters of text.	yes	yes	yes	`Edit`, `ComboBox`, `RadioGroupButton`
`Boolean`	An object class property of the type `Boolean` has the permissible values `True` or `False`.	yes	yes	no	`CheckBox`
`Date`	Users must specify a date.	no	yes	no	`Edit` (The **Calendar** button will be automatically added to the `Edit` field.)

Custom Property Data Types	Description	Default Value	Is Searchable	Enumeration	Interface Control
`DateTime`	Users must specify a date and time.	no	yes	no	`Edit` (Users must explicitly enter a date and time in the editor field.)
`Integer`	An object class property of the type Integer requires a positive or negative integer number as value.	yes	yes	yes	`Edit`
`Real`	An object class property of the type `Real` requires a positive or negative decimal number as value.	yes	yes	yes	`Edit`
`Reference`	An object class property of the type Reference is used to define relationship information between two objects that have a 1:n relationship. **NOTE**: A custom object class property of the type `Reference` should be defined with the help of Software AG Support	no	no	no	`EditSearch`, `ComboBox`, `ListBox`, `RadioButtonGroup`
`ReferenceArray`	An object class property of the type `ReferenceArray` is used to define relationship information between two objects that have an n:n relationship. **NOTE**: A custom object class property of the type `ReferenceArray` should be defined with the help of Software AG Support	no	no	no	`CheckedListBox`, `EditSearch`
`StringArray`	For properties of the type `StringArray`, multiple values of the enumeration can be selected.	no	no	yes	`CheckedListBox`
`Text`	An object class property of the type `Text` allows a large amount of text to be captured. An HTML editor may be implemented in custom editors, object profiles,	no	no	no	`Memo`, `CheckedListBox`, `ListBox`, `ComboBox`

Custom Property Data Types	Description	Default Value	Is Searchable	Enumeration	Interface Control
	and object cockpits for properties of type `Text`.				
`URL`	An object class property of the type `URL` allows users to define a URL. The URL can be displayed as a link in the **Attributes** section of the object's profile or an object cockpit. Clicking the link in the object profile/object cockpit or preview will open the URL in a separate browser window.	no	no	no	`Edit`

Creating a New Custom Property

The procedure described below is a general approach to configuring custom object class properties and therefore not all attributes available for all property types are described below. The attributes available in the attribute window will depend on the object class property type that you select for the custom object class property.

If you plan to use native SQL instead of the Alfabet query language for queries, you must ensure that a technical name exists for each custom object class property.

To create a new custom object class property for a selected object class:

1) Expand the **Classes** node and right-click the relevant object class  and select **Add New Property**. The **Create New Property** editor opens. Define the following fields:

- **Property Name**: Enter a unique name for the custom object class property. This value is displayed in the solution interface if the **Caption** attribute is not defined.
- **Caption**: Specify a caption to be displayed for the property in the Alfabet user interface.
- **Tech Name**: Enter a unique technical name for the custom object class property that will be used in the Alfabet database table. Click **OK** to save the definition.

Please note that the `Tech Name` is the name of the column that will be created in the database table of the object class for storing values for the custom property. The following rules apply:

- The technical name may not begin with an empty space nor include special characters. For a list of the special characters that are not allowed, see the section Defining Attributes for Configuration Objects in the chapter Getting Started with Alfabet Expand.

- The technical name should only contain standard `ASCII` characters.
- The technical name should consist of upper-case letters only.
- The maximum length of a technical name may not exceed 30 characters for properties that are not translatable and may not exceed 25 characters for properties that have the **Enable Data Translation** attribute set to `True`.
- The technical name may not coincide with any of the reserved key words of the relational database management system.

A validation mechanism checks for correct syntax when defining a technical name.

2) In the toolbar, click the **Save**  button to save the new custom object class property.

For detailed information about the configuration of the various types of custom object class property:

- Configuring Custom Properties of the Type String and StringArray
- Configuring Custom Properties of the Type Boolean
- Configuring Custom Properties of the Type Date and DateTime
- Configuring Custom Properties of the Type Text
- Configuring Custom Properties of the Type Real
- Configuring Custom Properties of the Type Integer
- Configuring Custom Properties of the Type URL
- Configuring Custom Properties of the Type Reference
- Configuring Custom Properties of the Type ReferenceArray
- Configuring Custom Properties of the Type Email

Configuring Custom Properties of the Type String and StringArray

A property of the type `String` allows a value to be manually entered in a custom editor by the end user. It is also possible to provide a set of preconfigured values for the user to select from. In this case, the custom object class property must be associated with an enumeration. An enumeration is made up of enumeration items that can be selected as the value for the custom object class property.

An enumeration can be associated with an object class property of the type `String`, whereby a single enumeration item to be selected as a value. An enumeration can also be associated with an object class property of the type `StringArray`, whereby multiple enumeration items can be selected.

Please note that an enumeration cannot be translated if it is assigned to an object class property of the type `StringArray`. If you need to configure an object class property in which multiple selection of values is possible, then the enumeration must be assigned to an object class property of the type `Text`. For more information, see the section Configuring Custom Properties of the Type Text. The translation capability is described in detail in the section Modifying, Translating

and Managing the Vocabularies in the chapter Localization and Multi-Language Support for the Alfabet Interface.

If the custom object class property is associated with an enumeration, the enumeration items can also be selected in a multiple selection combo box available in diagrams associated with the relevant object class.

If the custom object class property is to be associated with an enumeration, the enumeration must first be defined before it can be assigned to the custom object class property. For information about how to configure an enumeration for a `String` or `StringArray` property, see the section Defining Protected and Custom Enumerations.

To add a custom object class property of the type `String` to a custom editor, add an `Edit`, `ComboBox`, or `RadioGroupButton` interface control to the custom editor. To add a custom object class property of the type `StringArray` to a custom editor, add a `CheckedListBox` interface control to the custom editor. Please note that a `CheckedComboBox` should not be used. For more information, see the section Configuring the Interface Controls in the Custom Editor.

A color selector can be added to any custom editor created for an object class that has a `Color` property of the type `String`. When the user creates or edits an object in the custom editor, he/she can change the color in the custom editor. The color will then be used for the display of that object in business graphics for all Alfabet views and configured reports for all users. For more information, see the section Adding a Color Selector to the Custom Editor.

To define a custom object class property of the type `String` or `StringArray`:

1) In the attribute window, define the following attributes, as needed:

- **Property Type**: Select `String` or `StringArray`.
- **Name**: Enter a name of the object class property. The name must be unique in the scope of the selected object class.
- **Caption**: Specify a caption to be displayed for the property in the Alfabet user interface. If no caption is defined, then no caption will be displayed in the Alfabet user interface.
- **Enable for Data Capture Templates**: Select `True` if the object class property may be captured via data capture templates. Select `False` if the object class property may not be captured via data capture templates. The **Enable for Data Capture Templates** attribute must be set to `True` for the object class that the object class property is assigned to. For more information about data collection via data capture templates, see the section *Capturing Data with Data Capture Templates* in the reference manual *User and Solution Administration*.

  If the protected property is inherited from the parent object class `Artifact` or `ArtifactAuthorized`, then the **Enable for Data Capture Templates** attribute will be greyed out. In this case, you must specify a local setting for the property that will apply to the property only in the context of this object class. To do so, expand the **Local Settings** section and set the **Enable for Data Capture Templates** attribute to `True` to override the inherited setting from the parent object class. Please note that in order to prevent the ID of objects being erroneously changed via data capture templates, the `ID` property cannot be enabled as a class property.

  Properties of the type `BinData`, `Picture`, `DateArray`, `POSIX`, `ByteArray`, `DateArray`, `DateTimeArray`, `BindataArray`, `IntegerArray`, `TimeArray`, `PropertySet`, `StringArray`, and `URLArray` are not suitable for data capture templates.

- **Size** attribute: Specify the maximum number of characters that the string may consist of. An object class property of the type `String` may have between 1-1999 characters of text.

  Please note however, strings with more than 600 characters might exceed the maximum size restrictions of your enterprise's database server that hosts the Alfabet database.

- **Searchable**: Please consider the following:

- For custom object class properties of the type `String` only: Set to `True`. if the object class property is to be searchable in the search functionalities. The custom object class property will be displayed in the searchable properties field in the standard search functionalities as well as relevant standard or custom selectors implemented for search filters. If you select `False`, the custom object class property will not be searchable in the standard search functionalities nor in the standard or custom selectors implemented for search filters.

- . For custom properties of type `String` that have an enumeration specified for the **Enum** attribute. Set to `True` to include the property in the **Object Filter** field in diagrams. The multiple selection combo box displays searchable standard and custom object class properties using the following nomenclature: `<ClassName>.<CustomPropertyName> = <CustomPropertyValue>` For more information about the use of object filters in diagrams and other views, see the section *Defining Multiple Selection Combo Box Fields* in the reference manual *Getting Started with Alfabet*.

  You should carefully consider which custom object class properties should be searchable. Unwarranted searchable custom object class properties make drop-down lists excessively long. Additionally, some properties (such as telephone numbers) should not be searchable for reasons of data security. For more information about configuring the search functionalities in Alfabet, see the chapter Configuring Custom Selectors and Search Functionalities. For more information about the use of the search functionalities available, see the section *Searching for Your Objects* in the reference manual *Getting Started with Alfabet*.

  .

- **Enable Data Translation**: Optional for a `String` property only: If the **Enable Data Translation** attribute is set to `True` for the object class, you can further refine the permissibility to translate data for the custom property.

  Please consider the following:

  - The specification of the **Enable Data Translation** attribute applies to all cultures defined for your enterprise. Therefore, if you specify that a data translation is not permissible for an object class property, then object data cannot be specified for that object class for all defined cultures. Please note that regardless of the specification of the **Enable Data Translation** attribute for an object class/object class property, if the **Support Data Translation** attribute is set to `False` for a culture, data translation will not be possible at all for the culture and the language code will not be displayed in the language field in all object editors.

  - The specification of the **Enable Data Translation** attribute for an object class property will have precedence over the specification made in the **Automated Translation Rules for Class Properties** field for the object class. In other words, if the **Enable Data Translation** attribute for the

property is set to `None` or `Manual` and the property is set to `True` in the **Automated Translation Rules for Class Properties** field for the object class, the property will not be automatically translated.

- For more information about the translation capability, see the chapter Localization and Multi-Language Support for the Alfabet Interface.

- Set the **Enable Data Translation** attribute to `Manual` to allow data translation for the custom property to be translated manually by the user in the object editor.
- Set the **Enable Data Translation** attribute to `ManualAndAutomated` to allow data translation for the custom property to be translated manually by the user in the object editor or translated via the automated translation capability.
- Set the **Enable Data Translation** attribute to `None` to disable data translation for the custom property.
- **Translatable in Meta-Model Vocabulary**: Optional for a `String` property that has an enumeration defined: Set to `True` if the values defined for the associated enumeration should be available in the vocabularies for translation. For more information about the translation capability, see the section Modifying, Translating and Managing the Vocabularies in the chapter Localization and Multi-Language Support for the Alfabet Interface.
- **Enumeration**: Optional for a `String` property only: If the possible values available are to be provided based on a configured enumeration, select the custom enumeration. If the enumeration items configured for the custom enumeration should be available in the vocabularies for translation, set the **Translatable in Meta-Model Vocabulary** attribute to `True`. For information about how to configure an enumeration for a `String` or `StringArray` property, see the section Defining Protected and Custom Enumerations.

  Please note that an enumeration cannot be translated if it is assigned to an object class property of the type `StringArray`. If you need to configure an object class property in which multiple selection of values is possible, then the enumeration must be assigned to an object class property of the type `Text`. For more information, see the section Configuring Custom Properties of the Type Text. For more information about the translation capability, see the section Modifying, Translating and Managing the Vocabularies in the chapter Localization and Multi-Language Support for the Alfabet Interface.

- **Default Value**: Optional for a `String` property only: To specify a default value for the object class property, enter a default value for the object class property. The default value is automatically entered for the object class property when a new object is created but can be edited by the user as needed. The value entered must correspond to the object class property type defined. If an enumeration is specified for the **Enum** attribute, enter a value that has been configured for the enumeration.

  In some cases, you may want to display a predefined default value that cannot be edited in the custom editor. In this case, you could define the interface control to be non-editable (ReadOnly). It will be displayed in grey and thus disabled and therefore cannot be edited. For more information about configuring an editor field to be non-editable, see the section Specifying an Editor Field To Be Non-Editable.

- **Validator**: Optional for a `String` property only: In order to enforce values with a specific structure (for example, that version numbers should always be defined as two digits made up of a period and another digit), define a regular expression. In the **Comments** attribute, provide information to help users define the object class property according to the requirements defined in the **Validator** attribute. The comments will be shown in the error message displayed in the input value has an invalid format.

The validator is enforced on all editors where the object class property is editable. Users will be prompted with an error message if the value provided does not match the validator specified. The error message will state that the input value has an invalid format and will display the text defined in the **Comments** attribute for the custom object class property. Please note that specific enforcement mechanisms must be implemented for existing records or records that are imported into Alfabet from external systems. For more information about the syntax conventions for regular expressions, see http://msdn.microsoft.com/en-us/library/hs600312(VS.71).aspx.

- **Hint**: Enter informational text about the custom object class property to be displayed in the Alfabet interface. Users can view the tooltip for the custom object class property in the **Attributes** section of the respective object view. Please note that the **Hint** attribute defined for the custom object class property will not be displayed in a custom editor. The **Hint** attribute must be explicitly configured for the interface control associated with the custom object class property in the custom editor. For more information about the specification of custom editors, see the section Adding Help Text to Interface Controls in the Custom Editor in the chapter Configuring Custom Editors.

  Please note the following:

  - The text entered in the **Hint** attribute may not be longer than 600 characters. Texts exceeding 600 characters cannot be saved to the Alfabet database. Please note that if the hint is to be translated, the translated text may also not exceed 600 characters.
  - Hints are displayed in the tooltip functionality available via Microsoft Internet Explorer. Therefore, a tooltip will only remain open for a few seconds. As a consequence, the content of the tooltip should not be excessively long. If extensive information is required to guide users in defining the object class property, you should consider configuring static text that is displayed on the editor. For more information, see the section Adding Static Text to the Custom Editor in the chapter Configuring Custom Editors.

- **Alias**: If the **Analysis Intent Mode** attribute of the object class is set to `Full`, a list of synonyms for the object class property caption can be defined in this attribute. If a user searches for one of the synonyms in the `Analyze` intent of the AlfaBot, the AlfaBot will provide search results for the object class property that the synonym is defined for.

2) In the toolbar, click the **Save** button to save your changes.

Configuring Custom Properties of the Type Boolean

An object class property of the type `Boolean` has the permissible values `True` or `False`.

Please note that a `NULL` value will be stored in the Alfabet database for a data type if no value is defined for the custom object class property. In the case of custom object class properties of the type `Boolean`, it is highly recommended that a default value is configured to ensure that the value `False` (rather than `NULL`) is stored for a custom object class property if the associated checkbox that is not selected.

To add a custom object class property of the type `Boolean` to a custom editor, add a `CheckBox` interface control to the custom editor. For more information, see the section Adding a Checkbox to the Custom Editor in the chapter Configuring Custom Editors.

To define a custom object class property of the type `Boolean`:

1) In the attribute window, define the following attributes, as needed:

- **Property Type**: Select `Boolean`.
- **Name**: Enter a name of the object class property. The name must be unique in the scope of the selected object class.
- **Caption**: Specify a caption to be displayed for the property in the Alfabet user interface. If no caption is defined, then no caption will be displayed in the Alfabet user interface.
- **Comments**: Provide information relevant to solution designers regarding the maintenance of the custom object class property.
- **Enable for Data Capture Templates**: Select `True` if the object class property may be captured via data capture templates. Select `False` if the object class property may not be captured via data capture templates. The **Enable for Data Capture Templates** attribute must be set to `True` for the object class that the object class property is assigned to. For more information about data collection via data capture templates, see the section *Capturing Data with Data Capture Templates* in the reference manual *User and Solution Administration*.

  If the protected property is inherited from the parent object class `Artifact` or `ArtifactAuthorized`, then the **Enable for Data Capture Templates** attribute will be greyed out. In this case, you must specify a local setting for the property that will apply to the property only in the context of this object class. To do so, expand the **Local Settings** section and set the **Enable for Data Capture Templates** attribute to `True` to override the inherited setting from the parent object class. Please note that in order to prevent the ID of objects being erroneously changed via data capture templates, the `ID` property cannot be enabled as a class property.

  Properties of the type `BinData`, `Picture`, `DateArray`, `POSIX`, `ByteArray`, `DateArray`, `DateTimeArray`, `BindataArray`, `IntegerArray`, `TimeArray`, `PropertySet`, `StringArray`, and `URLArray` are not suitable for data capture templates.

- **Searchable**: Please consider the following:
- Set to `True`. if the object class property is to be searchable in the search functionalities. The custom object class property will be displayed in the searchable properties field in the standard search functionalities as well as relevant standard or custom selectors implemented for search filters. If you select `False`, the custom object class property will not be searchable in the standard search functionalities nor in the standard or custom selectors implemented for search filters.
- Set to `True` to include the property in the **Object Filter** field in diagrams. The multiple selection combo box displays searchable standard and custom object class properties using the following nomenclature: `<ClassName>.<CustomPropertyName> = <CustomPropertyValue>` For more information about the use of object filters in diagrams and other views, see the section *Defining Multiple Selection Combo Box Fields* in the reference manual *Getting Started with Alfabet*.

You should carefully consider which custom object class properties should be searchable. Unwarranted searchable custom object class properties make drop-down lists excessively long. Additionally, some properties (such as telephone numbers) should not be searchable for reasons of data security. For more information about configuring the search functionalities in Alfabet, see the chapter Configuring Custom Selectors and Search Functionalities. For more information about the use of the search functionalities available, see the section *Searching for Your Objects* in the reference manual *Getting Started with Alfabet*.

.

- **Default Value**: Optional for a `String` property only: Enter a default value for the object class property. The default value is automatically entered for the object class property when a new object is created, but can be edited by the user as needed. The value entered must correspond to the object class property type defined. If an enumeration is specified for the **Enum** attribute, enter a value that has been configured for the enumeration.

  In some cases, you may want to display a predefined default value that cannot be edited in the custom editor. In this case, you could define the interface control to be non-editable (ReadOnly). It will be displayed in grey and thus disabled and therefore cannot be edited. For more information about configuring an editor field to be non-editable, see the section Specifying an Editor Field To Be Non-Editable in the chapter Configuring Custom Editors.

- **Hint**: Enter informational text about the custom object class property to be displayed in the Alfabet interface. Users can view the tooltip for the custom object class property in the **Attributes** section of the respective object view. Please note that the **Hint** attribute defined for the custom object class property will not be displayed in a custom editor. The **Hint** attribute must be explicitly configured for the interface control associated with the custom object class property in the custom editor. For more information about the specification of custom editors, see the section Adding Help Text to Interface Controls in the Custom Editor in the chapter Configuring Custom Editors.

  Please note the following:

  - The text entered in the **Hint** attribute may not be longer than 600 characters. Texts exceeding 600 characters cannot be saved to the Alfabet database. Please note that if the hint is to be translated, the translated text may also not exceed 600 characters.
  - Hints are displayed in the tooltip functionality available via Microsoft Internet Explorer. Therefore, a tooltip will only remain open for a few seconds. As a consequence, the content of the tooltip should not be excessively long. If extensive information is required to guide users in defining the object class property, you should consider configuring static text that is displayed on the editor. For more information, see the section Adding Static Text to the Custom Editor in the chapter Configuring Custom Editors.

- **Alias**: If the **Analysis Intent Mode** attribute of the object class is set to `Full`, a list of synonyms for the object class property caption can be defined in this attribute. If a user searches for one of the synonyms in the `Analyze` intent of the AlfaBot, the AlfaBot will provide search results for the object class property that the synonym is defined for.

2) In the toolbar, click the **Save** button to save your changes.

Configuring Custom Properties of the Type Date and DateTime

A property of the type `Date` allows a date (day, month, year) to be captured for the custom object class property. User will be able to enter a date or select a date in a calendar. A property of the type `DateTime` allows a date (day, month, year, timestamp) to be captured for the custom object class property. In this case, users must manually enter the date and time information in the edit field.

The format used to display and capture the date/time information on the user interface is determined by the cultures configured by your enterprise for the Alfabet solution. For more information about configuring the cultures, see the section Specifying the Cultures Relevant to Your Enterprise in the chapter Localization and Multi-Language Support for the Alfabet Interface.

The format used to store the date/time information in the Alfabet database is determined by the setup of the Alfabet database.

To add a custom object class property of the type `Date`or `DateTime` to a custom editor, add an `Edit` interface control to the custom editor. For more information, see the section Adding a Checkbox to the Custom Editor in the chapter Configuring Custom Editors.

To define a custom object class property of the type `Date` or `DateTime`:

1) In the attribute window, define the following attributes, as needed:

- **Property Type**: Select `Date` or `DateTime`.
- **Name**: Enter a name of the object class property. The name must be unique in the scope of the selected object class.
- **Caption**: Specify a caption to be displayed for the property in the Alfabet user interface. If no caption is defined, then no caption will be displayed in the Alfabet user interface.
- **Comments**: Provide information relevant to solution designers regarding the maintenance of the custom object class property.
- **Enable for Data Capture Templates**: Select `True` if the object class property may be captured via data capture templates. Select `False` if the object class property may not be captured via data capture templates. The **Enable for Data Capture Templates** attribute must be set to `True` for the object class that the object class property is assigned to. For more information about data collection via data capture templates, see the section *Capturing Data with Data Capture Templates* in the reference manual *User and Solution Administration*.

If the protected property is inherited from the parent object class `Artifact` or `ArtifactAuthorized`, then the **Enable for Data Capture Templates** attribute will be greyed out. In this case, you must specify a local setting for the property that will apply to the property only in the context of this object class. To do so, expand the **Local Settings** section and set the **Enable for Data Capture Templates** attribute to `True` to override the inherited setting from the parent object class. Please note that in order to prevent the ID of objects being erroneously changed via data capture templates, the `ID` property cannot be enabled as a class property.

Properties of the type `BinData`, `Picture`, `DateArray`, `POSIX`, `ByteArray`, `DateArray`, `DateTimeArray`, `BindataArray`, `IntegerArray`, `TimeArray`, `PropertySet`, `StringArray`, and `URLArray` are not suitable for data capture templates.

- **Searchable**: If the custom object class property is to be searchable in the search functionalities, select `True`. The custom object class property will be displayed in the searchable properties field in the standard search functionalities as well as relevant standard or custom selectors implemented for search filters. If you select `False`, the custom object class property will not be searchable in the standard search functionalities nor in the standard or custom selectors implemented for search filters.

  You should carefully consider which custom object class properties should be searchable. Unwarranted searchable custom object class properties make drop-down lists excessively long. Additionally, some properties (such as telephone numbers) should not be searchable for reasons of data security. For more information about the use of the search functionalities available, see the section *Searching for Your Objects* in the reference manual *Getting Started with Alfabet*.

- **Hint**: Enter informational text about the custom object class property to be displayed in the Alfabet interface. Users can view the tooltip for the custom object class property in the **Attributes** section of the respective object view. Please note that the **Hint** attribute defined for the custom object class property will not be displayed in a custom editor. The **Hint** attribute must be explicitly configured for the interface control associated with the custom object class property in the custom editor. For more information about the specification of custom editors, see the section Adding Help Text to Interface Controls in the Custom Editor in the chapter Configuring Custom Editors.

  Please note the following:

  - The text entered in the **Hint** attribute may not be longer than 600 characters. Texts exceeding 600 characters cannot be saved to the Alfabet database. Please note that if the hint is to be translated, the translated text may also not exceed 600 characters.
  - Hints are displayed in the tooltip functionality available via Microsoft Internet Explorer. Therefore, a tooltip will only remain open for a few seconds. As a consequence, the content of the tooltip should not be excessively long. If extensive information is required to guide users in defining the object class property, you should consider configuring static text that is displayed on the editor. For more information, see the section Adding Static Text to the Custom Editor in the chapter Configuring Custom Editors.

- **Alias**: If the **Analysis Intent Mode** attribute of the object class is set to `Full`, a list of synonyms for the object class property caption can be defined in this attribute. If a user searches for one of the synonyms in the `Analyze` intent of the AlfaBot, the AlfaBot will provide search results for the object class property that the synonym is defined for.

2) In the toolbar, click the **Save**  button to save your changes.

Configuring Custom Properties of the Type Text

An object class property of the type `Text` allows a large amount of text to be captured. In this case, you would add a `Memo` interface control to the custom editor. An HTML editor may also be implemented in custom editors, object profiles, and object cockpits to capture custom properties of the type `Text`. For more information, see the section Adding a Text Box to Capture ASCII and HTML in the Custom Editor in the chapter Configuring Custom Editors.

You can also use an object class property of the type `Text`in conjunction with an enumeration in order to allow the users to select a single value or to select multiple values for an object class property. If you want users to select a single value, you could add a `ListBox`, `ComboBox`, and `RadioButtonGroup` interface control to the custom editor. If you want users to have the open of selecting multiple values for an object class property, you would add a `CheckedListBox` interface control to the custom editor. In this case, the enumeration items can be translated via the translation capability.

Please note that translation is not possible for an object class property of the type `StringArray` and that is why an object class property of the type `Text` is the preferred method for selection of multiple properties.

Please refer to the following documentation in the chapter Configuring Custom Editors to further configure the object class property of the type `Text` in a custom editor.

- To add an `Memo` interface control to the custom editor. For more information, see the section Adding a Text Box to Capture ASCII and HTML in the Custom Editor.
- To add an `ListBox` interface control to the custom editor. For more information, see the section Adding a List Box to Display Enumerations in the Custom Editor.
- To add a `ComboBox` interface control to the custom editor. For more information, see the section Adding a Combo Box to the Custom Editor.
- To add a `RadioButtonGroup` interface control to the custom editor. For more information, see the sectionAdding a Radio Button Group to the Custom Editor .
- To add a `CheckedListBox` interface control to the custom editor. For more information, see the section Adding a Checked List Box to the Custom Editor.

.To define a custom object class property of the type `Text`:

1) In the attribute window, define the following attributes, as needed:

- **Property Type**: Select `Text`.
- **Name**: Enter a name of the object class property. The name must be unique in the scope of the selected object class.
- **Caption**: Specify a caption to be displayed for the property in the Alfabet user interface. If no caption is defined, then no caption will be displayed in the Alfabet user interface.
- **Comments**: Provide information relevant to solution designers regarding the maintenance of the custom object class property.
- **Can Have HTML Content**: Select `True` to allow the implementation of an HTML editor to capture values for the property in custom editors, object profiles, and object cockpits.

If the **Can Have HTML Content** is set to `True` for a property, the **Enable HTML Content** attribute will automatically be set to `True` for the associated Memo interface control in the standard and custom editor. The **HTML Content** attribute can be set to `False` for the Memo interface control if needed. For more information about configuring HTML editors in custom editors, see the section Adding a Text Box to Capture ASCII and HTML in the Custom Editor.

If the HTML editor is enabled and the **Enable Data Translation** attribute is set to `True`for the custom property, the XML attribute `TranslateContentExceedingHTMLLengthLimit` must be configured in the XML object ***AlfaTranslationServicesConfig***. For more information about configuring the XML object

AlfaTranslationServicesConfig, see the section Configuring the Connection to the Translation Service.

- **Enable Data Translation**: Optional for a `Text` property only: If the **Enable Data Translation** attribute is set to `True` for the object class, you can further refine the permissibility to translate data for the custom property.

  Please consider the following:

  - The specification of the **Enable Data Translation** attribute applies to all cultures defined for your enterprise. Therefore, if you specify that a data translation is not permissible for an object class property, then object data cannot be specified for that object class for all defined cultures. Please note that regardless of the specification of the **Enable Data Translation** attribute for an object class/object class property, if the **Support Data Translation** attribute is set to `False` for a culture, data translation will not be possible at all for the culture and the language code will not be displayed in the language field in all object editors.
  - The specification of the **Enable Data Translation** attribute for an object class property will have precedence over the specification made in the **Automated Translation Rules for Class Properties** field for the object class. In other words, if the **Enable Data Translation** attribute for the property is set to `None` or `Manual` and the property is set to `True` in the **Automated Translation Rules for Class Properties** field for the object class, the property will not be automatically translated.
  - For more information about the translation capability, see the section Configuring the Translation of Object Data in the chapter Localization and Multi-Language Support for the Alfabet Interface.

- Set the **Enable Data Translation** attribute to `Manual` to allow data translation for the custom property to be translated manually by the user in the object editor.
- Set the **Enable Data Translation** attribute to `ManualAndAutomated` to allow data translation for the custom property to be translated manually by the user in the object editor or translated via the automated translation capability.
- Set the **Enable Data Translation** attribute to `None` to disable data translation for the custom property.
- **Searchable**: If the custom object class property is to be searchable in the search functionalities, select `True`. The custom object class property will be displayed in the searchable properties field in the standard search functionalities as well as relevant standard or custom selectors implemented for search filters. If you select `False`, the custom object class property will not be searchable in the standard search functionalities nor in the standard or custom selectors implemented for search filters.

  You should carefully consider which custom object class properties should be searchable. Unwarranted searchable custom object class properties make drop-down lists excessively long. Additionally, some properties (such as telephone numbers) should not be searchable for reasons of data security. For more information about the use of the search functionalities available, see the section *Searching for Your Objects* in the reference manual *Getting Started with Alfabet*.

- **Hint**: Enter informational text about the custom object class property to be displayed in the Alfabet interface. Users can view the tooltip for the custom object class property in the **Attributes** section of the respective object view. Please note that the **Hint** attribute defined for the custom object class property will not be displayed in a custom editor. The **Hint** attribute must be explicitly configured for the interface control associated with the custom object class property in the custom editor. For more information about the specification of custom editors, see the section Adding Help Text to Interface Controls in the Custom Editor in the chapter Configuring Custom Editors.

  Please note the following:

  - The text entered in the **Hint** attribute may not be longer than 600 characters. Texts exceeding 600 characters cannot be saved to the Alfabet database. Please note that if the hint is to be translated, the translated text may also not exceed 600 characters.
  - Hints are displayed in the tooltip functionality available via Microsoft Internet Explorer. Therefore, a tooltip will only remain open for a few seconds. As a consequence, the content of the tooltip should not be excessively long. If extensive information is required to guide users in defining the object class property, you should consider configuring static text that is displayed on the editor. For more information, see the section Adding Static Text to the Custom Editor in the chapter Configuring Custom Editors.

- **Alias**: If the **Analysis Intent Mode** attribute of the object class is set to `Full`, a list of synonyms for the object class property caption can be defined in this attribute. If a user searches for one of the synonyms in the `Analyze` intent of the AlfaBot, the AlfaBot will provide search results for the object class property that the synonym is defined for.

2) In the toolbar, click the **Save** button to save your changes.

Configuring Custom Properties of the Type Real

An object class property of the type `Real` requires a positive or negative decimal number as value. The values that may be defined for an object class property of the type Integer may be restricted by associating an enumeration with the custom object class property. The digit symbol used to display numbers on the user interface is determined by the cultures configured by your enterprise for the Alfabet solution. For more information about configuring the cultures, see the section Specifying the Cultures Relevant to Your Enterprise in the chapter Localization and Multi-Language Support for the Alfabet Interface.

To add a custom object class property of the type `Real` to a custom editor, add an `Edit` interface control to the custom editor. For more information, see the section Adding a Checkbox to the Custom Editor in the chapter Configuring Custom Editors.

To define a custom object class property of the type `Real`:

1) In the attribute window, define the following attributes, as needed:

- **Property Type**: Select `Real`.
- **Name**: Enter a name of the object class property. The name must be unique in the scope of the selected object class.

- **Caption**: Specify a caption to be displayed for the property in the Alfabet user interface. If no caption is defined, then no caption will be displayed in the Alfabet user interface.
- **Comments**: Provide information relevant to solution designers regarding the maintenance of the custom object class property.
- **Enable for Data Capture Templates**: Select `True` if the object class property may be captured via data capture templates. Select `False` if the object class property may not be captured via data capture templates. The **Enable for Data Capture Templates** attribute must be set to `True` for the object class that the object class property is assigned to. For more information about data collection via data capture templates, see the section *Capturing Data with Data Capture Templates* in the reference manual *User and Solution Administration*.

  If the protected property is inherited from the parent object class `Artifact` or `ArtifactAuthorized`, then the **Enable for Data Capture Templates** attribute will be greyed out. In this case, you must specify a local setting for the property that will apply to the property only in the context of this object class. To do so, expand the **Local Settings** section and set the **Enable for Data Capture Templates** attribute to `True` to override the inherited setting from the parent object class. Please note that in order to prevent the ID of objects being erroneously changed via data capture templates, the `ID` property cannot be enabled as a class property.

  Properties of the type `BinData`, `Picture`, `DateArray`, `POSIX`, `ByteArray`, `DateArray`, `DateTimeArray`, `BindataArray`, `IntegerArray`, `TimeArray`, `PropertySet`, `StringArray`, and `URLArray` are not suitable for data capture templates.

- **Precision**: To specify the number of decimal places allowed, enter an integer for the object class property.
- **Enumeration**: If the possible values available are to be provided based on a configured enumeration, select the custom enumeration. For information about how to configure an enumeration for a `Integer` property, see the section Defining Protected and Custom Enumerations.
- **Searchable**: If the custom object class property is to be searchable in the search functionalities, select `True`. The custom object class property will be displayed in the searchable properties field in the standard search functionalities as well as relevant standard or custom selectors implemented for search filters. If you select `False`, the custom object class property will not be searchable in the standard search functionalities nor in the standard or custom selectors implemented for search filters.

  You should carefully consider which custom object class properties should be searchable. Unwarranted searchable custom object class properties make drop-down lists excessively long. Additionally, some properties (such as telephone numbers) should not be searchable for reasons of data security. For more information about the use of the search functionalities available, see the section *Searching for Your Objects* in the reference manual *Getting Started with Alfabet*.

- **Hint**: Enter informational text about the custom object class property to be displayed in the Alfabet interface. Users can view the tooltip for the custom object class property in the **Attributes** section of the respective object view. Please note that the **Hint** attribute defined for the custom object class property will not be displayed in a custom editor. The **Hint** attribute must be explicitly configured for the interface control associated with the custom object class property in the custom editor. For more information about the specification of custom editors, see the section Adding Help Text to Interface Controls in the Custom Editor in the chapter Configuring Custom Editors.

Please note the following:

- The text entered in the **Hint** attribute may not be longer than 600 characters. Texts exceeding 600 characters cannot be saved to the Alfabet database. Please note that if the hint is to be translated, the translated text may also not exceed 600 characters.
- Hints are displayed in the tooltip functionality available via Microsoft Internet Explorer. Therefore, a tooltip will only remain open for a few seconds. As a consequence, the content of the tooltip should not be excessively long. If extensive information is required to guide users in defining the object class property, you should consider configuring static text that is displayed on the editor. For more information, see the section Adding Static Text to the Custom Editor in the chapter Configuring Custom Editors.

- **Alias**: If the **Analysis Intent Mode** attribute of the object class is set to `Full`, a list of synonyms for the object class property caption can be defined in this attribute. If a user searches for one of the synonyms in the `Analyze` intent of the AlfaBot, the AlfaBot will provide search results for the object class property that the synonym is defined for.

2) In the toolbar, click the **Save** button to save your changes.

Configuring Custom Properties of the Type Integer

An object class property of the type `Integer` requires a positive or negative integer number as value. The values that may be defined for an object class property of the type Integer may be restricted by associating an enumeration with the custom object class property. The digit symbol used to display numbers on the user interface is determined by the cultures configured by your enterprise for the Alfabet solution. For more information about configuring the cultures, see the section Specifying the Cultures Relevant to Your Enterprise in the chapter Localization and Multi-Language Support for the Alfabet Interface.

To add a custom object class property of the type `Integer` to a custom editor, add an `Edit` interface control to the custom editor. For more information, see the section Adding an Edit Field to the Custom Editor in the chapter Configuring Custom Editors.

To define a custom object class property of the type `Integer`:

1) In the attribute window, define the following attributes, as needed:

- **Property Type**: Select `Integer`.
- **Name**: Enter a name of the object class property. The name must be unique in the scope of the selected object class.
- **Caption**: Specify a caption to be displayed for the property in the Alfabet user interface. If no caption is defined, then no caption will be displayed in the Alfabet user interface.
- **Comments**: Provide information relevant to solution designers regarding the maintenance of the custom object class property.
- **Enable for Data Capture Templates**: Select `True` if the object class property may be captured via data capture templates. Select `False` if the object class property may not be captured via data capture

templates. The **Enable for Data Capture Templates** attribute must be set to `True` for the object class that the object class property is assigned to. For more information about data collection via data capture templates, see the section *Capturing Data with Data Capture Templates* in the reference manual *User and Solution Administration*.

If the protected property is inherited from the parent object class `Artifact` or `ArtifactAuthorized`, then the **Enable for Data Capture Templates** attribute will be greyed out. In this case, you must specify a local setting for the property that will apply to the property only in the context of this object class. To do so, expand the **Local Settings** section and set the **Enable for Data Capture Templates** attribute to `True` to override the inherited setting from the parent object class. Please note that in order to prevent the ID of objects being erroneously changed via data capture templates, the `ID` property cannot be enabled as a class property.

Properties of the type `BinData`, `Picture`, `DateArray`, `POSIX`, `ByteArray`, `DateArray`, `DateTimeArray`, `BindataArray`, `IntegerArray`, `TimeArray`, `PropertySet`, `StringArray`, and `URLArray` are not suitable for data capture templates.

- **Counter Start**: Enter a start value to be entered in order to set the value larger than any of the current IDs of objects imported from a legacy record system. The value in this property is populated only on creation of an object as the sum of the value specified in the **Counter Start** attribute and the numerical part of the object ID (i.e. `REFSTR`).
- **Enumeration**: If the possible values available are to be provided based on a configured enumeration, select the custom enumeration. For information about how to configure an enumeration for a `Integer` property, see the section Defining Protected and Custom Enumerations.
- **Searchable**: If the custom object class property is to be searchable in the search functionalities, select `True`. The custom object class property will be displayed in the searchable properties field in the standard search functionalities as well as relevant standard or custom selectors implemented for search filters. If you select `False`, the custom object class property will not be searchable in the standard search functionalities nor in the standard or custom selectors implemented for search filters.

You should carefully consider which custom object class properties should be searchable. Unwarranted searchable custom object class properties make drop-down lists excessively long. Additionally, some properties (such as telephone numbers) should not be searchable for reasons of data security. For more information about the use of the search functionalities available, see the section *Searching for Your Objects* in the reference manual *Getting Started with Alfabet*.

- **Hint**: Enter informational text about the custom object class property to be displayed in the Alfabet interface. Users can view the tooltip for the custom object class property in the **Attributes** section of the respective object view. Please note that the **Hint** attribute defined for the custom object class property will not be displayed in a custom editor. The **Hint** attribute must be explicitly configured for the interface control associated with the custom object class property in the custom editor. For more information about the specification of custom editors, see the section Adding Help Text to Interface Controls in the Custom Editor in the chapter Configuring Custom Editors.

Please note the following:

  - The text entered in the **Hint** attribute may not be longer than 600 characters. Texts exceeding 600 characters cannot be saved to the Alfabet database. Please note that if the hint is to be translated, the translated text may also not exceed 600 characters.

- Hints are displayed in the tooltip functionality available via Microsoft Internet Explorer. Therefore, a tooltip will only remain open for a few seconds. As a consequence, the content of the tooltip should not be excessively long. If extensive information is required to guide users in defining the object class property, you should consider configuring static text that is displayed on the editor. For more information, see the section Adding Static Text to the Custom Editor in the chapter Configuring Custom Editors.

- **Alias**: If the **Analysis Intent Mode** attribute of the object class is set to `Full`, a list of synonyms for the object class property caption can be defined in this attribute. If a user searches for one of the synonyms in the `Analyze` intent of the AlfaBot, the AlfaBot will provide search results for the object class property that the synonym is defined for.

2) In the toolbar, click the **Save** button to save your changes.

Configuring Custom Properties of the Type URL

A custom object class property of the type URL allows the user to enter a URL or a link that opens a document located in the **Internal Document Selector**. The URL can be displayed as a hyperlink in the **Attributes** section of the object's profile, object cockpit, or configured report. Properties of the type URL that are displayed in previews may be clicked in order to open the target link. The URL must start with `http://` or `https://`. The target link will open in a new browser window.

Please note that custom object class properties that display URLs (**Property Type** = `URL`) cannot be displayed via columns in a page view/configured report.

To add a custom object class property of the type `URL` to a custom editor, add an `Edit` interface control to the custom editor. For more information, see the section Adding an Edit Field to the Custom Editor in the chapter Configuring Custom Editors. To add the custom object class property of the type `URL` to a custom object view, see the section Adding Standard or Custom Properties to the Attributes Section. To add the custom object class property of the type `URL` to an object cockpit, see the section Adding a URL to the Object Cockpit.

Alternatively, the interface control `HTML Content` can be added to a custom editor in order to make a URL, document link, or HTML text available in the custom editor. In this case, the HTML is available only in the custom editor. For more information, see the section Adding an HTML Document Stored in the Internal Document Selector to the Custom Editor in the chapter Configuring Custom Editors.

To define a custom object class property of the type `URL`:

1) In the attribute window, define the following attributes, as needed:

- **Property Type**: Select `URL`.
- **Name**: Enter a name of the object class property. The name must be unique in the scope of the selected object class.
- **Caption**: Specify a caption to be displayed for the property in the Alfabet user interface. If no caption is defined, then no caption will be displayed in the Alfabet user interface.

- **Comments**: Provide information relevant to solution designers regarding the maintenance of the custom object class property.
- **Enable for Data Capture Templates**: Select `True` if the object class property may be captured via data capture templates. Select `False` if the object class property may not be captured via data capture templates. The **Enable for Data Capture Templates** attribute must be set to `True` for the object class that the object class property is assigned to. For more information about data collection via data capture templates, see the section *Capturing Data with Data Capture Templates* in the reference manual *User and Solution Administration*.

  If the protected property is inherited from the parent object class `Artifact` or `ArtifactAuthorized`, then the **Enable for Data Capture Templates** attribute will be greyed out. In this case, you must specify a local setting for the property that will apply to the property only in the context of this object class. To do so, expand the **Local Settings** section and set the **Enable for Data Capture Templates** attribute to `True` to override the inherited setting from the parent object class. Please note that in order to prevent the ID of objects being erroneously changed via data capture templates, the `ID` property cannot be enabled as a class property.

  Properties of the type `BinData`, `Picture`, `DateArray`, `POSIX`, `ByteArray`, `DateArray`, `DateTimeArray`, `BindataArray`, `IntegerArray`, `TimeArray`, `PropertySet`, `StringArray`, and `URLArray` are not suitable for data capture templates.

- **Hint**: Enter informational text about the custom object class property to be displayed in the Alfabet interface. Users can view the tooltip for the custom object class property in the **Attributes** section of the respective object view. Please note that the **Hint** attribute defined for the custom object class property will not be displayed in a custom editor. The **Hint** attribute must be explicitly configured for the interface control associated with the custom object class property in the custom editor. For more information about the specification of custom editors, see the section Adding Help Text to Interface Controls in the Custom Editor in the chapter Configuring Custom Editors.

  Please note the following:

  - The text entered in the **Hint** attribute may not be longer than 600 characters. Texts exceeding 600 characters cannot be saved to the Alfabet database. Please note that if the hint is to be translated, the translated text may also not exceed 600 characters.
  - Hints are displayed in the tooltip functionality available via Microsoft Internet Explorer. Therefore, a tooltip will only remain open for a few seconds. As a consequence, the content of the tooltip should not be excessively long. If extensive information is required to guide users in defining the object class property, you should consider configuring static text that is displayed on the editor. For more information, see the section Adding Static Text to the Custom Editor in the chapter Configuring Custom Editors.

- **Alias**: If the **Analysis Intent Mode** attribute of the object class is set to `Full`, a list of synonyms for the object class property caption can be defined in this attribute. If a user searches for one of the synonyms in the `Analyze` intent of the AlfaBot, the AlfaBot will provide search results for the object class property that the synonym is defined for.

2) In the toolbar, click the **Save**  button to save your changes.

Configuring Custom Properties of the Type Reference

A custom object class property of the type `Reference` is used to define relationship information between two objects that have a one-to-one (1:n) relationship.

A custom object class property of the type `Reference` should only be defined with the help of Software AG Support.

To add a custom object class property of the type `Reference` to a custom editor, you must add either an `EditSearch`, `ComboBox`, or `RadioButtonGroup` interface control to the custom editor. For more information, see the chapter Configuring Custom Editors.

To define a custom object class property of the type `Reference`:

1) In the attribute window, define the following attributes, as needed:

- **Property Type**: Select `Reference`.
- **Name**: Enter a name of the object class property. The name must be unique in the scope of the selected object class.
- **Caption**: Specify a caption to be displayed for the property in the Alfabet user interface. If no caption is defined, then no caption will be displayed in the Alfabet user interface.
- **Comments**: Provide information relevant to solution designers regarding the maintenance of the custom object class property.
- **Enable for Data Capture Templates**: Select `True` if the object class property may be captured via data capture templates. Select `False` if the object class property may not be captured via data capture templates. The **Enable for Data Capture Templates** attribute must be set to `True` for the object class that the object class property is assigned to. For more information about data collection via data capture templates, see the section *Capturing Data with Data Capture Templates* in the reference manual *User and Solution Administration*.

  If the protected property is inherited from the parent object class `Artifact` or `ArtifactAuthorized`, then the **Enable for Data Capture Templates** attribute will be greyed out. In this case, you must specify a local setting for the property that will apply to the property only in the context of this object class. To do so, expand the **Local Settings** section and set the **Enable for Data Capture Templates** attribute to `True` to override the inherited setting from the parent object class. Please note that in order to prevent the ID of objects being erroneously changed via data capture templates, the `ID` property cannot be enabled as a class property.

  Properties of the type `BinData`, `Picture`, `DateArray`, `POSIX`, `ByteArray`, `DateArray`, `DateTimeArray`, `BindataArray`, `IntegerArray`, `TimeArray`, `PropertySet`, `StringArray`, and `URLArray` are not suitable for data capture templates.

- **Type Info**: This attribute allows you to restrict the values that may be defined for an object class property of the type `Reference`. Select the object classes that the reference may target. This attribute should only be defined with the help of Software AG Support.
- **Hint**: Enter informational text about the custom object class property to be displayed in the Alfabet interface. Users can view the tooltip for the custom object class property in the **Attributes** section of the respective object view. Please note that the **Hint** attribute defined for the custom object class

property will not be displayed in a custom editor. The **Hint** attribute must be explicitly configured for the interface control associated with the custom object class property in the custom editor. For more information about the specification of custom editors, see the section Adding Help Text to Interface Controls in the Custom Editor in the chapter Configuring Custom Editors.

Please note the following:

- The text entered in the **Hint** attribute may not be longer than 600 characters. Texts exceeding 600 characters cannot be saved to the Alfabet database. Please note that if the hint is to be translated, the translated text may also not exceed 600 characters.
- Hints are displayed in the tooltip functionality available via Microsoft Internet Explorer. Therefore, a tooltip will only remain open for a few seconds. As a consequence, the content of the tooltip should not be excessively long. If extensive information is required to guide users in defining the object class property, you should consider configuring static text that is displayed on the editor. For more information, see the section Adding Static Text to the Custom Editor in the chapter Configuring Custom Editors.

- **Alias**: If the **Analysis Intent Mode** attribute of the object class is set to `Full`, a list of synonyms for the object class property caption can be defined in this attribute. If a user searches for one of the synonyms in the `Analyze` intent of the AlfaBot, the AlfaBot will provide search results for the object class property that the synonym is defined for.

2) In the toolbar, click the **Save** button to save your changes.

Configuring Custom Properties of the Type ReferenceArray

An object class property of the type `ReferenceArray` is used to define relationship information between two objects that have a one-to-many (n:n) relationship. For details about the Alfabet database storage of a custom object class property of the type `ReferenceArray` based on the configuration of the custom object class property, see the entry for `ReferenceArray` in the *Glossary* in the reference manual *Alfabet Meta-Model*.

A custom object class property of the type `ReferenceArray` should only be defined with the help of Software AG Support.

To add a custom object class property of the type `ReferenceArray` to a custom editor, you must add an `EditSearch` or `CheckedListBox` interface control to the custom editor. For more information, see the sections Adding an Edit Search Field to the Custom Editor and Adding a Checked List Box to the Custom Editor in the chapter Configuring Custom Editors.

To define a custom object class property of the type `ReferenceArray`:

1) In the attribute window, define the following attributes, as needed:

- **Property Type**: Select `ReferenceArray`.
- **Name**: Enter a name of the object class property. The name must be unique in the scope of the selected object class.

- **Caption**: Specify a caption to be displayed for the property in the Alfabet user interface. If no caption is defined, then no caption will be displayed in the Alfabet user interface.
- **Comments**: Provide information relevant to solution designers regarding the maintenance of the custom object class property.
- **Enable for Data Capture Templates**: Select `True` if the object class property may be captured via data capture templates. Select `False` if the object class property may not be captured via data capture templates. The **Enable for Data Capture Templates** attribute must be set to `True` for the object class that the object class property is assigned to. For more information about data collection via data capture templates, see the section *Capturing Data with Data Capture Templates* in the reference manual *User and Solution Administration*.

  If the protected property is inherited from the parent object class `Artifact` or `ArtifactAuthorized`, then the **Enable for Data Capture Templates** attribute will be greyed out. In this case, you must specify a local setting for the property that will apply to the property only in the context of this object class. To do so, expand the **Local Settings** section and set the **Enable for Data Capture Templates** attribute to `True` to override the inherited setting from the parent object class. Please note that in order to prevent the ID of objects being erroneously changed via data capture templates, the `ID` property cannot be enabled as a class property.

  Properties of the type `BinData`, `Picture`, `DateArray`, `POSIX`, `ByteArray`, `DateArray`, `DateTimeArray`, `BindataArray`, `IntegerArray`, `TimeArray`, `PropertySet`, `StringArray`, and `URLArray` are not suitable for data capture templates.

- **Reference Support**: The values that may be defined for an object class property of the type `ReferenceArray` may be restricted by the **Reference Support** attribute and the **Type Info** attribute defined for the object class property:
- If the **Reference Support** attribute is set to `False`, the references can be created to objects of the object classes specified in the **Type Info** attribute. The data is stored in the Alfabet database table of the object class <`TECHNAME` of Object Class> in the column <`TECHNAME` of Object Class Property>.These attributes should only be defined with the help of Software AG Support.
- If the **Reference Support** attribute is set to `True`, the references specified by the object class property are stored in the `RELATIONS` table in the Alfabet database. No database column is available for the object class property in the table of the object itself. This attribute should only be defined with the help of Software AG Support.
- **Hint**: Enter informational text about the custom object class property to be displayed in the Alfabet interface. Users can view the tooltip for the custom object class property in the **Attributes** section of the respective object view. Please note that the **Hint** attribute defined for the custom object class property will not be displayed in a custom editor. The **Hint** attribute must be explicitly configured for the interface control associated with the custom object class property in the custom editor. For more information about the specification of custom editors, see the section Adding Help Text to Interface Controls in the Custom Editor in the chapter Configuring Custom Editors.

  Please note the following:

  - The text entered in the **Hint** attribute may not be longer than 600 characters. Texts exceeding 600 characters cannot be saved to the Alfabet database. Please note that if the hint is to be translated, the translated text may also not exceed 600 characters.

- Hints are displayed in the tooltip functionality available via Microsoft Internet Explorer. Therefore, a tooltip will only remain open for a few seconds. As a consequence, the content of the tooltip should not be excessively long. If extensive information is required to guide users in defining the object class property, you should consider configuring static text that is displayed on the editor. For more information, see the section Adding Static Text to the Custom Editor in the chapter Configuring Custom Editors.

- **Alias**: If the **Analysis Intent Mode** attribute of the object class is set to `Full`, a list of synonyms for the object class property caption can be defined in this attribute. If a user searches for one of the synonyms in the `Analyze` intent of the AlfaBot, the AlfaBot will provide search results for the object class property that the synonym is defined for.

2) In the toolbar, click the **Save** button to save your changes.

Configuring Custom Properties of the Type Email

An object class property of the type `Email` is used to define email addresses for persons or artifacts in Alfabet.

To define a custom object class property of the type `Email`:

1) In the attribute window, define the following attributes, as needed:

- **Property Type**: Select `Email`.
- **Name**: Enter a name of the object class property. The name must be unique in the scope of the selected object class.
- **Caption**: Specify a caption to be displayed for the property in the Alfabet user interface. If no caption is defined, then no caption will be displayed in the Alfabet user interface.
- **Comments**: Provide information relevant to solution designers regarding the maintenance of the custom object class property.
- **Enable for Data Capture Templates**: Select `True` if the object class property may be captured via data capture templates. Select `False` if the object class property may not be captured via data capture templates. The **Enable for Data Capture Templates** attribute must be set to `True` for the object class that the object class property is assigned to. For more information about data collection via data capture templates, see the section *Capturing Data with Data Capture Templates* in the reference manual *User and Solution Administration*.

If the protected property is inherited from the parent object class `Artifact` or `ArtifactAuthorized`, then the **Enable for Data Capture Templates** attribute will be greyed out. In this case, you must specify a local setting for the property that will apply to the property only in the context of this object class. To do so, expand the **Local Settings** section and set the **Enable for Data Capture Templates** attribute to `True` to override the inherited setting from the parent object class. Please note that in order to prevent the ID of objects being erroneously changed via data capture templates, the `ID` property cannot be enabled as a class property.

Properties of the type `BinData, Picture, DateArray, POSIX, ByteArray, DateArray, DateTimeArray, BindataArray, IntegerArray, TimeArray,`

`PropertySet`, `StringArray`, and `URLArray` are not suitable for data capture templates.

- **Enumeration**: If the possible values available are to be provided based on a configured enumeration, select the custom enumeration. For information about how to configure an enumeration for an `Email` property, see the section Defining Protected and Custom Enumerations.
- **Hint**: Enter informational text about the custom object class property to be displayed in the Alfabet interface. Users can view the tooltip for the custom object class property in the **Attributes** section of the respective object view. Please note that the **Hint** attribute defined for the custom object class property will not be displayed in a custom editor. The **Hint** attribute must be explicitly configured for the interface control associated with the custom object class property in the custom editor. For more information about the specification of custom editors, see the section Adding Help Text to Interface Controls in the Custom Editor in the chapter Configuring Custom Editors.

  Please note the following:

  - The text entered in the **Hint** attribute may not be longer than 600 characters. Texts exceeding 600 characters cannot be saved to the Alfabet database. Please note that if the hint is to be translated, the translated text may also not exceed 600 characters.
  - Hints are displayed in the tooltip functionality available via Microsoft Internet Explorer. Therefore, a tooltip will only remain open for a few seconds. As a consequence, the content of the tooltip should not be excessively long. If extensive information is required to guide users in defining the object class property, you should consider configuring static text that is displayed on the editor. For more information, see the section Adding Static Text to the Custom Editor in the chapter Configuring Custom Editors.
- **Alias**: If the **Analysis Intent Mode** attribute of the object class is set to `Full`, a list of synonyms for the object class property caption can be defined in this attribute. If a user searches for one of the synonyms in the `Analyze` intent of the AlfaBot, the AlfaBot will provide search results for the object class property that the synonym is defined for.

2) In the toolbar, click the **Save** button to save your changes.

Changing an Existing Custom Property

With the exception of the **Name** attribute, all editable attributes for a custom object class property must be edited in the test environment and merged to the production environment.

The **Name** attribute can only be changed directly in the production environment. If the **Name** attribute of an existing custom object class property is changed in the test environment and the configuration is merged/read to an existing configuration (production environment), the custom object class property cannot be correctly identified during the merging process and data loss can occur. For more information about changing the technical name of a custom property, see the section Changing the Technical Name for a Custom Object Class Property or Custom Object Class.

It is highly recommended that the **Property Type** attribute of a custom object class property is not changed once the object class property has been implemented in the production environment and users have already defined and saved property values to the Alfabet database. Please note that if the **Property Type** attribute is changed for a custom object class property for an object class for which the history tracking capability is enabled, history data may be lost. The data in an object class property being converted to an object class property type `String` or `StringArray` cannot be more than 255 characters. Otherwise, information will be truncated.

The following table lists the changes that can be made to property types without losing history data.

FROM	TO
`String`	`Text, StringArray`
`Text`	`String, StringArray`
`StringArray`	`Text, String`
`Date, DateTime, Real, Integer`	`String, Text, StringArray`

Editing a Protected Property

A protected object class property  has an orange lock displayed on the icon. This is a standard property that allows some property values to be edited. A protected object class property may not be deleted.

To edit a protected object class property, click the protected object class property  in the explorer to open its attribute window. Define the following, as needed, and click the **Save** button to save the configuration:

- If the protected property is inherited from the parent object class `Artifact` or `ArtifactAuthorized`, then some attributes including the **Enable for Data Capture Templates** attribute will be greyed out. In this case, you must specify a local setting for the property that will apply to the property only in the context of this object class. To do so, expand the **Local Settings** section and define the relevant attributes to override the inherited setting from the parent object class. Expand the **Local Settings** section of the table and define the relevant attributes for the protected property:
- **Caption**:
- **Default Caption**:
- **Hint**: Specify the tooltip that shall be displayed for the property in the **Attributes** section of an object profile and, if relevant, in extended data capture templates. Please note that the **Hint** attribute will not be displayed for properties of the type `ReferenceArray`.

- **Default Hint**:
- **Can Have HTML Content**: Select True to allow the implementation of an HTML editor to capture values for the property in custom editors, object profiles, and object cockpits. the HTML editor will be available for the property for all object class stereotypes specified for the parent object class.
- **Enable for Data Capture Templates**: Select `True` if the object class property may be captured via data capture templates. Select `False` if the object class property may not be captured via data capture templates. The **Enable for Data Capture Templates** attribute must be set to `True` for the object class that the object class property is assigned to. For more information about data collection via data capture templates, see the section *Capturing Data with Data Capture Templates* in the reference manual *User and Solution Administration*.

Please note that in order to prevent the ID of objects being erroneously changed via data capture templates, the `ID` property cannot be enabled as a class property.

Properties of the type `BinData`, `Picture`, `DateArray`, `POSIX`, `ByteArray`, `DateArray`, `DateTimeArray`, `BindataArray`, `IntegerArray`, `TimeArray`, `PropertySet`, `StringArray`, and `URLArray` are not suitable for data capture templates.

- **Caption**: Edit the caption of the object class property that is displayed in the Alfabet interface. The **Caption** attribute will be added to the vocabulary and can be translated.
- **Default Value**: Optional for a `String` property only: To specify a default value for the object class property, enter a default value for the object class property. The default value is automatically entered for the object class property when a new object is created but can be edited by the user as needed. The value entered must correspond to the object class property type defined. If an enumeration is specified for the **Enum** attribute, enter a value that has been configured for the enumeration.
- **Searchable**: Please consider the following:
- Set to `True`. if the object class property is to be searchable in the search functionalities. The custom object class property will be displayed in the searchable properties field in the standard search functionalities as well as relevant standard or custom selectors implemented for search filters. If you select `False`, the custom object class property will not be searchable in the standard search functionalities nor in the standard or custom selectors implemented for search filters.
- . For custom properties of type `Boolean` and `String` that have an enumeration specified for the **Enum** attribute. Set to `True` to include the property in the **Object Filter** field in diagrams. The multiple selection combo box displays searchable standard and custom object class properties using the following nomenclature: `<ClassName>.<CustomPropertyName>` = `<CustomPropertyValue>` For more information about the use of object filters in diagrams and other views, see the section *Defining Multiple Selection Combo Box Fields* in the reference manual *Getting Started with Alfabet*.

You should carefully consider which custom object class properties should be searchable. Unwarranted searchable custom object class properties make drop-down lists excessively long. Additionally, some properties (such as telephone numbers) should not be searchable for reasons of data security. For more information about configuring the search functionalities in Alfabet, see the chapter Configuring Custom Selectors and Search Functionalities. For more information about the use of the search functionalities available, see the section *Searching for Your Objects* in the reference manual *Getting Started with Alfabet*.

.

Defining Protected and Custom Enumerations

An enumeration is a set of preconfigured enumeration items available to users when defining an object class property in Alfabet. An enumeration is associated with a standard or custom object class property. Enumerations are reusable and the same enumeration may be assigned to multiple custom object class properties in different object classes. An enumeration has two or more enumeration items.

The enumeration items represent the values that users can select in a combo-box, checked combo box, list box or checked list box in a standard or custom editor or in standard object filters available in relevant views. For example, an enumeration could consist of the four enumeration items `Mainframe`, `Client Server`, `eBusiness`, and `Other` that are assigned to the custom object class property `Application Type`.

There are two types of enumerations displayed in the **Class Model** explorer in Alfabet Expand:

- A protected enumeration  is an enumeration that has been preconfigured by Alfabet Expand. A protected enumeration cannot be deleted but the enumeration items can be modified according to the needs of your enterprise.
- A public enumeration  is a custom enumeration created by your enterprise. A custom enumeration can be created and configured for custom object class properties of the type `String`, `Text`, `Real`, `Integer`, or `StringArray`. A custom enumeration can be edited and deleted, if necessary.

Please be aware that any modifications that you make to protected and public enumerations will only impact objects created after the modification to the enumeration! All existing objects in the Alfabet database will have the values defined before the modification was made to the enumeration. As a result, there may be inconsistencies in the Alfabet database that can only be rectified by editing the relevant objects in the Alfabet database. For more information about the available protected enumerations, see the section *Overview of Protected Enumerations* in the reference manual *Configuring Alfabet with Alfabet Expand - Appendix*.

Please note that a service is offered by Software AG that allows erroneous enumeration item names to be corrected for objects in the Alfabet database. For more information about renaming such enumeration items, please contact Software AG Support.

If a custom object class property that has enumerations assigned to it is associated with an object class for which diagrams are available in Alfabet, then the enumerations will be displayed in the **Object Filter** field for all relevant diagrams. For more information about filter fields, see the chapter *Navigating the Alfabet Interface* in the reference manual *Getting Started with Alfabet*.

The object class `GenericReferenceData` allows objects representing classifications to be captured and provides an alternative to enumerations to capture custom data. Typical classifications that already exist in Alfabet are the reference data types **Connection Types**, **Connection Methods**, **Connection Frequencies**, and **Connection Data Formats**.

For example, the object class `GenericReferenceData` could allow accountability levels for strategic decisions (Direct), management checks (Control), and business actions (Execute) such as those in the IBM® Business Capability Model to be captured for domains/business capabilities in Alfabet. Object class stereotypes must be configured for the object class `GenericReferenceData` to capture each relevant classification system. A custom property should then be configured for the relevant object class to allow the data for the object class stereotype to be captured. In the example object, for example, the object class stereotypes Direct, Control, and Execute would be configured for the class `GenericReferenceData` and a custom property

would be defined for each object class stereotype on the object class Domain (which is used to capture data for business capabilities).

The full range of configuration options such as custom properties (including properties of the type `Reference` and `ReferenceArray`), custom editors, wizards, object views, selectors, and configured reports to analyze and understand the information are available. For more information about configuring object class stereotypes and custom properties for the class `GenericReferenceData`, see the sections Configuring Object Class Stereotypes for Object Classes and Configuring Custom Properties for Protected or Public Object Classes.

The objects for the object class stereotypes can be created in the **Generic Reference Data** page view in the **Reference Data** functionality. For more information, see the section *Configuring Objects for the Object Class Generic Reference Data* in the reference manual *Configuring Evaluation and Reference Data in Alfabet*.

The following information is available:

- Creating a Custom Enumeration
- Modifying Protected and Custom Enumerations
- Assigning an Enumeration to a Custom Property
- Providing a Translation for the Custom Enumeration
- Deleting a Custom Enumeration

Creating a Custom Enumeration

A public enumeration  is a custom enumeration created by your enterprise. A custom enumeration can be created and configured for custom object class properties of the type `String`, `Real`, or `Integer`. A custom enumeration can be edited and deleted, if necessary.

The following steps must be carried out in order to implement the enumeration in Alfabet:

- Create the enumeration.
- Create all relevant enumeration items for the custom enumeration. An enumeration item with no value can be created if definition of the custom object class property is optional.
- Assign the enumeration to the relevant custom object class property via the **Enum** attribute of the custom object class property. The **Property Type** attribute of the custom object class property must be either `String`, `Text`, `Real`, `Integer`, or `StringArray`.

Please note that an enumeration cannot be translated if it is assigned to an object class property of the type `StringArray`. If you need to configure an object class property in which multiple selection of values is possible, then the enumeration must be assigned to an object class property of the type `Text`.

- It is recommended that you define a default value for the custom object class property in the **Default Value** attribute.

To create a custom enumeration:

1) Go to the **Meta-Model** tab and expand the **Enums** node. You will see all existing protected enumerations and any existing custom enumerations .

2) Right-click the **Enums** node and select **Add New Enum** . You will see a new custom enumeration labelled `Noname` in the **Enums** node.

3) In the attribute window, edit the **Name** attribute. The enumeration name is a technical name and must be unique.

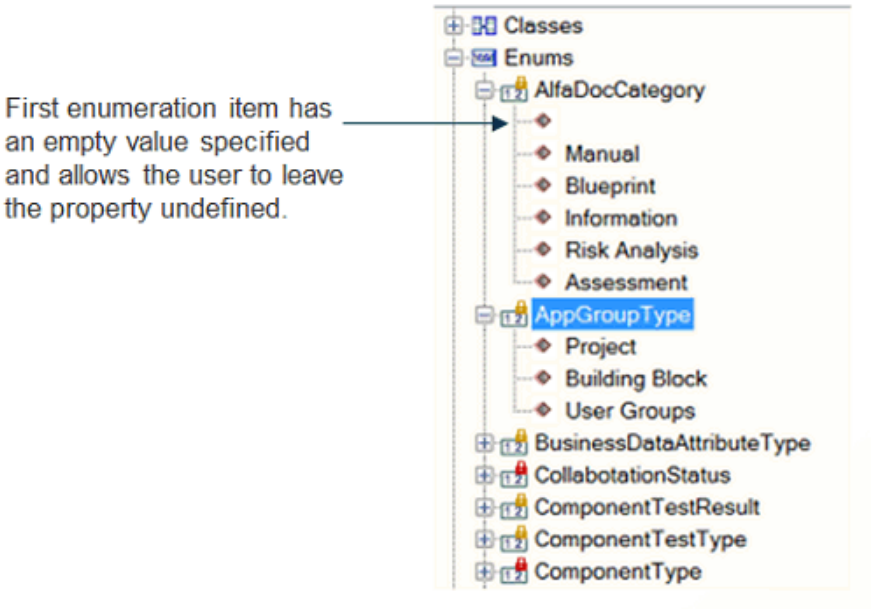
   A validation mechanism checks for correct syntax when defining a technical name. The technical name of a configuration object may not begin with an empty space nor include any of the following special characters: **\ / * ? " > < | ':**

   Furthermore, please note that names may not begin with an empty space nor include special characters. For a list of the special characters that are not allowed, see the section Defining Attributes for Configuration Objects in the chapter Getting Started with Alfabet Expand.

   Furthermore, if the technical name of a configuration object is changed, the name will be correctly updated in other configuration objects referencing the changed object during design time. Please note that the name of a changed configuration object will not be updated in guide pages nor if the guide pages reference a configuration object listed in the **Show Usage** functionality. If you plan to change the name of a configuration object, the reference in the guide page should be changed prior to changing the configuration object name.

4) In the **Caption** field, enter a caption for the enumeration. The caption will be displayed in the Alfabet user interface.

5) Next, create the enumeration items for the enumeration. To do so, right-click the custom enumeration and select **Add New Enumeration Items**. The text editor opens.



6) In the text editor, type in the items that should be displayed for the enumeration. These are the values that will appear in the relevant editor fields or object filters. An empty line should be included in the list of items if the users will not be required to select a specific value. A value

should only be entered once in the text editor, otherwise it will be repeated in the interface control. Click **OK** to close the editor.

Only ASCII characters made be used in the name of an enumeration item. Please note that NO error will be displayed if you use characters that are not conform to ASCII.

7) Next, order the sequence of the enumeration items as they should appear in the editor field. Click the **Browse** button for the **Sort Enumeration Items** attribute and in the editor that opens, click each enumeration item as needed and click the **Up/Down** buttons to sequence the items. Click **OK** to save the defined sequence of enumeration items.

8) In order to provide users with information about the meaning of the enumeration values when capturing data in editors, enter information in the **Hint** attribute for each enumeration item. Please note that the **Hint** attribute must be defined for the custom object class property in order to display the hints defined for the enumeration. The text defined in the **Hint** attributes for the enumeration items will be line-separated and appended below the Help text for the object class property.

   The text defined in the **Hint** attribute for the enumeration will be line-separated and appended below the texts for the custom object class property, which is defined via the **Hint** attribute on the custom object class property. The enumeration item Help text will be listed in the sequence defined in the **Sort Enumeration Items** attribute of the enumeration. To define Help text providing information about the enumeration and enumeration items:

- Click the custom enumeration to open its attribute window in the right pane. In the **Hint** field, click the **Browse** button and enter the Help text in the editor. Click **OK** to save the Help text.
- Click the custom enumeration item to open its attribute window in the right pane. In the **Hint** field, click the **Browse** button and enter the Help text in the editor. Click **OK** to save the hint text. Repeat for all enumeration items that require Help text.

9) If the enumeration is to be available in the vocabulary for translation, set the **Extract for Translation** field to `True`. Only enumerations set to **True** will be added to the vocabularies for translation. Note that the enumeration values will only be displayed in the Alfabet interface for supported languages if the **Translate in Meta-Model Vocabulary** attribute of the object class property associated with the enumeration is also set to `True`. This mechanism allows the enumeration to be translated for one object class property of the type `String` and displayed in the original language for another object class property. For more information about translating enumerations, see the section Understanding the Configuration Required to Translate Enumerations in the chapter Localization and Multi-Language Support for the Alfabet Interface.

10) If the enumeration is to be available in the context of a *generic attribute*, set the **Enabled for Generic Attribute** field to `True`. Only enumerations set to **True** will be displayed in the relevant **Type** field in the **Generic Attribute** editor. For more information about generic attributes, see the section Implementing the Generic Attribute Concept Instead of Custom Properties.

11) In the toolbar, click the **Save** button.

You can now assign the custom enumeration to a custom object class property. For more information, see the section Assigning an Enumeration to a Custom Property.

Modifying Protected and Custom Enumerations

For an overview of all protected enumerations that are available below the **Enums** node, see the section *Overview of Protected Enumerations* in the reference manual *Configuring Alfabet with Alfabet Expand - Appendix*.

To edit a protected enumeration:

1) Go to the **Meta-Model** tab and expand the **Enums** node. You will see all existing protected enumerations and any existing custom enumerations.
2) To understand which standard and custom object class properties the protected enumerations are assigned to, right-click the protected enumeration  that you want to edit and select **Show Usage in Meta-Model**. An information box will show the all standard and custom object classes and properties <ObjectClass.Property> that use the enumeration. Click **OK** to close the information box.
3) Expand the protected enumeration  to view all preconfigured enumeration items.
4) If the enumeration is to be available in the context of a generic attribute, set the **Enabled for Generic Attribute** field to `True`. For more information about generic attributes, see the section Implementing the Generic Attribute Concept Instead of Custom Properties.
5) In the **Caption** field, enter a caption for the enumeration. The caption will be displayed in the Alfabet user interface.
6) To change the caption of a enumeration item, click the enumeration item  and edit the caption in the **Value** attribute. Repeat for all enumeration items, as needed.

   If the option to specify an undefined value shall be available, you can create an enumeration item with an empty caption in the **Value** attribute. The enumeration item with the empty value should be defined as the first enumeration item in the **Sort Enumeration Items** attribute of the enumeration.

7) To order the sequence of the enumeration items as they should appear in the editor field, click the protected enumeration  to open its attribute window. Click the **Browse**  button in the **Sort Enumeration Items** field. In the editor that opens, click an enumeration item and click the **Up/Down**  buttons to sequence the items. Click **OK** to save the defined sequence of enumeration items.
8) In order to provide the user community with information about the enumeration and the enumeration values, you can optionally provide additional Help text for the associated property. The text defined in the **Hint** attribute for the enumeration will be line-separated and appended below the standard Help text available for the object class property in the relevant editor. The text defined in the **Hint** attributes for the enumeration items will be line-separated and appended below the text for the enumeration Help text. The enumeration item Help texts will be listed in the sequence defined in the **Sort Enumeration Items** attribute of the enumeration. To define additional Help text providing information about the enumeration and enumeration items:

- Click the protected enumeration  to open its attribute window in the right pane. In the **Hint** field, click the **Browse**  button and enter the Help text in the editor. Click **OK** to save the hint text.

- Click the enumeration item  to open its attribute window in the right pane. In the **Hint** field, click the **Browse**  button and enter the Help text in the editor. Click **OK** to save the hint text. Repeat for all enumeration items that require Help text.

9) In the toolbar, click the **Save**  button.

Assigning an Enumeration to a Custom Property

You may assign a protected or public enumeration to one or more custom object class properties of the type `String`, `Text`, `Real`, `Integer`, or `StringArray`. For an overview of all protected enumerations that are available below the **Enums** node, see the section *Overview of Protected Enumerations* in the reference manual *Configuring Alfabet with Alfabet Expand - Appendix*.

To assign an enumeration to a custom object class property:

1) Go to the **Meta-Model** tab, navigate to the relevant protected class  or custom class  and click the custom object class property  that you want to assign the enumeration to. The attribute window is displayed in the right pane.
2) In the **Enum** field, select the enumeration that you want to assign to the custom object class property in the drop-down list.
3) Ensure that on of the values `String`, `Text`, `Real`, `Integer`, or `StringArray` is defined for the **Property Type** attribute of the custom object class property.
4) If necessary, select an enumeration item as the default value for the custom object class property in the **Default Value** attribute.
5) In the toolbar, click the **Save**  button. The enumeration is now assigned to the custom object class property.

You can review the enumeration in the custom editor. For more information, see the section Creating a Custom Editor in the chapter Configuring Custom Editors.

Providing a Translation for the Custom Enumeration

The enumeration items configured for protected and custom enumeration items can be translated to a language other than English (United States). For more information about the translation of terms in the Alfabet interface, see the section Modifying, Translating and Managing the Vocabularies in the chapter Localization and Multi-Language Support for the Alfabet Interface.

The following requirements must be met to display translation enumeration items:

- Enumeration values will only be displayed in the Alfabet interface for supported languages if the attribute **Translatable in Meta-Model Vocabulary** of the object class property associated with the enumeration is set to `True`. This mechanism allows the enumeration to be translated for one object class property and displayed in the original language for another object class property.

- The translations specified for enumerations will only be displayed in custom object views and object cockpits if the associated object class property is specified as translatable in the object view or object cockpit:
- For object views, the **Enable Data Translation** attribute must be set to `True` for the object class property displayed in the **Attributes** section.
- For object cockpits, the **Enable Data Translation** attribute must be set to `True` for the Value Control interface control associated with the object class property.
- Configured reports require the specification of instructions to display the translated enumeration values. This is described in detail in the section below Understanding the Additional Configuration Required to Translate Configured Reports in the chapter Localization and Multi-Language Support for the Alfabet Interface.

Deleting a Custom Enumeration

You can delete a custom enumeration that is no longer needed. If you delete an enumeration, you must adjust all properties that reference the enumeration.

To delete a custom enumeration:

1) Go to the **Meta-Model** tab and expand the **Enums** node. You will see all enumerations including any existing custom enumerations.
2) Right-click the custom enumeration that you want to delete and select **Delete**.
3) Confirm the warning by clicking **Yes**.
4) In the toolbar, click the **Save** button. The custom enumeration is removed from the custom editor.

Changing the Technical Name for a Custom Object Class Property or Custom Object Class

In order to allow the Alfabet database to be accessed from external applications or interfaces, the technical name of a custom object class property or, if relevant, custom object class can be changed.

You can assign a new technical name to any custom object class property/custom object class that you create or that already exists in the Alfabet database. Before the technical name of an object class or object class property can be changed, all other changes that have been made must first be saved to the Alfabet database. The changed technical name is written directly to the Alfabet database.

Please keep the following in mind:

- The technical name may not begin with an empty space nor include special characters. For a list of the special characters that are not allowed, see the section Defining Attributes for Configuration Objects in the chapter Getting Started with Alfabet Expand.

- The technical name should only contain standard `ASCII` characters.
- The technical name should consist of upper-case letters only.
- The maximum length of a technical name may not exceed 30 characters.
- The technical name may not coincide with any of the reserved key words of the relational database management system.

A validation mechanism checks for correct syntax when defining a technical name. Please note that if the technical name of a configuration object is changed, the name will be correctly updated in other configuration objects referencing the changed object during design time. However, the name of a changed configuration object will not be updated in guide pages nor if the guide pages reference a configuration object listed in the **Show Usage** functionality. If you plan to change the name of a configuration object, the reference in the guide page should be changed prior to changing the configuration object name.

To change the technical name of a custom object class property or custom object class:

1) Right-click the custom object class property/object class and select **Database** < **Change Class/Property** > **Technical Name**.
2) In the dialog box that opens, enter the new technical name and click **OK**. You will see the name in the **Tech Name** attribute in the attribute window of the relevant object.
3) In the toolbar, click the **Save**  button.

Configuring Release Status Definitions for Object Classes

A release status describes the state of approval for or agreement about an object in the enterprise. Typical status values could be, for example, `Draft`, `Described`, `Reviewed`, `Approved`,`Rejected`, and `Retired`. However, the release statuses will largely depend on the object class that they describe. For example, the release statuses for an architecture element such as an application, component, or standard platform is typically used to express agreement to the state of the documented information whereas, the release statuses for a planning artifact like a demand or project reflects an approval status. The release status for an assignment describes the state of progress or completion of the task that the assignment is about.

An object's release status can be changed by a user with Read/Write access permissions. For all release statuses that are configured as non-editable release statuses, users will not be able to edit the attributes in the object's editor and page views. Users will see the  icon at the top of the object profile of an object that may not be edited due to its current release status definition.

Release status definitions can be customized per object class.

For each relevant object class, you should consider if a release status concept should be implemented for that object class or object class stereotype and, if so, which release statuses are necessary.

For an overview of the object classes that support the concept of release statuses, see the chapter *Overview of Configurable Features for Object Classes* in the reference manual *Configuring Alfabet with Alfabet Expand - Appendix*. For more information about configuring release statuses

for object class stereotypes, see the section Configuring the Release Status Definition of Object Class Stereotypes.

When configuring the release statuses for an object class, you should also consider the sequence of release statuses. In other words, which release statuses may transition to a specified release status (for example, which release statuses may transition to a `Retired` status). You should also specify which release statuses allow an object to be edited and which release statuses should be non-editable (for example, typically an object with a `Retired` status would not be editable. Custom tooltips can be defined for each release status in order to help the Alfabet user community to understand the meaning of the release status for the object they are working with.

The XML object ***ReleaseStatusDefs*** in the **Presentation** tab in Alfabet Expand allows you to configure the release statuses available for various objects.

This XML object ***ReleaseStatusDefs*** should be defined as part of the initial configuration of the Alfabet solution. You should NOT change these definitions once the Alfabet database is in use. Please note that a service is offered by Software AG that allows erroneous release status names to be corrected for objects in the Alfabet database. For more information about renaming such release statuses, please contact Software AG Support.

A user logged on with an administrative user profile has edit permissions to all objects at all times, regardless of the user authorization definition or the release status assigned to an object.

Release status definitions may be differently configured for different object classes depending on their context in Alfabet. The number of statuses defined for an object class is determined by the needs of your enterprise. For example:

- Assignments might have the status definitions Created, Accepted, In Progress, Work Completed, Returned, Re-Assigned, Closed. Additional attributes must be defined for the object class Assignment that are necessary for the assignment process in Alfabet. The release status definition for Assignment is described in the table below.
- Architecture-related objects like applications or components might have the status definitions Draft, Under Review, Approved, Archived, Closed.
- Architecture-related objects like business supports might have the status definitions Draft, Under Review, Approved, Retired.
- Test-related objects like component tests might have the status definitions Proposed, Planned, In Execution, Completed, Signed Off, Discarded.
- Planning-related objects like demands might have the status definitions New, Discarded, Described, Reviewed, Assessed, Designed, Redefined, Approved, Rejected, Complete.
- Planning-related objects like projects might have the status definitions New, Created, Supported, Endorsed, Pre-Approved, Approved, Rejected.
- Planning-related objects like solution domain projects or solution business process models might have the status definitions Draft, In Review, Completed.

Please note that an Approved Status (XML element `ApprovedStatus` in the XML object ***ReleaseStatusDefs***) definition is required for the following object classes

- `SolutionProject`

- `SolutionDomainProject`
- `SolutionBusinessProcessModel` (Please note that in the case of the object class `SolutionBusinessProcessModel`, the value entered in the XML element `ApprovedStatus` may not be entered in the XML element `EditableStatusSet`.)
- `ComplianceControlSet`
- `ComplianceProject`

For detailed information about the definition of the attributes in the XML object `ReleaseStatusDefs`, see the following:

- Configuring the Release Status Definition of Object Class Stereotypes
- Defining the Release Statuses Used for the Assignment Functionality
- Configuring the Release Status for Objects Requiring Approval
- Configuring the Release Status Definition for Enterprise Releases
- Configuring the Release Status Definition for Demands
- Configuring the Release Status Definition for Project Stereotypes
- Configuring a Default Release Status for Copied or Version Objects
- Configuring the XML Object ReleaseStatusDefs

Configuring the Release Status Definition of Object Class Stereotypes

If object class stereotypes are configured for an object class, a release status definition must be created for the object class as a whole as well as each object class stereotype. Please note the following:

- The release status definition for the object class must include the complete set of release statuses configured for its object class stereotypes. This is defined in the XML attribute `StatusSet` for the object class. This ensures that the release statuses are available in the **Status** filters available in relevant functionalities. Other than the XML attributes `ClassNames` and `StatusSet`, the other attributes are irrelevant for the release status definition of the object class because the object class stereotype definition will have precedence.
- The release status definition for the object class stereotype should contain only the release statuses relevant for the object class stereotype as well as the sequences of release statuses that are available in order to reach a specific target release status.

For detailed information about the configuration of the XML object ***ReleaseStatusDefs***, see the section Configuring the XML Object ReleaseStatusDefs

Defining the Release Statuses Used for the Assignment Functionality

Assignments allow users to collaborate with one another about objects in the enterprise architecture. For more information about the implementation and configuration required for the assignment capability, see

the section Configuring the Assignment Capability in the chapter Configuring Alfabet Functionalities Implemented in the Solution Environment.

The XML object ***ReleaseStatusDefs*** allows you to configure the statuses available for the assignment capability as well as the transition from one status to the next. A default configuration is available in the XML object. However, the status definitions can be edited and adapted to the needs of your enterprise.

This XML object should be defined as part of the initial configuration of the Alfabet solution. These definitions should not be changed once the Alfabet database is in use.

To edit the XML object ***ReleaseStatusDefs*** for assignments

1) Go to the **Presentation** tab and expand the **XML Objects** node.
2) Right-click the XML object ***ReleaseStatusDefs*** and select **Edit XML**. The XML editor is displayed in the center pane.

```
<ReleaseStatusDef
        ClassNames = "Assignment"

        StatusSet = "Created,Accepted,In Progress,Work Completed,Returned,
                Re-Assigned,Closed"
        RetiredStatusSet = "Created,Closed"
        EditableStatusSet = "Created,Accepted,In Progress,Returned,Re-Assigned,
                Work Completed"
        PrivateStatus = "Returned"
        RedefinedStatus = "Re-Assigned"
        ApprovedStatus = "Work Completed"
        ClosedStatus = "Closed"
        DefaultStatus = "Created">

        <StatusTransition ToStatus="Created" FromStatuses=""/>
        <StatusTransition ToStatus="Accepted" FromStatuses="Created,Re-Assigned"/>
        <StatusTransition ToStatus="In Progress"  FromStatuses="Created,Accepted,
                Work Completed,Re-Assigned"/>
        <StatusTransition ToStatus="Work Completed"  FromStatuses="Created,Accepted,
                In Progress,Re-Assigned"/>
        <StatusTransition ToStatus="Returned" FromStatuses=""/>
        <StatusTransition ToStatus="Re-Assigned" FromStatuses="Created,Accepted,
                In Progress,Returned"/>
        <StatusTransition ToStatus="Closed" FromStatuses=""/>

</ReleaseStatusDef>
```

3) Edit the XML attributes in the status definition for the object class `Assignment`. The table below explains the XML attributes that may be defined.

XML Element (bold) / XML Attribute	Description
ReleaseStatusDef	
`ClassNames`	Enter `Assignment`.

XML Element (bold) / XML Attribute	Description
`StatusSet`	Enter a comma-separated list of all statuses that are to be implemented in the assignment workflow.  `"Created,Accepted,In Progress,Work Completed,Returned,Re-Assigned,Closed"`  Only ASCII characters made be used in the name of an enumeration item. Please note that NO error will be displayed if you use characters that are not conform to ASCII.
`RetiredStatusSet`	Enter a comma-separated list of statuses defined in the XML attribute `StatusSet` in order to indicate that an assignment is retired and may be deleted. If an object with the release status specified in the XML attribute `RetiredStatusSet` may not be edited by users, it should not be listed in the XML attribute `EditableStatusSet`. Users with relevant access permissions may delete an assignment with a status defined in the XML attribute `RetiredStatusSet`. If no status is defined in the XML attribute `RetiredStatusSet`, the deletion of assignments will be forbidden for all users other than a user with administrative permissions.
`EditableStatusSet`	Enter a comma-separated list of statuses defined in the XML attribute `StatusSet` that may be edited by users with relevant access permissions. If an object with the release status specified in the XML attribute `RetiredStatusSet` may not be edited by users, it should not be listed in the XML attribute `EditableStatusSet`.
`PrivateStatus`	Enter one status defined in the XML attribute `StatusSet` that should be assigned to expired mandatory assignments. If the XML attribute `PrivateStatus` is not included in the XML object ***ReleaseStatusDefs*** of it is left unspecified, the value will be defined as `Private` per default.  Expired mandatory assignments are automatically reassigned to the assignment's originator: Only the originator will have edit permissions for the reassigned assignment. In contrast, expired optional assignment will be automatically assigned the XML attribute `ClosedStatus`.
`RedefinedStatus`	Enter one status defined in the XML attribute `StatusSet` to indicate that an assignment has been reassigned to a different user. The status value of the assignment will automatically be changed to the valued specified in the

XML Element (bold) / XML Attribute	Description
	XML attribute `RedefinedStatus` if the assignment is reassigned to another user. If the XML attribute `RedefinedStatus` is not included in the XML object ***ReleaseStatusDefs*** of it is left unspecified, the value will be defined as `Redefined` per default.
`ApprovedStatus`	Enter one status defined in the XML attribute `StatusSet` that indicates that the assignment is complete. Once a user assigns the status specified in the XML attribute `ApprovedStatus` to the assignment, the assignment will no longer be automatically reassigned to the originator when the target date is reached. If the XML attribute `ApprovedStatus` is not included in the XML object ***ReleaseStatusDefs*** of it is left unspecified, the value will be defined as `Approved` per default.
`ClosedStatus`	Enter one status defined in the XML attribute `StatusSet` that should be assigned to an assignment that has been completed by the assignee and has been confirmed as completed by the originator. If the XML attribute `ClosedStatus` is not included in the XML object ***ReleaseStatusDefs*** of it is left unspecified, the value will be defined as `Closed` per default. Expired optional assignments will be automatically assigned the status specified in the XML attribute `ClosedStatus`. In contrast, expired mandatory assignments will automatically be assigned the status specified in the XML attribute `PrivateStatus`.
`DefaultStatus`	Enter one status that is the default status for assignments. The default status is automatically assigned to a new assignment upon its creation.

4) The XML element ***StatusTransition*** allows the sequence of statuses to be defined. You should create an XML element ***StatusTransition*** for each status listed in the XML attribute `StatusSet`. The definition for status transitions is determined by the configuration of the XML attributes `FromStatuses` and `ToStatus`. The status defined for the XML attribute `ToStatus` can be selected by the user subsequent to the status(es) defined in the XML attribute `FromStatuses`. The table below explains the XML attributes that may be defined.

For example, an object must have the statuses `Created` or `Re-Assigned` in order to allow a transition to the status `Accepted`.

```
<StatusTransition ToStatus="Accepted"
FromStatuses="Created,Re-Assigned"/>
```

If you do not enter a value in the quotation marks, no statuses can be selected in order to transition for a status by the user.

XML Element (bold) / XML Attribute	Description
StatusTransition	
`ToStatus`	Enter one status that may follow the statuses described in the XML attribute `FromStatuses`. An XML attribute `ToStatus` definition should be made for each status in the status set.
`FromStatuses`	Enter one or more statuses in a comma-separated list that may precede the status described in the XML attribute `ToStatus`. It is recommended that a XML attribute `FromStatuses` definition should be made for each XML attribute `ToStatus` definition in the status set. Enter the word "any" in the quotation marks if all statuses may be defined for either the XML attribute `ToStatus` or the XML attribute `FromStatuses`. For example: `<StatusTransition ToStatus="Planned" FromStatuses="any"/>`

5) The XML element `Status` definitions allow tooltip texts to be defined for the statuses available for assignments.

XML Element (bold) / XML Attribute	Description
Status	Allows you to provide custom tooltips for each status. Users will see the tooltips for the statuses in the relevant editor. The tooltip text you define in the context of the status configuration will be added to the tooltip hover box for the object class property `Status`. The text defined in the XML attribute `Hint` for the statuses will be line-separated and appended below the text for the standard tooltip.
`Name`	Enter the name of the status.
`Hint`	Enter a Help text that will help users to understand the meaning of the status. It is recommended that the text is not excessively long. The value defined in the XML attribute `Hint` will be displayed as custom Help in editors, filters, and legends. The texts for the individual statuses will be line-separated. The texts defined for custom Help can be translated in the **Translation**

XML Element (bold) / XML Attribute	Description
	Editor. For more information about the translation of custom terminology, see the chapter Localization and Multi-Language Support for the Alfabet Interface.

6) In the toolbar, click the **Save**  button to save the XML definition.

Configuring the Release Status for Objects Requiring Approval

Several functionalities in Alfabet target the approval process of objects. For example, several functionalities include a check-in process where objects are checked into the inventory and thus overwrite existing objects in the Alfabet database. Such processes require an explicit approval before check-in can occur. Therefore, for such Alfabet functionalities to work properly, the XML attribute `ApprovedStatus` is required as part of the objects release status definition in the XML object ***ReleaseStatusDefs***.

To define the `ApprovedStatus` attribute, enter one status that is the approved status for the object's release status. The XML attribute `ApprovedStatus` must be defined for the following object classes:

- `SolutionDomainProject`
- `SolutionBusinessProcessModel` (Please note that in the case of the object class `SolutionBusinessProcessModel`, the value entered in the XML element `ApprovedStatus` may not be entered in the XML element `EditableStatusSet`.)
- `SolutionProject` (For more detailed information about configuring release statuses for projects, see the section Configuring Release Status Definitions for Projects in the chapter Configuring Alfabet Functionalities Implemented in the Solution Environment.).
- `ComplianceProject`and `ComplianceControlSet` (For more detailed information about configuring release statuses for the compliance management capabilities, see the section Configuring Release Status Definitions for Compliance Projects in the chapter Configuring Alfabet Functionalities Implemented in the Solution Environment.).

For detailed information about the configuration of the XML object ***ReleaseStatusDefs***, see the section Configuring the XML Object ReleaseStatusDefs.

Configuring the Release Status Definition for Enterprise Releases

A release status definition must be created for the object classes `EnterpriseRelease` and `ReleaseItem` in the XML object ***ReleaseStatusDefs*** in the configuration tool Alfabet Expand. The release status definition includes the complete set of release statuses implemented in the context of the `ENTRLS_CaptureReleases` functionality as well as the possible sequences permissible for the release statuses to reach a specific target status.

Please note that the `RetiredStatusSet` property for the object class `EnterpriseRelease` should be defined. Otherwise all release statuses will be considered a retired status for an enterprise release and can be deleted.

For detailed information about the configuration of enterprise releases, see the section Configuring Release Status Definitions for the Capture Enterprise Releases Capability. in the chapter Configuring Alfabet Functionalities Implemented in the Solution Environment. For detailed information about the configuration of the XML object ***ReleaseStatusDefs***, see the section Configuring the XML Object ReleaseStatusDefs.

Configuring the Release Status Definition for Demands

In the *Redefining Demands Page View*, users can redefine a demand that is perhaps too vaguely or too broadly defined. Depending on the configuration of release statuses for the object class Demand, the user may be able to create one or multiple new demands. The release status of the original demand will automatically be set to the status `Redefined` and the release status of the new demand(s) will automatically be set to `New`.

Whether a user can create only one new demand to replace the original demand or whether he/she can create multiple demands will depend on the configuration of the release status `Redefined`. If the status `Redefined` is included in the set of release statuses specified in the XML attribute `EditableStatusSet`, then it is possible to create multiple demands for any demand with the `Redefined` status (as well as demands with any other status specified in the XML attribute `EditableStatusSet`.) If the status `Redefined` is not specified in the XML attribute `EditableStatusSet`, then a demand can no longer be redefined once its status has changed to `Redefined`.

For detailed information about the configuration of the XML object ***ReleaseStatusDefs***, see the section Configuring the XML Object ReleaseStatusDefs

Configuring the Release Status Definition for Project Stereotypes

A release status definition must be created for the object class `Project` and for each object class stereotype created for the object class `Project`. The release status definition for the object class `Project` must include the complete set of release statuses implemented in the project management functionalities. These must be specified in the XML attribute `StatusSet` in the release status definition for the object class `Project`. Furthermore, an element `Project:<ProjectStereotype>` should be defined in the XML object ***ReleaseStatusDefs*** for each project stereotype in your enterprise's project framework.

Please note the following regarding the release status definition for projects:

- **Multiple release status set definitions should not be defined for the project management functionalities.** You should conceptualize one release status set that includes all possible release statuses for all project stereotypes. The release statuses in the XML attribute `StatusSet` can be configured as needed for each project stereotype specified in the XML attribute `ClassNames`. Release statuses that are irrelevant for a given project stereotype may be excluded in the XML attribute `StatusSet` of that stereotype.

For example, the XML attribute `StatusSet`of the overall project is conceptualized to include the release statuses: `New, Discarded, Described, InReview, ReviewFailed, Reviewed, Planned, Closed, Discarded`.

- For the object class Project, the following is specified: `StatusSet = "New,Discarded,Described,InReview,ReviewFailed,Reviewed,Planned,Closed,Discarded"`
- For the object class Project:Program, the following is specified: `StatusSet = "New,Discarded,Described,Reviewed,Planned,Closed"`
- For the object class Project:Project, the following is specified: `StatusSet = "New,Described,InReview,ReviewFailed,Reviewed,Planned,Closed,Discarded"`
- For the object class Project:ProjectStep, the following is specified: `StatusSet = "New,Described,Planned,Closed,Discarded"`

- It is recommended that the release status values `Draft` and `Closed` are not included in the XML attribute `RetiredStatusSet`. The status `Draft` typically indicates a new request for a project and the status `Closed` typically indicates that a project is completed. When configuring the retired release status definition for projects, it is recommended that the statuses `Discarded` or `Archived` are implemented in the `RetiredStatusSet`.
- Each project stereotype requires a release status to indicate that the project is approved. This is configured in the XML attribute `ApprovedStatus`. For more information about defining an approval workflow for projects, see the section Configuring the Release Status for Objects Requiring Approval.
- For general information about how to configure release statuses in the XML object ***ReleaseStatusDefs***, see the section Configuring the XML Object ReleaseStatusDefs.

Configuring a Default Release Status for Copied or Version Objects

Typically, when a new object is created as a copy, version, or variant of another object, the value of the **Status** attribute of the base object is copied to the new object. However, it is possible to specify that the XML attribute `DefaultStatus` specified for the object class in the XML object `ReleaseStatusDefs` is used instead.

This is relevant for the following classes: `Application, Component, ComponentTest, Contract, Device, ICTObject, InformationFlow, ITPolicy, ServiceProduct, Sack, StandardPlatform, VendorProduct` as well as the various classes available for integration solution database connections.

To specify that the default status configured for an object class shall be used if a new object is created as a copy, version, or variant of a base object:

1) Go to the **Presentation** tab and expand the **XML Objects** node. You will see all XML objects that can be edited.
2) Right-click the XML object ***SolutionObjects*** and select **Edit XML**. The XML editor is displayed in the center pane.

3) For the XML attribute `SetDefaultStatusOnCreateAsCopy`, specify `"true"` if the value of the XML attribute `DefaultStatus` specified in the XML object `ReleaseStatusDefs` for all relevant object classes shall be used when a new copy, version, or variant is created for an object of that object class. Specify `"false"` if the status of the base objects shall be copied to new objects.

4) In the toolbar, click the **Save** button to save the XML definition.

Configuring the XML Object ReleaseStatusDefs

The XML object ***ReleaseStatusDefs*** allows you to configure the release statuses available for the object classes used in the enterprise as well as the transition from one status to the next. A default configuration is available in the XML object. However, the release status definitions can be edited and adapted to the needs of your enterprise.

If object class stereotypes have been defined for an object class, a release status definition must be created for each object class stereotype. For each object class stereotype, a separate XML element ***ReleaseStatusDefs*** should be created, whereby each specifies `ClassNames = <Object Class:ObectClassStereotype>` should be defined.

This XML object should be defined as part of the initial configuration of the Alfabet solution. These definitions should not be changed once the Alfabet database is in use.

To edit the XML object ***ReleaseStatusDefs*** for object classes in the enterprise

1) Go to the **Presentation** tab and expand the **XML Objects** node. You will see all XML objects that can be edited.
2) Right-click the XML object ***ReleaseStatusDefs*** and select **Edit XML**. The XML editor is displayed in the center pane.
3) Edit the attributes in the release status definition for the relevant object classes. The image above shows how different release status definitions can be configured for various sets of object classes. The table below explains the XML attributes that may be defined.

XML Element (bold) / XML Attribute	Description
ReleaseStatusDefs	
`ClassNames`	Enter the name of the object class(es) that the release statuses specified in the XML attribute `StatusSet` apply to. Specify an XML element ***ReleaseStatusDefs*** for each relevant set of object classes that require a release status definition.  The value of the **Name** attribute of the object class must be used to specify the object class.

XML Element (bold) / XML Attribute	Description
StatusSet	Enter a comma-separated list of all release statuses that are to be implemented in order to describe the progress of the objects in the object classes specified in the XML attribute StatusSet. For example: enter "Draft, Under Review, Approved, Retired". The release statuses you specify will depend on the methodology implemented for the relevant object class. Please note the following: • If the XML attribute PrivateStatus is not included in the XML object ***ReleaseStatusDefs*** of it is left unspecified, the value will be defined as Private per default. • If the XML attribute RedefinedStatus is not included in the XML object ***ReleaseStatusDefs*** of it is left unspecified, the value will be defined as Redefined per default. • If the XML attribute ApprovedStatus is not included in the XML object ***ReleaseStatusDefs*** of it is left unspecified, the value will be defined as Approved per default. • If the XML attribute ClosedStatus is not included in the XML object ***ReleaseStatusDefs*** of it is left unspecified, the value will be defined as Closed per default. ⚠ Only ASCII characters made be used in the name of an enumeration item. Please note that NO error will be displayed if you use characters that are not conform to ASCII.
RetiredStatusSet	Enter a comma-separated list of statuses defined in the XML attribute StatusSet in order to indicate that an object is retired and may be deleted. If an object with the release status specified in the XML attribute RetiredStatusSet may not be edited by users, it should not be listed in the XML attribute EditableStatusSet. Users with relevant access permissions may delete an object with a status defined in the XML attribute RetiredStatusSet. If no status is defined in the XML attribute RetiredStatusSet, the deletion of objects will be forbidden for all users other than a user with administrative permissions.
EditableStatusSet	Enter a comma-separated list of statuses defined in the XML attribute StatusSet that may be edited by users with relevant access permissions.
DefaultStatus	Enter one status that is the default status for the object's release status. The default status is automatically assigned to a new object upon its creation. For example, enter "Draft".

4) The StatusTransition definitions allow the sequence of statuses to be defined. You should create an XML attribute ToStatus for each status listed in the XML attribute StatusSet. The definition for release status transitions is determined by the configuration of the XML attribute

FromStatuses and the XML attribute ToStatus. The release status defined for the XML attribute ToStatus can be selected by the user subsequent to the status(es) defined in the XML attribute FromStatuses. The table below explains the XML attributes that may be defined.

If you do not enter a value in the quotation marks, no release statuses can be selected in order to transition for a release status by the user.

For example, an object must have the release statuses Created or Re-Assigned in order to allow a transition to the release status Accepted.

```
<StatusTransition ToStatus="Accepted"
FromStatuses="Created,Re-Assigned"/>
```

XML Element (bold) / XML Attribute	Description
StatusTransition	
ToStatus	Enter one release status that may follow the statuses described in the XML attribute FromStatuses. An XML attribute ToStatus definition should be made for each release status in the status set.
FromStatuses	: Enter one or more release statuses in a comma-separated list that may precede the release status described in the XML attribute ToStatus. It is recommended that a n XML attribute FromStatuses should be specified for each XML attribute ToStatus in the status set.  Enter the word "any" in the quotation marks if all release statuses may be defined for either the XML attribute ToStatus or the XML attribute FromStatuses. For example: `<StatusTransition ToStatus="Planned" FromStatuses="any"/>`

5) The Status definitions allow tooltip texts to be defined for the release statuses.

XML Element (bold) / XML Attribute	Description
Status	Allows you to provide custom Help text for each release status. The Help text will be available for the release statuses in the relevant editor. The Help text you define in the context of the release status configuration will be in the editor Help for

XML Element (bold) / XML Attribute	Description
	the **Status** field in the relevant editor. The text defined in the ***Hint*** attribute for the release statuses will be line-separated and appended below the text for the standard Help text.
`Name`	Enter the name of the release status.
`Hint`	It is recommended that the text is not excessively long. Enter a Help text that will help users to understand the meaning of the release status. The value defined in the XML attribute `Hint` allows you to provide custom Help text that will be displayed for editors, filters, and legends. The texts for the individual release statuses will be line-separated. The texts defined for custom Help text can be translated in the **Translation Editor**. For more information about the translation of custom terminology, see the chapter Localization and Multi-Language Support for the Alfabet Interface.

6) In the toolbar, click the **Save** button to save the XML definition.

Configuring Object State Definitions for Object Classes

An object state describes the operational status of an object in the enterprise. The object state indicates whether an object is actively used, planned to be used, or has been used in the past. Because an object's start and end dates specify the planned period of activity for the object, the object state should be changed from **Plan** to **Active** once the object's start date is reached. Equally, the object state should be changed from **Active** to **Retired** when the object's end date is reached. If the lifecycle concept is available for an object class the object's start and end dates will initially be aligned with the active period of the object.

An object's object state can be changed by a user with Read/Write access permissions. For objects like applications or components, relevant object dependencies must be taken into consideration when the object state is changed. For applications, for example, the user changing the object state should consider whether the object state should be propagated to the application's associated information flows or business supports.

The number of available states Retired, Active, and Plan cannot be changed, however the names of the preconfigured object states can be customized per object class.

The XML object ***ObjectStateManager*** in the **Presentation** tab in Alfabet Expand allows you to configure the object states available for a preconfigured set of object classes in Alfabet. The object states configured in the XML object ***ObjectStateManager*** are relevant for all object classes that support the object state concept. If object class stereotypes are configured for a relevant object class, then the object state concept will also be available for the object class stereotype.

For an overview of the object classes that support the concept of object states, see the chapter *Overview of Configurable Features for Object Classes* in the reference manual *Configuring Alfabet with Alfabet Expand - Appendix*.

Only the three standard object states are permissible for the object state definition.

- `Retired`: This object state indicates that an object is no longer in use and that there is currently no plan to make it active again.
- `Active`: This object state indicates that an object is presently in active use.
- `Plan`: This object state indicates that an object is currently planned to be used and will be made active at some time in the future.

The number of object states (three) cannot be changed. However, you can edit the name of the object state (for example, you could change `Retired` to `Shut Down`) and change the color used to visualize the object state in page views. You can provide custom tooltips for each object state in order to help the Alfabet user community in specifying the object state definition for an object. The object states must be specified in the XML object ***ObjectStateManager*** in the order `Retired`, `Active`, `Plan`.

This XML object should be defined as part of the initial configuration of the Alfabet solution. These definitions should not be changed once the Alfabet database is in use.

Please note that a service is offered by Software AG that allows erroneous object state names to be corrected for objects in the Alfabet database. For more information about renaming such object states, please contact Software AG Support.

To edit the XML object ***ObjectStateManager***:

1) Go to the **Presentation** tab and expand the **XML Objects** node. You will see all XML objects that can be edited.

2) Right-click the XML object ***ObjectStateManager*** and select **Edit XML**. The XML editor is displayed in the center pane. For general information about editing XML objects in Alfabet Expand, see Working with XML Objects.

3) Define the attributes, as needed. The table below displays the attributes that can be edited for the XML object ***ObjectStateManager***:

XML Element (bold) / XML Attribute	Explanation
ObjectStateDef	 They ***ObjectStateDef*** elements must be specified in the order `Retired`, `Active`, `Plan`, otherwise errors may occur when users attempt to create information flows.
`Name`	Enter a name to represent the respective object state. For example, the object state `Retired` could be renamed `Shut-Down`.  Only ASCII characters made be used in the name of an enumeration item. Please note that NO error will be displayed if you use characters that are not conform to ASCII.
`ShortName`	Enter an abbreviation for the object state. This is useful for object state information displayed in business support matrices.
`Color`	Enter the color that should be used to represent this object state in the relevant page views. The value entered should be a Windows, Web, hexadecimal, or RGB color value.
`Hint`	It is recommended that the text is not excessively long. Enter a Help text that will help users to understand the meaning of the object state. The value defined in the XML attribute `Hint` allows you to provide custom Help text that will be displayed for editors, filters, and legends. The texts for the individual object states will be line-separated. The texts defined for custom Help text can be translated in the **Translation Editor**. For more information about the translation of custom terminology, see the chapter Localization and Multi-Language Support for the Alfabet Interface.

4) In the toolbar, click the **Save**  button to save the XML definition.

Configuring Lifecycle Definitions for Object Classes

When an object class is configured, you should consider if the lifecycle concept should be implemented and, if so, which lifecycle phases are necessary for the specific object class. The XML object ***ObjectLifeCycleManager*** allows you to configure the lifecycle definition and lifecycle phases for the object classes that support lifecycle definition.

For an overview of the object classes for which lifecycle definitions can be configured, see the chapter *Overview of Configurable Features for Object Classes* in the reference manual *Configuring Alfabet with Alfabet Expand - Appendix*. Lifecycle definitions cannot be configured for individual object class stereotypes. The object class stereotype will inherit the lifecycle concept of the object class that it is based on.

An object's lifecycle describes the succession of stages that an architecture element goes through. Many objects in Alfabet have a lifecycle, although a lifecycle does not have to be defined for all objects.

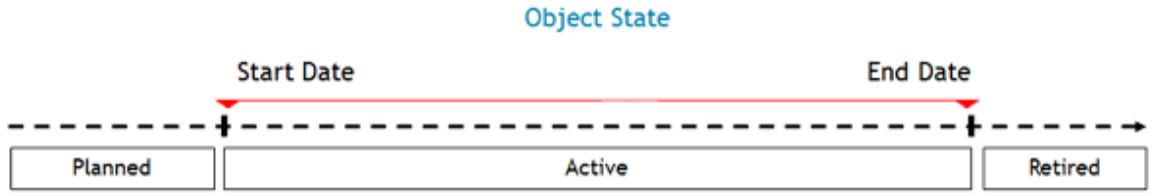


FIGURE: Application object state

The lifecycle definition includes the specification of the object's active period, which corresponds to the object's start and end dates. When the object is first created, the object state will be set to `Active` in alignment with the active period. Even if the object state is later changed, the active period of the lifecycle with correspond to the defined start and end dates of the object.

For reasons of performance, the maximum period of time displayed for lifecycles in the *Lifecycle Page View* is limited to 40 years. The time displayed will be based on 20 years prior to the current date and 20 years after the current date.

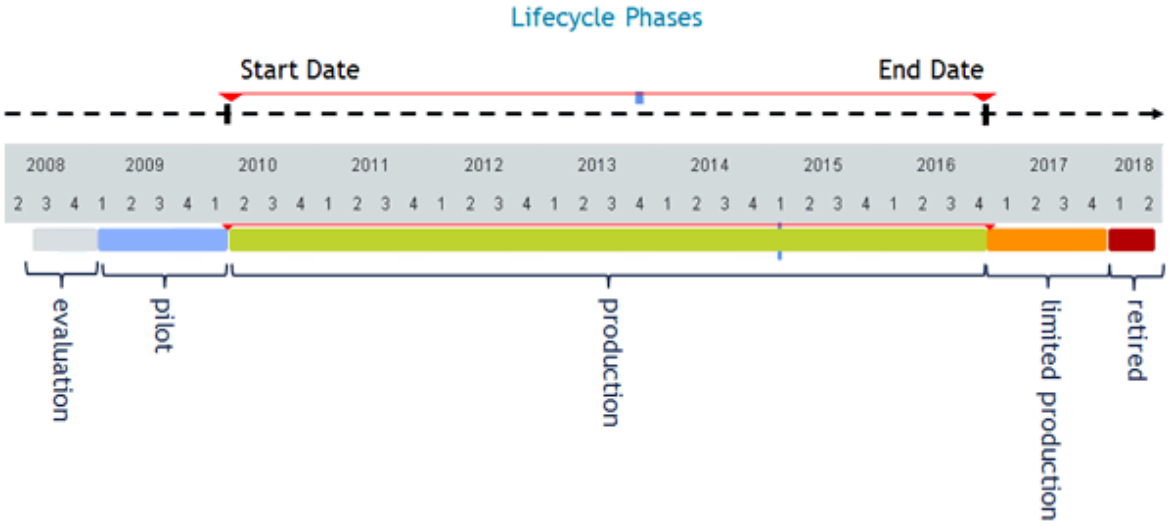

FIGURE: Application lifecycle

The lifecycle is comprised of lifecycle phases that describe the object's status of activity or production. Each lifecycle phase is aligned with its proceeding and succeeding lifecycle phase. A user may choose to skip a lifecycle phase if it is not relevant to the object. One or more lifecycle phases may constitute the active period.

The XML object ***ObjectLifeCycleManager*** allows you to configure the lifecycle definition and lifecycle phases for the object classes that support lifecycle definition. You may configure the number of lifecycle phases that make up the lifecycle definition of a specific object class as well as specify the name and default duration of each lifecycle phase. The actual duration of a lifecycle phase defined for an object may be manually edited in the **Lifecycle** editor available in the *Lifecycle Page View* by a user with relevant access permissions. You can also configure the color used to visualize the lifecycle phase in various relevant time schedule views as well as hint texts for each lifecycle phase in order to provide information about the meaning of the lifecycle phase for the Alfabet user community.

Additionally, you can configure which lifecycle phases are mapped to the active period, the period of time starting with the object's start date and ending with the object's end date. The active period may be configured to represent one or more specified lifecycle phases. For example, the solution designer may configure the active period to constitute the lifecycles phases `Pilot`, `Production`, and `LimitedProduction` but not the lifecycle phases `Evaluation` and `Shut Down`. When new object is created, the active period will correspond to the object's start and end dates. The lifecycle phases must be explicitly defined in the *Lifecycle Page View* available for the relevant object.

It is recommended that you do NOT change the configuration of an object class's lifecycle definition once object lifecycles have been defined in the production environment. If you modify the configuration of an object class's lifecycle definition by adding or removing configured lifecycle phases and objects with the original lifecycle configuration already exist in the Alfabet database, it will be necessary to delete the existing lifecycle and redefine a new lifecycle for all objects for which the new lifecycle phase definition should apply! If an object displayed in a Gantt chart has a set of lifecycle phases that are different than the actual lifecycle phases of the selected object, the misaligned lifecycle will be displayed as a light grey bar in the report.

Please note that a service is offered by Software AG that allows erroneous names of lifecycle phases to be corrected for objects in the Alfabet database. For more information about renaming such lifecycle phases, please contact Software AG Support.

For more information about the methodology of application lifecycle management, see the chapter *Lifecycle Management* in the reference manual *IT Planning Basic*.

To edit the XML object ***ObjectLifeCycleManager***:

1) Go to the **Presentation** tab and expand the **XML Objects** node. You will see all XML objects that can be edited.
2) Right-click the XML object ***ObjectLifeCycleManager*** and select **Edit XML**. The XML editor is displayed in the center pane. For general information about editing XML objects in Alfabet Expand, see Working with XML Objects.
3) Define the attributes, as needed. The table below displays the attributes that can be edited for the XML object ***ObjectLifeCycleManager***:

XML Element (bold) / XML Attribute	Explanation
ObjectLifeCycle	
`ClassNames`	Enter a comma-separated list of object class names that the lifecycle definition defined in this XML element ***ObjectLifecycle*** applies to. **NOTE**: For more information about which object classes support the lifecycle concept, see the chapter *Overview of Configurable Features for Object Classes* in the reference manual *Configuring Alfabet with Alfabet Expand - Appendix*.
ObjectStatusDef	Add an XML element ***ObjectStatusDef*** for each lifecycle phase that shall be available in the lifecycle of the object classes listed in the XML attribute `ClassNames`.
`Name`	Enter text to define the name of the lifecycle phase. **NOTE**: Only ASCII characters made be used in the name of an lifecycle phase. Please note that NO error will be displayed if you use characters that are not conform to ASCII.
`Color`	Enter text to define the color to be used when representing this lifecycle phase in the visualization of the lifecycle. The value entered should be a Windows, Web, hexadecimal, or RGB color value.
`Length`	Enter an integer that represents the default duration of the lifecycle phase in months in the lifecycle definition. Users can later change the length of the lifecycle phase, as needed. **NOTE**: Depending on the start and end dates defined for an object, the active period of an object may be longer than the sum of the lengths of all lifecycle phases.
`ActivePeriodStart`	Enter "`true`" if the lifecycle phase is the first lifecycle phase of the active period. Only one XML element ***ObjectStatusDef*** should have an XML attribute `ActivePeriodStart`. If only one lifecycle phase shall constitute the active period, then the lifecycle phase should have both the XML attribute `ActivePeriodStart` and XML attribute `ActivePeriodEnd` specified.
`ActivePeriodEnd`	Enter "`true`" if the lifecycle phase is the last lifecycle phase of the active period. Only one XML element ***ObjectStatusDef*** should have an XML attribute `ActivePeriodEnd`.

XML Element (bold) / XML Attribute	Explanation
`Hint`	The value defined in the XML attribute `Hint` allows you to provide custom Help text that may be displayed in editors, filters, and legends. The texts for the individual lifecycle phases will be line-separated. Enter a Help text that will help users to understand the meaning of the lifecycle phase. It is recommended that the text is not excessively long. The texts defined for custom Help text can be translated in the **Translation Editor**. For more information about the translation of custom terminology, see the chapter Localization and Multi-Language Support for the Alfabet Interface.

4) In the toolbar, click the **Save** button to save the XML definition.

Configuring Class Keys for Object Classes

A class key is the specification of one or a combination of standard and custom object class property for an object class. Typically, class keys are defined to implement uniqueness constraints. A standard or configured class key provides an enforcement mechanism for the definition of standard properties and custom object class properties when an object is created. In this case, the combination of properties must be unique for all objects in the object class. If the uniqueness constraint is violated by a user when defining data, a message will be displayed prompting the user to provide a unique combination of values. For example, class keys for the object class Application could require a unique combination of values for the object class properties Name, Version, and Object State.

Index creation is a side effect of a class key definition. For each class key that is configured for the object classes in Alfabet Expand, an index is created. The definition of class keys can therefore be used to speed up query-based searches and thus increase performance.

Please note the following:

- Multiple class keys can be defined as needed for an object class. All custom class keys are public class keys.
- Private class keys cannot be edited or deleted. Private class keys are typically preconfigured for indexing purposes.
- Protected class keys may be edited but not deleted.
- Public class keys may be edited and deleted.

Please keep the following in mind:

- Preconfigured keys override customer-defined class keys. You cannot create a key that duplicates or neutralizes an existing preconfigured class key.

- You cannot create a key that duplicates existing public or preconfigured class keys of the same object class. Two class keys are identical if the values for their attributes **Properties**, **Unique** and **Strict Null Handling** are identical.
- When you create a new class key, any existing data in the Alfabet database will be validated to see if it complies with the new class key constraint. If existing data violates the class key constraints you are currently creating, the class key will be refused. In this case, you will first need to edit the objects in the Alfabet database that violate the class key.
- Class keys are configured on the level of the base object class. Uniqueness constraints cannot be explicitly defined for a specific object class stereotype. The class key configuration is thus inherited by all object class stereotypes configured for the object class. For more information about configuring object class stereotypes, see the section Configuring Object Class Stereotypes for Object Classes.
- If a class key violation occurs when a user attempts to create a new object, a warning message will open listing the object class properties that caused the violation to the defined uniqueness constraints as well as a link to the existing object that is the source of the violation. The user can click the link to open the configured object view specified for the associated class setting in order to understand more about the conflicting object.
- For an overview of all preconfigured private, protected, and public class keys specified for protected object classes, see *Standard Class Keys of Protected Alfabet Object Classes* in the reference manual *Configuring Alfabet with Alfabet Expand - Appendix*.
- An index is created for all data included in a class key. Class keys can also be defined to exclusively trigger index creation to increase the speed of query-based searches. For more information about index creation based on class keys, see Configuring Class Keys for Object Classes.

To create a class key for a selected object class:

1) Go to the **Meta-Model** tab and right-click the protected object class  that you want to create the class key for and select **Add New Class Key**. You will see the **Class Key Group** node and the new public class key  subordinate to the selected object class.
2) Click the new public class key  to open the attribute window.
3) In the attribute widow, specify the following attributes:

- **Name**: Edit the name for the class key, if necessary.

A validation mechanism checks for correct syntax when defining a technical name. The technical name of a configuration object may not begin with an empty space nor include any of the following special characters: **\ / * ? " > < | ':**

Furthermore, please note that names may not begin with an empty space nor include special characters. For a list of the special characters that are not allowed, see the section Defining Attributes for Configuration Objects in the chapter Getting Started with Alfabet Expand.

Furthermore, if the technical name of a configuration object is changed, the name will be correctly updated in other configuration objects referencing the changed object during design time. Please note that the name of a changed configuration object will not be updated in guide pages nor if the guide pages reference a

configuration object listed in the **Show Usage** functionality. If you plan to change the name of a configuration object, the reference in the guide page should be changed prior to changing the configuration object name.

- **Properties**: Click the **Browse** button to open the editor in which you can define the object class properties relevant for the class key constraint. Click each object class property that you want to include in the class key definition. After all necessary properties have been selected, click **OK**.
- **Unique**: Select `True` to implement the uniqueness definition for the object class. Select `False` to allow creation of an index for the key without implementing the uniqueness constraint for the object class.
- **Strict Null Handling**: This attribute is available in order to support various integration scenarios. Set to `False` if all entries with NULL values will be excluded from unique indexes. This allows duplicate entries to be inserted if one of the index attributes is set to NULL. Set to `True` if all entries with NULL values will be checked. The **Strict Null Handling** attribute is set to `True` per default.

4) In the toolbar, click the **Save** button to save your changes.

To delete all protected and custom class keys that have been configured for a protected or custom object class, click the **Class Key Group** node below the relevant object class and select **Delete All Public/Protected Class Keys**. The protected and public class keys will be deleted and no longer displayed below the **Class Key Group** node. Private class keys that have been configured by Software AG will not be deleted.

Specifying History Tracking for an Object Class

Alfabet provides a history tracking functionality that documents the changes made to an object. All changes made to an object's standard and custom object class properties and relations are documented. The *Object Audit Page View* (`Object_Audit`) displays the type of change to the object, the user making the change, the time of the change, and the object class property or relation that has been changed. The data can be exported to an MS Excel file or HTML file. For more information about viewing the audit history of an object, see the section *Viewing the Change History of an Object* in the reference manual *Getting Started with Alfabet*.

The history tracking functionality is implemented on a class-by-class basis. For an overview of the object classes for which an audit table is generated per default as well as an overview of the object classes for which the history tracking functionality is available, see the chapter *Overview of Configurable Features for Object Classes* in the reference manual *Configuring Alfabet with Alfabet Expand - Appendix*.

Please note that the `LAST_UPDATE_USER` and `LASTUPDATE` properties are only updated in the Alfabet database when changes are made via the object's editor, or the editor embedded in a wizard. The `LAST_UPDATE_USER` and `LASTUPDATE` properties are NOT updated when changes are made in page views.

Please note that the history tracking functionality tracks only the change history of objects in the Alfabet solution. An object deleted from the Alfabet database cannot be restored via the history tracking functionality. If an object has been erroneously deleted, the object must be recreated and redefined in the Alfabet solution.

An **Archive Manager** functionality is also available in the **Solution Administration** functionality that allows Alfabet objects to be deleted and an archive object to be created. For more

information about the **Archive Manager** functionality, see the section *Deleting and Archiving Alfabet Objects* in the reference manual *User and Solution Administration*.

Please note the following:

- All object classes in the meta-model have an **Audit** attribute. If the **Audit** attribute is set to `True`, an audit table will be generated in the Alfabet database. Per default, the **Audit** attribute has been set to `True` for most protected classes  . Please be aware that tracking the history of a significant number of object classes may lead to a decrease in performance. Furthermore, changes to some properties for some classes may also produce an excessive number of entries in the Alfabet database table. For example, if the class `Person` is specified to be audited, then every time the user logs in, a new audit record will be created due to changes to the `LASTLOGIN` property.

  

  The **Audit Key Group** node is only displayed if the **Audit** attribute of the object class is set to `True`. Below the **Audit Key Group** node, all private audit keys  and all custom audit keys  are displayed. An audit key can be configured for a protected object class  in order to trigger index creation to increase the speed of query-based searches in audit tables. For information about creating an index, see the section *Creating an Index to Improve Performance for Query Searches in Database Tables* in the chapter Defining Queries.

- Alfabet provides a standard *Object Audit Page View* (`Object_Audit` can be opened via the **Audit Trail**  displayed in the toolbar of the relevant object profile. This view is available for all artifact classes. Users with ReadOnly and ReadWrite access permissions may view the report. For other object classes requiring history tracking, a report can be configured to display history tracking information.

- The *Object Audit Page View* (`Object_Audit`) can be included in the custom object views configured for a public class  .

Any changes made to the meta-model will impact both the relevant class table and audit table in the Alfabet database. For example, if a custom object class property is deleted from the class model, it will also be deleted from the audit table and thus will no longer be displayed in the *Object Audit Page View* available in your Alfabet solution.

It is highly recommended that you do not change the meta-model once the auditing capability is implemented, otherwise errors may occur in the audit information.

It is highly recommended that the **Property Type** attribute of a custom object class property is not changed once the object class property has been implemented in the production environment and users have already defined and saved property values to the Alfabet database. Please note that if the **Property Type** attribute is changed for a custom object class property for an object class for which the history tracking capability is enabled, history data may be lost. The data in an object class property being converted to an object class property type `String` or `StringArray` cannot be more than 255 characters. Otherwise, information will be truncated.

The following table lists the changes that can be made to property types without losing history data.

FROM	TO
String	Text, StringArray
Text	String, StringArray
StringArray	Text, String
Date, DateTime, Real, Integer	String, Text, StringArray

Users with ReadOnly and ReadWrite access permissions may view the *Object Audit Page View* (Object_Audit). Because the *Object Audit Page View* (Object_Audit) displayed for a selected object displays all information about the object independent of the access permission available to the user viewing the audit information, it is recommended that you customize the display of audit information for users. Please note the following configuration requirements

- Create a native SQL-based configured reports to extract specific information from the audit history such as the changes made to the object by a specific user or specific types of changes made to the object (for example, new information flows added to an application). For information about the structure of the Alfabet database table for auditing and how to configure such a report, see the section Defining Audit Management Related Configured Reports in the chapter Configuring Reports.
- Once the report is configured, you must make it available in the relevant custom object view by configuring a custom button for the relevant custom object view. For more information about how to configure a custom button, see the section Configuring Custom Buttons for the Toolbar of a Custom Object View in the chapter Configuring Object Views.
- The standard **Audit Trail** button can be hidden from the relevant custom object view in the context of the user profile configuration. For more information, see the section Hiding Functionalities in an Object View in the chapter Configuring User Profiles for the User Community.

Please note the following configuration information:

- The parameter **Enable Audit** must be set to True in the server settings configuration in order for the history tracking functionality to be enabled. If the **Enable Audit** parameter is not set to True, history tracking will not occur regardless of the configuration of the **Audit** attribute on object classes. For more information about configuring server settings, see *Activating the History Tracking Functionality* in the reference manual *System Administration*. Please note that if the **Audit** attribute is changed to False, the audit table in the Alfabet database will be deleted.
- By default, the user name of the user performing a change to an object is stored in the audit table in the Alfabet database and displayed to other users in the history of the object when clicking the **Audit Trail** button. The Alfabet Server can be configured to use the **Technical Name** attribute of the user instead of the user name for the history

tracking functionality. This specification is carried out in the Update History User Name attribute in the server alias. For more information, see the section *Configuring User Information Displayed in History Tracking* in the reference manual *System Administration*.

- A change in an object's relationship to another object (captured via an object class property of the type `Reference` or `ReferenceArray`) will only be documented in the **Object Audit** view if BOTH object classes in the relationship have the **Audit** attribute set to `True`. For example, to capture the information that an assignment assigned to an application is reassigned to an ICT object, both of the object classes `Application` and `ICT Object` must have the history tracking capability enabled.
- Any properties that have been specified in the **Excluded Properties** attribute for a class setting will be hidden in he **Object Audit** view. Audit entries associated with hidden reference array properties will be completely hidden from the audit history. Audit entries for **Create Object**, **Update Object**, and **Delete Object** will not be hidden,but they will be displayed without the detail information about which property has been changed.
- If the Alfabet database already contains objects of the object classes for which audit is enabled, audit tables must be initiated by creating audit entries for the already existing objects. Software AG provides the executable `AuditInitTables.exe` to initialize audit tables. Initialization is only performed for empty tables. It is therefore important to execute `AuditInitTables.exe` immediately after activation of audit. For information about how to perform the initialization, see *Activating the History Tracking Functionality* in the reference manual *System Administration*.
- An index can be created for audit tables of individual object classes via the **Audit Key Group** node below the respective object class. The **Audit Key Group** node is only displayed if the **Audit** attribute of the object class is set to `True`. The availability of an index considerably increases the speed of query-based searches in audit tables. To trigger index creation, an audit key must be configured for the relevant object class. For more information about creating an index, see the section *Creating an Index to Improve Performance for Query Searches in Database Tables* in the chapter Defining Queries.
- A class that has the history tracking enabled can also be monitored for activity and inactivity. Therefore, if you plan to implement the activity monitors or inactivity monitors for an object class, you must also set the **Audit** attribute to `True`. For more information about configuring monitors, see the section Configuring Monitors in the chapter Configuring Alfabet Functionalities Implemented in the Solution Environment.
- If the **Audit** attribute is set to `True` for the object class `Indicator Type` and multiple indicator types are edited via the multi-edit functionality, a history entry will be added to the **Object Audit** view for each indicator. This could lead to a significantly large number of audit entries.

The **Audit** attribute can be set to `True` for all object classes by clicking the **Classes** node and selecting **Turn Audit On for All Protected/Public Classes**. If selected The **Audit** attribute will be set to `True` for all protected and public object classes. The **Audit** attribute can be set to `False` for individual classes or set to `False` for all protected and public classes by selecting **Turn Audit Off for All Protected/Public Classes**.

To implement the history tracking capability for a selected object class:

1) Go to the **Meta-Model** tab, expand the **Classes** node, and click the protected class  or public class  that you want to implement the history tracking for.

2) In the attribute window, set the **Audit** attribute to `True`. If the **Audit** attribute is set to `False`, the object class will not be audited. Please note that if the **Audit** attribute is changed to `False`, the audit table in the Alfabet database will be deleted.

3) In the toolbar, click the **Save**  button to save your changes.

Chapter 6: Configuring Custom Editors

A custom editor is a customized data entry view that allows users to capture data for the custom object class properties that have been created for a protected or public (custom) object class. A custom editor is typically configured for the needs of users working with a specific user profile. A custom editor can only be created for an object class that has custom object class properties defined. A custom editor cannot be created for a protected class that has no custom object class properties defined.

A custom editor typically consists of one or more tabbed pages that are automatically appended to the standard editor available for the object class. The solution designer designs the interface controls such as combo boxes, checkboxes, etc. that users need to capture the required data. Additional text fields or URLs may be included in the custom editor in order to provide users with additional information to help them define data. All captions created for the interface controls can be translated for the languages implemented in the Alfabet interface.

Custom editors are displayed in the context of standard data capture editors but can also be implemented in wizards and workflows configured for the enterprise. Multiple custom editors can be created for an object class, but only one custom editor can be assigned to a class setting. Therefore, only one custom editor can be implemented per object class per user profile.

The following describes the general procedure for configuring and implementing a custom editor:

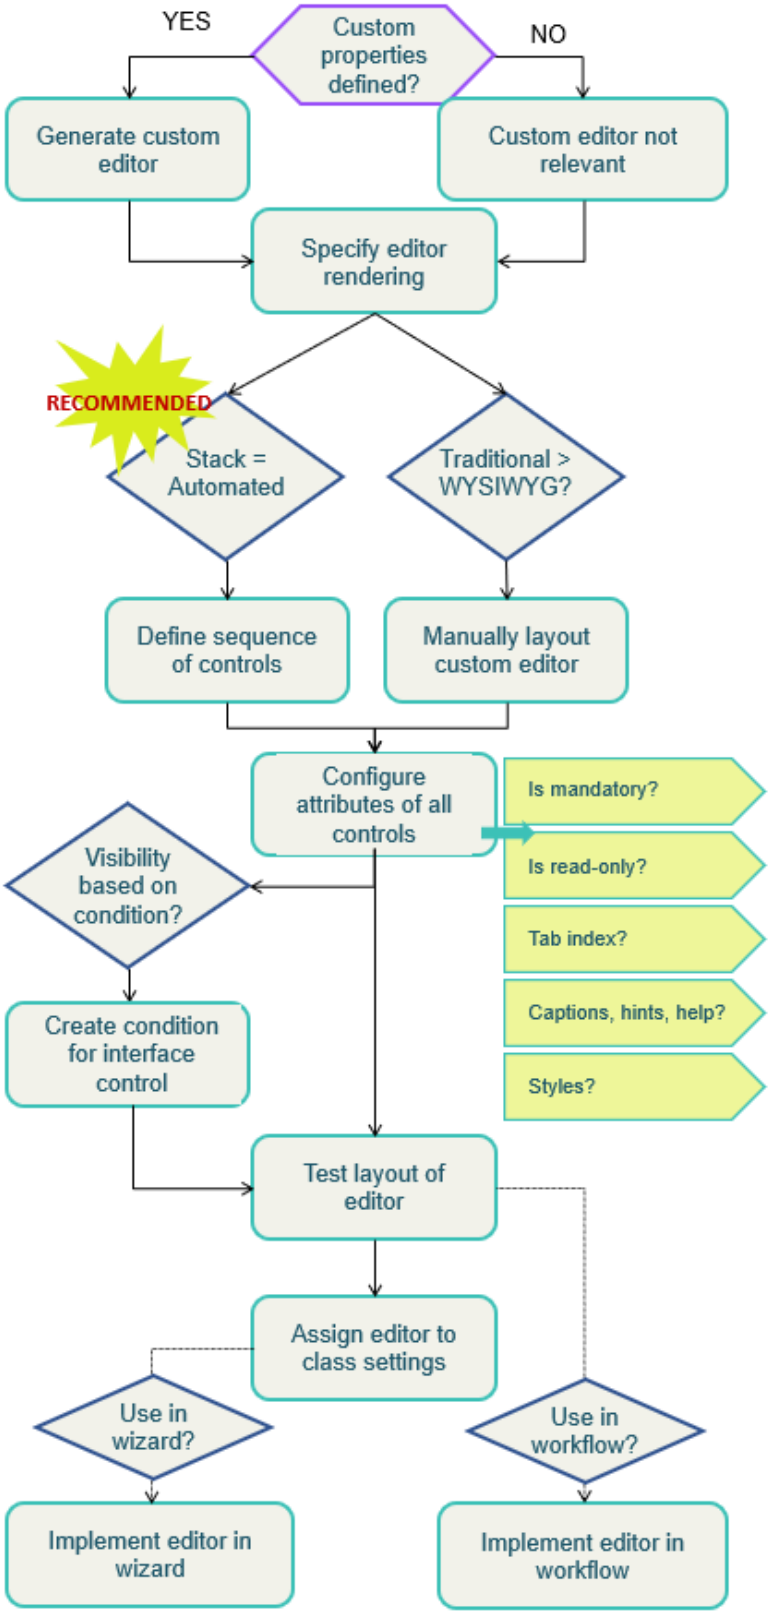

FIGURE: Steps to configure a custom editor

- Ideally, you have already configured all custom object class properties that you want to display in the custom editor.

- You can manually create a custom editor or automatically generate a default custom editor as a starting point for the editor configuration. Please note the following advantages if you automatically generate a default custom editor:
- Each property type is automatically converted to one predefined interface control and placed on a custom editor tab. This default interface control can be deleted and replaced with a different interface control, as needed.
- If more than ten custom object class properties have been defined, additional tabs will be automatically generated in the custom editor. The order of the custom object class properties is determined by the sequence in which they were created. The distribution of custom object class properties on tabbed pages can be modified, if needed.
- After you automatically generate the custom editor, you can implement it and display the default layout in Alfabet. If you are not satisfied with the layout of the custom editor or you want to further design it, you can manually revise the layout of the interface controls, edit the attributes specifying the interface control, and add or delete interface controls. Additionally, you can change the captions and size of the interface controls, redistribute the interface controls across tabbed pages, add instructional text to the editor, add URL or document links to the editor, and customize the custom editor by adding color and images to the custom editor.
- Add and refine the interface controls as needed. You can add and delete interface controls and add additional information to the custom editor such as instructional text, URL and document links, help text, icons, and color and formatting.
- Test the layout of the custom editor via the **Review Custom Editor** functionality.
- Assign the custom editor to a class setting, thus making it available for a specific user profile. For more information about assigning a custom editor to a class setting, see Configuring Class Settings for Object Classes and Object Class Stereotypes in the chapter Configuring User Profiles for the User Community.
- If relevant, assign the custom editor to a wizard or workflow in which it is to be implemented. For more information, see the sections Configuring a Wizard Step to Display a Standard or Custom Editor in the chapter Configuring Wizards and Defining the View Implemented for a Workflow Stepin the chapter Configuring Workflows.

- Modifying Preconfigured Editors Provided by Software AG

Conceptualizing a Custom Editor

A custom editor allows you to make some or all of the custom object class properties defined for an object class available to Alfabet user community. A custom editor is appended to the standard editor as one or more tabbed pages. Once the custom editor is designed, you can associate the custom editor to the relevant standard editor by assigning it to one or more class settings. You can create multiple custom editors per object class and assign each to a different class setting, thus providing a custom editor for the various user profiles implemented to capture data for the object class.

In the context of configuring visibility issues for a user profile, you may exclude standard properties as well as entire standard tabs available in the standard editor. However, you should take careful consideration to not hide tabs with mandatory properties if users will be required to create new objects or edit mandatory properties when they access the editor via the configured user profile. For more information about configuring the visibility of a standard and/or custom editor, see the section Hiding Object Class Properties in Editors and Wizards in the chapter Configuring User Profiles for the User Community.

A custom editor can be reused in multiple contexts. Not only can custom editors be implemented in the context of standard data capture editors, they can also be used in standard and custom wizards as well as workflows. For more information about the configuration of wizards, see the chapter Configuring Wizards. For more information about the configuration of workflows, see the chapter Configuring Workflows.

Please note that some standard page views in Alfabet implement a predefined editor when creating and editing objects. For an overview of the page views with a predefined editor, see the section *Alfabet Page Views with Preconfigured Editing and Navigation Behavior* in the reference manual *Configuring Alfabet with Alfabet Expand - Appendix*.

Please note the following regarding the inline editing functionality:

- Only scalar and reference properties that are editable in the editor/wizard available in the object profile or object cockpit can be edited via inline editing.
- All unique constraints defined for the class as well as any post-conditions configured for the wizard associated with the object profile/object cockpit will be applied to the data entered.

  

  Please note that data is saved to the Alfabet database prior to the post-condition being validated. Therefore, data entered via inline editing will be saved even if the post-condition is not fulfilled. This is because the data must be available in the Alfabet database in order to be evaluated for the post-condition. If the data entered does not fulfill the post-condition, the configured warning message will be displayed explaining that the input must be corrected in order to fulfill the post-condition.

- Inline editing may be limited or prevented if the syntax of the post-condition is not correct. In this case, an error will be displayed if the user tries to open the wizard.

The following issues must be considered when you configure custom editors:

- How will the custom editor be used? Is the custom editor being configured in order to capture enterprise-specific data in the standard editor? Will the custom editor be used in a wizard configuration? Will the custom editor be used in a workflow configuration?
- Which custom object class properties need to be included in the custom editor for the context for which it is being configured?
- How should the custom object class properties be grouped? Should all custom object class properties be on one tabbed page or split up among several tabbed pages.
- What kind of interface controls should be used to capture values for the custom object class properties? The type of interface control is usually dependent on the property type of the custom object class property it is associated with. For an overview of the interface controls available for a specific property type, see the section Configuring Custom Editors.
- Do the captions for custom object class properties need to be translated for other interface languages used in your Alfabet solution?

Creating a Custom Editor

Multiple custom editors can be created per object class. There are a number of different ways to create a custom editor. The method you choose will depend on the number of custom object class properties defined for an object class and the kind of interface controls that should visualize these custom object class properties:

- Create a new custom editor from scratch. This method requires that you add each individual custom object class property to the editor and define and specify the associated interface controls.
- Automatically generate a custom editor with a default layout. This method is easier than creating a custom editor from scratch because the default layout serves as a starting point in editor configuration. All custom object class properties including their captions are automatically added to the editor. The standard interface control type available for the property type of the custom object class property will be automatically generated. If more than ten custom object class properties have been defined for the object class, additional tabbed pages will be generated, and the custom object class properties will be distributed among the tabbed pages.

If you choose to modify the default design of the custom editor, you can change the type of interface controls generated for the custom object class properties, redistribute the custom object class properties among different tabbed pages in the custom editor, reposition and change the captions of the interface controls in a tabbed page, add or delete interface controls, and add text, color, links, and icons to the custom editor.

- Create a custom editor based on a copy of an existing custom editor for the object class. Once the custom editor is copied, you can delete and add interface controls, as needed.

Multiple class settings can be created for an object class and a different custom editor can be assigned to each class setting. For more information about class settings, see Configuring Class Settings for Object Classes and Object Class Stereotypes.

For an overview of the options to consider when working with custom editors, see the section Conceptualizing a Custom Editor.

The following information is available:

- Creating a New Custom Editor from Scratch
- Generating a Default Custom Editor
- Copying an Existing Custom Editor
- Specifying the Size of the Custom Editor

Creating a New Custom Editor from Scratch

You can create a new custom editor and add individual interface controls as needed.

1) In the **Presentations** tab, click the + symbol next to the **Custom Editors** folder. You will see all existing custom editors listed in the tree.
2) Right-click the **Custom Editors** folder and select **New Custom Editor**.
3) In the dialog that opens, select the object class defined for the custom editor that you want to copy and click **OK**. A new custom editor is displayed in the tree.
4) Right-click the existing custom editor that you want to copy and select **Copy**.
5) Right-click the new custom editor and select **Paste**.
6) Double-click the editor to view the definition of the new custom editor.
7) Enter a technical name in the **Name** field and the caption to display on the editor in the **Caption** field.

   A validation mechanism checks for correct syntax when defining a technical name. The technical name of a configuration object may not begin with an empty space nor include any of the following special characters: **\ / * ? " > < | ':**

   Furthermore, please note that names may not begin with an empty space nor include special characters. For a list of the special characters that are not allowed, see the section Defining Attributes for Configuration Objects in the chapter Getting Started with Alfabet Expand.

   Furthermore, if the technical name of a configuration object is changed, the name will be correctly updated in other configuration objects referencing the changed object during design time. Please note that the name of a changed configuration object will not be updated in guide pages nor if the guide pages reference a configuration object listed in the **Show Usage** functionality. If you plan to change the name of a configuration object, the reference in the guide page should be changed prior to changing the configuration object name.

8) If the editor should check the access permissions for the object managed by the editor when the user attempts to open the editor, select `True` in the **Check Rights** field. Select `False` if the editor should not check the access permissions for the object managed by the editor.

   It may be useful to set the **Check Rights** attribute to `False` in the context of a custom wizard which already verifies the access permissions and only shows objects the current user has Read/Write permissions for. Setting this attribute to `False` can improve performance. For more information about access permission concepts in Alfabet, see the

section Overview of Access Permissions for Objects in the chapter Configuring Access Permissions for Alfabet .

9) If custom help content should be available for the custom editor via the automated assistant capability, enter the URL or server variable that targets the content to display in the Assistant in the **Automated Assistant URL** attribute. For more information about configuring the automated assistant capability, see the chapter Providing Custom Online Help to the User Community.

10) You can modify the visualization of the new custom editor by adding and deleting interface controls, as needed. The options available to visualize the custom object class properties that are to be defined in the custom editor are described in detail in the section Configuring the Interface Controls in the Custom Editor.

11) In the toolbar, click the **Save** button.

Generating a Default Custom Editor

To generate a custom editor.

1) Go to the **Presentations** tab, right-click the **Custom Editors** folder, and select **Generate Custom Editor**.

2) In the dialog box that opens, select the object class for which you want to generate a custom editor and click **OK**. The new custom editor is added to the **Custom Editors** folder and is displayed in the editor in the center pane. All custom object class properties defined for the object class will be automatically distributed in the custom editor. If more than 10 custom object class properties have been defined for the object class, additional tabbed pages will be created and the custom object class properties distributed among the tabbed pages. See the section Specifying the Size of the Custom Editor. If the size of the custom editor must be altered.

3) Continue to define the basic attributes of the custom editor as described in the section Creating a New Custom Editor from Scratch.

After the custom editor is generated, you can review its visualization by right-clicking the custom editor node in the **Custom Editors** folder and selecting **Review Custom Editor.** If you are satisfied with the default layout that has been generated, you can implement the custom editor as is. Most likely, however, you will want to further refine and design the layout of the custom editor. The options available to visualize the custom object class properties that are to be defined in the custom editor are described in detail in the section Configuring the Interface Controls in the Custom Editor.

Copying an Existing Custom Editor

An existing custom editor can be copied and modified in order to create another custom editor. The custom editor may only be copied to the same class as the base object class defined for the original custom editor.

You should NOT copy an editor created for one object class and paste it to an editor created for a different object class.

1) Go to the **Presentations** tab, right-click the **Custom Editors** folder, and select **New Custom Editor** .
2) In the editor that opens, select the object class defined for the custom editor that you want to copy and click **OK**. A new custom editor is displayed in the tree.
3) Right-click the existing custom editor that you want to copy and select **Copy**.
4) Right-click the new custom editor and select **Paste**. Confirm the warning that you are replacing the content of the new custom editor.
5) Double-click the editor to view the definition of the new custom editor. You can modify the visualization of the new custom editor by adding and deleting interface controls, as needed.
6) Continue to define the basic attributes of the custom editor as described in the section Creating a New Custom Editor from Scratch.

Specifying the Size of the Custom Editor

The custom editor you create will be appended to the relevant standard editor for the object class that you specify in a class setting. The resulting size of the editor will be based on the maximum width and height defined for the standard editor and the custom editor. If the number of controls placed on the custom editor is high, you will need to add additional tabs to the custom editor. The size of static controls in custom editors will be adjusted automatically to the content to be displayed. Please note that the font and styles displayed in the editors are preconfigured by Software AG and cannot be customized.

Please note that all standard editors are designed to ensure display on a 1024 x 768 monitor screen. Because a standard editor may be implemented in a custom wizard, the height of standard editors is limited to 630 pixel. Therefore, it is highly recommended that the custom editor height does not exceed 630 pixel. The width of a custom editor should not exceed 850 pixel.

Once all of the interface controls have been added to the custom editor, you can refine the layout and design of the editor.

1) Go to the **Presentations** tab and expand the **Custom Editors** folder.
2) Right-click the custom editor that you want to define and select **Design Editor**. The custom editor is displayed in the editor in the center pane.
3) In the **Height** attribute, enter the height in pixel of the custom editor. The default height of the custom editor is 300 pixel. The value you enter should not exceed 630.
4) In the **Width** attribute, enter the width in pixel of the custom editor. The default width of the custom editor is 400 pixel. The value you enter should not exceed 850.
5) Click in the editor in the design editor to activate the **Edit** menu and **Format** menu.

- To cut, copy, paste, or delete an interface control, select the interface control, click **Edit** in the toolbar, and select the relevant option. For example, you can copy an interface control from one custom editor to another. To do so, select the interface control in the custom editor and select **Edit** > **Copy** in the main toolbar. Select **Edit** > **Paste** in the main toolbar, go to the other custom editor that is displayed in the center design pane and click in that custom editor to add the interface control to it.
- To define the alignment and spacing of the interface controls, click the relevant interface controls and select the relevant alignment or spacing options. **Format** menu with alignment and spacing options are added to the toolbar of Alfabet Expand.

- To sequence the interface controls in the editor in order to guide the user through the filter fields when using the keyboard shortcuts as well as to specify the order of hints in the custom online help, select **Format** > **Define Tab Order**. Click the blue boxes in the order that they should be sequenced.

6) In the toolbar, click the **Save** button to save your changes.

If you are dissatisfied with the layout of the custom editor you have created, you can modify the size, placement, and captions of the individual property types and interface controls. The options available to visualize the custom object class properties that are to be defined in the custom editor are described in detail in the section Configuring the Interface Controls in the Custom Editor.

Specifying the Rendering Definition of the Custom Editor

Before you begin adding interface controls to the custom editor, you should consider how you want to render the layout of the interface controls in the custom editor. Two options are possible and the method you choose will determine how you go about designing the custom editor. You can choose the traditional rendering style, which reflects the explicit design you make as you add and position the interface controls in the custom editor, or the stack rendering style which allows the interface controls to be automatically positioned at runtime in the editor based on a one- or two-column linear list. Please consider the following consequences of the different rendering styles:

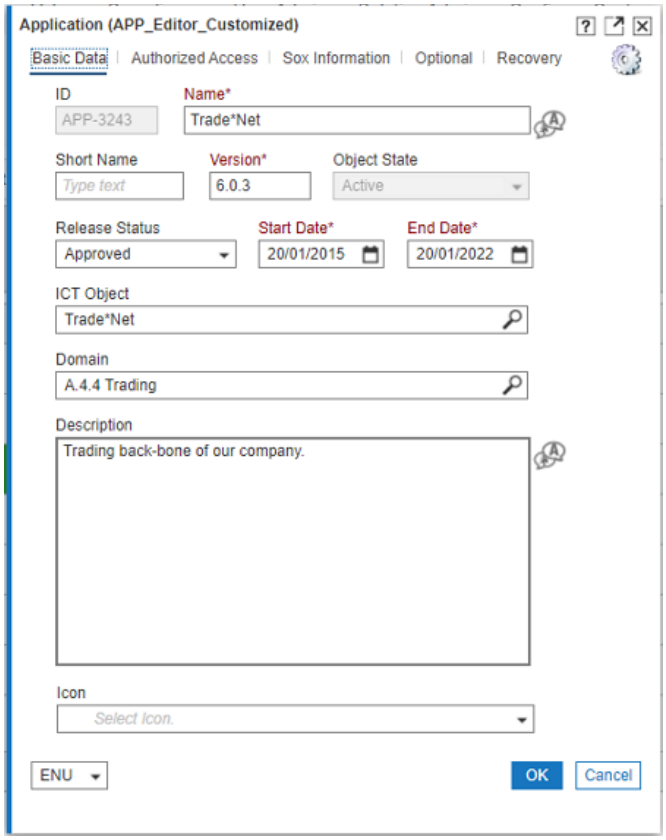

FIGURE: Editor above shows the editor with the traditional rendering style

Traditional Rendering Style: The traditional rendering of interface controls is determined by the explicit placement of the interface controls by the solution designer in the editor (WYSIWYG). In the traditional rendering style, the position, size, and alignment of the interface controls is defined by the solution designer. If

you configure conditional constraints for the interface controls and an interface control is not displayed as the result of a condition, the positioning of the visible interface controls will not be adjusted. Interface controls that are not visible due to the outcome of a conditional constraint will simply be displayed as a blank space in the editor. The traditional rendering can be reviewed when you right-click the custom editor and select **Review Custom Editor**.

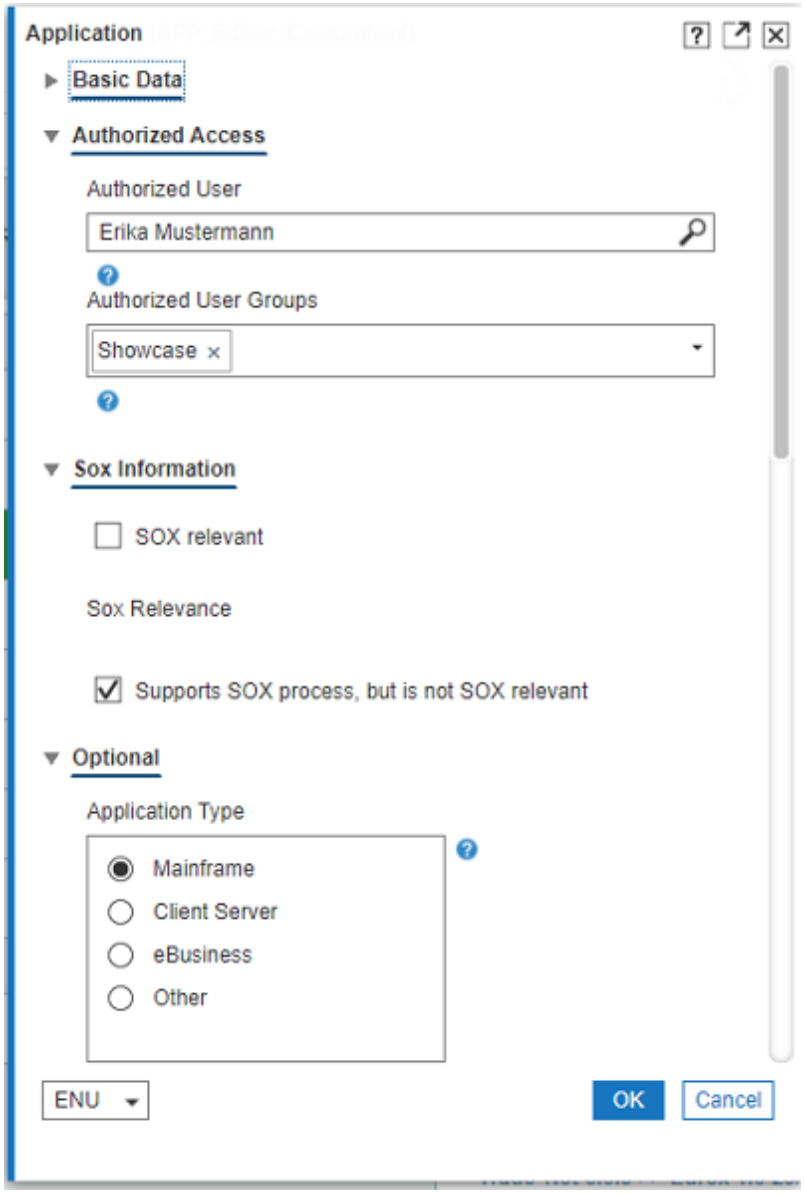

FIGURE: Editor above shows the editor with the stack rendering style

Stack Rendering Style: The stack rendering style greatly simplifies the task of designing the custom editor and provides a consistent and streamlined layout. In the stack rendering style, the interface controls are added to the custom editor but the solution designer does not need to pay attention to their placement or alignment in the editor. The placement and alignment of the interface controls is carried out at runtime. Please note however that when you add the interface controls to the custom editor, you must size them as needed for the data input. The size will not be automatically adjusted in the custom editor at runtime. Each tabbed page of the editor will be displayed as an expandable/collapsible section that, when expanded, displays the interface controls available in the tabbed page.

The stack rendering style has the advantage that if you configure conditional constraints for the interface controls and an interface control is not displayed as a result of a condition, the positioning of the visible interface controls will be automatically adjusted so that no blank spaces occur in the custom editor. Furthermore, it is also possible to group some interface controls in Group Box interface controls and maintain the explicit layout in the group box.

Please consider the following:

- **Editor Rendering Options** attributes are defined for GUI schemes and apply to all standard and custom editors in the solution. The **Editor Rendering Options** attributes are also available for class settings, allowing for the editors to be managed on a class-by-class basis. For example, stack rendering may be specified for the GUI scheme that is assigned to a user profile, but the traditional rendering style may be applied to the editors associated with the class settings for the classes Application and Component (or object class stereotypes of the classes Application and Component). If stack rendering is specified for a class setting, all standard and custom editors of the class will be displayed using the stack rendering style. Please note however that some standard editors that have buttons or presentation objects embedded (such as `APP_CopyFrom_Editor` or `APP_State_Editor`) will be rendered in the traditional layout, regardless of the **Editor Rendering Options** attributes defined for the GUI scheme (user profile) and class setting.

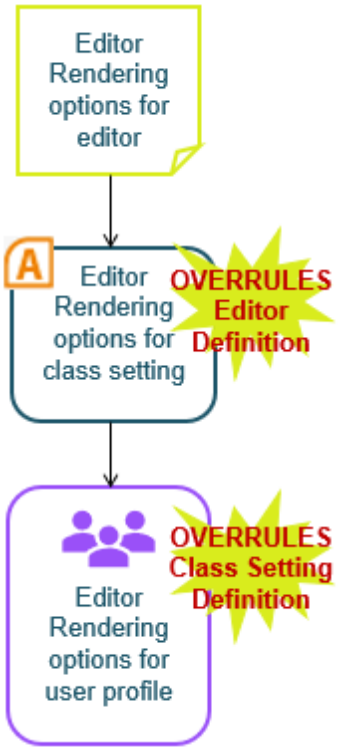

FIGURE: Precedence rules for the Editor Rendering attribute

- The **Editor Rendering Options** attributes allow you to specify whether the captions and interface controls are structured in one column that is left-aligned (as shown in the example above), or in two columns whereby the captions and interface controls are in one row with the captions in one column and the interface controls in a second column. The interface controls are ordered based on the **Tab Index** setting. You can also specify whether the help text defined in the **Hint** attributes of interface controls shall be displayed below the editor field in the custom editor or available in a pop-up that can be opened by clicking a help button next to the editor field.

- The stack rendering can be reviewed when you right-click the custom editor and select **Review Custom Editor**.
- For details about defining the GUI scheme, see the section Configuring GUI Scheme Definitions for the Alfabet Interface. For details about defining class settings, see the section Configuring Class Settings for Object Classes and Object Class Stereotypes.

To define the rendering of standard and custom editors in your solution:

1) Go to the relevant GUI scheme below the **GUI Schemes** node in the **Presentation** tab.
2) In the **Application** section of the attribute window, expand the **Editor Rendering Options** attribute and define the following:

- **Rendering Style**: Select either **Traditional** to display standard and custom editors as the have been explicitly designed or select **Stack** to display standard and custom editors as a one- or two-columnar linear list. If you select **Stack**, define the attributes listed below.

> Please note that if you change the Rendering Style attribute, you must delete the value in the **Editor Rendering Options** field and click the **Save** button to update the attributes in the **Editor Rendering Options** section of the attribute window.

- **Stack Layout Type**: If **Stack** has been selected for the **Rendering Style** attribute: Select **One Column** if the captions and interface controls shall be displayed as a single left-aligned column in the editor. Select **Two Columns** if the captions and interface controls shall be displayed as two left-aligned columns in the editor. Please note that the sequence of the interface controls is determined by the **Tab Index** attribute defined for each interface control.
- **Preserve Layout in Group Boxes**: Select `True` if the position of interface controls in a Group Box interface control should follow a traditional rendering style and not be changed to have a stack rendering style. Select `False` if the interface controls in a Group Box interface control should have a stack rendering style.
- **Show Hint In-Line**: Select `True` if the help texts defined via the **Hint** attribute of the interface controls shall be displayed in the editor below the editor field. The hint icon specified in the **Interface Control Hint Icon** attribute will not be displayed if the **Show Hint In-Line** attribute is set to `True`. Select `False` if the help texts should not be displayed below the editor field.
- **Interface Control Hint Icon**: Displays the icon displayed to show the help texts defined for the **Hint** attribute of interface controls. It is recommended that this attribute is not changed. The hint icon will only be displayed if the **Show Hint In-Line** attribute is set to `False`.

3) Click the **Save** button to save the configuration.
4) To specify editor rendering options that are different than the editor rendering options defined for the GUI scheme, go to the relevant class setting below the **Class Settings** node in the **Presentation** tab.
5) Expand the **Editor Rendering Options** attribute and define the following:

- **Rendering Style**: Select either `Traditional` to display standard and custom editors as the have been explicitly designed or select `Stack` to display standard and custom editors as a one- or two-columnar linear list. If you select `Stack`, define the attributes listed below.

- **Stack Layout Type**: If **Stack** has been selected for the **Rendering Style** attribute: Select `OneColumn` if the captions and interface controls shall be displayed as a single left-aligned column in the editor. Select `TwoColumns` if the captions and interface controls shall be displayed as two left-aligned columns in the editor. Please note that the sequence of the interface controls is determined by the **Tab Index** attribute defined for each interface control.
- **Preserve Layout in Group Boxes**: Select `True` if the position of interface controls in a Group Box interface control should follow a traditional rendering style and not be changed to have a stack rendering style. Select `False` if the interface controls in a Group Box interface control should have a stack rendering style.
- **Show Hint In-Line**: Select `True` if the help texts defined via the **Hint** attribute of the interface controls shall be displayed in the editor below the editor field. The hint icon specified in the **Interface Control Hint Icon** attribute will not be displayed if the **Show Hint In-Line** attribute is set to `True`. Select `False` if the help texts should not be displayed below the editor field.
- **Override GUI Scheme Settings**: Select `True` if the class setting shall override the GUI scheme setting of the editor rendering options. Select `False` if the class setting shall not override the GUI scheme definition of the editor rendering options.

6) Click the **Save** button to save the configuration.

Configuring the Interface Controls in the Custom Editor

New interface controls can be added to the custom editor and edited as needed. Likewise, any interface controls that have been automatically added to the custom editor via the **Generate Custom Editor** option can also be further edited. You can determine the placement and size of the interface controls in the custom editor. Additionally, you can define the number of tabs that comprise a custom editor and choose which interface controls will appear on each tab.

If you delete a custom editor, you can recreate a default version of it again at any time. For more information, see Generating a Default Custom Editor.

To add new interface controls and design the layout of the custom editor, the custom editor must be displayed in the center pane of Alfabet Expand. To display the custom editor in the center pane:

1) Go to the **Presentations** tab and expand the **Custom Editors** folder.
2) Right-click the custom editor that you want to define and select **Design Editor**. The custom editor is displayed in the editor in the center pane. Depending on the method used to create the custom editor, the editor may be empty or may have a default layout displaying interface controls associated with custom object class properties.
3) If the number of controls that you plan to place in the custom editor is high, you will need to redefine the size of the standard custom editor by redefining its **Width** and **Height** values.
4) Above the custom editor, you will see a toolbar with the interface controls that can be added to the custom editor. Please note that not all interface controls are relevant for the configuration of custom editors.
5) Please note the following general information about the definition of interface controls:

- To add an interface control to the custom editor, click the interface control icon in the toolbar and click in the custom editor. The interface control is added to the custom editor. Depending on the interface control you select, various attributes can be defined in the attribute window.
- Each new interface control must be associated with a custom object class property via the **Property** attribute of the interface control. You must select a custom object class property that is relevant for the type of interface control (for example, a check box control is relevant for a Boolean property). For an overview of all interface controls and their corresponding property types, see the section Overview of the Interface Controls Available for Custom Editors.

6) Click the **Save**  button to save the configuration.

The following information is available:

- Overview of the Interface Controls Available for Custom Editors
- Adding Tabbed Pages to the Custom Editor
- Adding an Edit Field to the Custom Editor
- Adding a Text Box to Capture ASCII and HTML in the Custom Editor
- Adding a Text Box to Capture ASCII Format
- Adding a Text Box with an Embedded HTML Editor
- Adding a Field to Capture Dates in the Custom Editor
- Adding a Checked List Box to the Custom Editor
- Adding a Checkbox to the Custom Editor
- Adding a Combo Box to the Custom Editor
- Adding a Radio Button Group to the Custom Editor
- Adding an Edit Search Field to the Custom Editor
- Adding a Role Edit Search Field to the Custom Editor
- Adding Static Text to the Custom Editor
- Adding a List Box to Display Enumerations in the Custom Editor
- Adding Icons to the Custom Editor
- Adding an HTML Document Stored in the Internal Document Selector to the Custom Editor
- Adding a URL to the Custom Editor
- Adding HTML Text to the Custom Editor
- Adding a Color Selector to the Custom Editor
- Specifying the Interface Control To Be Mandatory
- Specifying an Editor Field To Be Non-Editable
- Specifying Conditional Constraints in the Custom Editor

Overview of the Interface Controls Available for Custom Editors

The following table lists all interface controls that can meaningfully be defined in a custom editor as well as the relevant custom object class property types that they can be associated with. Interface controls that are not relevant to custom editors are not included in the table.

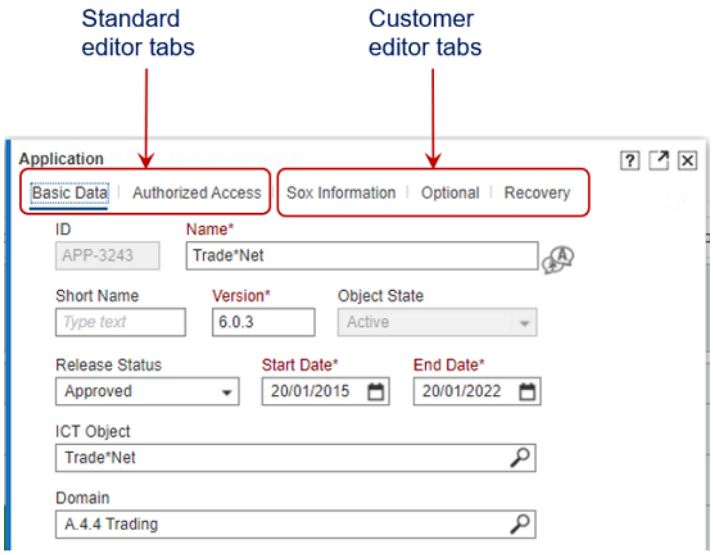
Interface Control	Description	Property Type
Flow Panel	Not relevant for custom editors.	
Table Layout Panel	Not relevant for custom editors.	
 Panel	Used to create a panel in the layout that can be used to visually frame and group a set of interface controls. The panel may have a different color than the rest of the custom editor and display a caption. Interface controls can be placed on the panel so that they appear to be grouped in the frame.	Not applicable.
 Page	Used to create a tabbed page in the custom editor. For more information, see Adding Tabbed Pages to the Custom Editor.	Not applicable.
 Static Text	Used to add static text to the customer editor in order to provide, for example, instructions to the users about capturing data. The static text interface control is not associated with a custom object class property. For more information, see Adding Static Text to the Custom Editor.	Not applicable

Interface Control	Description	Property Type
Edit Field	Used to create a one-line edit field in which users can enter data. If created for a property of type `Date` or `DateTime`, a **Calendar** icon will be displayed that opens a calendar to define a date. For more, see Adding an Edit Field to the Custom Editor and Adding a Field to Capture Dates in the Custom Editor. **NOTE**: An edit field can also display a Color button that allows users to select a color for an object's display. For more information, see the section Adding a Color Selector to the Custom Editor.	`String`, `Integer`, `Real`, `Text`, `URL`, `Date`, or `DateTime`
Memo	Used to display a large text field to capture longer texts. vertical scroll bar will be automatically displayed if the captured text exceeds the available space. For more, see Adding a Text Box to Capture ASCII and HTML in the Custom Editor.	`Text`
Check Box	Used to create a checkbox that allows the user to specify `True` (checked) or `False` (cleared) for the property. For more, see Adding a Checkbox to the Custom Editor.	`Boolean`
List Box	Used to display enumeration items in the box. Values cannot be defined via this interface control. For more information, see Adding a List Box to Display Enumerations in the Custom Editor.	Used for `String` and `Text` for which an enumeration has been defined.
Checked List Box	Used to allow multiple values to be selected. A vertical scroll bar will be automatically displayed if the list of available values (determined by the enumeration defined) is too long for the standard box. For more information, see Adding a Checked List Box to the Custom Editor.	Used for a `Text` property for which an enumeration has been defined or for a `ReferenceArray` property which will require the configuration of a query.
Checked Combo Box	Used to allow multiple values to be selected. Please note that a checked combo box is typically used as a filter field and is typically not meaningful for a custom editor.	
Combo Box	Used to create a drop-down list displaying the possible values. The user can select one value. For more information, see Adding a Combo Box to the Custom Editor.	Used for `String` and `Text` for which an enumeration has been defined or for `Reference` property which will require the configuration of a query.

Interface Control	Description	Property Type
 Radio Button Group	Used to display a list of buttons displaying the possible values. The user can select one value. For more information, see Adding a Radio Button Group to the Custom Editor.	Used for `String` and `Text` for which an enumeration has been defined or for `Reference` property which will require the configuration of a query.
 Edit Search Field	Used to display a search field search for properties of the type `Reference`. When the user clicks the **Search**  icon, a standard or custom selector will open in which the value can be selected. The user can select one value. For more information, see Adding an Edit Search Field to the Custom Editor.	`Reference`
 Role Edit Search	Used to specify the role for the relevant object directly in the custom editor rather than requiring the user to define the role in the *Responsibilities Page View*.	
 Icon	Used to display relevant icons or graphic images in the custom editor. For more information, see Adding Icons to the Custom Editor.	Not applicable.
 Group Box	Used as a visual frame that wraps a set of related interface controls. This is for purposes of visualization only. Please note it is not recommended that a Group Box interface control is set to ReadOnly. Instead, the controls included in the group box should individually be set to ReadOnly.	Not applicable.
 HTML Content	Used to add HTML text, URL, or a link that opens a document located in the **Internal Document Selector**. For more information, see Adding an HTML Document Stored in the Internal Document Selector to the Custom Editor, Adding a URL to the Custom Editor, and Adding HTML Text to the Custom Editor.	Not applicable.
Presentation Object	Not relevant for custom editors.	
Slider	Not relevant for custom editors.	

Adding Tabbed Pages to the Custom Editor

The Page interface control allows you to add tabbed pages to a custom editor.



While a custom editor can have multiple custom object class properties as well as multiple tabbed pages, for the sake of usability, it is recommended that you not create more than three tabbed pages per custom editor. When you create an automatically-generated custom editor that has more than ten custom object class properties, additional tabs are automatically created and the custom object class properties are automatically assigned to the tabs in the sequence in which they were created. If the number of controls placed on the custom editor is high, you will need to redefine the size of the standard custom editor by redefining its **Width** and **Height** attributes.

1) Go to the **Presentations** tab and expand the **Custom Editors** folder.
2) Right-click the custom editor that you want to define and select **Design Editor**. The custom editor is displayed in the editor in the center pane. Depending on the method used to create the custom editor, the editor may be empty or may have a default layout displaying interface controls associated with custom object class properties.
3) If the number of controls that you plan to place in the custom editor is high, you will need to redefine the size of the standard custom editor by redefining the **Width** and **Height** attributes.
4) Above the custom editor, you will see a toolbar with the interface controls that can be added to the custom editor. Please note that not all interface controls are relevant for the configuration of custom editors.
5) To add one or more tabs to a custom editor, click the **Page** button in the interface control toolbar and click in the editor. Add the necessary interface controls to the selected page. You may define additional tabs as needed. Alternatively, you can add all interface controls to a single tab page, and then copy and paste the interface controls to the tab pages where you want to display them.
6) In the **Caption** attribute, enter a short text that should be displayed on the tab for the Page interface control.
7) Click the **Save** button to save the configuration.

Adding an Edit Field to the Custom Editor

An Edit Field interface control allows the user to enter data in a one-line text field.

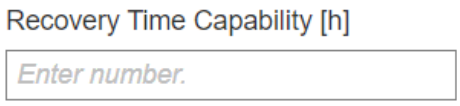


FIGURE: Edit field with placeholder text

Please consider the following:

- For properties of the type `Text`: A Memo interface control can be used instead of an Edit Field interface control to capture extensive text such is needed for **Description** properties. In this case, the text can be captured as ASCI text in a conventional text box or in HTML format using an embedded HTML editor. For more information, see the section Adding a Text Box to Capture ASCII and HTML in the Custom Editor.
- For properties of the type `Date`: An Edit Field interface control can be used to add a calendar field. For details about adding a field with a calendar, see the section Adding a Field to Capture Dates in the Custom Editor
- For properties of the type `Color`: An Edit Field interface control can be used to add a color picker. For details about adding a color picker, see the section Adding a Color Selector to the Custom Editor

To add and configure an Edit Field interface control:

1) Right-click the custom editor that you want to define and select **Design Editor**. The custom editor is displayed in the editor in the center pane.
2) In the toolbar of the design editor, click the **Edit** button and click in the editor where you want to place it. The Edit Field interface control is added to the editor.
3) Click the Edit Field interface control in the design editor to activate its attribute window. The **Control Type** attribute is automatically set to `Edit`.
4) In the **Property** attribute, specify the custom object class property of the types `String`, `Integer`, `Real`, `Text`, `URL`, or `Date` that should be captured via the interface control. The **Value Type** attribute should display either `String`, `Integer`, `Real`, `Text`, `URL`, or `Date`, depending on the property type selected in the **Property** attribute.
5) In the **Caption** attribute, enter the text that should be displayed for the Edit Field interface control. This could be the name of the custom object class property associated with the Edit Field interface control or more descriptive text.

   To use the ampersand (&) character in the caption, enter: &&

   A caption should not be more than 255 characters. If the field caption requires more characters or formatting, then you should leave the **Caption** attribute empty and create a static text interface control for which you can define the **Style** attributes. For more information, see the section Adding Static Text to the Custom Editor.
6) In the **Read-Only** attribute, select `False` if the field may be defined or select `True` if the field is read-only.
7) To provide cursory information about how to define the data, enter a short text in the **Placeholder** attribute. The text will be displayed as a hint in the text field. The text will be truncated if it is

longer than the field. The placeholder text will not be displayed if the **Read-Only** attribute is set to `True`. The display of the placeholder text can be configured via the GUI scheme attribute **Placeholders Text Color**. For more information, see the section *Overview of GUI Scheme Attributes* in the reference manual *Configuring Alfabet with Alfabet Expand - Appendix*.

8) **Validator**: In order to enforce values with a specific structure (for example, that version numbers should always be defined as two digits made up of a period and another digit), define a regular expression. Please note that specific enforcement mechanisms must be implemented for existing records or records that are imported into Alfabet from external systems. For more information about the syntax conventions for regular expressions, see http://msdn.microsoft.com/en-us/library/hs600312(VS.71).aspx

Alternatively, the **Validator** attribute may be defined for an object class property. In this case, it is enforced on **all** editors where the object class property is editable.

9) **Validator Message**: This attribute is only relevant if the **Validator** attribute is defined. Specify the message to help the user provide relevant data. If the validation message is specified, users will be prompted with the validation message if the value provided does not match the specified validator. If a validation message is not specified, an error message will state that the input value has an invalid format and will display the informational text specified in the **Hints** attribute for the interface control.

10) Specify the position of the interface control in the sequence of all interface controls. To do so, enter an integer in the **Tab Index** attribute. New interface controls will have a default value set to 0. Please note the following:

- The order that the interface controls are listed in the editor if stack layout is defined for rendering editors. For more information about stack vs. traditional rendering style for editors, see the section Specifying the Rendering Definition of the Custom Editor.
- The order that is used when the user moves the focus in the custom editor via the TAB key. The correct definition of tabbing is especially critical in order to provide barrier-free accessibility. For more information, see the section Configuring Barrier-Free User Profiles.
- The sequence that the help texts defined via the **Hint** attribute for an interface are listed in the modal Help window.

11) If a help text is required for the interface control, enter the text in the **Hint** attribute. If the **Hint** attribute is defined, the help text will be available in the modal Help window that opens when the editor's Help button is clicked. If stack rendering style is defined for editors, the help texts may be displayed below the editor field or via a Help button next to the editor field. For more information about stack rendering for editors, see the section Specifying the Rendering Definition of the Custom Editor.

12) In the toolbar, click the **Save**  button to save your changes.

Adding a Text Box to Capture ASCII and HTML in the Custom Editor

Custom object class properties of the type `Text` are usually configured to capture extensive comments or descriptions about an object. The Memo interface control provides a text box that can be sized as needed and will automatically display a vertical scroll bar if the captured text exceeds the available space. Per default, the text will be captured in ASCII format. Alternatively, you can configure the text box to embed an HTML editor so that users can capture the text in HTML format.

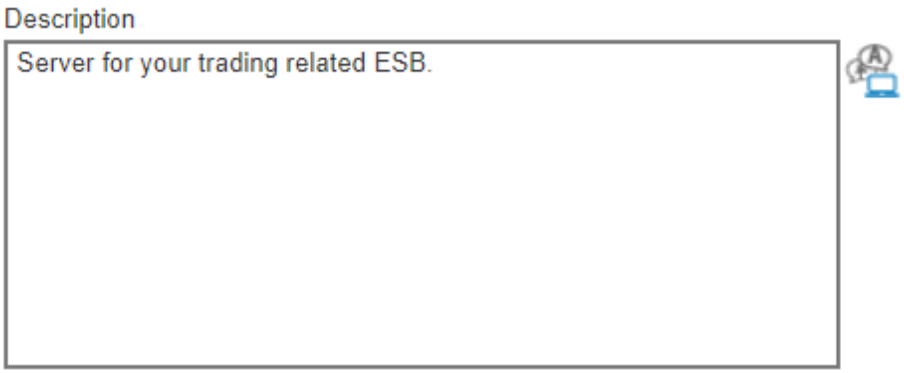

FIGURE: Text field to capture ASCII format

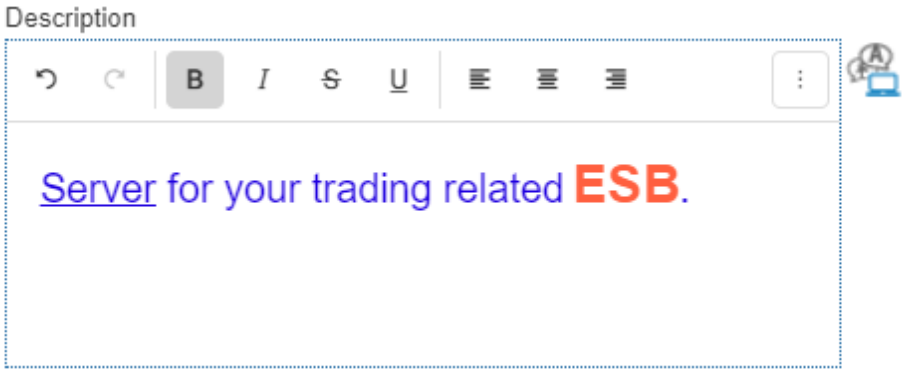

FIGURE: Text field with embedded HTML editor

The following information is available:

- Adding a Text Box to Capture ASCII Format
- Adding a Text Box with an Embedded HTML Editor

Adding a Text Box to Capture ASCII Format

A Memo interfaced control can be created for a property to capture text in ASCII format. This is the default format if no further configuration to enable HTML content is specified.

To add a Memo interface control to the custom editor:

1) Right-click the custom editor that you want to define and select **Design Editor**. The custom editor is displayed in the editor in the center pane.
2) In the toolbar of the design editor, click the **Memo** button and click in the editor where you want to place it. The Memo interface control is added to the editor.
3) Click the Memo interface control in the design editor to activate its attribute window. The **Control Type** attribute is automatically set to `Memo`.
4) In the **Property** attribute, specify the custom object class property of the type `Text` that should be captured via the interface control. The **Value Type** attribute should display `Text`.

5) In the **Caption** attribute, enter text for the caption that should be displayed for the Memo interface control. This could be the name of the object class property associated with the Memo interface control or more descriptive text.

To use the ampersand (&) character in the caption, enter: &&

A caption should not be more than 255 characters. If the field caption requires more characters or formatting, then you should leave the **Caption** attribute empty and create a static text interface control for which you can define the **Style** attributes. For more information, see the section Adding Static Text to the Custom Editor.

6) Specify the position of the interface control in the sequence of all interface controls. To do so, enter an integer in the **Tab Index** attribute. New interface controls will have a default value set to 0. Please note the following:

- The order that the interface controls are listed in the editor if stack layout is defined for rendering editors. For more information about stack vs. traditional rendering style for editors, see the section Specifying the Rendering Definition of the Custom Editor.
- The order that is used when the user moves the focus in the custom editor via the TAB key. The correct definition of tabbing is especially critical in order to provide barrier-free accessibility. For more information, see the section Configuring Barrier-Free User Profiles.
- The sequence that the help texts defined via the **Hint** attribute for an interface are listed in the modal Help window.

7) If a help text is required for the interface control, enter the text in the **Hint** attribute. If the **Hint** attribute is defined, the help text will be available in the modal Help window that opens when the editor's Help button is clicked. If stack rendering style is defined for editors, the help texts may be displayed below the editor field or via a Help button next to the editor field. For more information about stack rendering for editors, see the section Specifying the Rendering Definition of the Custom Editor.

8) To provide information about how to define the data, enter a text in the **Placeholder** attribute. The text will be displayed as a hint in the search field. Linebreaks can be configured in placeholder texts in order to structure long placeholder texts in Memo interface controls in editors. The display of the placeholder text can be configured via the GUI scheme attribute **Placeholders Text Color**. For more information, see the section *Overview of GUI Scheme Attributes* in the reference manual *Configuring Alfabet with Alfabet Expand - Appendix*.

9) In the toolbar, click the **Save**  button to save your changes.

Adding a Text Box with an Embedded HTML Editor

The following configuration is required to implement a HTML editor for the Memo interface control:

The **Can Have HTML Content** attribute must be set to `True` for the relevant property of type `Text`. For more information, see the section Configuring Custom Properties of the Type Text.

If the HTML editor is enabled and the **Enable Data Translation** attribute is set to `True`for the custom property, the XML attribute `TranslateContentExceedingHTMLLengthLimit` must be configured in the XML object ***AlfaTranslationServicesConfig***. For more information about

configuring the XML object ***AlfaTranslationServicesConfig***, see the section Configuring the Connection to the Translation Service

To add a Memo interface control to the custom editor:

1) Right-click the custom editor that you want to define and select **Design Editor**. The custom editor is displayed in the editor in the center pane.

2) In the toolbar of the design editor, click the **Memo** button and click in the editor where you want to place it. The Memo interface control is added to the editor.

3) Click the Memo interface control in the design editor to activate its attribute window. The **Control Type** attribute is automatically set to `Memo`. Define the following attributes:

- **Property**: Specify the custom object class property of the type `Text` that should be captured via the interface control. The **Value Type** attribute should display `Text`.
- **Caption**: Enter text for the caption that should be displayed for the Memo interface control. This could be the name of the object class property associated with the Memo interface control or more descriptive text.

  To use the ampersand (&) character in the caption, enter: &&

  A caption should not be more than 255 characters. If the field caption requires more characters or formatting, then you should leave the **Caption** attribute empty and create a static text interface control for which you can define the **Style** attributes. For more information, see the section Adding Static Text to the Custom Editor.

- **Enable HTML Content**: Set to `True` to display the HTML editor for the text field. If the **HTML Content** attribute has been set to `True` for the Memo interface control, the **Enable HTML Content** attribute will be automatically set to `True` for the property in the **Attributes** section of the standard and custom object profiles as well as for the Value Control interface control in an object cockpit. The **Enable HTML Content** attribute can be set to `False` for either the property in the custom object profile or the Value Control interface control if needed.

4) In the toolbar, click the **Save** button to save your changes.

5) Next, it is necessary to copy and generate the custom editors as HTF editors so that the Memo interface controls will be correctly sized and that the other interface controls will be retrofitted to the width of the embedded HTML editor. This is done for all editors containing Memo interface controls for either a specific object class or for all relevant object classes with Memo interface controls configured in the associated standard and custom editors. Go to the **Meta-Model** tab and navigate to the class node of the class that the custom editor has been created for (the class selected in the **Select Class** editor when the custom editor was created).

6) Right-click the object class and select **Generate HTF Editors**. Confirm the info message about how many HTF editors have been created. This number will include all custom editors with Memo interface controls as well as any private editors with Memo interface controls for the selected class. Please note the following:

- The original custom editors have been copied below the **HTF** node in the **Custom Editors** folder and appended with the suffix `_HTF`.
- Private editors as well as editors configured to replace standard editors will be displayed below the **HTF** node in the **Editors** folder. Editors configured to replace standard editors may be updated with HTF editors as described below.

Alternatively you can generate HTF editors for all relevant object classes with Memo interface controls configured in the associated standard and custom editors. Go to the **Presentation** tab and right-click **Generate HTF Editors**. Confirm the info message about how many HTF editors have been created.

7) Check the usage of the original custom editor in class settings, object views, view schemes, wizards, and workflows in order to decide whether to update the copied HTF editor to those usages. In the **Presentation** tab, expand the **Custom Editors** folder to view the generated HTF editors. Right-click the relevant HTF editor and select **Show Usage for Original Custom Editor**. The **Objects Usage** editor displays all usages of the original custom editor. Click **Close** to close the editor.

8) To replace the original custom editor in the class settings, object views, view schemes, wizards, and workflows displayed in the **Objects Usage** editor with the _HTF editor:

- To automatically update all relevant public class settings, object views, view schemes, wizards, and workflows: Right-click the HTF editor and select **Update All Possible Usages for Original Editor**. Confirm the info message about how many usages have been updated. The HTF editors will be specified instead of the original custom editor for the relevant class settings, object views, view schemes, wizards, and workflows. Please note that only public class settings, object views, view schemes, wizards, and workflows will be updated. Private configuration objects preconfigured by Software AG will not be updated.
- To manually update specific class settings, object views, view schemes, wizard, and workflows, navigate to the relevant configuration object listed in the **Objects Usage** editor and specify the relevant HTF editor as needed.

9) In the toolbar, click the **Save** button to save your changes.

Adding a Field to Capture Dates in the Custom Editor

If a custom object class property of the type `Date` is to be captured in the custom editor, an Edit Field interface control should be added to the custom editor. A calendar button will be automatically added to any edit field for which the **Value Type** attribute is set to `Date`. Users can enter a date directly in the edit field or click the **Calendar** button to open the calendar and select the date.

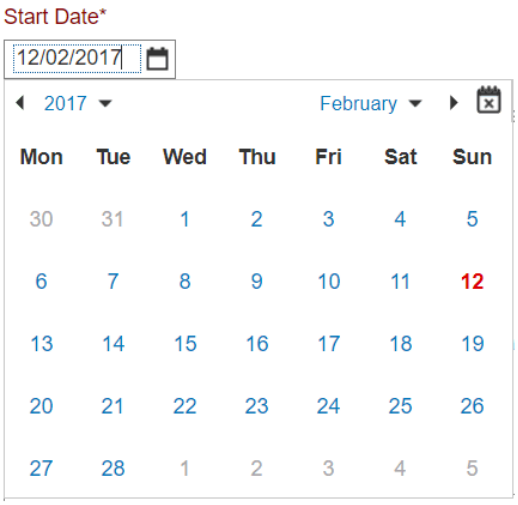

FIGURE: Clicking Calendar button opens date picker

A custom object class property of the type `DateTime` can also be captured in an Edit Field interface control. However, in contrast to an object class property of the type `Date`, a **Calendar** button is not available for properties of the type `DateTime`. If the edit field is associated with a custom object class property of the type `DateTime`, the user must explicitly enter the date and time in the appropriate format in the edit field.

The format used to display and capture the date and time information on the user interface is determined by the cultures configured by your enterprise for the Alfabet solution. For more information about configuring cultures, see the section Specifying the Cultures Relevant to Your Enterprise in the chapter Localization and Multi-Language Support for the Alfabet Interface.

To add a Edit Field interface control with a calendar button to the custom editor:

1) Right-click the custom editor that you want to define and select **Design Editor**. The custom editor is displayed in the editor in the center pane.

2) In the toolbar of the design editor, click the **Edit** button and click in the editor where you want to place it. The Edit Field interface control is added to the editor.

3) Click the Edit Field interface control in the design editor to activate its attribute window. The **Control Type** attribute is automatically set to `Edit`.

4) In the **Property** attribute, specify the custom object class property o the type `Date` or `DateTime` that should be captured via the interface control. The **Value Type** attribute should display `Date` or `DateTime`.

5) In the **Caption** attribute, enter the text that should be displayed for the Edit Field interface control. This could be the name of the object class property associated with the Edit Field interface control or more descriptive text.

   To use the ampersand (&) character in the caption, enter: &&

   A caption should not be more than 255 characters. If the field caption requires more characters or formatting, then you should leave the **Caption** attribute empty and create a static text interface control for which you can define the **Style** attributes. For more information, see the section Adding Static Text to the Custom Editor.

6) Specify the position of the interface control in the sequence of all interface controls. To do so, enter an integer in the **Tab Index** attribute. New interface controls will have a default value set to 0. Please note the following:

- The order that the interface controls are listed in the editor if stack layout is defined for rendering editors. For more information about stack vs. traditional rendering style for editors, see the section Specifying the Rendering Definition of the Custom Editor.
- The order that is used when the user moves the focus in the custom editor via the TAB key. The correct definition of tabbing is especially critical in order to provide barrier-free accessibility. For more information, see the section Configuring Barrier-Free User Profiles.
- The sequence that the help texts defined via the **Hint** attribute for an interface are listed in the modal Help window.

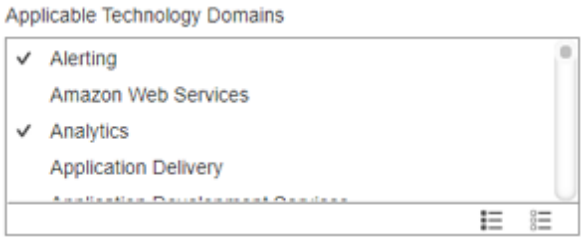
7) If a help text is required for the interface control, enter the text in the **Hint** attribute. If the **Hint** attribute is defined, the help text will be available in the modal Help window that opens when the editor's Help button is clicked. If stack rendering style is defined for editors, the help texts may be

displayed below the editor field or via a Help button next to the editor field. For more information about stack rendering for editors, see the section Specifying the Rendering Definition of the Custom Editor.

8) In the toolbar, click the **Save** button to save your changes. Please note that the **Calendar** button will not be displayed in the **Design Editor** mode that you are working in. However, if you right-click the custom editor and select **Review Custom Editor**, the **Calendar** button will be visible and can be clicked in order to open it.

Adding a Checked List Box to the Custom Editor

A Checked List Box interface control box allows a user to select multiple values by setting a checkmark next to each relevant value. The Checked List Box interface control automatically displays a vertical scroll bar if the list of available values (determined by the enumeration defined) is too long for the standard box.



The Checked List Box interface control can be defined for custom object class properties of the type `StringArray` for which an enumeration has been defined, or for custom object class properties of the type `ReferenceArray`, which will require the additional configuration of an Alfabet query or native SQL query.

If the editor is rendered in a stacked layout, an auto-complete function may be available if the checked list box field has a significant number of entries. Once a letter is entered in the search field, the auto-complete function will display a list of matching text. Users can hit the ENTER key or select the object in the drop-down menu to add it to the editor field. The editor field will increase in size to display all selected objects in the field. An X will be displayed next to each object to allow it to be cleared and removed from the editor field. The auto-complete function can be specified for checked list box editor fields in custom editors rendered in a stacked layout by setting the **Use Multi-Edit Search** attribute for the Checked List Box interface control to `True`. For more information about rendering editors in a stacked layout, see the section Configuring Styles and GUI Scheme Settings for Standard and Custom Editors.

To add and configure a checked list box:

1) Right-click the custom editor that you want to define and select **Design Editor**. The custom editor is displayed in the editor in the center pane.
2) In the toolbar of the design editor, click the **Checked List Box** button and click in the editor where you want to place it. The Checked List Box interface control is added to the editor.
3) Click the Checked List Box interface control in the design editor to activate its attribute window. The **Control Type** attribute is automatically set to `CheckedListBox`.
4) In the **Caption** attribute, enter the text that should be displayed for the Checked List Box interface control. This could be the name of the custom object class property associated with the Checked List Box interface control or more descriptive text.

To use the ampersand (&) character in the caption, enter: &&

A caption should not be more than 255 characters. If the field caption requires more characters or formatting, then you should leave the **Caption** attribute empty and create a static text interface control for which you can define the **Style** attributes. For more information, see the section Adding Static Text to the Custom Editor.

5) For properties of the type `StringArray`:

- In the **Property** attribute, specify the custom object class property of the type `StringArray` that should be captured via the interface control. The custom object class property must have an enumeration defined. The **Value Type** attribute should display `StringArray`. The **SubType** attribute should display `Enum`.

6) For properties of the type `ReferenceArray`:

- In the **Property** attribute, specify the custom object class property of the type `ReferenceArray` that should be captured via the interface control. The custom object class property must have an enumeration defined. The **Value Type** attribute should display `ReferenceArray`.
- In the **SubType** attribute, select `SqlEnum`.
- In the **Range** attribute, enter the Alfabet query or native SQL query to find the relevant objects for the `ReferenceArray`. The information about the object displayed in the caption of the respective entry in the checked list box is defined via the `SHOW` properties of the Alfabet query or the `SELECT` statement of the native SQL query. For details about defining a query, see the chapter Defining Queries.

In this example, a principle shall be defined for a project. A custom object class property of the type `ReferenceArray` has been created for the object class `Project`. The class `Principle` is defined in the **Type Info** attribute for the custom object class property. The following Alfabet query is specified in the **Range** attribute for the `Checked List Box` interface control:

```
Alfabet_QUERY_500
FIND Principle
SHOW Principle.Name
SORT Principle.Name
```

The resulting entries in the Checked List Box interface control display the name of the principles found by the Alfabet query via the `SHOW` property.

7) Specify the position of the interface control in the sequence of all interface controls. To do so, enter an integer in the **Tab Index** attribute. New interface controls will have a default value set to 0. Please note the following:

- The order that the interface controls are listed in the editor if stack layout is defined for rendering editors. For more information about stack vs. traditional rendering style for editors, see the section Specifying the Rendering Definition of the Custom Editor.
- The order that is used when the user moves the focus in the custom editor via the TAB key. The correct definition of tabbing is especially critical in order to provide barrier-free accessibility. For more information, see the section Configuring Barrier-Free User Profiles.
- The sequence that the help texts defined via the **Hint** attribute for an interface are listed in the modal Help window.

8) If a help text is required for the interface control, enter the text in the **Hint** attribute. If the **Hint** attribute is defined, the help text will be available in the modal Help window that opens when the editor's Help button is clicked. If stack rendering style is defined for editors, the help texts may be displayed below the editor field or via a Help button next to the editor field. For more information about stack rendering for editors, see the section Specifying the Rendering Definition of the Custom Editor.

9) In the toolbar, click the **Save** button to save your changes.

Adding a Checkbox to the Custom Editor

The Check Box interface control allows the user to define a custom object class property of the type `Boolean`. A user can click the checkbox to set a checkmark (= `True`) or clear the checkbox (= `False`).

Please note the following regarding the checkbox for a custom object class property of the type `Boolean`.

- A user will not be able to differentiate between a checkbox for which no value has been set (= `NULL`) vs. a checkbox that has been cleared (= `False`). Therefore, it is highly recommended that a default value be configured for a custom object class property of the type `Boolean` in order to ensure that the object class property is either `True` or `False`. For more information about configuring the default value, see the section Configuring Custom Properties of the Type Boolean in the chapter Configuring the Class Model.
- If the **Read Only** attribute is set to `True` for a `CheckBox` interface control, the checkbox will be disabled and the value defined in the **Hint** attribute of the associated custom object class property of the type `Boolean` cannot be displayed as a tooltip. It is recommended that you add the tooltip as static text to the editor if it should be visible for a non-editable checkbox. For more information about defining a non-editable checkbox displaying a default value, see the section Specifying an Editor Field To Be Non-Editable.

To add a Check Box interface control to the custom editor:

1) Right-click the custom editor that you want to define and select **Design Editor**. The custom editor is displayed in the editor in the center pane.
2) In the toolbar of the design editor, click the **Check Box** button and click in the editor where you want to place it. The Check Box interface control is added to the editor.
3) Click the Check Box interface control in the design editor to activate its attribute window. The **Control Type** attribute is automatically set to `CheckBox`.
4) In the **Property** attribute, specify the custom object class property of the type `Boolean` that should be captured via the interface control. The **Value Type** attribute should display `Boolean`.
5) In the **Caption** attribute, enter the text that should be displayed for the checkbox interface control. This could be the name of the object class property associated with the Check Box interface control or more descriptive text.

To use the ampersand (&) character in the caption, enter: &&

A caption should not be more than 255 characters. If the field caption requires more characters or formatting, then you should leave the **Caption** attribute empty and create a static text interface control for which you can define the **Style** attributes. For more information, see the section Adding Static Text to the Custom Editor.

6) **Validator**: In order to enforce values with a specific structure (for example, that version numbers should always be defined as two digits made up of a period and another digit), define a regular expression. Please note that specific enforcement mechanisms must be implemented for existing records or records that are imported into Alfabet from external systems. For more information about the syntax conventions for regular expressions, see http://msdn.microsoft.com/en-us/library/hs600312(VS.71).aspx

Alternatively, the **Validator** attribute may be defined for an object class property. In this case, it is enforced on **all** editors where the object class property is editable.

7) **Validator Message**: This attribute is only relevant if the **Validator** attribute is defined. Specify the message to help the user provide relevant data. If the validation message is specified, users will be prompted with the validation message if the value provided does not match the specified validator. If a validation message is not specified, an error message will state that the input value has an invalid format and will display the informational text specified in the **Hints** attribute for the interface control.

8) Specify the position of the interface control in the sequence of all interface controls. To do so, enter an integer in the **Tab Index** attribute. New interface controls will have a default value set to 0. Please note the following:

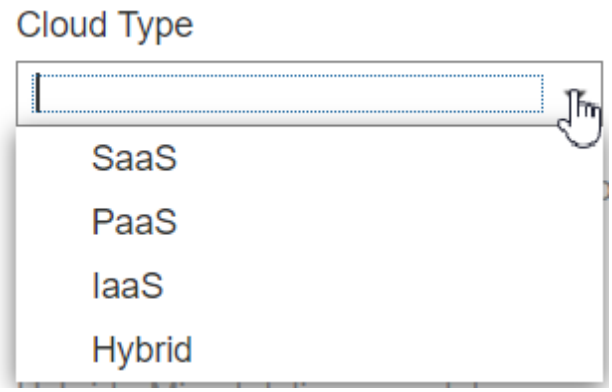
- The order that the interface controls are listed in the editor if stack layout is defined for rendering editors. For more information about stack vs. traditional rendering style for editors, see the section Specifying the Rendering Definition of the Custom Editor.
- The order that is used when the user moves the focus in the custom editor via the TAB key. The correct definition of tabbing is especially critical in order to provide barrier-free accessibility. For more information, see the section Configuring Barrier-Free User Profiles.
- The sequence that the help texts defined via the **Hint** attribute for an interface are listed in the modal Help window.

9) If a help text is required for the interface control, enter the text in the **Hint** attribute. If the **Hint** attribute is defined, the help text will be available in the modal Help window that opens when the editor's Help button is clicked. If stack rendering style is defined for editors, the help texts may be displayed below the editor field or via a Help button next to the editor field. For more information about stack rendering for editors, see the section Specifying the Rendering Definition of the Custom Editor.

10) In the toolbar, click the **Save** button to save your changes.

Adding a Combo Box to the Custom Editor

A Combo Box interface control provides a drop-down field that displays a list of values that can be selected for a custom object class property. The user can select only one value for the custom object class property. The first line of the combo box may be blank if no value may be defined.



Users can click the arrow to open the drop-down list or begin to type in the name of the object they are searching for. The auto-complete function will display a list of matching text. Please note that the auto-complete capability will not be implemented for a user profile for which the **Use WAI-ARIA** attribute is set to `True`.

The Combo Box interface control can be defined for custom object class properties of the type `String` or `Text` for which an enumeration has been defined, or for custom object class properties of the type `Reference`. However, this requires the additional configuration of an Alfabet query or a native SQL query.

To add a Combo Box interface control to the custom editor:

1) Right-click the custom editor that you want to define and select **Design Editor**. The custom editor is displayed in the editor in the center pane.
2) In the toolbar of the design editor, click the **Combo Box** interface control and click in the editor where you want to place it. The Combo Box interface control is added to the editor.
3) Click the Combo Box interface control in the editor to open its attribute window. The **Control Type** attribute is automatically set to `ComboBox`.
4) For properties of the type `String` or `Text` that have an enumeration defined: In the **Property** attribute, specify the custom object class property of the type `String` or `Text` that should be captured via the interface control. The custom object class property must have an enumeration defined. The **Value Type** attribute should display either `String` or `Text`.
5) For properties of the type `Reference`:

- In the **Property** attribute, specify the custom object class property of the type `Reference` that should be captured via the interface control. The custom object class property must have an enumeration defined. The **Value Type** attribute should display `Reference`.
- In the **SubType** attribute, select `SqlEnum`.
- In the **Range** attribute, enter the Alfabet query or native SQL query to find the relevant objects for the `Reference`. The information about the object displayed in the caption of the respective entry in the combo box is defined via the `SHOW` properties of the Alfabet query or the `SELECT` statement of the native SQL query. For details about defining a query, see the chapter Defining Queries.

In this example, a project group shall be defined as the approved scenario for a selected project portfolio (also a project group). A custom object class property of the type `Reference` has been created for the object class `ProjectGroup`. The class `ProjectGroup` is defined in the **Type Info** attribute for the custom object class property. The following native SQL query is specified in the **Range** attribute for the `Combo Box` interface control:

```
SELECT pg.REFSTR, pg.NAME
FROM PROJECTGROUP pg
WHERE pg.BELONGSTO = @BASE
ORDER BY pg.NAME
```

The resulting entries in the combo box display the name of the project groups found by the native SQL query via the `NAME` property in the `SELECT` statement. Please note that the `REFSTR` of the object must be defined as the first argument in the `SELECT` statement for technical reasons and is not displayed in the radio button caption.

6) In the **Caption** attribute, enter the text that should be displayed for the radio button group. This could be the name of the object class property associated with the combo box or more descriptive text.

   To use the ampersand (&) character in the caption, enter: &&

   A caption should not be more than 255 characters. If the field caption requires more characters or formatting, then you should leave the **Caption** attribute empty and create a static text interface control for which you can define the **Style** attributes. For more information, see the section Adding Static Text to the Custom Editor.

7) To provide cursory information about how to define the data, enter a short text in the **Placeholder** attribute. The text will be displayed as a hint in the combo box field. The text will be truncated if it is longer than the field. The display of the placeholder text can be configured via the GUI scheme attribute **Placeholders Text Color**. For more information, see the section *Overview of GUI Scheme Attributes* in the reference manual *Configuring Alfabet with Alfabet Expand - Appendix*.

8) **Validator**: In order to enforce values with a specific structure (for example, that version numbers should always be defined as two digits made up of a period and another digit), define a regular expression. Please note that specific enforcement mechanisms must be implemented for existing records or records that are imported into Alfabet from external systems. For more information about the syntax conventions for regular expressions, see http://msdn.microsoft.com/en-us/library/hs600312(VS.71).aspx

   Alternatively, the **Validator** attribute may be defined for an object class property. In this case, it is enforced on **all** editors where the object class property is editable.

9) **Validator Message**: This attribute is only relevant if the **Validator** attribute is defined. Specify the message to help the user provide relevant data. If the validation message is specified, users will be prompted with the validation message if the value provided does not match the specified validator. If a validation message is not specified, an error message will state that the input value has an invalid format and will display the informational text specified in the **Hints** attribute for the interface control.

10) Specify the position of the interface control in the sequence of all interface controls. To do so, enter an integer in the **Tab Index** attribute. New interface controls will have a default value set to 0. Please note the following:

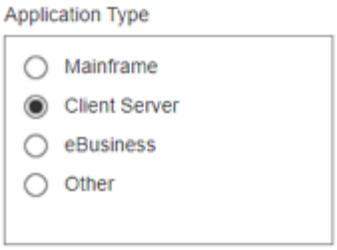
- The order that the interface controls are listed in the editor if stack layout is defined for rendering editors. For more information about stack vs. traditional rendering style for editors, see the section Specifying the Rendering Definition of the Custom Editor.
- The order that is used when the user moves the focus in the custom editor via the TAB key. The correct definition of tabbing is especially critical in order to provide barrier-free accessibility. For more information, see the section Configuring Barrier-Free User Profiles.
- The sequence that the help texts defined via the **Hint** attribute for an interface are listed in the modal Help window.

11) If a help text is required for the interface control, enter the text in the **Hint** attribute. If the **Hint** attribute is defined, the help text will be available in the modal Help window that opens when the editor's Help button is clicked. If stack rendering style is defined for editors, the help texts may be displayed below the editor field or via a Help button next to the editor field. For more information about stack rendering for editors, see the section Specifying the Rendering Definition of the Custom Editor.

12) In the toolbar, click the **Save** button to save your changes.

Adding a Radio Button Group to the Custom Editor

A Radio Button Group interface control provides a list of values that can be selected for a custom object class property by clicking a button. The user can select only one value for the custom object class property.



The Radio Button Group interface control can be defined for custom object class properties of the type `String` or `Text` for which an enumeration has been defined, or for custom object class properties of the type `Reference`, which will require the additional configuration of a query. You can configure either an Alfabet query or a native SQL query.

A Radio Button Group interface control is appropriate if only a few values are to be displayed for selection in the custom editor. If an excessive number of objects are expected to be found by the query defined for properties of the type `Reference`, you should define a `ComboBox` interface control where the query results can be listed in a drop-down field. For information about the configuration of a query for a `ComboBox` interface control for custom object class properties of the type `Reference`, see the section Adding a Combo Box to the Custom Editor.

To add a Radio Button Group interface control to the custom editor:

1) Right-click the custom editor that you want to define and select **Design Editor**. The custom editor is displayed in the editor in the center pane.

2) In the toolbar of the design editor, click the **Radio Button Group**  interface control and click in the editor where you want to place it. The Radio Button Group interface control is added to the editor.

3) Click the Radio Button Group interface control in the design editor to activate its attribute window. The **Control Type** attribute is automatically set to `RadioButtonGroup`.

4) For properties of the type `String` or `Text` that have an enumeration defined: In the **Property** attribute, specify the custom object class property of the type `String` or `Text` that should be captured via the interface control. The custom object class property must have an enumeration defined. The **Value Type** attribute should display either `String` or `Text`.

5) For properties of the type `Reference`:

- In the **Property** attribute, specify the custom object class property of the type `Reference` that should be captured via the interface control. The custom object class property must have an enumeration defined. The **Value Type** attribute should display `Reference`.
- In the **SubType** attribute, select `SqlEnum`.
- In the **Range** attribute, enter the Alfabet query or native SQL query to find the relevant objects for the `Reference`. The information about the object displayed in the caption of the respective radio button is defined via the `SHOW` properties of the Alfabet query or the `SELECT` statement of the native SQL query. For details about defining a query, see the chapter Defining Queries.

In this example, a project group shall be defined as the approved scenario for a selected project portfolio (also a project group). A custom object class property of the type `Reference` has been created for the object class `ProjectGroup`. The class `ProjectGroup` is defined in the **Type Info** attribute for the custom object class property. The following native SQL query is specified in the **Range** attribute for the `Radio Group Button` interface control:

```
SELECT pg.REFSTR, pg.NAME
FROM PROJECTGROUP pg
WHERE pg.BELONGSTO = @BASE
ORDER BY pg.NAME
```

The resulting radio buttons display the name of the project groups found by the native SQL query via the `NAME` property in the `SELECT` statement. Please note that the `REFSTR` of the object must be defined as the first argument in the `SELECT` statement for technical reasons and is not displayed in the radio button caption.

6) You should resize the radio button group interface control to ensure that all enumeration values or objects returned by the query will be visible. To do so, grab a handle on the radio button group interface control and drag it to the correct size.

7) In the **Caption** attribute, enter the text that should be displayed for the radio button group. This could be the name of the object class property associated with the radio button group or more descriptive text.

To use the ampersand (&) character in the caption, enter: &&

A caption should not be more than 255 characters. If the field caption requires more characters or formatting, then you should leave the **Caption** attribute empty and create

a static text interface control for which you can define the **Style** attributes. For more information, see the section Adding Static Text to the Custom Editor.

8) **Validator**: In order to enforce values with a specific structure (for example, that version numbers should always be defined as two digits made up of a period and another digit), define a regular expression. Please note that specific enforcement mechanisms must be implemented for existing records or records that are imported into Alfabet from external systems. For more information about the syntax conventions for regular expressions, see http://msdn.microsoft.com/en-us/library/hs600312(VS.71).aspx

Alternatively, the **Validator** attribute may be defined for an object class property. In this case, it is enforced on **all** editors where the object class property is editable.

9) **Validator Message**: This attribute is only relevant if the **Validator** attribute is defined. Specify the message to help the user provide relevant data. If the validation message is specified, users will be prompted with the validation message if the value provided does not match the specified validator. If a validation message is not specified, an error message will state that the input value has an invalid format and will display the informational text specified in the **Hints** attribute for the interface control.

10) Specify the position of the interface control in the sequence of all interface controls. To do so, enter an integer in the **Tab Index** attribute. New interface controls will have a default value set to 0. Please note the following:

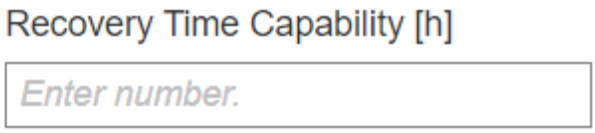
- The order that the interface controls are listed in the editor if stack layout is defined for rendering editors. For more information about stack vs. traditional rendering style for editors, see the section Specifying the Rendering Definition of the Custom Editor.
- The order that is used when the user moves the focus in the custom editor via the TAB key. The correct definition of tabbing is especially critical in order to provide barrier-free accessibility. For more information, see the section Configuring Barrier-Free User Profiles.
- The sequence that the help texts defined via the **Hint** attribute for an interface are listed in the modal Help window.

11) If a help text is required for the interface control, enter the text in the **Hint** attribute. If the **Hint** attribute is defined, the help text will be available in the modal Help window that opens when the editor's Help button is clicked. If stack rendering style is defined for editors, the help texts may be displayed below the editor field or via a Help button next to the editor field. For more information about stack rendering for editors, see the section Specifying the Rendering Definition of the Custom Editor.

12) In the toolbar, click the **Save**  button to save your changes.

Adding an Edit Search Field to the Custom Editor

An Edit Search Field interface control displays an edit field with a **Search**  icon that is automatically placed to the right of the field. When the user clicks the **Search**  icon, a standard or custom selector will open in which the value can be selected.



An Edit Search Field interface control can be defined for custom object class properties of the type `Reference`.

For more information about the configuration of custom selectors, see the section Configuring a Custom Selector for Search Functionalities.

To add an Edit Search Field interface control to the custom editor:

1) Right-click the custom editor that you want to define and select **Design Editor**. The custom editor is displayed in the editor in the center pane.

2) In the toolbar of the design editor, click the **Edit Search** button and click in the editor where you want to place it. The edit search interface control is added to the editor.

3) Click the Edit Search Field interface control in the design editor to activate its attribute window. The **Control Type** attribute is automatically set to `EditSearch`.

4) In the **Caption** attribute, enter the text that should be displayed for the edit search interface control. This could be the name of the object class property associated with the Edit Search Field interface control or more descriptive text.

   To use the ampersand (&) character in the caption, enter: &&

   A caption should not be more than 255 characters. If the field caption requires more characters or formatting, then you should leave the **Caption** attribute empty and create a static text interface control for which you can define the **Style** attributes. For more information, see the section Adding Static Text to the Custom Editor.

5) In the **Property** attribute, specify the custom object class property of the type `Reference` that should be captured via the interface control. The **Value Type** attribute should display `Reference`.

6) In the **Object Selector** attribute, select either the relevant standard selector or a custom selector that should open when the user clicks the **Search** icon. To find the name of the correct standard selector, navigate to the private class setting of the object class and copy the name of the standard selector displayed in the **Selector Definition** attribute. For more information about the configuration of custom selectors, see the section Configuring a Custom Selector for Search Functionalities.

7) To provide cursory information about how to define the data, enter a short text in the **Placeholder** attribute. The text will be displayed as a hint in the search field. The text will be truncated if it is longer than the field. The display of the placeholder text can be configured via the GUI scheme attribute **Placeholders Text Color**. For more information, see the section *Overview of GUI Scheme Attributes* in the reference manual *Configuring Alfabet with Alfabet Expand - Appendix*.

8) Specify the position of the interface control in the sequence of all interface controls. To do so, enter an integer in the **Tab Index** attribute. New interface controls will have a default value set to 0. Please note the following:

- The order that the interface controls are listed in the editor if stack layout is defined for rendering editors. For more information about stack vs. traditional rendering style for editors, see the section Specifying the Rendering Definition of the Custom Editor.
- The order that is used when the user moves the focus in the custom editor via the TAB key. The correct definition of tabbing is especially critical in order to provide barrier-free accessibility. For more information, see the section Configuring Barrier-Free User Profiles.
- The sequence that the help texts defined via the **Hint** attribute for an interface are listed in the modal Help window.

9) If a help text is required for the interface control, enter the text in the **Hint** attribute. If the **Hint** attribute is defined, the help text will be available in the modal Help window that opens when the editor's Help button is clicked. If stack rendering style is defined for editors, the help texts may be displayed below the editor field or via a Help button next to the editor field. For more information about stack rendering for editors, see the section Specifying the Rendering Definition of the Custom Editor.

10) In the toolbar, click the **Save** button to save your changes.

Adding a Role Edit Search Field to the Custom Editor

A Role Edit Search Field interface control allows a user to specify the role for the relevant object directly in the custom editor rather than requiring the user to define the role in the *Responsibilities Page View*.

A role type is configured in order to allow a functional role to be defined for objects in a specified object class. Role types can be configured to be explicitly available for a user or organization or both.

Only one role type can be captured per Role Edit Search Field interface control. Therefore, if several different role types may be possible for the specific objects captured in the custom editor, you must create a Role Edit Search Field interface control for each potential role type that may be captured. Typically, this configuration would be used if only a single role holder is relevant for the objects being captured in the custom editor. If many different role types may be captured for the objects, then users should specify the roles for the object directly in the *Responsibilities Page View*.

To add an Role Edit Search Field interface control to the custom editor:

1) Right-click the custom editor that you want to define and select **Design Editor**. The custom editor is displayed in the editor in the center pane.

2) In the toolbar of the design editor, click the **Role Edit Search Field** button and click in the editor where you want to place it. The role edit search interface control is added to the editor.

3) Click the Role Edit Search Field interface control in the design editor to activate its attribute window. The **Control Type** attribute is automatically set to `RoleEditSearch`.

4) In the **Caption** attribute, enter the text that should be displayed for the Role Edit Search Field interface control. Typically the caption should give the user some indication of which role type is being captured.

To use the ampersand (&) character in the caption, enter: &&

A caption should not be more than 255 characters. If the field caption requires more characters or formatting, then you should leave the **Caption** attribute empty and create

a static text interface control for which you can define the **Style** attributes. For more information, see the section Adding Static Text to the Custom Editor.

5) In the **Role Type** attribute, select the role type that may be captured via the interface control. All role types that have been configured in the **Reference Data** functionality will be displayed in the drop-down list. For more information about creating role types, see the section *Configuring Role Types to Define Roles in the Responsibilities Page View* in the reference manual *Configuring Evaluation and Reference Data in Alfabet*.

6) In the **Object Selector** attribute, the selector `StandardSelector:PERS_ORG_SelectorDef` will be displayed. If you want to specify a custom selector that should open when the user clicks the **Search** icon, select the custom selector in the **Object Selector** attribute. For more information about the configuration of custom selectors, see the section Configuring a Custom Selector for Search Functionalities.

7) To provide cursory information about how to define the data, enter a short text in the **Placeholder** attribute. The text will be displayed as a hint in the search field. The text will be truncated if it is longer than the field. The display of the placeholder text can be configured via the GUI scheme attribute **Placeholders Text Color**. For more information, see the section *Overview of GUI Scheme Attributes* in the reference manual *Configuring Alfabet with Alfabet Expand - Appendix*.

8) Specify the position of the interface control in the sequence of all interface controls. To do so, enter an integer in the **Tab Index** attribute. New interface controls will have a default value set to 0. Please note the following:

- The order that the interface controls are listed in the editor if stack layout is defined for rendering editors. For more information about stack vs. traditional rendering style for editors, see the section Specifying the Rendering Definition of the Custom Editor.
- The order that is used when the user moves the focus in the custom editor via the TAB key. The correct definition of tabbing is especially critical in order to provide barrier-free accessibility. For more information, see the section Configuring Barrier-Free User Profiles.
- The sequence that the help texts defined via the **Hint** attribute for an interface are listed in the modal Help window.

9) If a help text is required for the interface control, enter the text in the **Hint** attribute. If the **Hint** attribute is defined, the help text will be available in the modal Help window that opens when the editor's Help button is clicked. If stack rendering style is defined for editors, the help texts may be displayed below the editor field or via a Help button next to the editor field. For more information about stack rendering for editors, see the section Specifying the Rendering Definition of the Custom Editor.

10) In the toolbar, click the **Save**  button to save your changes.

Adding Static Text to the Custom Editor

The Static Text interface control allows you to add text to the custom editor to provide instructional text to provide the user community with specific information. Typically, this is used to provide instructions for users entering data in an Edit Field interface control. The size of Static Text interface controls will be adjusted automatically to the content to be displayed.

To add a Static Text interface control to the custom editor:

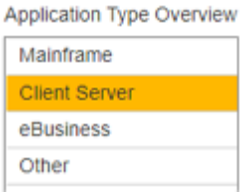
1) Right-click the custom editor that you want to define and select **Design Editor**. The custom editor is displayed in the editor in the center pane.
2) In the toolbar of the design editor, click the **Static Text** button and click in the editor where you want to place it. The Static Text interface control is added to the editor.
3) Click the Static Text interface control in the design editor to activate its attribute window. The **Control Type** attribute is automatically set to `StaticText`.
4) In the **Caption** attribute, enter the text that should be displayed for the Static Text interface control. This could be a short text such to elaborate a property caption or comprehensive information.
5) To format the font of the static text, expand the **Style** section of the attribute window by clicking the + symbol and define the formatting, as needed.
6) Specify the position of **Tab Index** attribute of the interface control. Please note the following:

- The order that the interface controls are listed in the editor if stack layout is defined for rendering editors. For more information about rendering editors in stack vs. traditional layout, see the section Specifying the Rendering Definition of the Custom Editor.
- The order that is used when the user moves the focus in the custom editor via the TAB key.

7) In the toolbar, click the **Save** button to save your changes.

Adding a List Box to Display Enumerations in the Custom Editor

The List Box interface control allows the user to view a list of values specified in an enumeration. The values are only listed as a source of information and cannot be selected by the user for the custom object class property. The value defined for the selected object is highlighted in the list box.



The List Box interface control is only available for properties of the type `String`, `Text`, or `StringArray` for which an enumeration has been defined.

To add a List Box interface control to the custom editor:

1) Right-click the custom editor that you want to define and select **Design Editor**. The custom editor is displayed in the editor in the center pane.
2) In the toolbar of the design editor, click the **List Box** button and click in the editor where you want to place it. The List Box interface control is added to the editor.
3) Click the List Box interface control in the design editor to activate its attribute window. The **Control Type** attribute is automatically set to `ListBox`.

4) In the **Property** attribute, specify the custom object class property of the types `String`, `Text`, or `StringArray` that should be captured via the interface control. The **Value Type** attribute should display `String` or `StringArray`.

5) In the **Caption** attribute, enter the text that should be displayed for the List Box interface control. This could be the name of the custom object class property associated with the List Box interface control or more descriptive text.

To use the ampersand (&) character in the caption, enter: &&

A caption should not be more than 255 characters. If the field caption requires more characters or formatting, then you should leave the **Caption** attribute empty and create a static text interface control for which you can define the **Style** attributes. For more information, see the section Adding Static Text to the Custom Editor.

6) Specify the position of the interface control in the sequence of all interface controls. To do so, enter an integer in the **Tab Index** attribute. New interface controls will have a default value set to 0. Please note the following:

- The order that the interface controls are listed in the editor if stack layout is defined for rendering editors. For more information about stack vs. traditional rendering style for editors, see the section Specifying the Rendering Definition of the Custom Editor.
- The order that is used when the user moves the focus in the custom editor via the TAB key. The correct definition of tabbing is especially critical in order to provide barrier-free accessibility. For more information, see the section Configuring Barrier-Free User Profiles.
- The sequence that the help texts defined via the **Hint** attribute for an interface are listed in the modal Help window.

7) If a help text is required for the interface control, enter the text in the **Hint** attribute. If the **Hint** attribute is defined, the help text will be available in the modal Help window that opens when the editor's Help button is clicked. If stack rendering style is defined for editors, the help texts may be displayed below the editor field or via a Help button next to the editor field. For more information about stack rendering for editors, see the section Specifying the Rendering Definition of the Custom Editor.

8) In the toolbar, click the **Save**  button to save your changes.

Adding Icons to the Custom Editor

The Icon interface control add any icons to the custom editor that are available in the icon gallery in Alfabet Expand. Any icon that you want to add to the custom editor first must be imported to the icon gallery.

FIGURE: Example of an icon displayed in a custom editor

For more information, see the section Adding and Maintaining Icons for the Alfabet Interface.

1) Right-click the custom editor  that you want to define and select **Design Editor**. The custom editor is displayed in the editor in the center pane.

2) In the toolbar of the design editor, click the **Icon** button and click in the editor where you want to place it. The Icon interface control is added to the custom editor.

3) Click the Icon interface control in the custom editor to open its attribute window. The **Control Type** attribute is automatically set to `Icon`.

4) In the **SubType** attribute, select the relevant option based on the size of the icon that you want to add:

- `Icon`: To add an icon that is 22x22 pixel in size.
- `IconLarge`: To add an icon that is 30x30 pixel in size.
- `IconFree`: To add an icon that has an arbitrary size.

5) In the **Icon** attribute, select the relevant icon that you want to display in the custom editor. The icons that you can choose from are based on the value you selected in the **SubType** attribute.

6) To adjust the Icon interface control to the general size of the icon, enter pixel values in the **Height** and **Width** attributes. For example, if you plan to add an icon that is 22x22 pixel in size, you could enter values 22 or larger in the **Height** and **Width** attribute to make handling the Icon interface control easier while designing the custom editor.

7) To provide cursory information about how to define the data, enter a short text in the **Placeholder** attribute. The text will be displayed as a hint in the icon field. The text will be truncated if it is longer than the field. The display of the placeholder text can be configured via the GUI scheme attribute **Placeholders Text Color**. For more information, see the section *Overview of GUI Scheme Attributes* in the reference manual *Configuring Alfabet with Alfabet Expand - Appendix*.

8) Specify the position of **Tab Index** attribute of the interface control. Please note the following:

- The order that the interface controls are listed in the editor if stack layout is defined for rendering editors. For more information about rendering editors in stack vs. traditional layout, see the section Specifying the Rendering Definition of the Custom Editor.
- The order that is used when the user moves the focus in the custom editor via the TAB key.

9) In the toolbar, click the **Save** button to save your changes.

Adding an HTML Document Stored in the Internal Document Selector to the Custom Editor

An HTML Content interface control can be added to a custom editor in order to provide a link to an HTML document stored in the **Internal Document Selector**. For information about adding documents to the **Internal Document Selector**, see the section *Uploading Documents and Managing User Permissions to Document Folders in the Internal Document Selector* in the reference manual *User and Solution Administration*.

Embedded images may not be included in the HTML code defined for a custom editor.

Adding an HTML Content interface control to the custom editor makes the link available only on the interface in the custom editor. Alternatively, a custom object class property of the type `URL` can be configured which allows a user to enter a URL or document link that will be available as a custom object class property and can therefore be displayed in the object profile or relevant

page view or configured report. For more information, see the section Configuring Custom Properties of the Type URL in the chapter Configuring the Class Model.

To add a document link via an HTML Content interface control to a custom editor:

1) Right-click the custom editor that you want to define and select **Design Editor**. The custom editor is displayed in the editor in the center pane.

2) In the toolbar of the design editor, click the **HTML Content** icon and click in the custom editor where you want to place the HTML Content interface control.

3) Click in the HTML Content interface control that you have added to the custom editor to open its attribute window.

4) In the **SubType** attribute, select `IDocument`.

5) In the **HTML Source** attribute, specify the full path to the HTML document in the **Internal Document Selector**. For example:

```
IDOC:\Documents\Links_Emergency_Plan.html
```

6) Specify the position of the interface control in the sequence of all interface controls. To do so, enter an integer in the **Tab Index** attribute. New interface controls will have a default value set to 0. Please note the following:

- The order that the interface controls are listed in the editor if stack layout is defined for rendering editors. For more information about stack vs. traditional rendering style for editors, see the section Specifying the Rendering Definition of the Custom Editor.
- The order that is used when the user moves the focus in the custom editor via the TAB key. The correct definition of tabbing is especially critical in order to provide barrier-free accessibility. For more information, see the section Configuring Barrier-Free User Profiles.
- The sequence that the help texts defined via the **Hint** attribute for an interface are listed in the modal Help window.

7) If a help text is required for the interface control, enter the text in the **Hint** attribute. If the **Hint** attribute is defined, the help text will be available in the modal Help window that opens when the editor's Help button is clicked. If stack rendering style is defined for editors, the help texts may be displayed below the editor field or via a Help button next to the editor field. For more information about stack rendering for editors, see the section Specifying the Rendering Definition of the Custom Editor.

8) In the toolbar, click the **Save** button to save your changes.

Adding a URL to the Custom Editor

An HTML Content interface control can be added to a custom editor to provide a URL that is external to the Alfabet components.

Embedded images may not be included in the HTML code defined for a custom editor.

Adding an HTML Content interface control to the custom editor makes the link available only in the custom editor. Alternatively, a custom object class property of the type `URL` can be configured which allows a user to enter a URL or document link to an object profile, object cockpit, page view or configured report. For more information, see the section Configuring Custom Properties of the Type URL in the chapter Configuring the Class Model.

To add a URL via an HTML Content interface control to a custom editor:

1) Right-click the custom editor that you want to define and select **Design Editor**. The custom editor is displayed in the editor in the center pane.
2) In the toolbar of the design editor, click the **HTML Content** icon and click in the custom editor where you want to place the HTML Content interface control.
3) Click the HTML Content interface control that you have added to the custom editor to open its attribute window.
4) In the **SubType** attribute, select `EmbeddedHTML`.

   The HTML Content interface control has additional options in the drop-down list for the specification of the `SubType` attribute. These other options are currently not activated.

5) In the **HTML Source** attribute, enter the HTML code. The HTML must be XML-conform HTML, compliant with HTML 5, and use standard HTML tags. The code must start with the tag `<html>` and end with the tag `</html>`. The definition of `<head>` and `<body>` specification is optional. The tags `<xhtml>`, `<html>`, `<body>`, and `<culture_>` are case-sensitive. The HTML code can include links to external URLs.

   For example, to add a link to a document containing additional information about the permissible property values that can be edited, the following code can be used to define the link. The example link calls a URL with parameters. Please note that the parameters must be defined XHTML conform using an entity definition for the character &. This example provides only HTML text in English. For information about providing HTML text in other languages, see the section Adding HTML Text to the Custom Editor.

```
<xhtml>
    <culture_1033>
        <html>
            <head>
                <title>Additional Information</title>
                <link type="text/css" rel="stylesheet"
                href="IDOC:\CSS\my_style_file.css"></link>
            </head>
            <body>
                <p class="hint">For information about the meaning
                of the available options, see<a
                href="http://companyserver/optionhelp/options.html
                ?option1=editorname&#83;option2=classname"
                target="_blank">Available Values</a>.</p>
            </body>
        </html>
```

```
        </culture_1033>
    </xhtml>
```

6) Specify the position of the interface control in the sequence of all interface controls. To do so, enter an integer in the **Tab Index** attribute. New interface controls will have a default value set to 0. Please note the following:

- The order that the interface controls are listed in the editor if stack layout is defined for rendering editors. For more information about stack vs. traditional rendering style for editors, see the section Specifying the Rendering Definition of the Custom Editor.
- The order that is used when the user moves the focus in the custom editor via the TAB key. The correct definition of tabbing is especially critical in order to provide barrier-free accessibility. For more information, see the section Configuring Barrier-Free User Profiles.
- The sequence that the help texts defined via the **Hint** attribute for an interface are listed in the modal Help window.

7) If a help text is required for the interface control, enter the text in the **Hint** attribute. If the **Hint** attribute is defined, the help text will be available in the modal Help window that opens when the editor's Help button is clicked. If stack rendering style is defined for editors, the help texts may be displayed below the editor field or via a Help button next to the editor field. For more information about stack rendering for editors, see the section Specifying the Rendering Definition of the Custom Editor.

8) In the toolbar, click the **Save** button to save your changes.

Adding HTML Text to the Custom Editor

An HTML Content interface control can be added to a custom editor to display text with HTML formatting (font and color). The HTML code can include text as well as links to external URLs and can reference stylesheets stored in the **Internal Document Selector**.

Embedded images may not be included in the HTML code defined for a custom editor.

To add HTML text via an HTML Content interface control to a custom editor:

1) Right-click the custom editor that you want to define and select **Design Editor**. The custom editor is displayed in the editor in the center pane.

2) In the toolbar of the design editor, click the **HTML Content** icon and click in the custom editor where you want to place the HTML Content interface control.

3) Click in the HTML Content interface control that you have added to the custom editor to open its attribute window.

4) In the **Sub-Type** attribute, select `EmbeddedHTML`.

The HTML interface control has additional options in the drop-down list for the specification of the `SubType` attribute. These other options are currently not activated.

5) In the **HTML Source** attribute, enter the HTML code. Please keep the following in mind:

- The HTML must be compliant with XHTML, XML-conform HTML, compliant with HTML 5, and use standard HTML tags. The HTML header implements standard HTML elements.
- The code must start with an `<xhtml>` tag and end with `</xhtml>`. Standard HTML elements must be written in lower-case letters in order to be correctly parsed: `<xhtml>`, `<html>`, `<head>`, `<body>`, and `<culture_>`. The definition of `<head>`, `<body>`, and `<culture_>` is optional.
- The formatting of the HTML can either be written explicitly in the `<body>` element or can be specified via a stylesheet that is stored in the **Internal Document Selector**. In this case, the HTML must refer to the target CSS file in a `<link>` element. The CSS file should contain all necessary styles to display the content of the HTML. Please note that the CSS file may not be stored in the root folder of the **IDOC** explorer. The CSS file stored in the **Internal Document Selector** must be located in a document folder that is subordinate to the root folder of the **IDOC** explorer. To upload a file to the **Internal Document Selector**, see the section *Uploading Documents and Managing User Permissions to Document Folders in the Internal Document Selector* in the reference manual *User and Solution Administration*. For example:

```
<xhtml>
   <culture_1033>
      <html>
      <body style="margin:4px;background:#3d4b60;overflow:hidden;">
         <link type="text/css" rel="stylesheet"
         href="IDOC:\CSS\my_style_file.css"></link>
         <p>This is the content for the header of the wizard
         step.</p>
         ...
      </body>
      </html>
   </culture_1033>
</xhtml>
```

- All CSS formatting instructions must end with `!important` to ensure that they are processed by the Alfabet application. For example:

```
<xhtml>
   <culture_1033>
      <html>
      <body style="margin:4px !important;background:#3d4b60
      !important;overflow:hidden !important;">
         <style type="text/css">
            p.header
            {
               font-family:verdana !important;
               font-size:18px !important;
               color:#ff0000 !important;
               text-align: Left !important;
```

```
                    }
                </style>
                <p class="header">This is the content for the header of the
                wizard step.</p>
                ...
            </body>
            </html>
        </culture_1033>
    </xhtml>
```

- If translation to a secondary language is required, you must provide the translation in the HTML specification. Please note that HTML texts cannot be translated via the **Translation Editor** available in Alfabet Expand. Please consider the following:
- If the HTML description is required in additional languages, each language text must be defined within language elements (For example, `<culture_1031>` for English, `<culture_1033>` for German, etc.)
- The element `<culture_xxx>` must be specified as a child of the root element `<xhtml>`. The element `<html>` must be specified as a child of the element `<culture_xxx>`. The element `<html>` contains the HTML specification in the relevant language. For example, to provide information in English and German:

```
<xhtml>
    <culture_1033>
        <html>
            <body>
                <h3>Glossary: Application</h3>
                <p>An application is a fully-functional integrated IT
                product that provides functionality to end users
                and/or to other applications. As such, an application
                supports the business to accomplish its mission.
                Applications operate on a platform made up of
                hardware and software components necessary to run the
                application.</p>
            </body>
        </html>
    </culture_1033>
    </culture_1031>
        <html>
            <body>
                <h3>Glossar: Applikation</h3>
                <p>Eine Applikation ist ein voll funktionsfähiges,
                integriertes IT-Produkt, das Funktionalitäten für
                Endanwender und/oder für andere Applikationen bietet.
                Eine Applikation unterstützt das Unternehmen bei der
                Zielerreichung. Applikationen werden auf einer
                Plattform betrieben, die aus den für die Ausführung
```

```
                der Applikation erforderlichen Hardware- und
                Software-Komponenten besteht.</p>
            </body>
        </html>
    </culture_1031>
</xhtml>
```

6) Specify the position of **Tab Index** attribute of the interface control. Please note the following:

- The order that the interface controls are listed in the editor if stack layout is defined for rendering editors. For more information about rendering editors in stack vs. traditional layout, see the section Specifying the Rendering Definition of the Custom Editor.
- The order that is used when the user moves the focus in the custom editor via the TAB key.
- The sequence that the help texts defined via the **Hint** attribute for an interface are listed in the modal Help window.

7) In the toolbar, click the **Save** button to save your changes.

Adding a Color Selector to the Custom Editor

A color selector may be added in order to assign a color to the object being created or edited in the custom selector. The color is then displayed for the object in all Alfabet views and configured reports.

A color selector can be added to any custom editor created for an object class that has a `Color` property of the type `String`. When the user creates or edits an object in the custom editor, he/she can change the color in the custom editor. The color will then be used for the display of that object in business graphics for all Alfabet views and configured reports for all users.

To add a color selector to a custom editor:

1) Right-click the custom editor that you want to define and select **Design Editor**. The custom editor is displayed in the editor in the center pane.
2) In the toolbar of the design editor, click the **Edit** icon and click in the custom editor where you want to place the Edit Field interface control.
3) Click in the Edit Field interface control that you have added to the custom editor to open its attribute window.
4) In the **Name** attribute, enter a technical name for the interface control.
5) In the **Caption** attribute, enter a caption for the interface control. The term **Color** is the conventional caption for the color selector in standard Alfabet views.
6) In the **Value Type** attribute, ensure that `String` is selected.
7) In the **Property** attribute, enter `Color`. Please note that this option cannot be selected but rather must be typed in.
8) In the **SubType** attribute, select `Color`.
9) To provide cursory information about how to define the data, enter a short text in the **Placeholder** attribute. The text will be displayed as a hint in the color field. The text will be truncated if it is

longer than the field. The display of the placeholder text can be configured via the GUI scheme attribute **Placeholders Text Color**. For more information, see the section *Overview of GUI Scheme Attributes* in the reference manual *Configuring Alfabet with Alfabet Expand - Appendix*.

10) Specify the position of the interface control in the sequence of all interface controls. To do so, enter an integer in the **Tab Index** attribute. New interface controls will have a default value set to 0. Please note the following:

- The order that the interface controls are listed in the editor if stack layout is defined for rendering editors. For more information about stack vs. traditional rendering style for editors, see the section Specifying the Rendering Definition of the Custom Editor.
- The order that is used when the user moves the focus in the custom editor via the TAB key. The correct definition of tabbing is especially critical in order to provide barrier-free accessibility. For more information, see the section Configuring Barrier-Free User Profiles.
- The sequence that the help texts defined via the **Hint** attribute for an interface are listed in the modal Help window.

11) If a help text is required for the interface control, enter the text in the **Hint** attribute. If the **Hint** attribute is defined, the help text will be available in the modal Help window that opens when the editor's Help button is clicked. If stack rendering style is defined for editors, the help texts may be displayed below the editor field or via a Help button next to the editor field. For more information about stack rendering for editors, see the section Specifying the Rendering Definition of the Custom Editor.

12) In the toolbar, click the **Save**  button to save your changes.

13) The color selector can be reviewed by right-clicking the custom editor in the **Custom Editors** folder and selecting **Review Custom Editor**. The **Color Selector** button will be displayed next to the edit field. When a user selects a color, that color will fill the edit field.

Specifying the Interface Control To Be Mandatory

You can define an interface control to display a red star next to the field indicating to users that the field is mandatory. Please note that mandatory fields are only enforced in the editor or wizard. If data is imported via other means (for example, via ADIF), it will be necessary to systematically ensure that mandatory fields are filled. To configure an interface control as mandatory, select `Always` in the **Presence** attribute.

Specifying an Editor Field To Be Non-Editable

In some cases, you may want an editor field to display a predefined default value that cannot be edited by users when creating a new object via the custom editor. In this case, could define an Edit Field interface control for a custom object class property of the type `String`, `Integer`, `Real`, and `URL` as well as a Check Box interface control of the type `Boolean` to be non-editable. An interface control that is defined as non-editable (ReadOnly) will be displayed in grey and thus disabled and therefore cannot be edited.

To specify an interface control to display a default value and not be edited, ensure that the **Default Value** attribute of the custom object class property has been defined. For more information about specifying the default value for a custom object class property, see the section Configuring Custom Properties for Protected or Public Object Classes in the chapter Configuring the Class Model.

In the design editor, click the relevant **Edit** or **Check Box** button. In the attribute window, set the **Read Only** attribute to `True`. In the toolbar, click the **Save** button to save your changes.

Please note that if the **Read Only** attribute is set to `True` for a Check Box interface control, the checkbox will be disabled, and the value defined in the **Hint** attribute of the associated custom object class property of the type `Boolean` cannot be displayed as help text. It is recommended that you add the help text as static text to the editor if it should be visible for a non-editable checkbox.

Specifying Conditional Constraints in the Custom Editor

Specifying conditional constraints in custom editors can provide a more dynamic user experience and ensure that users are seeing and defining the data that is pertinent to the task at hand. The display of fields that aren't relevant to the current context can be suppressed based on the definition of a value in a specified editor field. Likewise, whether a field is mandatory or read-only can also be controlled based on the value defined for a specified editor field. For example, in the case of an **Application** editor, you may want to only display the **Sox Description** field if the **Is Sox Relevant** checkbox is selected (=`True`) for the application. Furthermore, you may want the **Sox Description** field to be mandatory if the **Is Sox Relevant** checkbox is selected. In this case, you would specify a condition that makes the **Sox Description** field visible and mandatory if the **Is Sox Relevant** checkbox is selected.

If the visibility and editability of an interface control shall depend on the value defined in another interface control, the condition has to be defined in two steps:

- A condition configuration object has to be created that specifies the general condition. A condition defines one or multiple parameters, each parameter having a unique name and an operator and condition that shall apply to the parameter. One condition can be used in multiple interface controls in multiple editors.
- In the editor field that shall be managed by the condition, the condition must be defined by first choosing the relevant condition configuration object and then mapping each parameter name in the condition to the interface control in the editor that shall fulfill the condition defined for the parameter in the context of the selected editor.

You can configure conditions for interface controls in custom editors to determine the visibility of other interface controls as well as whether editor fields are mandatory or read-only. Conditions can be defined for any interface control for which the **Refresh on Submit** attribute is available and parameters in the condition can be mapped to any interface control for which the **Submit** attribute is available (such as Check Box, Checked Combo Box, and Radio Button Group interface controls.).

The following steps are required to configure conditional constraints for interface controls in custom editors:

- Create a condition and specify one or more expressions needed for the condition. Please note that the valid syntax that is permissible in expressions is described in the section Specifying Conditional Constraints in the Custom Editor.
- For the interface control whose value determines the visibility/mandatory/read-only behavior, set the **Submit** attribute to `True`. These are the fields mapped to the parameters in the condition.

- For the interface control(s) that are the target of the condition, set the **Refresh on Submit** attribute to `True`. Specify one or more of the following for the interface control(s) that are the target of the condition:

- To specify that visibility is determined by the condition, configure the condition in the **Visibility Condition** attribute of the interface control.
- To specify that mandatory behavior is determined by the condition, configure the condition in the **Presence Condition** attribute of the interface control.
- To specify that read-only behavior is determined by the condition, configure the condition in the **Read-Only Condition** attribute of the interface control.

To configure a condition for one of the above listed attributes, click in the attribute field and click the button to the right of the field to open the condition editor. Specify the following according to demand:

- Select a condition in the drop-down list of the **Select Condition** field.
- For each parameter defined in the condition, a row will be displayed in the table below the **Select Condition** field. For each parameter, select the interface control that shall be mapped to the parameter in the drop-down list of the **Parameter Value Reference** field. All interface controls in the same custom editor are displayed. When the condition is evaluated, the parameter will be substituted with the current value in the specified field. For example, if the condition is `@Type=='CloudService'` and the `Type` parameter is mapped to an interface control that returns the value `CloudService`, the condition will read `'CloudService'=='CloudService'` and the condition will have a positive result.

If the condition contains a parameter that cannot be mapped to an interface control in this editor, you can alternatively select a static value in the field **Parameter Value**. This value is then used to substitute the parameter in the condition instead of a value of an interface control. The setting of the **Parameter Value Reference** attribute supersedes the setting of a **Parameter Value** attribute.

Please note if a custom editor is embedded in a wizard, the conditions may only be relevant for the current wizard step. The conditions cannot refer to interface controls that are available on other wizard steps. This applies in particular to the configuration of a wizard with a single wizard step of the type `Editor` and that has the **Tab as Separate Steps** attribute set to `True`. For more information about configuring wizard steps with an embedded custom editor, see the section Configuring a Wizard Step to Display a Standard or Custom Editor.

Syntactically incorrect conditions in editors (or editors embedded in wizards) may limit or prevent in-line editing in object profiles or object cockpits. If a condition has an incorrect syntax, an error will be displayed if the user tries to open the editor/wizard.

The following information is available:

- Creating Conditions to Implement in a Custom Editor
- Assigning Conditions to Interface Controls in the Custom Editor

The following information is available:

- Creating Conditions to Implement in a Custom Editor
- Assigning Conditions to Interface Controls in the Custom Editor

Creating Conditions to Implement in a Custom Editor

Conditions can be used in the context of custom editors, object cockpits, and filters in configured reports. The conditions can be reused as needed. Conditions can be based on either expressions or queries defined in configured reports. Please note the following:

- Conditions based on expressions can be defined for custom editors, configured reports, and object cockpits. The expression is evaluated for a value defined for a specified interface control. Please note that only conditions based on expressions can be implemented for custom editors or configured reports.
- Conditions based on configured reports can be defined for object cockpits. The query defined for the configured report must search for the results in the database in order to provide a value to be evaluated by the condition.

When you expand the Conditions folder, you may see planned conditions  , active conditions  , and retired conditions  . The condition state must be set to `Active` in order to make the condition available in the **Visibility Condition**, **Presence Condition**, and **Read-Only Condition** attributes for custom editor fields, filter fields in configured reports, and object cockpits.

To create a condition:

1) Go to the **Presentation** tab and right-click the **Conditions** folder and select **New Condition**. The condition state will be set to `Plan` per default for the new condition.

2) Click the new condition  and define the following in the attribute window:

- **Technical Name**: Enter a name for the condition. It is recommended that the name indicates the meaning of the condition. All active conditions will be displayed in drop-down lists for the **Presence Condition**, **Read-Only Condition**, and **Visibility Condition** attributes.
- **Group**: Enter the name of a new condition folder that you want to store the condition in or select an existing condition folder.
- **Check Result Type**: Select either `Positive` or `Negative` to define what constitutes a fulfilled condition.
- `Positive` means that the condition is fulfilled if the defined expression is true (if **Type** = `Expression`), or if the query associated with the configured report delivers a result (if **Type** = `Report`).
- `Negative` means that the condition is fulfilled if the defined expression is false (if **Type** = `Expression`) or the query delivers no results (if **Type** = `Report`).

For example, if the expression defined for the condition is `@Type=='CloudSer-vice'` and the `Type` parameter is mapped to an interface control that returns the value `CloudService`, the expression will read `'CloudService'=='CloudSer-vice'` and the expression is true. If **Check Result Type** is set to `Negative`, the condition is not fulfilled. If **Check Result Type** is set to `Positive`, the condition is fulfilled.

- **Type**: Select `Expression`.
- **Expression**: Click the **Browse**  button to open the editor and enter the expression that shall be evaluated for the condition matching the following rules:

- The required syntax is: For some operators, like EMPTY, the definition of a condition is not required.

```
@ParameterName Operator Condition
```

```
@Type == 'CloudService'
```

- String values and boolean values must be placed in single quotes. Please note that the strings in conditions are case-sensitive.
- Multiple expressions may be combined via `AND` or `OR`, whereby individual expressions must be placed in parenthesis.

```
(@Type == 'CloudService') I ((@Type == 'OnPremise') &
(@CloudCandidate == 'True'))
```

- A condition cannot be a second paramter. It is not possible to compare the values of two interface controls within one condition.
- The following operators and conditions may be used in the expression:

equals	`@Param == 'STRING'` (or `'True'` and `'False'` for Boolean values)
does not equal	`@Param != 'STRING'`
in	`@Param IN ['STRING', 'STRING', 'STRING']` (used when the value is a list)
not in	`!(IN ['STRING', 'STRING', 'STRING']` (used when the value is a list)
begins with	`@Param BEGINS_WITH 'STRING'`
ends with	`@Param ENDS_WITH 'STRING'`
contains	`@Param CONTAINS 'STRING'`
does not contain	`!(CONTAINS 'STRING')`
is between	`(@Param > NUMERIC1) & (@Param < NUMERIC2)`
is empty	`@Param EMPTY`
is not empty	`!(@Param EMPTY)`
is greater than	`@Param > NUMERIC`

is greater than or equal to	`@Param >= NUMERIC`
is less than	`@Param < NUMERIC`
is less than or equal to	`@Param <= NUMERIC`
AND	`&`
OR	`|`
NOT	`!`

3) Once the condition is complete, the condition state must be set to `Active`. To do so, right-click the condition and select **Set Condition State to 'Active'**. The active condition will be available in the **Visibility Condition**, **Presence Condition**, and **Read-Only Condition** attributes for custom editor fields, filter fields in configured reports, and object cockpits.
4) Once the condition is set to `Active`, you can test the condition. To do so, right-click the condition and select **Test Condition**. In the editor, enter a valid value in the **Parameter Value** field and click **OK**. Information will be displayed indicating if the condition is valid based on the value entered or if an error has occurred.
5) In the toolbar, click the **Save** button to save your changes.

Assigning Conditions to Interface Controls in the Custom Editor

You can assign the configured conditions to the interface controls in custom editors to determine visibility as well as whether the interface controls are mandatory or read-only. Conditions can be defined for any interface control for which the **Submit** attribute is available (such as Check Box, Checked Combo Box, and Radio Button Group interface controls.). The interface control with the **Submit** attribute is the interface control whose value determines the visibility/mandatory/read-only behavior.

The **Refresh on Submit** attribute must be specified for the interface control(s) that are the target of the condition. The variables in the condition must be mapped to the source interface control whose value determines the visibility/mandatory/read-only behavior.

For example, in the case of an **Application** editor, you may want to only display the **Sox Description** field (Interface Control 2) if the **Is Sox Relevant** checkbox (Interface Control 1) is selected (`=True`) for the application. Furthermore, you want the **Sox Description** field to be mandatory if the **Is Sox Relevant** checkbox is selected In this case, you would specify a condition that makes the **Sox Description** field visible and mandatory if the **Is Sox Relevant** checkbox is selected.

To define conditions for editor fields:

1) Go to the **Presentations** tab and expand the **Custom Editors** folder.

2) Right-click the custom editor  that you want to define and select **Design**. The custom editor is displayed in the editor in the center pane.

3) Click the interface control whose value shall determine the visibility/mandatory/read-only behavior and set the **Submit** attribute to `True`. The interface control with the **Submit** attribute is the interface control that has the value that is evaluated for the condition. This attribute is mandatory to define a condition.

4) Click the interface control whose behavior will be determined by the condition. Define the following attributes.

- **Refresh on Submit**: Select `True`. This attribute is mandatory to define a condition. You must specify at least one the following attributes to define the behavior of the interface control:

- **Visibility Condition**: Specify that the interface control will be visible if the condition is fulfilled. You must map the variables defined in the condition to the source interface control that they reference. To define the **Visibility Condition** attribute, click the **Browse**  button and in the **Visibility Condition** editor, and define the following:

  For example, in the case of example about the **SOX Relevance** and **SOX Description** fields in the **Application** editor: the `SimpleBooleanOnTrue` condition has been created with the expression `@VALUE == 'True'`. You would define the attributes for the **Visibility Condition** as follows:

  - **Select Condition**: Select `SimpleBooleanOnTrue`.
  - **Parameter Name**: Displays `VALUE`.
  - **Parameter Value Reference**: Select `SOXRelevant`. This parameter represents the variable to be evaluated for the parameter in the **Parameter Name** column.

  Therefore, if the **SOX Relevance** interface control is set to `True`, then the `SimpleBooleanOnTrue` condition is fulfilled, and the **SOX Description** interface control will be visible.

  - **Select Condition**: Select the condition to specify the visibility of the interface control.
  - **Parameter Name**: Displays the variables used in the condition.
  - **Parameter Value**: This column is not relevant for custom editors.
  - **Parameter Value Reference**: Select the interface control that shall be visible if the variable in the **Parameter Name** column to the source interface control (Interface Control 1) of the condition.

Click **OK** to save the definition and close the editor.

- **Presence Condition**: Specify that the interface control will be mandatory if the condition is fulfilled. Click the **Browse**  button and in the **Presence Condition** editor, and define the following:

  - **Select Condition**: Select the condition to specify the interface control as a mandatory field.
  - **Parameter Name**: Displays the variables used in the condition.

- **Parameter Value**: This column is not relevant for custom editors.
- **Parameter Value Reference**: Select the interface control that shall be mandatory if the variable in the **Parameter Name** column to the source interface control (Interface Control 1) of the condition.

- **Read-Only Condition**: Specify that the interface control will be read-only if the condition is fulfilled. Click the **Browse** button and in the **Read-Only Condition** editor, and define the following:
  - **Select Condition**: Select the condition to specify the interface control as a read-only field.
  - **Parameter Name**: Displays the variables used in the condition.
  - **Parameter Value**: This column is not relevant for custom editors.
  - **Parameter Value Reference**: Select the interface control that shall be read-only if the variable in the **Parameter Name** column to the source interface control (Interface Control 1) of the condition.

5) In the toolbar, click the **Save** button to save your changes.

Specifying the Tab Order of the Interface Controls

The **Tab Index** attribute of each interface control determines the sequence when a user presses the TAB key to move the focus in the user interface as well as the order that the Help texts are listed in the modal window that opens when the **Help** button is clicked in the editor.

To define the tab index of each field in the editor, click each interface control and specify its position in the sequence by entering the relevant integer in the **Tab Index** attribute. Click the **Save** button after defining the **Tab Index** attribute of each interface control.

Adding Help Text to Interface Controls in the Custom Editor

Help text can be created for any interface control in order to provide the Alfabet user community with specific instructions relevant to the data captured via the interface control. The help text will be available in the modal window that opens when the editor Help is opened.

Please note the following:

- The text entered in the **Hint** attribute may not be longer than 600 characters. Texts exceeding 600 characters will not be saved to the Alfabet database. Please note that if the hint is translated, the translated text may also not exceed 600 characters.
- Please note that the value defined for the **Hint** attribute for the custom object class property associated with the interface control will not be displayed as help text in the custom editor. The help text must be explicitly defined via the **Hint** attribute of the interface control.

- The **Tab Index** attribute of the interface control determines the sequence when a user presses the TAB key to move the focus in the user interface as well as the order that the Help texts are listed in the modal window that opens when the **Help** button is clicked in the editor. For more information, see the section Specifying the Tab Order of the Interface Controls.

To define help text for an interface control:

1) Click the interface control in the custom editor to open the attribute window.

   If the **Read Only** attribute is set to `True` for a Check Box interface control, the value defined in the **Hint** attribute of the custom object class property of the type `Boolean` cannot be displayed as a help text in the editor. It is recommended that you add the help text as static text to the editor.

2) In the **Hint** attribute, click the **Browse** button to open the editor.
3) Enter the help text in the editor and click **OK**.
4) In the toolbar, click the **Save** button to save your changes.

Hiding Fields in the Custom Editor

It is possible to hide properties in the custom editor in the context of a particular user profile. Please note that if the custom editor is embedded in a wizard, this will also impact the wizard. For more information about the consequences of hiding standard or custom properties in editors as well as the procedure to do this, see the section Specifying the Visibility of Object Class Properties in Page Views in the chapter Configuring User Profiles for the User Community.

Reviewing the Visualization of an Existing Custom Editor

All existing custom editors can be reviewed in the Alfabet interface in order to check their visualization in the solution interface. Please note that the layout and design of the custom editor in the Alfabet interface when rendered via Alfabet Expand is not identical to the layout and design of the editor when rendered in the browser interface.

1) In the **Presentations** tab, expand the **Custom Editors** folder to display all existing custom editors.

   If you have just created or edited a custom editor, you must right-click the **Custom Editors** folder and select **Rescan Tree** to update the folder.

2) Right-click the custom editor and select **Review Custom Editor**. The new custom editor is displayed. Please note that the layout and design of the custom editor in the Alfabet interface when rendered via Alfabet Expand is not identical to the layout and design of the editor when rendered in the browser interface.

Configuring Styles and GUI Scheme Settings for Standard and Custom Editors

Various GUI scheme settings should be defined to determine the layout and visualization of editors. The GUI scheme settings that are defined will apply to all standard and custom editors associated with the user profile that the GUI scheme is assigned to. The following GUI scheme attributes are relevant for custom editors:

- Layout of interface controls for standard and custom editors. Specify the rendering style of the interface controls for all standard and custom editors via the **Editor Rendering Options** attribute available for the relevant GUI scheme. Two options are possible and the method you choose will determine how you go about designing the custom editors. You can choose the traditional rendering style, which reflects the explicit layout of all interface controls in custom editors as designed by the solution designer, or the stack rendering style which automatically positions the visible interface controls in a one- or two-column linear list. For detailed information about defining the layout of interface controls in editors, see the section Specifying the Rendering Definition of the Custom Editor.
- Specify the font color of the placeholders displayed in the editor fields in standard and custom editors via the **Placeholders Text Color** attribute available for the relevant GUI scheme. Placeholders represent the cursory information displayed in the editor field about how to define the data. Texts can be specified via the **Placeholder** attribute of the relevant interface control in the context of the custom editor.
- Specify the foreground and background for the primary and secondary button in standard and custom editors as well as wizards via the **Primary Button Skin** and **Secondary Button Skin** attributes available for the relevant GUI scheme. The primary button is the button that would typically be clicked by the user. For example, in an editor, the primary button is the **OK** button and the secondary button is the **Cancel** button. In a wizard, the primary button is the **Next** button and the secondary button is the **Previous** button. The skin styles allow issues like borders, box shadowing, and font color to be specified.
- Specify the font color and font style for the captions of editor fields when displayed in the **Help for Editor** dialog via the **Editor Help Control Caption Font** attribute available for the relevant GUI scheme. The **Help for Editor** dialog opens when the **Help** button is clicked in standard and custom editors. Expand the **Caption Styling** section of the relevant GUI scheme to define the **Editor Help Control Caption Font** attribute.

For an explanation and example of each attribute that can be defined for a GUI scheme, see the section *Overview of GUI Scheme Attributes* in the reference manual *Configuring Alfabet with Alfabet Expand - Appendix*.

Deleting a Custom Editor from the Custom Editors Folder

Before a custom editor is deleted, you should check to see if the custom editor is implemented in other configuration objects such as object views or workflow templates. To do so, right-click the custom editor  and click **Show Usage**. A window will be displayed showing the configuration objects using the selected custom editor. For more information regarding the **Show Usage** functionality, see the section Using the Show Usage Functionality in the chapter Getting Started with Alfabet Expand.

When you delete a custom editor from the **Custom Editors** folder, the custom object class properties displayed in the editor will not be deleted. These custom object class properties are still assigned to the respective class and can be viewed in the **Meta-Model** explorer tree in the **Classes** folder.

1) In the **Presentation** tab, click the + symbol next to the **Custom Editors** folder. You will see all existing custom editors listed in the tree.
2) Right-click the custom editor  that you want to delete and select **Delete**.
3) Confirm the warning by clicking **Yes**. The custom editor is deleted from the explorer.

Configuring Editors for the Mass Update of Data Capture Objects and Information Flows

Alfabet provides the configuration of custom editors that allow users to bulk update applications, components, devices, ICT objects, peripherals, and information flows. A button labelled **Mass Update** is displayed in the views for which a multi-editor is configured. In the configured mass update editors, users may modify standard and custom object class properties for multiple objects in the **Capture** <ObjectClass> functionalities and **Information Flows** page views. The multi-editors are configured via the respective XML objects available in the **MultiEditors** folder in the **Presentation** tab. The XML objects allow editors to be configured that support users to simultaneously update standard and custom object class properties for a set of objects found via a configured query.

Please note the following:

- If a user selects a user group node in the explorer and accesses the mass update editor from this node, the objects found by the configured query will be displayed and the user group node selected in the explorer will not be reflected in the set of objects in the editor.
- The query configured for a multi-editor will be executed when a user clicks the **Mass Update** button. If no objects are found by the query that has been configured for the multi-editor, an error message will be displayed indicating that there are no objects to be updated.

Please note that there is no enforcement mechanism in the **Mass Update** editor to ensure that the values users define are permissible. For example, the editor will not prevent users from defining start and end dates for business supports that are outside of the start and end dates of the provider or from setting a business support object state to **Active** when the provider's object state is set to **Plan**. Therefore, users must ensure that the values defined are correct and meaningful based on the object they are working with.

The following XML objects are available:

- The XML object ***APP_InformationFlows_ME*** specifies the multi-editor available in the *Information Flows Page View* (`APP_InformationFlows`) for applications and peripherals.
- The XML object ***COM_InformationFlows_ME*** specifies the multi-editor available in the *Information Flows Page View* (`COM_InformationFlows`) for components.
- The XML object ***APP_UserApplicaions_ME*** specifies the multi-editor available in the *Document Application Functionality* (`APP_UserApplication`).

- The XML object ***COM_UserComponents_ME*** specifies the multi-editor available in the *Document Components Functionality* (`COM_UserComponents`).
- The XML object ***DVC_UserDevices_ME*** specifies the multi-editor available in the *Document Devices Functionality* (`DVC_UserDevices`).
- The XML object ***ICTO_UserICTObjects_ME*** specifies the multi-editor available in the *Document ICT Objects Functionality* (`ICTO_UserICTObjects`).
- The XML object ***PRF_UserPeripherals_ME*** specifies the multi-editor available in the *Document Peripherals Functionality* (`PRF_UserPeripherals`).

To edit the XML objects:

1) Go to the **Presentation** tab, expand the **XML Objects** folder, and expand the **MultiEditors** node. You will see all XML objects for multi-editors that can be edited.
2) Right-click the relevant XML object and select **Edit XML**. The XML editor is displayed in the center pane. For general information about editing XML objects in Alfabet Expand, see Working with XML Objects.

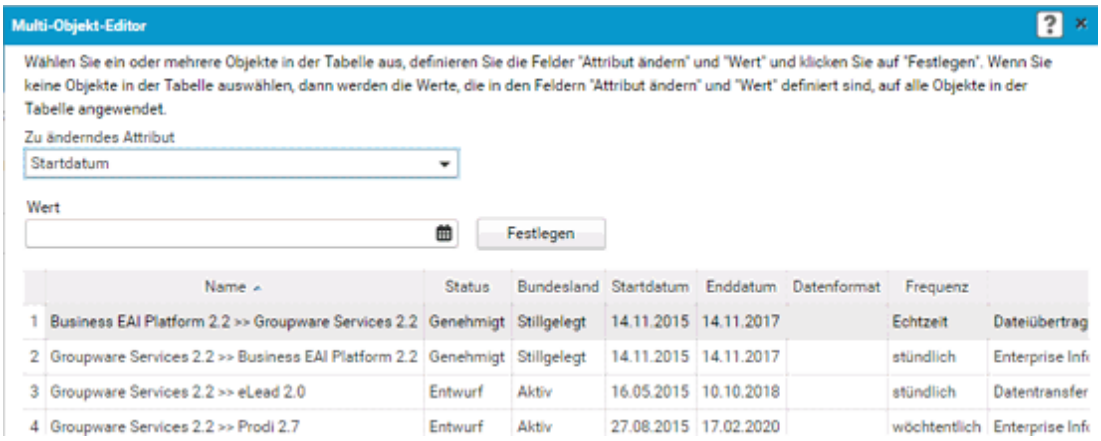


FIGURE: Example of the Multi-Object Editor the Information Flows page view

3) Define the XML attributes, as needed. The table below displays the XML attributes that can be edited for the relevant XML object:

XML Element (bold) / XML Attribute	Explanation
MO_Editor	
`ClassName`	Displays the object class that the custom editor targets. This should not be edited.
`CustomProperties`	Enter "`true`" if custom object class properties are included among the object class properties that may be changed for the selected object class.

XML Element (bold) / XML Attribute	Explanation
	NOTE: Please note that if the XML element `CustomProperties` is set to "`true`", not only will custom properties be included but you will no longer be able to specify displayed properties via the `ShowProperty` XML elements in the query. In other words, all properties will be displayed if the XML element `CustomProperties` is set to "`true`".
`CheckRights`	Enter "`true`" if access permissions should be honored in the editor. If you define "`true`", then an object that the currently logged on user has no access permissions for will not be displayed in the results found by the query
Query	Enter the Alfabet queries necessary to fill the dataset in the multi-editor. The query should specify the objects to be displayed in the editor's dataset and the `ShowProperty` XML elements should specify the object class properties displayed as columns in the tabular dataset. **NOTE**: If multiple queries are defined, the Show properties must be identical. Otherwise, an error will occur.XML restrictions do not apply when the Alfabet query is contained in the CDATA attribute. For more information, see the chapter ATO: Defining Queries. **EXAMPLE**:Query for `APP_UserApplications_ME`

Attribute	An XML element ***Attribute*** should be defined for each object class property that is to be displayed in the **Change Attribute** field in the **Multi-Object Editor** in the Alfabet interface.
	
	NOTE:Query for `APP_UserApplications_ME`
	
	`<Attribute Property="StartDate" CanBeNull="false" />`
	
	Query for `APP_InformationFlows_ME`
	
	`<Attribute Property="ConnectionDataFormat"`
	`CanBeNull="true">`
	`<Query><![CDATA[Alfabet_QUERY_500 FIND ConnectionDataFormat`
	`SHOW ConnectionDataFormat.Name] ]></Query>`
	`</Attribute>`

`Property`	Enter the name of the object class property that can be selected in the **Change Attribute** field in the **Multi-Object Editor** in the Alfabet interface. Scalar properties and object class properties of

XML Element (bold) / XML Attribute	Explanation
	type `Reference` are valid. Object class properties of type `ReferenceArray` are not supported.
`CanBeNull`	Enter "`true`" if the first value in the **Value** field in the **Multi-Object Editor** should be a blank line (null value). This ensures that a value is not selected per default. Please note that if the object class property is a mandatory property, you should enter "`false`" to ensure that a value is defined.
`Query`	For each XML element ***Attribute*** targeting an object class property of type `Reference`, a query must be defined that determines which objects must fill the **Value** field in the **Multi-Object Editor**. See the example for the query for `APP_InformationFlows_ME` described above for the XML element ***Attribute***.

4) In the toolbar, click the **Save** button to save the XML definition.

Modifying Preconfigured Editors Provided by Software AG

If you have been provided with preconfigured editors by Software AG, these will be displayed below the **Editors** node in Alfabet Expand. You can carry out any of the following on these editors:

- Right-click the relevant editor and select **Design Editor** to design and add additional interface controls to the editor. For more information, see the section Configuring the Interface Controls in the Custom Editor.
- Right-click the relevant editor and select **Review Editor** to view the visualization of the editor in the Web interface.

Chapter 7: Configuring Custom Selectors and Search Functionalities

Alfabet provides several methods to search for and find objects. Object classes and object class stereotypes may be configured to be searchable in the standard Alfabet search functionalities. Additionally, custom selectors can be created and implemented in the standard search functionalities as well as in page views, standard or custom editors, workflows, and configured reports. The solution designer can further configure whether a wildcard <*> should be automatically implemented when a user enters search criteria.

In addition to searching for objects, users can search for information about provided via configured reports.

The following information is available:

Configuring the Searchability of Alfabet Objects

If an object class is specified to be searchable, it can be searched via the **Simple Search**, **Full-Text Search** and **Glossary** functionalities as well as via object selectors available in page views, editors, wizards, and workflows. The searchability of an object class is specified via the class setting. In this way, the object class may be searchable in some user profiles but not in others. If object class stereotypes have been configured for an object class, the searchability of the object class stereotype is configured for the class setting of the object class stereotype.

If object class stereotypes have been defined for an object class, the solution designer can specify searchability on the level of the object class and/or object class stereotype. If the entire class is to be searchable irrespective of the object class stereotype, the **Searchable** attribute must also be set to `True`. The name of the object class will be displayed in the **Search for** filter in the search functionality. Please note that the caption of the object class should be different than the captions of its object class stereotypes.

Once the class setting is defined as searchable, objects in that object class or object class stereotype can be searched via the **Simple Search**, **Full-Text Search** and **Glossary** search functionalities as well as via object selectors available in page views, editors, wizards, and workflows. For an overview of the object classes that are searchable, see the chapter *Overview of Configurable Features for Object Classes* in the reference manual *Configuring Alfabet with Alfabet Expand - Appendix*.

For performance reasons, the return set for the standard search functionality is limited to 300 objects.

To configure an object class or object class stereotype as searchable:

1) Go to the **Presentation** tab, expand the **View Schemes** folder, and right-click the relevant view scheme  and select **Edit View Scheme**.
2) In the center pane, click the class setting that you want to define. You will see the attribute window in the right pane.
3) In the attribute window, ensure that the **Searchable** attribute is set to `True` to specify that users accessing Alfabet can search the object class. Select `False` if the object class should not be searchable in the search functionalities.
4) In the toolbar, click the **Save**  button to save the class setting definition.

Configuring a Custom Selector for Search Functionalities

Custom selectors can be configured in order to allow users to quickly and efficiently search for objects based on configured field filters and queries. Multiple custom selectors can be specified for an object class or object class stereotype and assigned to different user profiles in the user community, thus ensuring that only the relevant set of objects is available in the custom selector. The custom selectors that you configure can be specified to replace the standard search selectors in any of the following contexts:

- In the **Simple Search** functionality (`GenericSearch`)
- In page views in which an object selector is used to find an object in order to define a relationship. In this case, the configuration of the button operation used to open the selector will determine whether only a single object or multiple objects may be selected.

- In standard editors and custom editors in which an object selector is available for editor fields
- In workflows that are initiated for existing objects
- In configured reports for which the **Apply to Class** attribute is specified
- In any search selectors in which translated enumerations, release statuses, object states, or indicators are to be searched

Custom selectors assigned to a class setting will globally replace the standard selector except when a standard selector is required.

The **Selectors** node in the **Presentation** tab in Alfabet Expand allows you to create and configure custom selectors. Custom selectors may consist of a single page with one or two filter fields or they may contain multiple tabbed pages that allow users to search for objects in a specified object class using different search options.

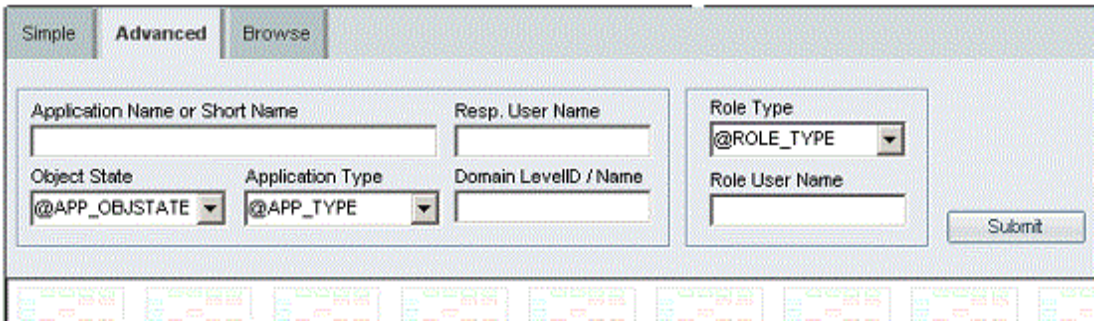

FIGURE: Example of a custom selector with multiple search options

In the example above, the custom selector is configured to include a **Simple** tab with a filter in which an application's name is entered to find the application as well as an **Advanced** tab with several filters that allow the search to be more defined in more detail. The filters allow, for example, the user to search for an application based on its object state, responsible user, and associated domain. The **Browse** tab is configured to allow the application to be searched by navigating through different explorer hierarchies including, for example, the organization structure containing the organization that owns the application or the domain model containing the domains that the application is associated with.

For each tabbed page configured for the custom selector, a search query must be written to find the objects to be searched. The search queries can be written in AQL or SQL. When a user opens the custom selector, the search query will be automatically triggered and the results immediately displayed. If the user modifies the search criteria, he/she must click the **Submit** button in order to update the results.

You can configure two optional buttons to be displayed in the filter areas. The **Collapse Filter** button allows users to close the filter area of the selector in order to increase the amount of space available to display the search results. The **Clear Search Patterns** button allows users to clear all filter settings with a single click.

Furthermore, an **Add to Clipboard** button is available in the toolbar as a convenient means to allow users to copy multiple objects and save them to the clipboard in order to easily define them as reference objects later in the user session. Data can be saved to the clipboard even if the user has read-only access to a standard page view or configured report. Objects saved to the clipboard will be available in custom selectors if the **Add My Objects Tab** attribute has been set to `True` for the class entry definition of the custom selector. The columns displayed in the **My Objects** tab are determined based on the **Preview Properties** attribute of the associated class setting for the base object class.

Once the custom selector has been defined, it can be assigned as the default selector for an object class or object class stereotype. The is done by selecting the custom selector in the **Selector Definition** attribute of the class setting of the relevant object class or object class stereotype.

Please note that new objects may be created in the context of class-based standard and custom object selectors with a minimal amount of navigation required. When ad-hoc adding of new objects is enabled, the **Add Missing <Class.Caption>** button will be available in the selector and uses can create objects needed to define a reference in the context of the selector. When the user clicks the **Add Missing <Class.Caption>** button, the configured functionality/explorer, configured report, or standard view in which the user can create the new object will open in a separate browser tab. Once the missing object has been created, the user can return to the original browser tab with the object selector and search in the selector for the new object. The the **View for Missing Object Button** attribute available for the class setting must be specified if the **Add Missing <Class.Caption>** button shall be available in the custom selector. For more information about specifying the **Selector Definition** and **View for Missing Object Button** attributes, see the section Configuring Class Settings for Object Classes and Object Class Stereotypes.

The following information is available:

- Creating a Custom Selector
- Adding a Full-Text Search Tabbed Page to the Custom Selector
- Configuring the Buttons Displayed in the Custom Selector
- Configuring a Query for the Auto-Fill Function in the Search Field
- Implementing the Custom Selector in Alfabet
- Implementing a Custom Selector in the Simple Search Functionality
- Implementing a Custom Selector in a Page View
- Implementing a Custom Selector in a Standard or Custom Editor
- Implementing a Custom Selector in a Workflow
- Implementing a Custom Selector in a Configured Report
- Testing the Custom Selector
- Deleting a Custom Selector

Creating a Custom Selector

Please keep the following in mind when configuring the custom selector:

- For each custom selector, one class entry should be created per relevant object class. The class entry defines which object class is selectable in the custom selector. For example, in a **Browse** search, a hierarchy of application groups and applications can be displayed. If the class entry for which the search is configured defines the object class Application as searchable class, only applications can be selected in the hierarchy. Application groups will be displayed for structuring purposes, but they cannot be selected.

- A graphic view is automatically created for each class entry and displayed in the center pane. The graphic view will have a header panel and a presentation area. The graphic view allows you to configure multiple tabbed pages with their respective filter fields. A query must be defined for each tabbed page in order to find the specified dataset or browse hierarchy.

In order for an object class to be searchable in object selectors as well as the **Simple Search** functionality, you must ensure that the **Searchable** attribute is set to `True` for the relevant class settings implemented in the user profiles that require the selector. For more information about configuring the searchability of an object class in a class setting, see the section Configuring the Searchability of Alfabet Objects.

To create a new selector:

1) Go to the **Presentations** tab, right-click the **Selectors** folder, and select **New Selector**. The new selector is displayed below the **Selectors** folder.
2) Click the new selector to activate the attribute window and enter a name for the selector in the **Name** attribute. It is recommended that you provide a name that makes the selector easy to identify. This name will be displayed, for example, when configuring the implementation of custom selectors for search fields in standard editors, custom editors, or configured reports.
3) In the **Caption** attribute, enter the caption to display in the title bar of the selector. For example, the caption will be displayed in the Alfabet interface if the custom selector is implemented in a page view to add new objects in the relevant object class.
4) Next, define the object class for which the selector should be implemented. Right-click the selector and select **New Class Entry**. In the editor that opens, select the object class for which you want to create the selector and click **OK**. The user will only be able to select objects in the defined object class via the selector, even if objects of other object classes are displayed in the selector window (for example, objects classes that structure the search results).

   You can also select object class stereotypes in the editor. An object class stereotype must be defined in the format ObjectClassName:ObjectClassStereotypeName. When you define a class entry for a stereotype, the queries defined for the pages in the class entry must have a valid syntax. For more information, see below or see the section Enabling a Stereotype-Specific Search in Custom Selectors in the chapter Defining Queries.

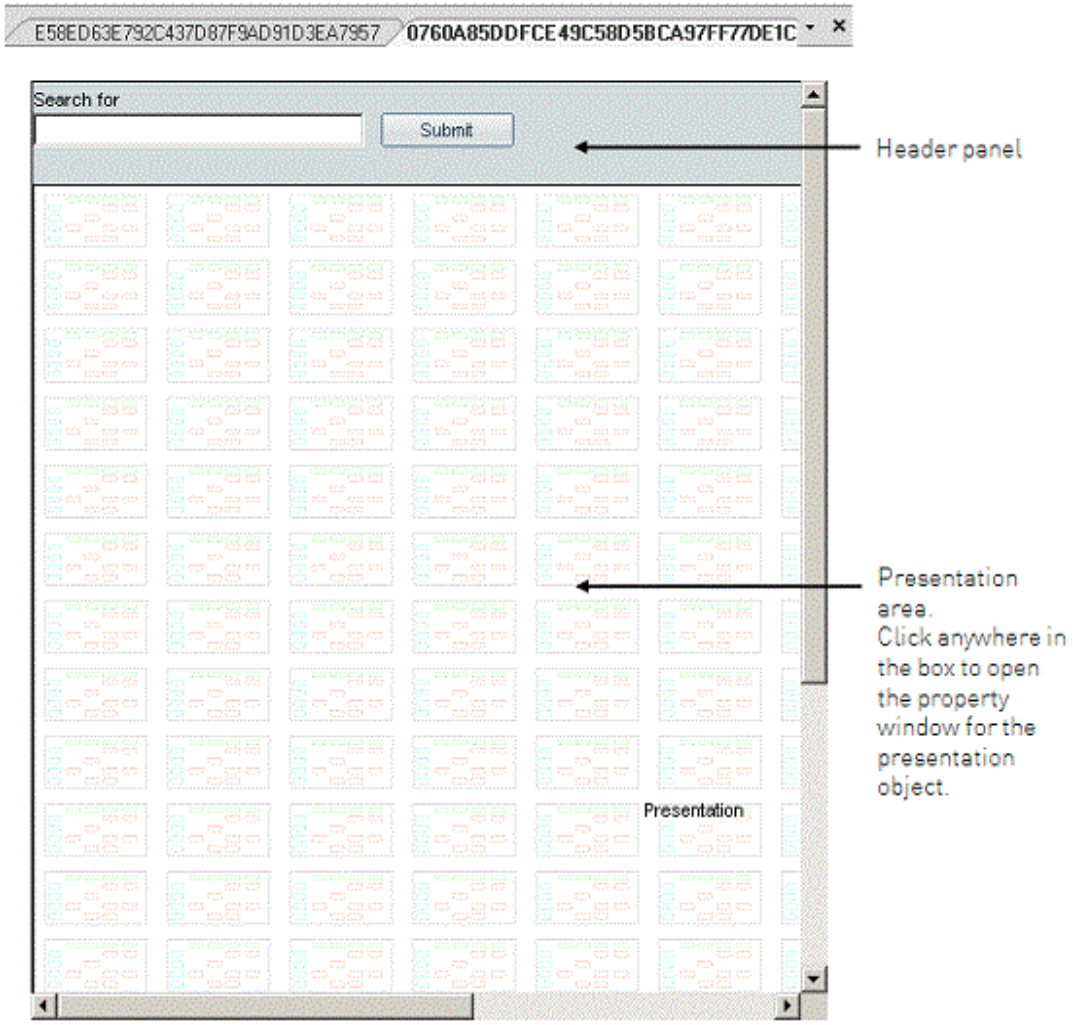
5) The class entry is displayed below the custom selector. Click the class entry and define the following attributes in attribute window:

- **Class**: Displays the object class selected in the selector when the class entry was created.
- **Max. Record Count**: Enter the number of objects found by the query that should be displayed. If all objects that are found by the query should be displayed, enter -1.
- **Add My Objects Tab**: Select `True` to include the **My Objects** tab in the custom selector. For custom selectors without tabs, a root tab will be added to the dataset of returned objects and the existing controls will be shown in a **Basic Data** tab. The **My Objects** tab will be dynamically added to the custom selector. For more information about the clipboard capability, see the section *Using the Clipboard Capability* in the reference manual *Getting Started with Alfabet*.

Please note the following about the clipboard functionality:

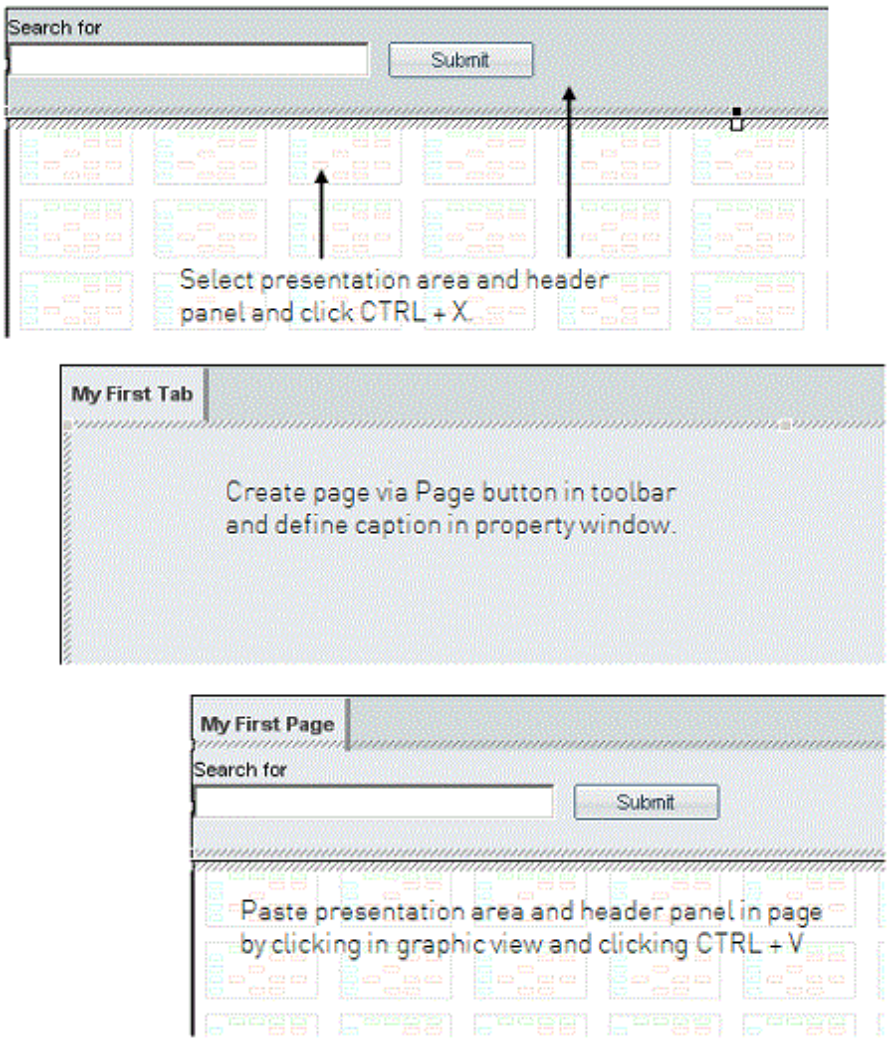
- Data added to the clipboard will remain in the clipboard during the running sub-session. If the user opens another browser tab to open Alfabet or if the user logs out, the data will be removed from the clipboard. Changing the user profile will not empty the clipboard.
- Each time a user adds objects to the clipboard within a running session, the data will be added to the existing data in the clipboard.
- The **My Objects** tab will only display the sub-set of objects in the clipboard that may be selected via the selector. For example, if components and applications have been added to the clipboard, only applications will be displayed in an application selector, only components will be displayed in a components selector, and none of the objects will be displayed in a device selector.

6) A presentation object is automatically generated for the class entry and is displayed below it. In the design editor in the center pane, the graphic view of the selector is displayed. The graphic view allows you to design the selector by adding tabbed pages, filters, as well as static text or other interface controls that might support the users when working with the selector. The graphic view automatically includes a header panel with a **Search for** field and a **Submit** button and a presentation area.



7) Next, define the tabbed pages required for the search selector. This will depend largely on the purpose of the search selector. If you require only a simple search selector with one view, then you can skip this step. However, if you need to define a search selector with multiple search options, then you will need to define a tabbed page for each search query that you plan to implement for the class entry.

   To create a page (tab) in the selector for each query you plan to define for the class entry.



- Click both the panel and presentation area while pressing the Shift key and cut the panel and presentation area out of the graphic view by clicking CTRL + X. The graphic view is now empty.
- Click in the graphic view to display the toolbar with interface controls that can be added to the graphic view. Click the **Page** control in the toolbar and click in the graphic view again. The page with a tab will be added. In the attribute window, enter a caption for the page's tab in the **Caption** attribute. Click the **Save** button to update the caption to the tab. Repeat until all pages have been created and their caption defined.
- For each tabbed page created, click in the graphic view and paste the panel by clicking CTRL + V. The panel will be added to the view. If the tabbed page is to be used to search a browse hierarchy, the header panel can be deleted.
- Create a page for all required search queries, pasting the header panel in each new tabbed page.

Please note the following:

- Do not place two presentation areas on top of one another.
- Do not right-click a tab and select **Cut** or **Delete**.

- If you have created multiple tabbed pages and want to move a tabbed page to the left or right, you must select all interface controls in a tabbed page by pressing the Shift key. Cut the panel and presentation area out of the graphic view by clicking CTRL + X. The graphic view is now empty. Right-click in the graphic view and select either **Move to Left** or **Move to Right**. Once the tab is in the correct position. Select CTRL + V to place the interface elements back in the tabbed page.

8) Next, you should add any additional filter fields required for each tabbed page. The filter fields are defined by adding the relevant interface element to the panel. For more information about the configuration of individual filter fields, see the section Defining Filters for Configured Reports and Selectors in the chapter Defining Queries.

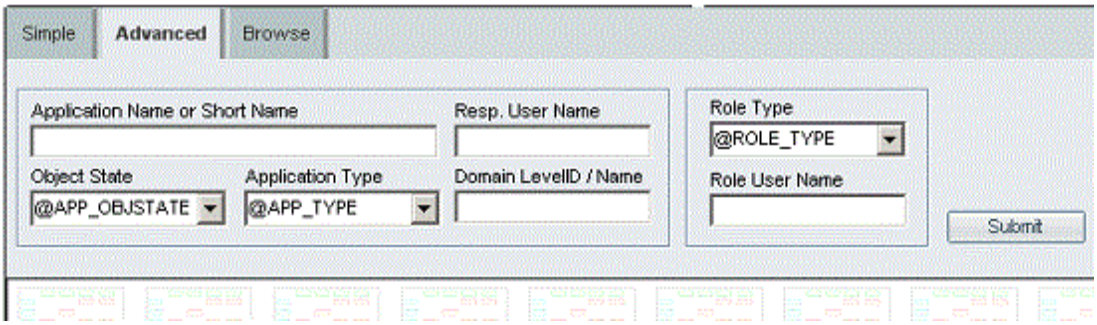


FIGURE: Example of a complex page with many filter fields

Please note the following:

- Each interface element that you add as a filter field should have a **Caption** attribute defined so that users can identify the purpose of the filter.
- Each filter field may have a tooltip explaining the purpose of the filter. Users will see the tooltip when they mouse over the field caption. The tooltip is defined in the **Hint** attribute.
- The filter fields you add to the tabbed page must be referenced by the search query that you will define for the page. Therefore, the filter fields MUST have the **Name** attribute defined and the syntax of the name must be written according to the conventions of the query language you intend to write the query in (AQL or SQL).
- In contrast to configured reports, filter controls cannot be automatically generated. They must be manually defined or copied from standard reports and pasted to the graphic views for custom selectors. References to parameters in filter controls are handled similarly as in configured reports. For more information about the procedure to create and specify filters, see the section Defining Filters for Configured Reports and Selectors in the chapter Defining Queries.
- If you plan to include a query for an explorer hierarchy (for example, similar to a browse search), you do not need to define a filter field. The field in which users will select the explorer will be automatically generated via the query definition.
- If the search selector is being defined to search for translated enumerations, release statuses, object states, or indicators, you must configure a Combo Box interface control for the search filter.

You can write the query first and then create a filter for each filter referenced in the query. Please note that if a filter referenced in the query is not defined, an error will occur.

9) Click the presentation area in the graphic view to open the attribute window. In the **Sub-Type** attribute, select `DataSet`.

10) Next, you need to define the search query that determines the set of objects to be searched in the tabbed page. This could be, for example, a simple data set determined by one or two filters, a complex data set determined by multiple filters, or an explorer browse hierarchy. A search query must be specified in the **XML Definition** attribute for each page:

    Ensure that you have clicked in the presentation area so that the attribute window displayed is for the graphic view. In the attribute window, click the **Browse** button in the **XML Definition** field. An editor opens in which you can define the search queries needed to find the objects to be returned when the search is triggered. The **XML Definition** attribute is filled automatically with the string `<DataSetDef Query="" />`. Define the query in the attribute `Query`.

    The search query may be specified in the Alfabet query language or native SQL and must match the following criteria:

- The query must return objects of the class defined in the class entry. In an Alfabet query, the class must be defined as a FIND class. In native SQL, the `REFSTR` of the class must be placed as the first `SELECT` property to be returned by the query.
- When you define a class entry for an object class stereotype, the queries defined for the tabbed pages in the class must return the stereotype of the objects in a column of the result dataset. The query must also include the instruction `SetRowsStereotypeIndex` ("ColumnName") that specifies the column in the dataset listing the stereotype information. For more information, see the section Enabling a Stereotype-Specific Search in Custom Selectors in the chapter Defining Queries.
- The classes specified for the custom selector must be valid according to the meta-model for the context in which the selector is used. An error message will be displayed in the user interface if the class specified for the custom selector does not match the context that is specified via, for example, a relevant button operation or Edit Search interface control.
- If you have defined filter fields for the selector page, the query must include a WHERE clause referencing the filter field via a parameter definition. When the query is executed, the parameter is substituted with the current value entered in the filter field. For more information about defining queries that reference filters, see Defining Filters for Configured Reports and Selectors in the chapter Defining Queries.
- The parameter `BASE` that references the current object can only be used if the selector opens after selecting a base object. The base object can be the object that the user is currently working with or the object the user has currently selected in a table in a view. For example, a selector that allows an application to be selected in order to assign it to an application group can refer to the current application group with the parameter `BASE`. Selectors that are used to perform a search in the **Simple Search** functionality cannot refer to a base object because a search is not performed in the context of working with a specific object. Selectors that are opened via an editor cannot refer to a base object because when the editor is used to create a new object, the base object is under creation and not available in the database yet.

For general information about writing Alfabet queries, see the chapter Defining Queries.

For general information about the rules that apply when using native SQL for configuring Alfabet, see the section Defining Native SQL Queries in the chapter Defining Queries.

Please note that the definition of a query inside an XML element requires a special syntax described in the section Defining Filters for Configured Reports and Selectors in the chapter Defining Queries.

For example, the following query is written for a simple search with only one filter field. This query is written in Alfabet query language and references the filter field using syntax required in AQL (for example,:`NameOrSN`):

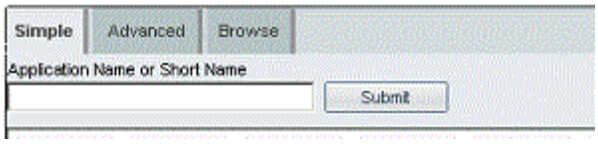

FIGURE: Query below specifies the field displayed in the selector

```
<DataSetDef Query="ALFABET_QUERY_500 FIND Application

    WHERE (OR
        Application.Name LIKE:NameOrSN
        Application.ShortName LIKE:NameOrSN)
  SHOW Application.Name Application.ShortName
  Application.Version Application.Status" />
```

For more information about writing queries, see the chapter Defining Queries.

For example, the following query is written for a complex search with multiple filter fields. This query is written in native SQL and references the filter field using the syntax required in SQL (for example, `@APP_NAM`, `@APP_OBJSTATE`, `@APP_TYPE`, etc):

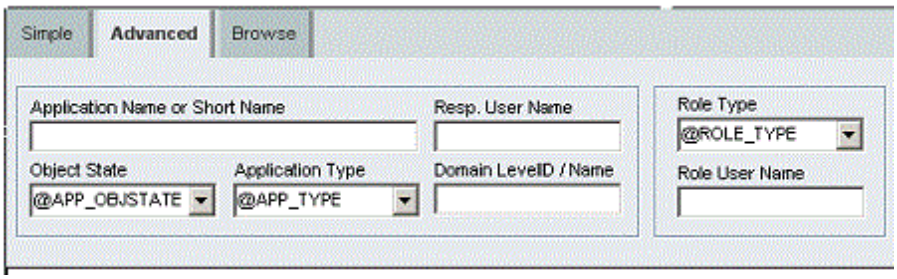

FIGURE: Query below specifies the filters displayed in the selector

```
<DataSetDef Query="
   SELECT app.REFSTR, app.ID,
      app.NAME + ' ' + app.VERSION AS 'Name and Version',
      app.SHORTNAME AS 'Short Name',
      app.OBJECTSTATE AS 'Object State',
      app.APPLICATIONTYPE AS 'Appl. Type',
      per.TECH_NAME AS 'Resp. User'
      dom.LEVELID + ' ' + dom.NAME AS 'Domain'
   FROM APPLICATION app
      LEFT JOIN PERSON per ON app.RESPONSIBLEUSER =
      per.REFSTR
      LEFT JOIN DOMAIN dom ON app.DOMAIN = dom.REFSTR
```

```
WHERE (app.NAME LIKE(@APP_NAME) OR app.SHORTNAME
LIKE(@APP_NAME))
    AND app.OBJECTSTATE = @APP_OBJSTATE
    AND app.APPLICATIONTYPE = @APP_TYPE
    AND per.TECH_NAME LIKE(@APP_USER_NAME)
    AND (dom.NAME LIKE(@APP_DOM_NAME) OR dom.LEVELID
    LIKE(@APP_DOM_NAME))
    AND (EXISTS(SELECT r.REFSTR
        FROM ROLE r, PERSON p
        WHERE r.OBJECT = app.REFSTR
        AND r.ROLETYPE = @ROLE_TYPE
        AND r.RESPONSIBLE = p.REFSTR
        AND p.TECH_NAME LIKE(@ROLE_USER_NAME))
    OR ('dummy' = @ROLE_TYPE AND 1=1))
" />
```

11) If the tab is to be used for a browse hierarchy:

- Click the presentation area in the graphic view to open the attribute window. In the **Sub-Type** attribute, select `ExplorerObject`.
- The string in the **XML Definition** attribute must be replaced with `<Explorers> </Explorers>`.
- Within the XML element ***Explorers***, there may be an arbitrary number of explorer definitions. If the tab is to be used to search a browse hierarchy, the header panel can be deleted.
- Within the XML element ***Explorers***, each explorer must be defined in an XML element ***ExplorerDef***. The required syntax for the definition of an explorer is explained in detail in the chapter Configuring Standard Business Functions and Custom Explorers.

When multiple explorers are defined, the user will see the explorers as sub-nodes in an **Explorer** root node when he/she selects the **Browse** search:

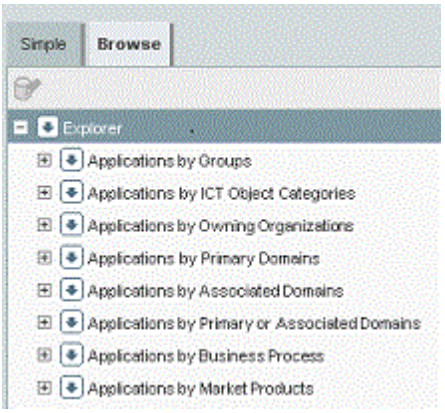

FIGURE: Multiple browse hierarchies to search for applications

For reasons of space, only the first explorer hierarchy in the example above is defined in the query below:

```
<Explorers>
    <ExplorerDef
        Name="Applications by Groups"
        BaseClasses = "ApplicationGroup,Application" >
        <Query ClassName="ICTObjectCategory"
        Query="BelongsTo IS NULL" />
        <ClassEntry ClassName="ICTObjectCategory"
        ShowProps="Name" SortProps="Name" >
            <Query ClassName="ICTObjectCategory"
            Query="BelongsTo Contains:BASE" />
            <Query ClassName="ICTObject" Query="Category
            Contains:BASE" />
        </ClassEntry>
        <ClassEntry ClassName="ICTObject"
        ShowProps="Name" SortProps="Name" >
            <Query ClassName="Application" Query="(AND
            ICTObject Contains:BASE VariantOf IS NULL)"
            />
        </ClassEntry>
        <ClassEntry ClassName="Application"
        ShowProps="Name,Version"
        SortProps="Name,Version" >
            <Query ClassName="Application"
            Query="VariantOf Contains:BASE"
            /></ClassEntry>
    </ExplorerDef>
</Explorers>
```

12) Once a query has been defined for each tabbed page in the custom selector has been defined, click the **Save**  button in the toolbar.

13) Below the class entry in the explorer, click the presentation object  . In the toolbar above the attribute grid, click the **Events**  button to open the event window. In the `OnGetExplorerNodes` event, select `GetExplorerNodes`. Click the **Save**  button in the toolbar and click the **Attributes**  button to return to the attribute window.

14) Click the class entry node below the selector node in the explorer tree and in the **Max. Record Count** field, enter the number of objects found by the query that should be displayed. If all objects that are found by the query should be displayed, enter `-1`.

15) You should now test the layout and search results of the custom selector. To do so, right-click the selector node in the explorer and select **Review Selector**. You can view the selector in the context of the Alfabet interface. If the results are not as expected, you can edit the XML definition until the output of the selector meets your expectations.

Adding a Full-Text Search Tabbed Page to the Custom Selector

If a full-text search should be available in the custom selector, you must explicitly create an additional tabbed page entailing the full-text search functionality.

You must ensure that a search group has been created for the relevant object class in the XML object ***SearchManager***. For more information, see the section Configuring an Object-Centric Search Group.

To configure a tabbed page with the full-text search functionality:

1) Add the page (tab) to the custom selector by clicking the **Page** interface control in the toolbar and clicking in the graphic view again. The page with a tab will be added. In the attribute window, enter a caption for the page's tab in the **Caption** attribute. Click the **Save** button to update the caption to the tab.
2) Create a **Panel** interface control in the tab. Click the panel and set the **Dock** attribute to `Top`.
3) Add a presentation object to the page by clicking the **Presentation Object** interface control in the toolbar and clicking in the graphic view below the panel.
4) Click the Presentation area in the graphic view to open the attribute window. Define the following attributes:

- **SubType**: Select `DataSet`.
- **Refresh on Submit**: Select `True`.
- **Dock**: Select `Fill`.

A validation mechanism checks for inconsistencies in the layout and docking definition of interface controls in guide views, configured reports, and other configured views. Please note that an error message will be displayed when the user attempts to open an incorrectly configured view if two or more interface controls have no docking defined in the view. The error message will provide detailed information about the faulty configuration.

- **XML Def**: Click the **Browse** button to open the editor in which you can define the relevant search group and the fuzziness factor for the full-text search. The **XML Def** attribute is filled automatically with the string `<DataSetDef Query="" />`. Delete the string and enter `<FullTextSearchDef SearchGroup="<SearchGroupName>" Fuzziness="<NumberFrom0To10>" />` and click the **Save** button to save the definition.

For example:

```
<FullTextSearchDef SearchGroup="ApplicationSearch"
Fuzziness="3" />
```

5) Add the edit field to the custom selector by clicking the **Edit** interface control in the toolbar and clicking in the graphic view again. In the attribute window, define the following attributes for the Edit interface control:

- **Name**: Enter `@aName`.
- **Caption**: Enter a caption for the page's tab.

6) Click the **Save** button to update the Edit interface control.
7) Next, click the **Submit** button next to the edit field in order to activate its attribute window. In the **Submit** attribute, select `True`. Click the **Save** button to save the definition.
8) Click the Presentation area and click the **Events** icon above the attribute window. In the **OnGetPresentationData** attribute, select `OnGetFullTextData`.
9) Click the **Save** button to save the definition.

Configuring the Buttons Displayed in the Custom Selector

Two buttons may be displayed in the header panel of a custom selector. The **Collapse Filter** button allows users to close the filter area of the selector in order to increase the amount of space available to display the search results. The **Clear Search Patterns** button allows users to clear all filter settings with a single click.

You can optionally configure individual filter fields to be excluded from the **Clear Search Patterns** functionality. To prevent a specified filter field to be cleared:

1) Click the filter field that you want to exclude from the **Clear Search Patterns** functionality to open its attribute window.
2) In the **Allow Clear Value** attribute, select `False` to prevent the value set by a user from being cleared when the user clicks the **Clear Search Patterns** button.

To include the button in the header panel of the custom selector:

1) Click in the header panel of the graphic view to open its attribute window. Define the following attributes:

- **Has Clear Button**. Select `True` to implement the **Clear Search Patterns** button.
- **Collapsible**. Select `True` to implement the **Collapse Filter** button

2) In the toolbar, click the **Save** button to save your changes.

Configuring a Query for the Auto-Fill Function in the Search Field

An auto-fill function is automatically available that provides potential matches when users enter text in a search field in standard selector. Potential matches for the text entered by the user are displayed in a drop-down list and must be explicitly selected to be entered in the search field. An auto-fill function may also be configured for custom selectors. This is done via an Alfabet query or native SQL query that finds potential matches for the selector field.

The auto-fill function is not available for a `Person` selector that is configured to access an external source. Please note that the auto-fill function for standard selectors is defined via the **Image Properties** attribute of the relevant class setting. For more information, see the section Creating a Custom Class Setting for a Protected Object Class or Object Class Stereotype.

1) Click the custom selector to activate the attribute window.

2) Next, you need to define the search query that determines the set of objects that may qualify as potential matches for the auto-fill function in the search field in the custom selector. In the **Lookahead Query** attribute, click the **Browse** button to open the editor in which you can define the query. Please note the following regarding the search query definition:

- The search query may be specified in the Alfabet query language or native SQL. The query must be written in SQL if multiple object classes are to be searched. Please note however that a query in native SQL requires that the `REFSTR` of the class is placed as the first `SELECT` property. For more information about syntax and guidelines for defining queries, see the chapter Defining Queries.
- The number of results to display in the drop-down list can be defined in the query. This number should not be excessively high.
- The parameter `SEARCH_PATTERN` can be used in the query. The parameter `SEARCH_PATTERN` is required to refer to the value entered in the filter field.
- The variables `CURRENT_USER`, `CURRENT_LANGUAGE`, `CURRENT_MANDATE`, and `TODAY` can be used in the query.. Please note that this does not enable the use of `BASE` variables. The selector does not have any knowledge about the underlying view, editor or presentation object.
- Show and sort properties define the visualization of the matching data in the drop-down list.

For example, the following query is written in native SQL. The auto-fill function will display the first 10 organizations based on the organization stereotype `External Organization` found matching the letters entered in the search field. The matches will be displayed alphabetically based on their names:

```
SELECT TOP 10 REFSTR, NAME
FROM ORGAUNIT
WHERE NAME LIKE @SEARCH_PATTERN
   AND STEREOTYPE = 'ExternalOrganization'
ORDER BY NAME
```

3) Save the query by clicking the **OK** button.

4) In the toolbar, click the **Save** button to save your changes.

Implementing the Custom Selector in Alfabet

The custom selectors that you configure can be specified to replace the standard search selectors or object selectors in any of the following contexts:

- In the **Simple Search** functionality (`GenericSearch`).
- In page views in which an object selector is used to find an object in order to define a relationship

- In standard editors and custom editors in which an object selector is available for editor fields
- In workflows that are initiated for existing objects
- In configured reports for which the **Apply to Class** attribute is specified

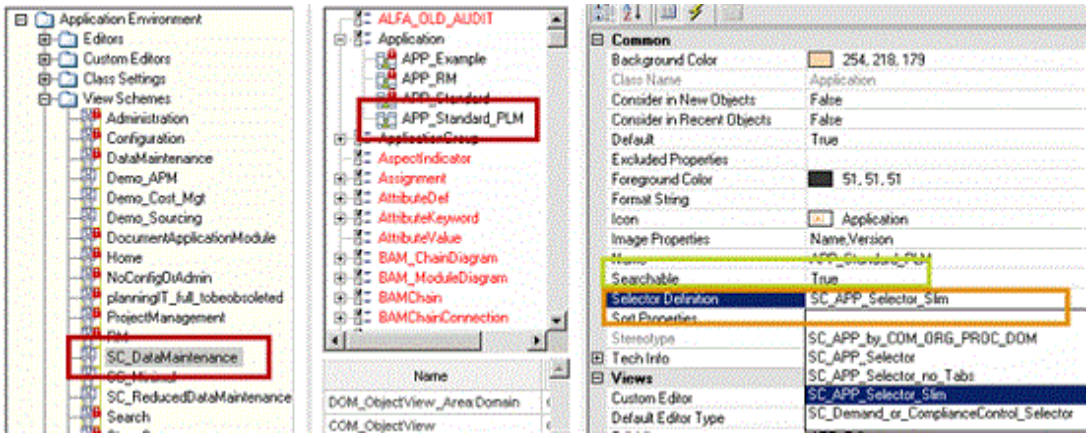
The following information is available:

Implementing a Custom Selector in the Simple Search Functionality

To implement a custom selector for the **Simple Search** (`GenericSearch`) functionality, you must explicitly specify the custom selector for each relevant class setting defined for the view scheme assigned to the relevant user profile.

To implement the custom selector in the **Simple Search** functionality:

1) Go to he **Presentation** tab, click the relevant view scheme and select **Edit View Scheme**.
2) In the center pane, select the class setting that you want to define. You will see the attribute window in the right pane.



3) In the attribute window, ensure that the **Searchable** attribute is set to `True` to specify that users accessing Alfabet can search the object class.
4) In the **Selector Definition** attribute, select the custom selector that should be displayed for the selected object class in the **Simple Search** functionality.

> All custom selectors that have been configured for your solution will be displayed. You must ensure that you select a custom selector that is meaningful for the view and defined for the relevant object class.

5) In the toolbar, click the **Save** button to save the class setting definition.

Implementing a Custom Selector in a Page View

You can implement a custom selector to replace the standard object selector in the page views accessible via a specified user profile.

Only a subset of the standard Alfabet page views can be configured. for some standard page views, the selector definition is fixed, and the configuration described below is not available.

To configure the custom selector for a page view:

1) Go to the **Admin** tab, right-click the user profile that you want to configure and select **Configure User Profile**. The Alfabet interface opens.
2) Navigate to the relevant view in which you want to specify the custom selector.
3) Click the **Configure** button in the upper right corner of the view to open the **View Configuration** editor.
4) In the **Custom Selector** column, select a custom selector in the drop-down menu in order to replace the standard custom selector displayed in the **Default Selector** column.

   All custom selectors that have been configured for your solution will be displayed. You must ensure that you select a custom selector that is meaningful for the view and defined for the relevant object class.

5) Click **OK** to close the **View Configuration** editor and save the selector definition.
6) Close the browser and reopen it to see the changes you specified in the **View Configuration** editor.
7) Repeat for other page views that should be configured for the selected user profile.
8) In the toolbar in Alfabet Expand, click the **Save** button to save the configuration

Implementing a Custom Selector in a Standard or Custom Editor

You can implement a custom selector to replace the standard object selector in standard and custom editors available in object views and page views that are accessed by a specified user profile.

To configure the custom selector for a standard or custom selector:

1) Go to the **Admin** tab, right-click the user profile that you want to configure and select **Configure User Profile** in order to access Alfabet. The Alfabet interface opens.
2) Navigate to the relevant object view or page view with the editor for which you want to specify the custom selector.
3) Click the **Edit** button in the view to open the editor.

4) In the upper right corner of the editor, click the **Configure** button.

5) In the **Custom Selector** column, select a custom selector in the drop-down menu in order to replace the standard custom selector displayed in the **Default Selector** column.

> All custom selectors that have been configured for your solution will be displayed. You must ensure that you select a custom selector that is meaningful for the view and defined for the relevant object class.

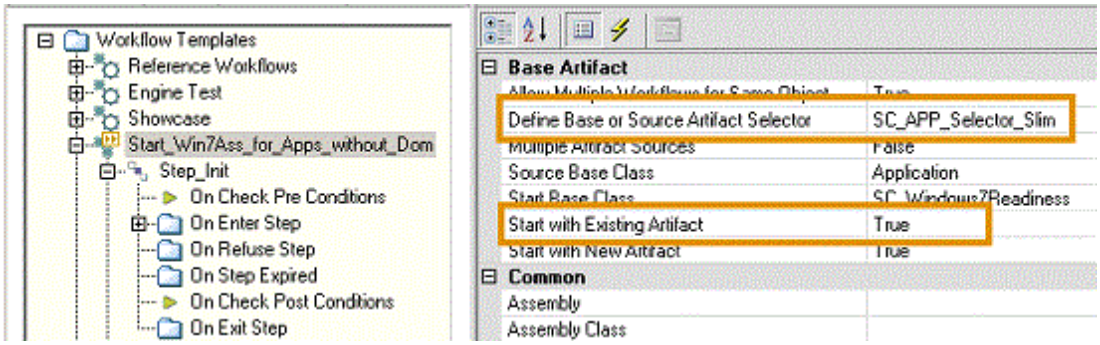
6) Click **OK** to save the selector definition.

7) Repeat for other editors that should be configured for the selected user profile.

8) In the toolbar in Alfabet Expand, click the **Save** button to save the configuration

Implementing a Custom Selector in a Workflow

A custom selector can be implemented in place of the standard selector for a workflow that is specified to start with an existing object.



To implement the custom selector in a workflow:

1) Go to the **Workflows** tab, click the relevant workflow template .

> The workflow template must have the state `Plan` in order to be edited. To change the state of the workflow template, right-click the workflow template and select **Set State to Plan**.

2) In the attribute window, ensure that the **Start with Existing Artifact** attribute is set to `True` to specify that the workflow should begin with existing objects.

3) In the **Define Base or Source Artifact Selector** attribute, select the custom selector that should be implemented for users to select the base object for the workspace.

4) In the toolbar, click the **Save** button to save the workflow template definition.

Implementing a Custom Selector in a Configured Report

A custom selector can be implemented for the standard object selector in configured reports for which the **Apply to Class** attribute is specified. Custom selectors can also be implemented for configured reports for which filters containing Edit Search interface controls are implemented. Depending on how the filter field is generated, custom selectors can be implemented using one of the following methods:

- Filter fields that are automatically added when the **Apply to Class** attribute of the configured report is set: The custom selector will be implemented if it is defined in the **Selector Definition** attribute of the class setting of the object class defined in the **Apply to Class** attribute of the configured report.
- Filter fields in configured reports of the type `Query`: The custom selector will be implemented if it is defined in the **Selector Definition** attribute of the class setting of the object class targeted by the Edit Search interface control.
- Filter fields in configured reports of the type `Native SQL` or `Custom`: Open the configured report view and click the Edit Search interface control for which you have defined a custom selector. In the attribute window, enter the name of the custom selector in the attribute **Object Selector**.

Testing the Custom Selector

You can test the custom selector to ensure that the query is returning the results you expect. To do so, right-click the selector and select **Review Selector**. The custom selector is opened in a browser tab. Test the configuration of the custom selector as needed.

Deleting a Custom Selector

Before a custom selector is deleted, you should check to see if the custom selector is implemented in other configuration objects such as custom editors or configured reports. To do so, right-click the custom selector and click **Show Usage**. A window will be displayed showing the configuration objects using the selected custom selector. For more information regarding the **Show Usage** functionality, see the section Using the Show Usage Functionality in the chapter Getting Started with Alfabet Expand.

1) Go to the **Presentation** tab and expand the **Selectors** folder. You will see all existing custom selectors listed in the tree.
2) Right-click the custom selector that you want to delete and select **Delete**.
3) Confirm the warning by clicking **Yes**. The custom selector is deleted from the explorer.

Configuring the Full-Text Search Capability

Alfabet supports full-text search within data in the Alfabet database. Full-text search is based on search groups defined by a solution designer in the XML object ***SearchManager***. A search group defines a scope for the full-text search. For each search group, the user can search in defined object class property values of all or a subset of objects of defined object classes. The full-text search can be conducted in all secondary languages supported by Alfabet. To enable full-text search based on a configured search group, a search index must be created for the search group for each supported language. Search indexes must be updated in regular intervals to include recent changes to the data in the Alfabet database.

There are two different methods of full text search in Alfabet:

- The global *Full-Text Search* functionality provides access to search groups defining full-text search for objects of an object class or a set of object classes such as applications and ICT objects or business processes and organizations. The search index for this search is created and updated centrally by an administrative user as a separate functionality. For each combination of search group and supported language a separate index is generated.
- Object-centric full-text search can be conducted via the **Full-Text Search** page view in the **Search** workspace available in an object profile of an object class. Search groups for object centric full-text search are configured to find objects related to the object the user is currently working with when accessing the **Full-Text Search** page view. The search index for an object centric full-text search is created and updated by the user conducting the search directly on the **Full-Text Search** page view available in the object profile of the object class. For each combination of search group, base object and supported language a separate index is generated.

  The following functionalities rely on object-centric full-text search groups. For these special use cases, the definition of the object-centric search group is described separately in the scope of the documentation of the functionality, to take functionality specific configuration requirements for the search groups into account:

  - An object-centric search group for the object class `ALFA_REPORT` is required to activate semantic search in the **Business Problem Statement** attribute of configured reports for the AlfaBot functionality. Semantic search enhances the ability of the AlfaBot to find a configured report that a user wants to access via the AlfaBot.
  - Object-centric search groups can be defined for the glossaries defined in the *Glossary Functionality* (`Glossary`) in the **Search** module. If a glossary is defined, a search group must be configured in order to search the glossary. For more information about the configuration of a search group for the **Glossary** functionality, see the section Configuring the Glossary Search Functionality.
  - Object-centric search groups are required for the implementation of the domain glossary defined in the *Domain Glossary Page View* (`DOM_Glossary`) in Alfabet. If a domain glossary is defined, a search group must be available in order to search the glossary. For more information about the configuration of a search group for domain glossaries, see the section Configuring the Domain Glossary Capability in the chapter Configuring Domain Models and Domain Planning.

The following configuration is required to activate full-text search for the full-text search functionalities:

- Full-text search indexes are not part of the Alfabet database but stored on the local file system. A search index directory must be defined for storage of the search indexes on the local file system.

This is done by a system administrator in the server alias of the Alfabet Web Application. For more information, see the section *Creating a Server Alias for the Alfabet Web Application* in the reference manual *System Administration*.

- Full-text search must be activated and general search parameters for all search groups must be specified in the XML object ***SearchManager***. For more information, see the section Specifying General Parameters for Index Creation.
- Search groups must be defined for the full-text search in the XML object ***SearchManager***:
  - For information about the definition of global search groups for the global Full-Text Search functionality, see the section Configuring a Global Search Group.
  - For information about the definition of object-centric search groups for object-centric full-text search, see the section Configuring an Object-Centric Search Group.
  - For information about the definition of object-centric search groups for the **Glossary** functionality, see the section Configuring the Glossary Search Functionality.
  - For information about the definition of search groups for the **Domain Glossary** functionality, see the section Configuring the Domain Glossary Capability in the chapter Configuring Domain Models and Domain Planning.
- The required views must be made available to the user via the user profile configuration. The following views or functionalities are required for the different full-text search functionalities:
  - **Global full-text search**: The **Full-Text Search** (`GlobalFullTextSearch`) functionality must be added to the user profile of the users that shall conduct the search. For more information about adding functionality to a user profile, see Making Functionalities Accessible to a User Profile in the chapter Configuring User Profiles for the User Community.
  - **Object centric full-text search including glossary and domain glossary search**: Object centric full-text search is limited to the object classes with a **Search** (`SRCH_GenericObject`) workspace with a **Full-Text Search** page view in the standard object view. For an overview of object classes with activated object-centric full-text search, see *Overview of Configurable Features for Object Classes* in the reference manual *Configuring Alfabet with Alfabet Expand - Appendix*. The workspace will only be visible to the user if the object class is the base class for an object centric search group in the XML object **SearchManager**. Therefore, it is not required to generate a custom object view to actively exclude the workspace if no object centric search shall be provided. The **Search** workspace is available for the object class Glossary to conduct full-text search for glossaries and for the object class Domain to conduct full-text search in domain glossaries and in any object centric search group for the base class Domain.
- For the global full-text search only, one of the functionalities to create and update the full-text search index must be configured and executed in regular intervals. The following options are available to update the search indexes for global search groups:
  - An administrative user can create and update the full-text search indexes for globally-defined search groups in the administrative **Full-Text Search** functionality on the Alfabet user interface. The functionality allows creation and update of indexes for all supported languages to be performed.

The view `ADMIN_FullTextSearch` must be added to the user profile of the administrative user to enable manual creation and update of the globally-defined full-text search. For information about how to manually create and update search indexes, see the section *Creating an Index for the Full-Text Search* in the reference manual *User and Solution Administration*.

- Via the **Job Schedule** functionality on the Alfabet user interface, administrative users can create job schedules for the automatic creation and update of search indexes for globally-defined full-text search groups in defined time intervals. A job schedule triggers the creation and update of the search index of a single full-text search group. Please note that the job schedule functionality currently supports only definition of full-text search indexes for the language English (United States).

For information about how to implement and configure the **Job Schedule** functionality, see the section Activating the Job Schedule Functionality. For information about how to schedule full-text search index update via a job schedule, see the section *Creating a Job Schedule for the Generation of a Full-Text Search Index* in the reference manual *User and Solution Administration*.

- Via the executable `FullTextSearchUtil.exe`, system administrators can configure a batch process to regularly create and update search indexes for globally-defined full-text search groups. The command line tool can create and update indexes for all supported languages. It can either update an index for a defined search group or for all globally-defined full-text search groups.

For more information about the configuration of the batch process, see the section *Updating Indexes with the FullTextSearchUtil.exe* in the reference manual *System Administration*.

The following information is available:

- Specifying General Parameters for Index Creation
- Configuring an Object-Centric Search Group
- Configuring a Global Search Group

Specifying General Parameters for Index Creation

Regardless of whether an object-centric search or a global search has been configured, a few general configurations are required in order to ensure that indexes can be created for all search groups that are defined in the XML object ***SearchManager***. This includes the activation of the search index and the configuration of the maximum number of matching words to display for the search results.

To edit the XML object ***SearchManager***:

1) Go to the **Presentation** tab and expand the **XML Objects** folder. You will see all XML objects that can be edited.
2) Right-click the XML object ***SearchManager*** and select **Edit XML**. The XML editor is displayed in the center pane. For general information about editing XML objects in Alfabet Expand, see Working with XML Objects.
3) If not already defined in the XML object, add the root element `SearchManager` to the XML object. If defined, edit the existing root element:

```
<SearchManager HighlightCount = "20000" AutoWildCard="false">
    ...
</SearchManager>
```

4) In the XML attribute `HighlightCount`, enter an integer to define the maximum number of matching words to highlight in the display of search results. The default count is 10,000.

The XML attribute `AutoWildCard` has no effect on the full-text search. For information about the configuration of the XML attribute `AutoWildCard`, see the section Configuring the Wildcard for Standard and Custom Search Functionalities.

5) In the toolbar, click the **Save** button to save the XML definition.

Configuring an Object-Centric Search Group

An object-centric search allows users to enter search terms to find objects related to a base object, like for example applications that are assigned to a selected application group. This search is indexed and executed by means of the *Full-Text Search* page view (`SRCH_FullTextSearch`) in the workspace **Search** (`SRCH_GenericObject`) for the base object.

An object centric search group must be configured if any of the following is to be implemented in your Alfabet solution:

- The implementation of one or more glossaries defined in the *Glossary Functionality* (`Glossary`) in the **Search** module. If a glossary is defined, a search group must be configured in order to search the glossary. For more information about the configuration of a search group for the **Glossary** functionality, see the section Configuring the Glossary Search Functionality.
- The implementation of the domain glossary defined in the *Domain Glossary Page View* (`DOM_Glossary`) in Alfabet. If a domain glossary is defined, a search group must be configured in order to search the glossary. The configuration of the search capabilities for the domain glossary are addressed separately in the section Configuring the Domain Glossary Capability in the chapter Configuring Domain Models and Domain Planning.

To edit the XML object ***SearchManager*** for an object-centric search:

1) Click the **Presentation** tab in the tab bar and expand the **XML Objects** folder by clicking the + symbol. You will see all XML objects that can be edited.
2) Right-click the XML object ***SearchManager*** and select **Edit XML**. The XML editor is displayed in the center pane. For general information about editing XML objects in Alfabet Expand, see Working with XML Objects.
3) Enter an XML element `SearchGroup` with the required child XML elements and XML attributes as child XML element of the root XML element `SearchManager` and define the XML attributes as needed. The table below displays the XML attributes that should be edited for an object-centric search in the XML object ***SearchManager***.

The following example displays a code for an object-centric search group searching within all applications in an application group:

```
<SearchGroup Name="Applications in Application Group"
BaseClass="ApplicationGroup" Type="Object">

   <ClassEntry ClassName="Application"
   ShowProps="Application.Name,Application.Version"

   ExportProps="Application.Name,Application.Description"
```

```
    ImageProps="Application.Name,Application.Version" />
    <Query Name="Applications in Group"
    ClassName="Application"
    Query="ALFABET_QUERY_500 FIND Application WHERE
    Application.ApplicationGroups CONTAINSOR:BASE" />
</SearchGroup>
```

XML Element (bold) / XML Attribute	Explanation
SearchGroup	
`Name`	Enter text that defines the name of the search group. This is the name that users will see when they select the search group in order to execute a search.
`Type`	Enter `Object` to define an object-centric search. **NOTE**: This XML attribute is mandatory for the definition of an object-centric search. If the XML attribute is not defined, the search is by default a global search.
`BaseClass`	Enter the name of the object class that is the base class for the search. **EXAMPLE**:To search for applications in an application group, enter `ApplicationGroup` for the XML attribute `BaseClass`. **NOTE**: Please note the following: • This XML attribute is mandatory for the definition of an object-centric search. • Only an object class that is predefined to provide the **Search** workspace in their object profile can be defined as base class. For an overview of the object classes for which an object-centric full-text search can be configured via the XML object ***SearchManager***, see *Overview of Configurable Features for Object Classes* in the reference manual *Configuring Alfabet with Alfabet Expand - Appendix*.
`Profiles`	Enter the user profiles that have access permissions to the search group. If no value is specified for the XML attribute `Profiles`, then all configured user profiles will have access permissions to the search group.
ClassEntry	A definition for the XML element ***ClassEntry*** should be created for the object class that is to be found by the Alfabet query defined for the object-centric search.

XML Element (bold) / XML Attribute	Explanation
ClassName	Enter the name of the object class associated with the base class that is to be queried. **EXAMPLE**: To search for applications in an application group, enter ApplicationGroup for the BaseClass attribute and Application for the XML attribute ClassName. The **Full-Text** tab will be automatically added to the standard object selector implemented for the object class specified in the ClassName attribute. If the **Full-Text** tab is required for a custom selector, additional configuration is required. For more information, see the section Configuring a Custom Selector for Search Functionalities.
ExportProps	Enter a comma-separated list of object class properties to define all object class properties of the object class to be indexed. Each object class property must be defined as: ObjectClassName.PropertyName The XML attribute ExportProps must include all object class properties defined in the XML attribute ShowProps and XML attribute ImageProps. The export properties are the object class properties written into the full-text search index file. The index file will only contain values for a language version if a translation exists in the Alfabet database. That means that the index only contains a value if the object class property is configured to be translatable and a translation is available for the current object. If full-text search shall be conducted in multiple languages, you should make sure that all object class properties that shall be included into the search are translatable and translations are provided. Please note that if the subset of object class properties defined both in the XML attributes ExportProps and ImageProps is not translated, the information displayed about the object in the headline of the record-by-record view as well as in the data set view will fall back to the primary language to ensure that the user can identify the object. Nevertheless, these object class properties are excluded from search.
ImageProps	Enter a comma-separated list of object class properties to create a concatenation that serves as the title line for each search result. The sequence of the object class properties listed in the XML attribute ImageProps determines the sequence displayed in the concatenated title. Each object class property must be defined as: ObjectClassName.PropertyName

XML Element (bold) / XML Attribute	Explanation
	The object class properties defined in the XML attribute `ImageProps` are read from the Alfabet database when the index is created. Results of a full text search can be displayed either record-by-record or as a data set. In the record-by-record view, the title of each record is the name of the object class defined with the attribute `ClassName` and the concatenation of the `ImageProps`. Object class properties defined in the `ExportProps` are listed as additional information if their value matches the search or if they are defined as `ShowProps`. **Application: BLOOMBERG 6.6.3** **Description** Application providing **marketdata** In the data set, the name of the object class defined with the attribute `ClassName` and the concatenation of the `ImageProps` are displayed in two different columns **Class** and **Object**. No other information is provided. Because the title line should be brief, the object class property `Description` should not be included in the XML attribute `ImageProps`.
`ShowProps`	Enter a comma-separated list of object class properties to be displayed in the search results for the objects found by the search. Each object class property must be defined as: `ObjectClassName.PropertyName` Please keep the following in mind: • The results will display matches for any of the object class properties defined in the XML attribute `ExportProps`. For example, if `Application.Description` is defined in the XML attribute `ExportProps` and the search term is found in an application's `Description` property, then the description will be displayed in the results with the matching words highlighted, even if `Application.Description` is not defined in the XML attribute `ShowProps`. • Any object class properties defined in the XML attribute `ImageProps` should not be redefined again in the XML attribute `ShowProps` since the object class properties defined in the XML attribute `ImageProps` will already be displayed as title line. • The object class properties defined in the XML attribute `ShowProps` are read from the Alfabet database when the index is created. The object

XML Element (bold) / XML Attribute	Explanation
	class properties are visualized in the results displayed record-by-record only.
`Export-Reference`	If you want the navigation functionality of the full text search not to open the object that was found by the search, but an object referenced by the found object, enter the object class property that determines which referenced object should be the target of the navigation. The reference must be established via an object class property of the type `Reference` of the object class defined with the XML attribute `ClassName`. Please note that the object class name displayed in the search results both in the record-by-record view and the data set will display the name of the object class that is the target of the navigation, although all information that is displayed informs about the object class that is searched.  If the search group is defined with the XML attribute `ClassName` set to `ICTObject` and the XML attribute `ExportReference` is defined as `ICTObject.Owner`, the search criteria will be applied to search for the ICT object, but the object view of the organization that is the owner of the ICT object will be opened if the user navigates from the search result to the underlying object. If the ICT object has no owner organization, then the ICT object itself will be the navigation target.
Query	A search group may contain multiple queries.
`Name`	Enter a name for the Alfabet query that shall be implemented in the object-centric search.
`ClassName`	Enter the name of the object class defined in the XML element ***ClassEntry***.  The **Full-Text** tab will be automatically added to the standard object selector implemented for the object class specified in the XML attribute `ClassName`.
`Query`	Enter the Alfabet query to search for the objects that the index should be generated for (via the object class properties defined in the XML attribute `ExportProps` of the XML element ***ClassEntry***). The Alfabet Query must match the following rules: • The `FIND` class must be the class defined with the XML attribute `ClassName`.

XML Element (bold) / XML Attribute	Explanation
	• A WHERE condition must be defined that specifies the relation with the current object of the base class defined with the XML attribute `BaseClass` of the XML element `SearchGroup`. The Alfabet query language parameter BASE can be used in the WHERE clause. At runtime, it will be substituted with the REFSTR of the current base object. • Show Properties shall not be defined. For example to search for applications in application groups, the query can be defined as: `ALFABET_QUERY_500 FIND Application WHERE Application.ApplicationGroups CONTAINSOR:BASE` For more information about defining an Alfabet query, see the chapter Defining Queries. Please note that only queries written in the Alfabet query language may be used in the XML object ***SearchManager***. Queries written in native SQL are not supported.

4) In the toolbar, click the **Save** button to save the XML definition.

Configuring a Global Search Group

A global search allows users to enter search terms for any objects defined via the global search groups that are configured in the XML object ***SearchManager***. This search is executed by means of the *Full-Text Search Functionality* (`GlobalFullTextSearch`) in the **Search** module.

To edit the XML object ***SearchManager*** for a global search:

1) Go to the **Presentation** tab and expand the **XML Objects** folder. You will see all XML objects that can be edited.
2) Right-click the XML object ***SearchManager*** and select **Edit XML**. The XML editor is displayed in the center pane. For general information about editing XML objects in Alfabet Expand, see Working with XML Objects.
3) Enter an XML element `SearchGroup` with the required child XML elements and XML attributes as child XML element of the root XML element `SearchManager` and define the XML attributes as needed. The table below displays the XML attributes that can be edited for the XML object ***SearchManager***:

The following example displays a code for a globally-defined search group searching within all applications in an application group:

```
<SearchGroup Name="Organizations and Business Processes"
Profiles="Viewer">
   <Query Name="Organization" ClassName="OrgaUnit"
   ShowProps="Name" ExportProps="Name,Description"
   ImageProps="Name"/>
   <Query Name="Business Process" ClassName="BusinessProcess"
   ShowProps="LevelID,Name"
   ExportProps="LevelID,Name,Description"
   ImageProps="LevelID,Name"/>
</SearchGroup>
```

XML Element (bold) / XML Attribute	Explanation
SearchGroup	
`Name`	Enter text that defines the name of the search group. This is the name that users will see when they select the search group in order to execute a search. The `Name` attribute also defines the name of the file containing the search index.
`Profiles`	Enter the user profiles that have access permissions to the search group. If no value is specified for the XML attribute `Profiles` then all configured user profiles will have access permissions to the search group.
Query	You should create an XML element ***Query*** for each object class that should be included in the XML element ***SearchGroup***.
`Name`	Enter a unique name for the query.
`ClassName`	Enter the name of the object class to be queried. The **Full-Text** tab will be automatically added to the standard object selector implemented for the object class specified in the XML attribute `ClassName`.
`ExportProps`	Enter a comma-separated list of object class property names to define all object class properties of the object class to be indexed. The XML attribute `ExportProps` must include all object class properties defined in the XML attribute `ShowProps` and XML attribute `ImageProps`.

XML Element (bold) / XML Attribute	Explanation
	 The export properties are the object class properties written into the full-text search index file. The index file will only contain values for a language version if a translation exists in the Alfabet database. That means that the index only contains a value if the object class property is configured to be translatable and a translation is available for the current object. If full-text search shall be conducted in multiple languages, you should make sure that all object class properties that shall be included into the search are translatable and translations are provided. Please note that if the subset of object class properties defined both in the XML attributes `ExportProps` and `ImageProps` is not translated, the information displayed about the object in the headline of the record-by-record view as well as in the data set view will fall back to the primary language to ensure that the user can identify the object. Nevertheless, these object class properties are excluded from search.
`ImageProps`	Enter a comma-separated list of the names of the object class properties to be displayed in the search results for the objects found by the search. Please keep the following in mind: • The results will display matches for any of the object class properties defined in the XML attribute `ExportProps`. For example, if `Description` is defined in the XML attribute `ExportProps` and the search term is found in an application's `Description` property, then the description will be displayed in the results with the matching words highlighted, even if `Description` is not defined in the XML attribute `ShowProps`. • Any object class properties defined in the XML attribute `ImageProps` should not be redefined again in the XML attribute `ShowProps` since the object class properties defined in the XML attribute `ImageProps` will already be displayed as title line. • The object class properties defined in the XML attribute `ShowProps` are read from the Alfabet database when the index is created. The object class properties are visualized in the results displayed record-by-record only.
`ShowProps`	Enter a comma-separated list of names of object class properties to create a concatenation that serves as the title line for each search result. The sequence of the object class properties listed in the XML attribute `ImageProps` determines the sequence displayed in the concatenated title. The object class properties defined in the XML attribute `ImageProps` are read from the Alfabet database when the index is created.

XML Element (bold) / XML Attribute	Explanation
	Results of a full text search can be displayed either record-by-record or as a data set. In the record-by-record view, the title of each record is the name of the object class defined with the attribute `ClassName` and the concatenation of the `ImageProps`. Object class properties defined in the `ExportProps` are listed as additional information if their value matches the search or if they are defined as `ShowProps`. **Application: BLOOMBERG 6.6.3** **Description** Application providing **marketdata** In the data set, the name of the object class defined with the attribute `ClassName` and the concatenation of the `ImageProps` are displayed in two different columns **Class** and **Object**. No other information is provided. Because the title line should be brief, the object class property `Description` should not be included in the XML attribute `ImageProps`.
`Query`	Optionally, you can define an Alfabet query with the XML attribute `Query` to search only for a sub-set for the objects of the object class that is defined with the XML attribute `ClassName`. • The `FIND` class must be the class defined with the XML attribute `ClassName`. • Show Properties shall not be defined. These are defined directly in the XML attribute `ShowProps`. For example to search only for applications that are currently active, define the following query: `ALFABET_QUERY_500 FIND Application WHERE Application.ObjectState = 'Active'` For more information about defining an Alfabet query, see the section Defining Queries. **NOTE**:The Alfabet query defined in the XML attribute `Query` should not include the definition of show properties. Please note that only queries written in the Alfabet query language may be used in the XML object ***SearchManager***. Queries written in native SQL are not supported.

4) In the toolbar, click the **Save**  button to save the XML definition.

Configuring Faceted Semantic Search for Information in Configured Reports

Users can search for content in configured reports in the **Faceted Semantic Search** (`SRCH_FacetedSearch`) functionality. The user can enter a description of the information he/she is looking for in a search field to search for the information in configured reports. In addition to the phrase entered by the user, synonyms and related words are taken into account.

The question the user entered into the search field will provide results via two mechanisms:

- **Search within available configured reports**:

In addition to the **Caption**, **Description**, and **Business Problem Statement** attributes of a configured report, the search will also use the **Apply To** attribute and the information from the **Semantic Analysis** sub-node of the configured report to find relevant reports. Strings in the **Alias** attribute of object classes and object class properties are taken into account to identify object classes.

- **Ad-hoc generation of new configured reports**:

Simple tabular datasets providing the information will be generated on the fly and presented to the user in addition to the search results derived from searching available configured reports defined by your company. The generation of ad-hoc reports is limited to a sub-set of user entries and will currently only be generated if the user looks for objects of an object class or object class stereotype with

- a specific value for an object class property and the object class property is based on an enumeration
- a value for a specific indicator
- a specific role assigned to a specific user

There are two ways users can access the **Faceted AlfaBot Semantic Search** functionality:

- The **Faceted Semantic Search** (`SRCH_FacetedSearch`) functionality can be made available via the user profile configuration. The user can access the functionality for example via a menu or a link in the guide page or guide view.

   For information about providing access to a functionality via the user profile configuration, see Making Functionalities Accessible to a User Profile.

- Users can access the view via the `Analyze` intent of the AlfaBot. The AlfaBot is available to the users via the slide-in toolbar.

The **Faceted Semantic Search** functionality is only available if the AlfaBot is activated and the `Analyze` intent of the AlfaBot is active. For information about activating the AlfaBot, see Implementing the AlfaBot for Navigation via a Full-Text Command in the chapter Configuring Alfabet Functionalities Implemented in the Solution Environment.

In addition, the functionality requires activation and regular maintenance. The complete procedure for configuration and maintenance is described in the scope of the AlfaBot functionality in the section Define AlfaBot Search Capabilities for Configured Reports.

Configuring the Glossary Search Functionality

Alfabet provides a **Glossary** functionality in which one or more enterprise-specific glossaries can be created with glossary entries (glossary term and description) and then searched in the **Full-Text Search** functionality. Before a defined glossary can be implemented however, a search group must be configure for the class Glossary in the XML object ***SearchManager***.

- The glossary and glossary items must be created in the *Glossary Functionality* (`Glossary`) in the **Search** module in Alfabet and a user or solution administrator must create and update the index for the glossary after the search group has been defined. For more information about these aspects of implementing the ***Glossary*** functionality, see the section *Searching an Enterprise Glossary via the Full-Text Search Capability* in the reference manual *Getting Started with Alfabet*.
- For more information about activating the *Full-Text Search Functionality* (`GlobalFullTextSearch`) which is necessary in order to create an index for the search group, see the section Specifying General Parameters for Index Creation.
- In order to create an index and execute a search, a path must be defined by your system administrator describing where the search indexes needed for the full-text search functionalities are found. For more information, see the section *Basic Configuration of the Alfabet Components* in the chapter *Installation* in the reference manual *System Administration* or contact your system administration.
- Alfabet also provides a domain glossary functionality. A domain glossary can be created in order to define and search for domain-specific terminology for objects assigned to a selected domain. The implementation of the domain glossary defined in the *Domain Glossary Page View* (`DOM_Glossary`) in Alfabet. If a domain glossary is defined, a search group must be configured in order to search the glossary. The configuration of the search capabilities for the domain glossary are addressed separately in the section Configuring the Domain Glossary Capability in the chapter Configuring Domain Models and Domain Planning.

Please note that only queries written in the Alfabet query language may be used in the XML object ***SearchManager***. Queries written in native SQL are not supported.

To edit the XML object ***SearchManager*** in order to create a search group for the Glossary functionality:

1) Go to the **Presentation** tab and expand the **XML Objects** folder. You will see all XML objects that can be edited.
2) Right-click the XML object ***SearchManager*** and select **Edit XML**. The XML editor is displayed in the center pane. For general information about editing XML objects in Alfabet Expand, see Working with XML Objects.

The following displays an example definition of a search group for the **Glossary** functionality in the XML object ***SearchManager***.

```
<SearchGroup Name="Glossary Search" BaseClass="Glossary"
Type="Object" >

   <ClassEntry ClassName="GlossaryItem"
   ShowProps="GlossaryItem.Alias, GlossaryItem.Description"
```

```
ExportProps="GlossaryItem.Alias,GlossaryItem.Description"
ImageProps="GlossaryItem.Alias" />

<Query Name="All Glossary Items" ClassName="GlossaryItem"
ImageProps="GlossaryItem.Alias" Query="ALFABET_QUERY_500
FIND GlossaryItem WHERE GlossaryItem.Glossary
CONTAINSOR:BASE" />

</SearchGroup>
```

3) Define the remaining attributes, as needed. The table below provides general information about the attributes that can be edited for the XML object ***SearchManager***:

XML Element (bold) / XML Attribute	Explanation
SearchGroup	
`Name`	Enter a name of the search group (for example, "`Glossary`"). This is the name that users will see when they select the search group in order to execute a search.
`Type`	Enter "`Object`" to define the object-centric search.
`BaseClass`	Enter "`Glossary` " as the base class for the search.
`ImageProps`	**NOTE**: Because the title line should be brief, the object class property `Description` should not be included in the XML attribute `ImageProps`. The attribute specifies the object class properties to display in the title line of the search results. Enter a comma-separated list of object class properties to create a concatenation that serves as the title line for each search result. The sequence of the object class properties listed in the XML attribute `ImageProps` determines the sequence displayed in the concatenated title. The object class properties defined in the XML attribute `ImageProps` are read from the Alfabet database when the index is created. The concatenation is displayed in the results displayed via a data set as well as record-by-record.
ClassEntry	The XML element ***ClassEntry*** should be created for the object class that is to be found by the Alfabet query defined for the object-centric search.
`ClassName`	Enter "`GlossaryItem`".
`ShowProps`	This attribute specifies the defined object class properties for all objects found by the search. Enter a comma-separated list of object class properties to be displayed in the search results for the objects found by the search. For

XML Element (bold) / XML Attribute	Explanation
	example, you may want `Application.Version` or `Application.ShortName` to be displayed for all applications displayed in the results. The object class properties are visualized in the results displayed via a data set as well as record-by-record. Please keep the following in mind. • Any object class properties defined in the XML attribute `ImageProps` should not be redefined again in the XML attribute `ShowProps` since the object class properties defined in the XML attribute `ImageProps` will already be displayed. • The results will display matches for any of the object class properties defined in the XML attribute `ExportProps`. For example, if `Application.Description` is defined in the `ExportProps` and the search term is found in an application's description, then the description will be displayed in the results with the matching words highlighted, even if `Application.Description` is not defined in the XML attribute `ShowProps`.
`ExportProps`	The attribute specifies the object class properties to be indexed. Enter a comma-separated list of object class properties to define all object class properties of the object class to be indexed. The XML attribute `ExportProps` must include all object class properties defined in the `ShowProps` and XML attribute `ImageProps`.
Query	
`Name`	Enter the name of the Alfabet query that shall be implemented in the object-centric search.
`ClassName`	Enter "`GlossaryItem`".
`Query`	Enter the Alfabet query to search for the objects that the index should be generated for (via the object class properties defined in the XML attribute `ExportProps`). For more information about defining an Alfabet query, see the section Defining Queries. Please note that only queries written in the Alfabet query language may be used in the XML object ***SearchManager***. Queries written in native SQL are not supported.

4) In the toolbar, click the **Save** button to save the XML definition.

Configuring the Wildcard for Standard and Custom Search Functionalities

The XML object ***SearchManager*** allows you to configure whether a wildcard <*> should be automatically implemented when a user enters search criteria for a relevant class in the following Alfabet search functionalities:

- *Simple Search Functionality* (`GenericSearch`, `Simple_Search`)
- explorer search capability
- standard and configured object selectors available in standard page views
- Any Edit Search interface controls implemented in custom editors, custom selectors, standard page views, or configured reports.

The wildcard capability is not implemented in the *Full-Text Search Functionality* (`Global-FullTextSearch`) nor in filters (such as **Name** fields) in standard Alfabet page views.

The implementation of the automatic wildcard ensures that for any search criteria entered in the search criteria field of a search functionality, the term will be wrapped automatically by the wildcard when the search is triggered. Thus, if a user enters Trade in the search pattern, the search criteria *Trade* will be applied and objects with Trade in any of the object class properties defined for the search will be returned in the result list.

If the `AutoWildCard` attribute is set to "`true`", a message will be displayed in the *Simple Search Functionality* (`GenericSearch`, `Simple_Search`) and selectors for standard page views stating "A wildcard is not required for the search."

Please note that this automatic text will not be displayed in configured reports. In the case of configured reports:

- If the search function is configured to set wildcards automatically via the XML object ***SearchManager***, you can configure individual filter fields in a configured report or custom selector to be excluded from the automatic wildcard setting. Depending on the underlying query, the setting of wildcards might be undesirable (for example, when comparing the entry in the filter field with a string using an equal to operator). For more information about configuring the wildcard for filter fields in configured reports, see the section Automatically Adding Wildcards to Search Strings in the chapter Defining Queries as well as the chapter Configuring Reports.
- A static text can be configured for the selector field informing the user that a wildcard is not required for the search. For more information about the configuration of search fields in configured reports, see the section Defining Filters for Configured Reports and Selectors in the chapter Defining Queries as well as the chapter Configuring Reports.

To configure the implementation of the wildcard via the XML object ***SearchManager***:

1) Go to the **Presentation** tab and expand the **XML Objects** folder. You will see all XML objects that can be edited.
2) Right-click the XML object ***SearchManager*** and select **Edit XML**. The XML editor is displayed in the center pane. For general information about editing XML objects in Alfabet Expand, see the section Working with XML Objects.

3) In the XML object ***SearchManager***, enter "`true`" in the XML attribute `AutoWildCard` of the root XML object `SearchManager` to implement the automatic wildcard.

```
<SearchManager HighlightCount="20000" AutoWildCard="true">
    ...
</SearchManager>
```

If "`false`" is defined, the wildcard will not be implemented in the search functionalities available in the *Simple Search Functionalities* (`GenericSearch`, `Simple_Search`), the explorer search capability, as well for the standard and configured object selectors and quick selectors available in standard page views as well as any Edit Search interface controls implemented in custom editors, custom selectors, or configured reports configured in Alfabet. In this case, the user must manually enter the wildcard.

4) In the toolbar, click the **Save**  button to save the XML definition.

Chapter 8: Configuring Wizards

Software AG provides a number of standard private wizards for commodity classes in which a large number of objects are typically documented as well as the means to configure custom wizards that allow users to capture a specified set of data for an object class or object class stereotype.

A wizard is an assistant that consists of a configured set of standard editors, custom editors, standard views, and configured reports. The wizard will typically guide a user through a linear multi-step process to capture data for an object that the user has access permissions to.

Standard data capture wizards are available for commodity classes in which a large number of objects are typically documented. An unlimited number of custom wizards may be configured for an object class in order to allow different users working in different contexts to capture the object data that they are responsible for. However, only one wizard may be available for an object class per user profile.

Software AG also provides a workflow that allows multiple users to collaborate in the context of a configured process in which roles and responsibilities are distributed. For more information about configuring a task-oriented process in which multiple users should be involved, see the chapter Configuring Workflows.

Private wizards provided by Software AG can be implemented in your enterprise as-is or copied and used as a basis for configuring your own custom wizards. Click the + symbol next to the private wizard to display the predefined wizard steps. To access a private wizard, go to the **Presentations** tab and expand the **Wizards** node. The following private wizards are available:

- `APP_Wizard` (for the object class `Application`)
- `BSPR_Wizard` (for the object class `Business Appraisal`)
- `COM_Wizard` (for the object class `Component`)
- `CNRT_Wizard` (for the object class `Contract`)
- `DEM_Wizard` (for the object class `Demand`)
- `DOM_Wizard` (for the object class `Domain`)
- `DVC_Wizard` (for the object class `Device`)
- `ICTO_Wizard` (for the object class `ICT Object`)
- `ITMPM_Wizard` (for the object class `Master Plan Map`)
- `PRF_Wizard` (for the object class `Peripheral`)
- `RISKOBJ_Wizard` (for the object class `Risk Object`)
- `SPL_Wizard` (for the object class `Standard Platform`)
- `User_Wizard` (for the object class `User`)

Custom wizards may also be configured by your enterprise for most object classes. Customized wizards are used primarily in three different contexts in Alfabet:

- Wizards are typically used to create new objects and define existing objects. You can configure the wizard to be used in place of an editor so that the wizard opens instead of the editor in object

profiles, views, etc. For information about additional configuration requirements to implement a wizard for data capture and definition in page views, see Implementing a Wizard Instead of an Editor to Capture and Define Data.

- A wizard may also be used in the context of the workflow capability to capture or edit objects targeted by a workflow step. For information about additional configuration requirements to implement a wizard in workflows, see Implementing a Wizard in the Workflow Capability. For more information about the configuration of workflows, see the chapter Configuring Workflows.

The general process of creating a wizard and configuring wizard steps is the same for all wizards, regardless of whether the wizard will be implemented in the context of creating or editing an object or in a workflow.

For an overview of the object classes for which custom wizards can be configured, see the chapter *Overview of Configurable Features for Object Classes* in the reference manual *Configuring Alfabet with Alfabet Expand - Appendix*. Please note the special considerations regarding the specification of wizards for specific object classes or their object class stereotypes:

- **Interface System**: If a wizard is implemented to capture data for objects of the class **Interface System**, the editor `ISystem_Editor` must be specified for the first wizard step.
- **Business Support**: If you are implementing the **Business Support** editor in the wizard step, you should implement the `BSP_Editor`. All other business support editors (for example, `BSP_APP_PROC_ORG_Editor`) are used in the context of views and may not be configured for a wizard step.
- **Tactical Business Support**: If a tactical business support is to be created, the relevant wizard(s) should be implemented in the context of a master plan map. The editor to implement is determined by the relevant combination of business support provider, X-dimension object, and Y-dimension object to be defined for the tactical business support
- **Strategic Business Support**: If a strategic business support is to be created, the wizard should be implemented in the context of an IT strategy map. The editor to implement is determined by the relevant combination of business support provider, X-dimension object, and Y-dimension object to be defined for the strategic business support
- **Object class stereotypes**: To create a custom wizard for an object class stereotype, you must first create the wizard for the base class and then assign the wizard to the relevant class setting configured for the object class stereotype. For more information about configuring class settings, see the section Configuring Class Settings for Object Classes and Object Class Stereotypes. For example:
  - **Project Stereotype**: If a wizard is configured for a project stereotype, you must set the **Class Name** attribute to `Project`. The wizard must then be selected in the **Wizard** attribute for the class setting for the relevant project stereotype. For specific information about configuring a wizard for the Project Management functionality, see the section Configuring Wizards for Project Stereotypes.
  - **Domain Stereotype**: If a wizard is configured for a domain stereotype, you must set the **Class Name** attribute to `Domain`. The wizard must then be selected in the **Wizard** attribute for the class setting for the relevant domain stereotype.

The following information is available:

- Implementing a Wizard in the Workflow Capability
- Testing the Wizard in the Alfabet User Interface

Understanding How Wizards Work

Various interface elements are preconfigured by Software AG whereas other interface elements can be customized. For example, each wizard step can be configured to display information about the task at hand that will be displayed in the header of the respective wizard step.

Each wizard step typically constitutes one screen with preconfigured buttons that control the wizard process. The following information explains the general behavior that is triggered by the buttons as well as additional information that will help you understand possible consequences if post-conditions are configured for a wizard step. The **Next** button and **Exit** button are preconfigured by Software AG and will be displayed per default. The **Back** button and **Go to Step** button are optional and must be configured to be displayed in the wizard.

A wizard step may have pre-conditions or post-conditions defined in order to validate whether data has been entered for a wizard step. Thus, depending on the configuration, it may be mandatory or desired that specific data is completed for a wizard step. Please note that any post-conditions that have been configured for that wizard step will be executed AFTER the data has been saved in the wizard step. This is of particular relevance for post-conditions defined for editors. The first database transaction will attempt to save the data that has been defined in the wizard step. However, this may fail if mandatory or uniqueness conditions are violated. Such errors must first be resolved before the system can check the post-conditions. A customized error message will be displayed providing the user with information about the data that is required.

Please note the following issues regarding the behavior of the wizard:

- **Mandatory Fields**: Mandatory fields in an editor must be completed in order to save the data and proceed to the next wizard step. If a wizard cannot advance to the next wizard step because mandatory properties have not been defined, an error message will list the mandatory properties that must be defined in order for the wizard to proceed to the next step.
- **NextButton**: The **Next** button allows the user to save the data entered during the wizard step and proceed to the next wizard step. If the automated translation is supported for the object class, the automated data translation capability will be triggered when the **Next** button is clicked. Please note the following:

- If a pre-condition is defined for the last wizard step and the pre-condition is not fulfilled, then the wizard will close when the user clicks the **Next** button in the wizard step before the last wizard step.
- If the post-condition specifies that the data is required (mandatory), a customized error message will be displayed when the user clicks the **Next** button. The user will not be able to advance to the next wizard step until the required data is provided. If the post-condition specifies that the data is desired (optional), a customized information message will be displayed if the data is missing. However, the user will not be prevented from advancing to the next wizard step.
- If multiple post-conditions have been configured for a wizard step, only one error message at a time will be displayed when the user attempts to save the data by clicking the **Next** button. Once the user corrects the first violation and attempts to advance to the next wizard step, a customized error message for the next violation will be displayed. This process will continue until all violations have been

corrected. The user will only be able to advance to the next wizard step when no violations have been found via the data entry prompts.

- **ExitButton**: The **Exit** button allows the user to save the data entered during the wizard step and close the wizard. The next time the user opens the wizard for the selected object, the wizard will automatically open to the wizard step that the user most recently exited. Likewise, if the user session is terminated while the wizard is open, the wizard will open to the wizard step that was last open when the session was terminated. Please note the following:

- If a user clicks the **Exit** button during the creation of a new object on a first wizard step, the new object will be deleted!

- The caption displayed on the **Exit** button is configurable and therefore, a different caption (such as **Save**) may be displayed on the button.

- **BackButton**: A **Back** button may be displayed that allows the user to return to the preceding wizard step. By clicking the **Back** button, the user saves the data entered during the wizard step and returns to the preceding wizard step. The **Back** button will be greyed out and inactive on the first step of a wizard.

- **Go to StepButton**: A **Go to Step** drop-down box may be displayed that will allow users to select another wizard step in the workflow. This enables the user to leave the linear sequence of steps and return to a subsequent or preceding wizard step in the wizard process. The **Go to Step** field is only available when an existing object is being edited. It is not available when a new object is being created. If the wizard is configured to include the **Go to Step** field, users will be able to traverse to any subsequent or proceeding wizard step. If post-conditions are configured for the wizard step that the user is leaving, the post-conditions will be executed and, if necessary, required data must be entered in order to leave the current wizard step. Please be aware, however, that post-conditions for any intermediary steps between the wizard step the user is leaving and the wizard step the user is going to will not be checked. For example, if a user goes from Wizard Step 2 to Wizard Step 4, the post-conditions for Wizard Step 2 will be checked and must be fulfilled, but post-conditions for Wizard Step 3 will not be triggered and must not be fulfilled in order to go to Wizard Step 4.

- **Close Button**: The wizard can be closed by clicking the **X** button in the upper right corner of the wizard. All data that has been saved via the **Next** button will be saved to the Alfabet database.

- **Online Help**: The standard and custom online help will be available to users working in the wizard:

- For wizard steps of the type `Editor`, users can point to a field caption to display a tooltip providing information about a standard Alfabet property or custom object class property (if the **Hint** attribute has been defined for the custom property field).

- For wizards steps of the type `View`, a link to the context-sensitive Help will be available.

- For wizard steps of the type `Report`, a link to your enterprise's custom Help may be available if custom Help has been configured. For more information about configuring a custom report, see the section Assigning Custom Help and Automated Help Assistants to Configured Reports.

- HTML text may be configured for the header to provide additional instructional content directly in a wizard step. For more information, see the section Configuring the Header Text of a Wizard Step.

Conceptualizing the Custom Wizard

The following displays the steps relevant to configuring a custom wizard.

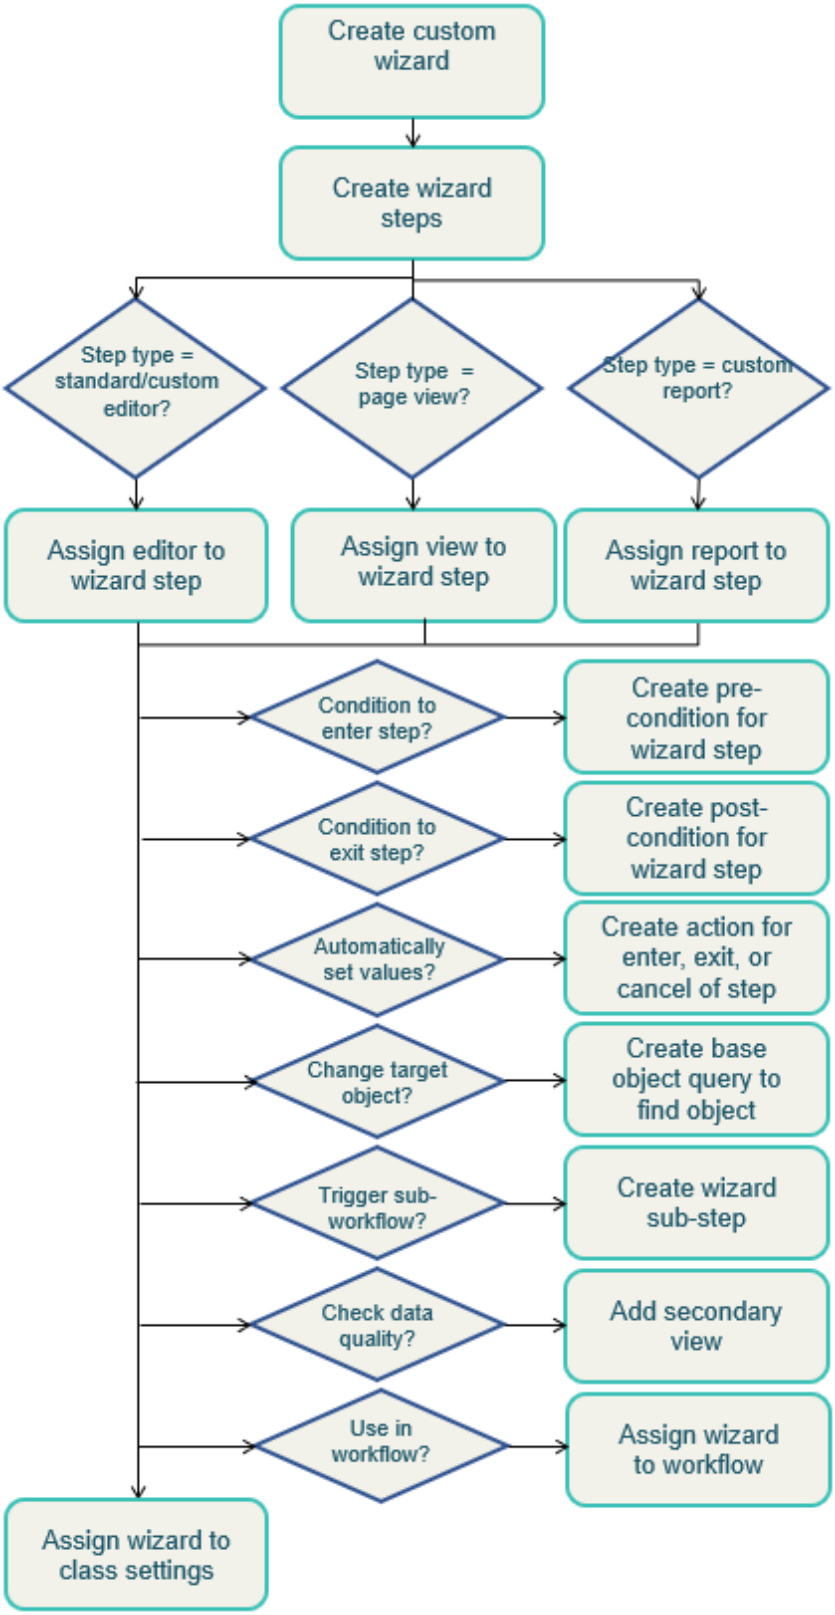


FIGURE: Steps to configure a custom wizard

Please keep the following in mind regarding the general configuration of a wizard:

- You can create multiple wizards for an object class. This allows you to create wizards for users with different roles in the enterprise or different levels of maturity working with Alfabet. Each wizard defined for an object class should be assigned to a different class setting. For an overview of the object classes for which custom wizards can be configured, see the chapter *Overview of Configurable Features for Object Classes* in the reference manual *Configuring Alfabet with Alfabet Expand - Appendix*.
- If object class stereotypes are configured for an object class, you can specify a different wizard for each object class stereotype via its class setting. This allows you, for example, to assign a wizard as the mechanism for data capture for one object class stereotype and assign a standard or custom editor for data capture in another object class stereotype.
- Only one wizard can be assigned to a class setting. Thus, only one wizard is allowed per object class (or object class stereotype) per user profile
- A custom wizard can be further refined for the user profile(s) in which it is implemented. In this case, you can hide object class property in the editors, page views, and configured reports embedded in the wizard as well as hide functionalities available in the toolbars in page views and configured reports.

The configuration of a custom wizard will apply to all instances of the custom wizard in Alfabet. For example, if you hide object class properties or functionalities in a custom wizard, the object class properties or functionalities will be hidden for all instances of the custom wizard. In other words, a selected wizard cannot be differently configured in the context of different object class stereotypes. The wizard configuration will apply to each object class stereotype that the custom wizard is assigned to. If different configurations are required for a custom wizard, it is recommended that you create a new wizard via the copy functionality and modify the new wizard as needed. Once the wizard is configured, it can be selected in the **Wizard** attribute for the class setting that you create for the object class stereotype.

The wizard designer should consider the following issues when defining a wizard

- Which object class is the wizard process targeting?
- Will the user need to define data for objects in other object classes as well? If object classes other than the base class are required, a query must be defined for the relevant wizard step to find the new target object.
- What task is to be completed in the wizard and which user profile(s) will be accessing the wizard? This information will help you to determine which wizard steps should be included in the wizard.

Please note that if a new object is to be created in the wizard, the first wizard step must implement an editor. Therefore, for a wizard in which a new object is to be created, the **Step Type** attribute of the first wizard step must be set to `Editor`.

- Does a standard or custom wizard already exist for the relevant object class that can be copied and used as a template for the new wizard, or do you need to create a new wizard from scratch?
- Which editors, views, and reports are required by the user to complete the tasks? A wizard step may consist of any of the following:

- a standard editor
- a custom editor
- a standard Alfabet page view
- a tabular query-based configured report
- a query-based configured report displaying graphics (such as a tree-map or layered diagram report)

- If a custom editor is implemented for a wizard step:

- Do you want the user to complete all editor tabs in thee editor at once or do you want to split the data collection in each tab in the editor across several wizard steps. By configuring each tabbed page in the custom editor as a separate wizard step, the user can enter data in one tab and complete a wizard step and therefore close the editor without losing data.
- Do you want to hide properties in the custom editor? If this is the case, you can customize the custom editor in the context of the wizard to show only properties relevant for the current wizard step.

- Do you want the user to be able to go to any step in the wizard at any time or should the user be required to navigate through the configured sequence of steps? By including the **Go to Step** field, a user will be able to navigate to any wizard step.
- Do you want to specify a subordinate wizard step for a wizard step? Should the subordinate wizard step also have subordinate wizard steps? By creating a branch of subordinate wizard steps, you can direct the user to complete a set of tasks if a pre-condition is fulfilled for the top-level subordinate wizard step in the hierarchy. Once the branch of subordinate wizard steps is complete, the user would continue with the next wizard step in the wizard process. If the pre-condition is not fulfilled for the subordinate wizard step, the wizard will ignore the branch of subordinate wizard steps.
- Do you want to specify pre-conditions for a wizard step? By defining one or more pre-conditions via queries, you can stipulate the criteria that must be fulfilled in order to enter a wizard step or subordinate wizard step.
- Do you want to specify post-conditions for a wizard step? By defining one or more post-conditions via queries, you can determine the object class properties or references that must be defined before a wizard step an be completed. You can also define the messages prompting the user to provide the relevant data.
- Do you want an action when a wizard step is entered, exited, or cancelled? Actions such as the update of properties, calculation of indicators, or triggering of events can be configured. For example an event can be triggered as an alternative to batch jobs which may typically be initiated daily. In this case, a configured ADIF scheme will be triggered to process the data.
- Do you want to provide instructions on the wizard interface in order to guide users through the wizard process? If so, do you want to provide plain text in the header or do you want to implement HTML with the option of using hyperlinks to additional information that is relevant for the wizard step?
- Do you want to hide properties in an editor that is embedded in a wizard step?
- Do you want to implement specific custom selectors in an editor that is embedded in a wizard step?
- Do you want to disable specific functionalities such as create, copy, edit, navigate, etc. in views and reports embedded in a wizard step?

Creating a Wizard

Multiple wizards can be created for an object class. You can copy a private wizard to create a new custom wizard, create a new wizard from scratch, or copy an existing custom wizard to create a new custom wizard. The new wizard can be created for any permissible object class and configured as needed. For an overview of the object classes for which wizards can be implemented, see *Overview of Configurable Features for Object Classes* in the reference manual *Configuring Alfabet with Alfabet Expand - Appendix*.

Please note the following about the creation of wizards:

- A custom wizard can be assigned to one or more class settings that have been defined for an object class or its object class stereotypes.
- The configuration of a custom wizard will apply to all implementations of the custom wizard. Therefore, if you assign a custom wizard to a class setting for stereotype 1 but need a slight modification for stereotype 2, then you must create a new custom wizard for stereotype 2. This can be done by copying the original custom wizard to create a new custom wizard that can be modified for stereotype 2.
- To create a custom wizard for an object class stereotype, you must first create the wizard for the base class and then assign the wizard to the relevant class setting configured for the object class stereotype. For example, if a wizard is required for the domain stereotype Technological Domains, then you must create the wizard for the object class `Domain`. Once the wizard is configured, it can be selected in the **Wizard** attribute for the class setting that you create for the domain stereotype Technological Domains. For more information about configuring class settings, see the section Configuring Class Settings for Object Classes and Object Class Stereotypes.

To create a new wizard:

1) Go to the **Presentations** tab, navigate to the **Wizards** node and carry out one of the following procedures:

- To create a new wizard based on an existing wizard, right-click the private wizard  that you want to copy and select **New Wizard as Copy**. The entire wizard configuration including all wizard steps and their view definitions, post-conditions, pre-conditions, etc. will be copied to the new wizard. These can be modified or deleted, as needed
- To create a new wizard from scratch, right-click the **Wizards** folder and select **New Wizard**. In the **Select Class** editor that opens, select a valid object class for which you want to create the wizard and click **OK**. If you are creating a wizard that is to be implemented for an object class stereotype, you must select the base object class. For an overview of the object classes for which wizards can be implemented, see *Overview of Configurable Features for Object Classes* in the reference manual *Configuring Alfabet with Alfabet Expand - Appendix*.

2) The new custom wizard  is displayed below the **Wizards** node in the explorer. Click the new wizard to open its attribute window and define the following attributes, as needed:

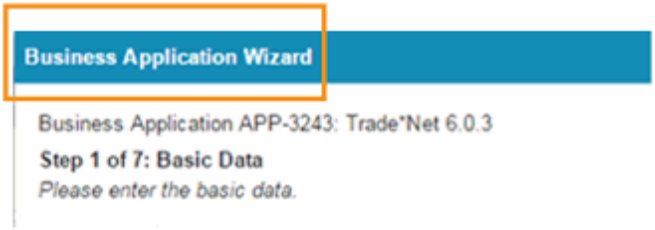
- **Class Name**: Displays the object class that you created the wizard for.
- **Name**: Enter a technical name for the wizard. This name is not displayed in the Alfabet user interface.

A validation mechanism checks for correct syntax when defining a technical name. The technical name of a configuration object may not begin with an empty space nor include any of the following special characters: **\ / * ? " > < | ':**

Furthermore, please note that names may not begin with an empty space nor include special characters. For a list of the special characters that are not allowed, see the section Defining Attributes for Configuration Objects in the chapter Getting Started with Alfabet Expand.

Furthermore, if the technical name of a configuration object is changed, the name will be correctly updated in other configuration objects referencing the changed object during design time. Please note that the name of a changed configuration object will not be updated in guide pages nor if the guide pages reference a configuration object listed in the **Show Usage** functionality. If you plan to change the name of a configuration object, the reference in the guide page should be changed prior to changing the configuration object name.

- **Caption**: Enter the caption that should be displayed in the header bar of the wizard in the Alfabet interface.



The text defined in the **Caption** attribute of a wizard can be translated to the other languages of your Alfabet interface. For more information, see the section Modifying, Translating and Managing the Vocabularies in the chapter Localization and Multi-Language Support for the Alfabet Interface

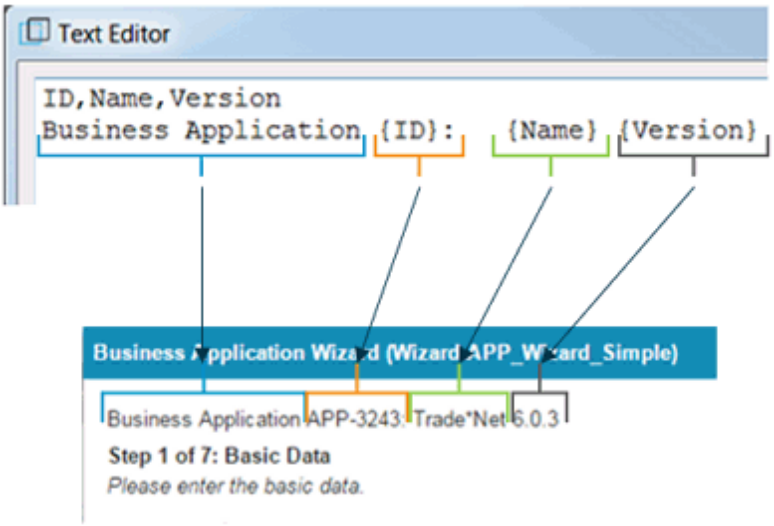
- **Group**: If the wizard should be stored in a wizard folder below the Wizards node, select an existing wizard folder in the drop-down list or enter a new folder name to create a new wizard folder. The wizard will be moved to the wizard folder.
- **Check Rights**: Enter `True` if access permissions should be checked for the object managed by the wizard when a user attempts to open the wizard. Enter `False` if the wizard should not check the access permissions for the objects managed by the wizard.

For example, it may be useful to set the **Check Rights** attribute to `False` in the context of a configured report which already verifies the access permissions and only shows objects the current user has Read/Write permissions for. Setting this attribute to `False` can improve performance.

- **Show Comments Panel**: Select `True` if you want to display a header that provides information about the object being edited as well as any instructions configured for the header for each wizard step. If you select `False`, no information specified for the Format String will be displayed about the object being processed and no instructional text will be available for the wizard step. Furthermore, no context-sensitive Help link will be available for views processed a wizard step.
- **Format String**: If you have selected `True` in the **Show Comments Panel** attribute, then you can specify a format string to determine the information to display in the header panel of the wizard steps. This attribute allows you to specify the information displayed in the header panel about the object targeted by the wizard step. For example, the identification number, name, and version of the object could be displayed for all wizard steps. The following example shows the configuration of the format string in the text editor and its display in the Alfabet interface:

To define the **Format String** attribute, click the **Browse** button to define the information to display about the object in the header of the wizard. Define the format string as follows:

- On the first line of the text editor, enter a comma-separated list of the standard or custom object class properties that shall be displayed. For example: `ID,Name,Version`
- On the second line of the text editor, define the content that should be displayed in the header of the wizard. This could include a combination of text, punctuation, and attributes. All attributes in the second line must be enclosed in brackets and spelled correctly. For example: <Text> {`ID`}: {`Name`} {`Version`}).



Alternatively, HTML text can be configured for the header text for one or more wizard steps. This allows you to format the text and provide more complex instructional information for a wizard step. In this case, the definition of HTML header text for a wizard step will override the specification in the **Format String** attribute of the wizard. For more information about the definition of instructional text to display in the header of the wizard step, see the section Configuring the Header Text of a Wizard Step.

- **Has Back Button**: Select `True` if the **Back** button should be displayed in the wizard. The **Back** button allows the user to return to the preceding wizard step. By clicking the **Back** button, the user saves the data entered during the wizard step and returns to the preceding wizard step. The **Back** button will be greyed out and inactive on the first step of a wizard.
- **Exit Button Alias**: If necessary, change the default caption on the **EXIT** button. Enter a new caption in the cell (for example, SAVE).
- **Show Wizard Steps Combo-Box**: Select `True` if the **Go to Step** field should be displayed in the wizard. The **Go to Step** field allow users to select another wizard step in the wizard via a drop-down list. This enables the user to leave the linear sequence of steps and return to any subsequent or preceding wizard step in the wizard process. The **Go to Step** field is only available in a wizard step when an existing object is being edited. It is not available in the first wizard step when a new object is being created. For more information about the impact of post-conditions on the **Go to Step** field as well as the impact of the **Execute Post-Conditions on Back Moves** attribute, see the section Defining a Post-Condition for a Wizard Step.
- **Type**: This attribute is relevant if subordinate wizard steps shall be specified.

- Select `Tree` to number all subordinate wizard steps so that subordinate wizard step 1, subordinate wizard step 2, and subordinate wizard step 3 that are subordinate to wizard step 1 will be numbered step 1.1, 1.2, and 1.3 in the wizard header. Please note that if the **Show Wizard Steps Combo-Box** attribute is set to `True` for the wizard, then the subordinate wizard steps will be displayed in the **Go to Step** field.
- Select `Straight` to number all subordinate wizard steps so that all subordinate wizard step that are subordinate to wizard step 1 will all have the same number as their ascendant wizard step. In this case, subordinate wizard step 1, subordinate wizard step 2, and subordinate wizard step 3 would all be numbered 1 of 7 in the wizard header. Please note that if the **Show Wizard Steps Combo-Box** attribute is set to `False` for the wizard, then the subordinate wizard steps will not be displayed in the **Go to Step** field.
- **Height** and **Width**: If necessary, change the default height and weight of the wizard. The default height of 700 pixels and width of 800 pixels should not be decreased. Any value you enter below these minimums will be ignored. Wizards are displayed as modal windows and can be resized by users as needed.
- **Automated Assistant URL**: If custom help content should be available via the automated assistant capability, enter the URL or server variable that targets the content to display in the assistant. Please note that if an automated assistant is configured for views embedded in the wizard, the automated assistant will be displayed for those views. If no automated assistant is defined for the individual views, the automated assistant specified for the wizard will be displayed. For more information about additional requirements to implement the automated assistant capability, see the chapter Providing Custom Online Help to the User Community.

3) After the wizard has been created, click the **Save**  button to save the wizard.

Specifying Wizard Steps for a Custom Wizard

A wizard step is an editor, view, or report in a wizard. The wizard step constitutes one aspect of data entry or review that is required in the data collection process. A wizard step may be reused for multiple wizards for the same object class.

Each wizard step may have instructions configured that are displayed in the header of the wizard step. The current step that the user is currently processing vs. the total number of wizard steps are automatically generated and displayed in the header of the wizard step.

A wizard step may consist of any of the following:

An editor, view, or report can be reused in the configuration of multiple wizard steps in the same wizard, thus enabling the user to enter the data in multiple steps rather than having to complete the data entry process all at once. Furthermore, each wizard step can be configured so that only the relevant standard and custom object class properties are displayed for a wizard step.

A wizard step may have an unlimited number of subordinate wizard steps that can constitute a branch in the wizard process. Any wizard step or subordinate wizard steps may be controlled by pre-conditions that determine whether the wizard step should be entered or skipped. The pre-conditions are configured as Alfabet queries or SQL queries that determine the criteria that must be fulfilled in order to enter a specified step. Multiple post-conditions may be defined per wizard step in order to prompt users to provide data for specified standard or custom object class properties before proceeding to the next wizard step.

A pre-condition may NOT be configured for the first wizard step NOR for the final wizard step or subordinate wizard step. If you do so and the pre-condition is not fulfilled, an error will occur. In this case, for example, the wizard could stagnate and not advance to the next wizard step. If a pre-condition is required for the last logical step or subordinate wizard step in the wizard, it is recommended that you add another final concluding wizard step with no pre-condition and only static text defined (for example, with a message such as "You have completed the wizard").

The following information is available:

Creating a Wizard Step

You can create a new wizard step from scratch or copy a wizard step from another wizard. To do so, you must create an empty wizard step for the wizard you are defining, copy an existing wizard step (via right-click > **Copy**), and paste the wizard step on the empty wizard step (right-click > **Paste**). The entire wizard step definition is copied to the new wizard step and can be modified, as needed.

The initial creation of a wizard step includes the specification of the technical name as well as the caption and description for the wizard step. Please note that instead of creating a caption and description in plain text for a wizard step, you could alternatively configure formatted HTML text as described in the section Configuring the Header Text of a Wizard Step.

The **Caption** and **Description** attributes will be available in the vocabularies and can be translated. For more information about the translation capability, see the section Modifying, Translating and Managing the Vocabularies the chapter Localization and Multi-Language Support for the Alfabet Interface.

Once a wizard step has been created, you can specify the content of the wizard, any pre- or post-conditions that must be fulfilled for a wizard step, and any actions such as the update of properties, calculation of indicators, or triggering of events that shall be associated with a wizard step.

To define wizard steps for the selected wizard:

1) Go to the **Presentations** tab, expand to the **Wizards** node, right-click the custom wizard and select **New Wizard Step**. A wizard step labelled `View` is added to the wizard step.

2) Click the wizard step to activate the attribute window. Define the following attributes as needed:

- **Name**: Enter a technical name for the wizard step. This name is not displayed in the Alfabet interface.

  A validation mechanism checks for correct syntax when defining a technical name. The technical name of a configuration object may not begin with an empty space nor include any of the following special characters: **\ / * ? " > < | ':**

  Furthermore, please note that names may not begin with an empty space nor include special characters. For a list of the special characters that are not allowed, see the section Defining Attributes for Configuration Objects in the chapter Getting Started with Alfabet Expand.

  Furthermore, if the technical name of a configuration object is changed, the name will be correctly updated in other configuration objects referencing the changed object during design time. Please note that the name of a changed configuration object will not be updated in guide pages nor if the guide pages reference a configuration object listed in the **Show Usage** functionality. If you plan to change the name of a configuration object, the reference in the guide page should be changed prior to changing the configuration object name.

- **Caption**: Enter the caption to display in the header panel of the wizard step in the Alfabet interface. If the wizard step is an editor, the caption will be displayed as well as the tab name (<Caption / Tab Name>). The caption you define here will replace the default name of standard and custom editors, standard Alfabet views, as well as the caption defined for configured reports. The caption will not be displayed if the **Header HTML** attribute is defined for the header. For more information about the

configuration of HTML text in the header of the wizard step, see the section Configuring the Header Text of a Wizard Step.

If the **Show Wizard Steps Combo-Box** attribute is set to `True` for the wizard, any wizard step captions that are longer than the **Go to Step** field will be truncated in the drop-down list. For more information about including the **Go to Step** field in the wizard, see the section Creating a Wizard.

- **Caption Step Color**: The captions of wizard steps can be colored to indicate, for example, that the wizard step is mandatory, important, optional, etc. The color will be applied to the text specified in the **Caption** attribute as well as in the **Go to Step** drop-down menu at the bottom of the wizard.
- **Caption Step Suffix**: The captions of wizard steps can be provided with a caption suffix to indicate, for example, that the wizard step is mandatory, important, optional, etc. The suffix will be appended to the text specified in the **Caption** attribute as well as in the **Go to Step** drop-down menu at the bottom of the wizard.
- **Close (X) Button Hint**: Specify a hint to replace the standard hint for the **Close (X)** button in the upper right corner of the editor/wizard which states " **Click here to exit without saving data.** " You can specify a differentiated hint to be displayed if, for example, an editor is embedded in the wizard step and the **Tab as Seperate Step** attribute is set to `True`. In this case, you could specify a text such as " **Click here to exit without saving data for the current wizard step.** " to let the user know that only the data in the current wizard step would be lost if the wizard were to be closed via the **Close (X)** button.
- **Description**: Enter a description to display in header panel of the wizard step. The description could provide the user with instructions about what to do in the wizard step. The description will not be displayed if the **HTML Header** attribute is defined for the header. For more information about the configuration of HTML text in the header of the wizard step, see the section Configuring the Header Text of a Wizard Step.

The text defined in the **Caption** and **Description** attributes of a wizard step can be translated to the other languages of your Alfabet interface. For more information, see the section Modifying, Translating and Managing the Vocabularies in the chapter Localization and Multi-Language Support for the Alfabet Interface

3) In the toolbar, click the **Save**  button to save your changes.

4) Next, you must specify the content of the wizard step. The following is possible:

- Specify an editor for the wizard step.

Please note that if a new object is to be created in the wizard, the first wizard step must implement an editor. Therefore, for a wizard in which a new object is to be created, the **Step Type** attribute of the first wizard step must be set to `Editor`.

- Specify a standard page view for the wizard step.
- Specify a configured report for the wizard step.

The following information is available:

- Configuring a Wizard Step to Display a Standard or Custom Editor
- Controlling the Visibility of Tabbed Pages in Wizard Steps

- Configuring a Wizard Step to Display a Standard Page View
- Configuring a Wizard Step to Display a Configured Report

Configuring a Wizard Step to Display a Standard or Custom Editor

If the wizard step is to be based on an editor, you must assign a standard editor to the wizard step. Once the standard editor has been defined, you can add a custom editor to be included in the wizard step.

Online help is available for wizard steps of the type `Editor` for all standard object class properties and custom object class properties for which the **Hint** attribute has been defined. It is also possible to configure instructional text in the header of the wizard step. For more information about configuring HTML text in the header of the wizard step, see the section Configuring the Header Text of a Wizard Step.

There are a number of configuration possibilities for a wizard step of the type `Editor`:

- A standard editor is displayed for the wizard step
- A standard editor and custom editor is displayed for the wizard step
- All tabbed pages in the editor are processed for the wizard step.
- Each tabbed page in the editor is processed as a separate wizard step.
- Only one tabbed page in the editor is visible for the wizard step.
- Only some properties are visible in the editor and other properties are hidden. This issue is not addressed in the description below. For more information about customizing the visibility of properties in the wizard, see the section Hiding Object Class Properties and Functionalities in the Wizard for a Specific User Profile.
- One or more properties must be defined in order to complete the wizard step and advance to the next wizard step. This issue is not addressed in the description below. For more information about defining post-conditions for a wizard step, see the section Defining a Post-Condition for a Wizard Step.

> Please note if a custom editor is embedded in a wizard and the **Tab as Separate Steps** attribute set to `True`, any conditions configured for the custom editor will only be relevant for the current tab/wizard step. The conditions cannot refer to interface controls that are available on other tabs/wizard steps. For more information about the configuration of conditions for custom editors, see the section Specifying Conditional Constraints in the Custom Editor.

To configure a wizard step of the type `Editor`:

1) Expand the custom wizard and click the wizard step to open its attribute window.
2) Define the following attributes, as needed:

- **Wizard Step Type**: Select `Editor` to specify a standard and, if relevant, custom editor for the wizard step.
- **View**: Select the standard editor relevant for the object class targeted by the wizard step.

Typically, this will be the object class that the wizard has been created for. However, it is also possible to configure the wizard step so that an object in a different object class is processed in the wizard step. In this case, you would select the base class of the query defined in the **Base Object via Query** attribute. For more information specifying a different object class for a wizard step, see the section Configuring a Different Target Object for a Wizard Step.

- **Custom Editor**: Select a custom editor if you want to include a custom editor in the wizard step.
- **Tab as Separate Step**: If the editor has multiple tabs, then you can specify that each tabbed page is treated as a separate wizard step in the wizard process. For example, if a standard editor with 2 tabs and a custom editor with 1 tab is assigned to the wizard step, the first tab of the standard editor would be step 1, the second tab would be step 2, and the custom editor would be step 3. To specify that each tab is treated as a separate step in the wizard process, select `True`. Select `False` if the tabbed pages in the standard and custom editors should constitute one wizard step.
- If you plan to implement post-conditions for the wizard step and the **Tab as Separate Step** attribute has been set to `True`, the post-conditions will be checked after the last tab of the standard or custom editor has been reached. In this case, you must ensure that the attribute **Execute Post-Conditions on Back Moves** for the wizard is set to `False`. For more information about the configuration requirements for wizard steps with post-conditions, see the section Defining a Post-Condition for a Wizard Step.
- **Page**: If you have defined a standard or custom editor with multiple tabbed pages for the wizard step, you can configure the wizard step to display only one of the tabbed pages and hide all other tabbed pages that are not relevant. To specify that only a selected tabbed page in the standard editor is displayed for the wizard step, select the relevant page for the wizard step. All other tabbed pages will be hidden.

  For example, if you have a situation where you have 5 tabbed pages in a standard editor and you want to display 2 of the tabbed pages, you could assign the standard editor to two different wizard steps, defining the visibility of one of the pages for each wizard step.

- **Is Read-Only**: Typically, users accessing a wizard step that is associated with an editor should have ReadWrite access permissions. Therefore, in order for users to be able to capture data and edit existing data for the selected wizard step, you must ensure that the **Is Read-Only** attribute is set to `False` If users should have read-only access permissions to the selected wizard step, set the **Is Read-Only** attribute to `True`.

3) If properties have been specified as excluded for a class setting, you may explicitly define them to be included in the context of a wizard step. To do so, define the following attributes:

- **Class Name**: Specify the class targeted by the wizard step to be defined. Once a class is specified in the **Class Name** attribute.
- **Override Property Exceptions**: Select the properties in the **Local Class Settings** editor that shall be included in the scope of the wizard step. Only the properties that have been excluded via the class settings of the class specified in the **Class Name** attribute will be displayed in the **Local Class Settings** editor.

4) In the toolbar, click the **Save** button to save your changes.

Controlling the Visibility of Tabbed Pages in Wizard Steps

Please note that visibility rules will not be further developed by Software AG. For reasons of backward compatibility, the following section is available regarding the definition of visibility rules for custom editors. However, wizard step pre-conditions and post-conditions are a much more flexible mechanism to control the visibility of tabbed pages in an editor as well as other types of wizard steps. It is highly recommended that you reconfigure existing visibility rules as pre-conditions or post-conditions for a wizard step. For more information, see the section Defining Pre-Conditions and Post-Conditions for a Wizard Step.

It is possible to configure a wizard so that the visibility of specified tabs in a custom editor that is assigned to a wizard step is determined by a set of visibility rules. Depending on the value selected by the user in the first wizard step, the user will proceed to the specified tab in the next wizard step that meets the condition specified by the visibility rule. In this way, the tabs displayed for a wizard step are controlled by the value the user defines for the custom object class property.

Visibility rules are defined for the custom editor embedded in the wizard. The visibility rules are applied to the custom editor after data has been entered for the custom object class property of the type `Boolean`, `String`, or `Integer` determining the visibility and the data has been saved to the database. This is either when the custom editor is closed and then reopened or when the user clicks the **Next** button in the wizard. Please note the following:

- A custom object class property of the type `Boolean`, `String`, or `Integer` must be created for the relevant object class. If the custom object class property is of the type `String` or `Integer`, then an enumeration with enumeration items must also be defined. The enumeration items represent the values that can be selected in the custom editor.
- The custom editor should have multiple pages (tabs). You must create one page on which the custom object class property is displayed and one additional page for every property value that can be selected for the custom object class property. A visibility rule for every option (`True`/`False`) available for the relevant `Boolean` property or every enumeration item available for the relevant custom object class property. For example, for `Boolean` properties, a page should be created of Yes is selected and a page should be created if No is selected; for properties with an enumeration, one page should be created for each enumeration item defined for the enumeration.
- The visibility of tabs can be controlled for a specified wizard step only.

To define visibility rules for a custom editor with multiple tabs:

1) Go to the **Presentation** tab, expand the **Custom Editors** folder, right-click the relevant custom editor  nd select **New Visibility Rule**. The visibility rule  is displayed below the custom editor.
2) Click the visibility rule to open the attribute window and define the following values:

- **Name**: Enter a unique name for the visibility rule.
- **Property**: Select the custom object class property that the visibility rule is based on.
- **Property Value**: Select the value of custom object class property for which the visibility rule is valid. You can select either `True` or `False` for a custom object class property of the type `Boolean` or an enumeration item for a custom object class property of the types `String` or `Integer`.

- **Check Result Type**: Select `Positive` if the value defined in the **Property Value** attribute indicates that the visibility rule is fulfilled if the value is selected. Select `Negative` if the value defined in the **Property Value** attribute indicates that the visibility rule is fulfilled if the value is not selected.
- **Description**: Enter text in order to provide information about the visibility rule. This text is not displayed in the Alfabet interface.

Instead of defining the visibility rule for a specified custom object class property, you can alternatively define an Alfabet query to determine the condition specified in the visibility rule via the **Alfabet Query** attribute. For more information about configuring an Alfabet query, see the section Defining Queries.

3) In the toolbar, click the **Save** button to save your changes.
4) Next, you must associate the page that the visibility rule is assigned to in the **Visibility Rules** attribute of the tabbed page. Expand the **Custom Editors** node, right-click the relevant custom editor and select **Design Editor**. The custom editor is displayed in the editor designer.
5) Click the tabbed page (not the tab) that should be displayed if the visibility rule is valid. In the attribute window, select the visibility rule that determines the visibility of the tabbed page in the **Visibility Rules** attribute.
6) Continue this procedure until all required visibility rules have been defined for the various tabbed pages of the custom editor.
7) In the toolbar, click the **Save** button to save your changes.
8) As a final step, you must ensure that the wizard step is correctly defined in order to allow for the execution of the visibility rules. Expand the **Wizards** folder and right-click the relevant wizard step that you want to associate the custom editor and its visibility rules with.
9) In the attribute window for the wizard step, ensure that the following attributes are specified:

- **Wizard Step Type**: Select `Editor`.
- **View**: Select the standard editor for the respective object class.
- **Custom Editor**: Select the relevant custom editor that has been defined with visibility rules.
- **Is Read-Only**: Select `False`.
- **Tab as Separate Step**: Select `False`.

10) In the toolbar, click the **Save** button to save your changes.

Configuring a Wizard Step to Display a Standard Page View

A wizard step can constitute a standard Alfabet view.

A link will be displayed per default in the header that opens the context-sensitive Help. You can replace the preconfigured text "Click to access Help for this wizard step." with a customized HTML text for the header. It is also possible to configure instructional text in the header of the wizard step. For more information

about configuring HTML text in the header of the wizard step, see the section Configuring the Header Text of a Wizard Step.

There are a number of configuration possibilities for a wizard step of the type `View`:

- You can configure the wizard step so that users may have ReadOnly access permissions or Read/Write access permissions.
- You can require that specific data is defined in the page view in order to complete the wizard step and advance to the next wizard step. This issue is not addressed in the description below. For more information about defining post-conditions for a wizard step, see the section Configuring Wizard Step Actions for a Wizard Step.

Please note that the **Show Collaboration Panel** button which opens the **Collaboration** capability is not available in page views embedded in a wizard step.

1) Expand the custom wizard and click the wizard step to open its attribute window.
2) Define the following attributes, as needed:

- **Step Type**: Select `View` to specify a standard Alfabet page view for the wizard step.
- **View**: Select the page view to display for the wizard step. All permissible standard page views in Alfabet are listed in the drop-down list. Typically, this will be a page view associated with the object class that the wizard has been created for. However, it is also possible to configure the wizard step so that an object in a different object class is processed in the wizard step. In this case, you would select the base class of the query defined in the **Query** attribute (or **Query as Text** attribute). For more information specifying a different object class for a wizard step, see the section Configuring a Different Target Object for a Wizard Step.
- **Is Read-Only**: If users accessing the selected wizard step should only have ReadOnly access permissions, select `True`. If users should have Read/Write access permissions, select `False`.

3) If properties have been specified as excluded for a class setting, you may explicitly define them to be included in the context of a wizard step. To do so, define the following attributes:

- **Class Name**: Specify the class targeted by the wizard step to be defined. Once a class is specified in the **Class Name** attribute.
- **Override Property Exceptions**: Select the properties in the **Local Class Settings** editor that shall be included in the scope of the wizard step. Only the properties that have been excluded via the class settings of the class specified in the **Class Name** attribute will be displayed in the **Local Class Settings** editor.

4) In the toolbar, click the **Save** button to save your changes.

Configuring a Wizard Step to Display a Configured Report

A wizard step can constitute a configured report. You can configure the wizard step so that users may view a tabular query-based custom report or a query-based custom report displaying graphics (such as a tree-map or layered diagram report). Please note that a report can only be viewed in a wizard. A report cannot be opened from within a wizard.

For wizard steps of the type `Report`, a link to your enterprise's custom Help may be available if custom Help has been configured. For more information about configuring a custom report, see the section Assigning Custom Help and Automated Help Assistants to Configured Reports. However, if you plan to implement custom HTML text in the header, you can embed your custom Help in the HTML text as a hyperlink. For more information about configuring HTML text in the header of the wizard step, see the section Configuring the Header Text of a Wizard Step.

1) Expand the custom wizard and click the wizard step to open its attribute window.
2) Define the following attributes, as needed:

- **Step Type**: Select `Report` to specify a configured report for the wizard step.
- **View**: Select the configured report to display for the wizard step. All reports configured for your enterprise are listed in the drop-down list.

3) If properties have been specified as excluded for a class setting, you may explicitly define them to be included in the context of a wizard step. To do so, define the following attributes:

- **Class Name**: Specify the class targeted by the wizard step to be defined. Once a class is specified in the **Class Name** attribute.
- **Override Property Exceptions**: Select the properties in the **Local Class Settings** editor that shall be included in the scope of the wizard step. Only the properties that have been excluded via the class settings of the class specified in the **Class Name** attribute will be displayed in the **Local Class Settings** editor.

4) In the toolbar, click the **Save** button to save your changes.

Defining a Subordinate Wizard Step or a Branch of Subordinate Wizard Steps

A subordinate wizard step is a wizard step that is subordinate to a wizard step and forms a branch of wizard steps in the wizard process. A wizard step can have a hierarchy of subordinate wizard steps, each of which could also have subordinate wizard steps. For each branch of subordinate wizard steps that you define, the root wizard step may have a pre-condition defined in order to determine whether the user should enter the wizard step and its branch of subordinate wizard steps. The pre-conditions are configured as Alfabet queries or SQL queries.

The logical condition would determine whether the wizard step is entered or whether it should be skipped. If the pre-conditions for the root wizard step are not met, the wizard step and its subordinate wizard steps will be skipped, and the wizard will advance to the next wizard step for which the pre-conditions are fulfilled. If the pre-condition for the root wizard step is met, the wizard will advance through the branch of wizard steps. When the leaf-level sub-step is reached, the wizard would then advance to the next wizard step on the root level of wizard steps.

Post-conditions may be defined for any subordinate wizard step in order to prompt users to provide data for specified standard or custom object class properties before proceeding to the next wizard step.

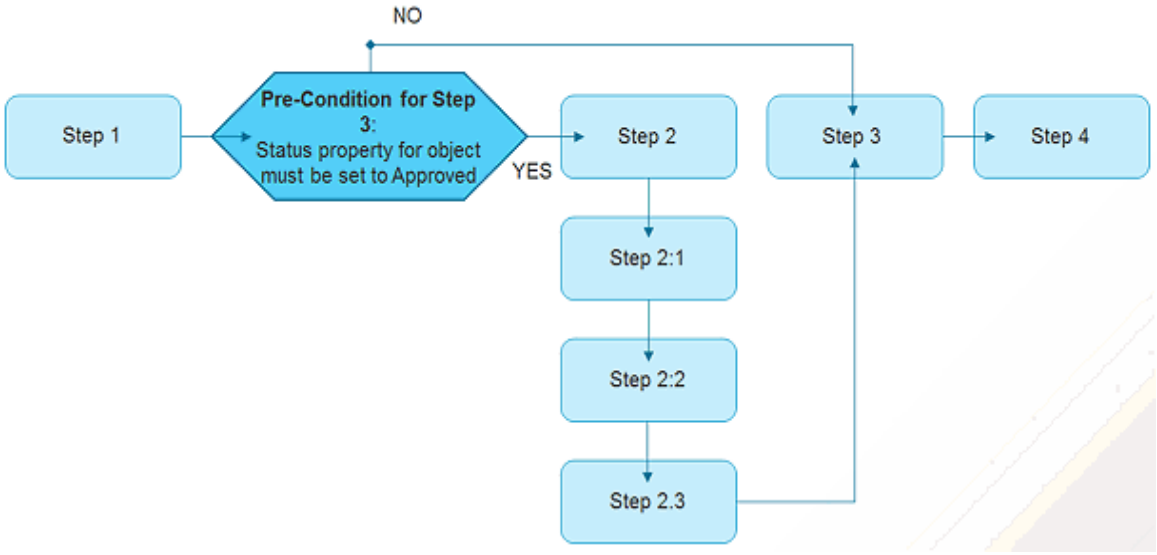


FIGURE: Wizard process with a branch of subordinate wizard steps

In the example above, if the pre-condition for wizard step 2 is not fulfilled, the wizard would ignore the Wizard Step 2 and all subordinate wizard steps and continue to Wizard Step 3. If the pre-condition is fulfilled, the wizard will enter Wizard Step 2. The wizard would then advance to the next subordinate wizard step in the branch. When Wizard Step 2.3 is reached at the leaf-level of the branch, the wizard would advance to Wizard Step 3.

Once a subordinate wizard step is created, the process of defining the subordinate wizard step and its attributes is similar to that of a conventional wizard step. Each subordinate wizard step may have instructions configured that are displayed in the header of the wizard step and like a wizard step, the subordinate wizard step may be an editor, view, or report in a wizard. A subordinate wizard step may be reused within a wizard as well as in other wizards.

The final wizard step in a wizard may not have a pre-condition defined. If a pre-condition is defined for the final wizard step or subordinate wizard step and the pre-condition is not fulfilled, an error will occur (for example, the wizard will not be able to advance to a next wizard step and the wizard will stagnate). If a pre-condition is required for the last logical step or subordinate wizard step in the wizard, it is recommended that you add another final concluding wizard step with no pre-condition and, for example, only static text defined (with a message such as "You have completed the wizard").

For example, the wizard scenario requires a branch at the end of the wizard where the last wizard step may be Wizard Step A or Wizard Step B; if the pre-condition for Wizard Step A is fulfilled, then the final wizard step will be Wizard Step A but if the pre-condition for Wizard Step B is fulfilled, then the final wizard step will be Wizard Step B. However, only one wizard step (for example, Wizard Step A) can be defined as the final wizard step which has the **Exit** button that allows the wizard process to be completed.

In the example, however, the wizard ends in a fork with two possible wizard steps as a potential last step. If the last wizard step is Wizard Step B, the **Exit** button will not be available. In this case, the wizard will stagnate and cannot be completed.

For a wizard scenario like this one, you must define a final wizard step that has no pre-condition configured to follow Wizard Step A and Wizard Step B. The final wizard step would require no data input but would simply allow the user to complete the wizard step via the **Exit** button.

If one or more wizards are configured to open as sub-branches of a base wizard, each new wizard that is triggered to open may be configured to open in a modal window. The user will not be able to return to a preceding wizard until the current wizard has been completed. The configuration of wizards stacked in modal windows is specified in the **Stacked Wizards** attribute in the server alias configuration. For more information, see the section *Configuration Attributes for the Alfabet Components* in the reference manual *System Administration*.

To define subordinate wizard steps for a selected wizard:

1) Go to the **Presentations** tab, expand the custom wizard and right-click the relevant wizard step that you want to define subordinate wizard steps for and select **New Wizard Sub-Step**. A wizard step labelled `Step_<Number>` is added to the wizard view.

   You can copy an existing subordinate wizard step and modify it as needed. To do so, you must create an empty wizard step for the wizard you are defining, copy the existing wizard step (via **right-click >Copy**), and paste the wizard step on the empty wizard view (**right-click >Paste**). The entire wizard step definition is copied and can be modified, as needed.

2) Define the wizard step as defined in the section Specifying Wizard Steps for a Custom Wizard. In addition, you must define the following:

- Go to the custom wizard node and click to open the attribute window. Specify the **Type** attribute for the selected wizard to determine the numbering to display in the wizard header for the subordinate wizard steps:
- Select `Tree` to number all subordinate wizard steps so that subordinate wizard step 1, subordinate wizard step 2, and subordinate wizard step 3 that are subordinate to wizard step 1 will be numbered step 1.1, 1.2, and 1.3 in the wizard header. Please note that if the **Show Wizard Steps Combo-Box** attribute is set to `True` for the wizard, then the subordinate wizard steps will be displayed in the **Go to Step** field.
- Select `Straight` to number all subordinate wizard steps so that all subordinate wizard step that are subordinate to wizard step 1 will all have the same number as their ascendant wizard step. In this case, subordinate wizard step 1, subordinate wizard step 2, and subordinate wizard step 3 would all be numbered 1 of 7 in the wizard header. Please note that if the **Show Wizard Steps Combo-Box** attribute is set to `False` for the wizard, then the subordinate wizard steps will not be displayed in the **Go to Step** field.

  If the **Go to Step** field is configured to be displayed in the wizard (**Show Wizard Steps Combo-Box** attribute = `True` for the wizard), then the subordinate wizard steps will be displayed in the **Go to Step** field if `Tree` is selected in the **Type** attribute. The subordinate wizard steps will not be displayed in the **Go to Step** field, if `Straight` is selected in the **Type** field.

- Define a pre-condition for the parent wizard step in the branch. This is required in order to provide the criteria that must be fulfilled to enter the subordinate wizard step. For more information about defining a pre-condition, see the section Defining Pre-Conditions and Post-Conditions for a Wizard Step.
- Optional: Create another subordinate wizard step or branch of sub-steps for each subordinate wizard step. In this way, you can create a hierarchy of subordinate wizard steps in the order in which they should be processed. To create a subordinate wizard step of an existing subordinate wizard step, right-

click the subordinate wizard step and select **New Wizard Sub-Step**. Continue this process until the branch of subordinate wizard steps is complete.

3) In the toolbar, click the **Save**  button to save your changes.

Configuring the Header Text of a Wizard Step

Instructional text can be configured for the header text for one or more wizard steps. You can either specify plain text by configuring the **Caption** and **Description** attributes of the wizard step or configure HTML text in the **Header HTML** attribute. The size of the header is static and will NOT adjust its size to display all text you define. Therefore, the header text should be short and succinct.

Please not the following advantages and disadvantages for each option:

- Plain text:

- Plain text is configured via the **Caption** and **Description** attributes of a wizard step. The configuration of the **Caption** and **Description** attributes is simple. For more information about configuring plain text via the **Caption** and **Description** attributes of a wizard step, see the section Creating a Wizard.
- The text is plain text and cannot be formatted.
- The **Caption** and **Description** attributes will be available in the vocabularies and can be translated using the standard translation capabilities available.
- The specification of the **Format String** attribute configured for the wizard will also be displayed. For more information about the configuration of the format string, see the section Creating a Wizard.
- The availability of the online Help for views and configured reports is not impacted. F

- HTML text:

- HTML text is configured via the **Header HTML** attribute of a wizard step. You must follow the guidelines described below to ensure the HTML is valid.
- The HTML must be XML-conform HTML, compliant with HTML 5, and use standard HTML tags. The HTML may contain basic elements to capture information about the wizard step as well as the object targeted by the wizard step.
- You can include text formatting and color, hyperlink to URLs, and multiple translations of the text.
- Alfabet proprietary elements may be included to retrieve data from the database.
- A stylesheet that specifies the layout and visualization of the data may be stored in the **Internal Document Selector**.
- The online Help for views and configured reports will not be available unless explicitly linked in the customized HTML text.
- The HTML text will not be available in the vocabularies and cannot be translated using the standard translation capabilities available. If translation to a secondary language is required, you must provide the translation in the HTML specification.

The specification in the **Header HTML** attribute for a wizard step supersedes the definition of the **Caption** or **Description** attribute of the wizard steps as well as the definition of the **Format String** attribute for the wizard.

To configure HTML text to display in the header of the wizard step:

1) Expand the custom wizard and click the wizard step to open its attribute window.
2) In the **HTML Header** attribute, configure HTML text for the header. Please note the following:

- The HTML may be defined in a standard XHTML editor and pasted in the **HTML Header** attribute.
- The HTML must be compliant with XHTML, XML-conform HTML, compliant with HTML 5, and use standard HTML tags. The HTML header implements standard HTML elements.
- The code must start with an `<xhtml>` tag and end with `</xhtml>`. Standard HTML elements must be written in lower-case letters in order to be correctly parsed: `<xhtml>`, `<html>`, `<head>`, `<body>`, and `<culture_>`. The definition of `<head>`, `<body>`, and `<culture_>` is optional.
- The formatting of the HTML can either be written explicitly in the `<body>` element or can be specified via a stylesheet that is stored in the **Internal Document Selector**. In this case, the HTML must refer to the target CSS file in a `<link>` element. The CSS file should contain all necessary styles to display the content of the HTML. Please note that the CSS file may not be stored in the root folder of the **IDOC** explorer. The CSS file stored in the **Internal Document Selector** must be located in a document folder that is subordinate to the root folder of the **IDOC** explorer. To upload a file to the **Internal Document Selector**, see the section *Uploading Documents and Managing User Permissions to Document Folders in the Internal Document Selector* in the reference manual *User and Solution Administration*. For example:

```
<xhtml>
   <culture_1033>
      <html>
      <body style="margin:4px;background:#3d4b60;overflow:hidden;">
         <link type="text/css" rel="stylesheet"
         href="IDOC:\CSS\my_style_file.css"></link>
         <p>This is the content for the header of the wizard
         step.</p>
         ...
      </body>
      </html>
   </culture_1033>
</xhtml>
```

- All CSS formatting instructions must end with `!important` to ensure that they are processed by the Alfabet application. For example:

```
<xhtml>
   <culture_1033>
      <html>
      <body style="margin:4px !important;background:#3d4b60
      !important;overflow:hidden !important;">
```

```
            <style type="text/css">
                p.header
                {
                    font-family:verdana !important;
                    font-size:18px !important;
                    color:#ff0000 !important;
                    text-align: Left !important;
                }
            </style>
            <p class="header">This is the content for the header of the
            wizard step.</p>
            ...
        </body>
        </html>
    </culture_1033>
</xhtml>
```

- If translation to a secondary language is required, you must provide the translation in the HTML specification. Please note that HTML texts cannot be translated via the **Translation Editor** available in Alfabet Expand. Please consider the following:
- If the HTML description is required in additional languages, each language text must be defined within language elements (For example, `<culture_1031>` for English, `<culture_1033>` for German, etc.)
- The element `<culture_xxx>` must be specified as a child of the root element `<xhtml>`. The element `<html>` must be specified as a child of the element `<culture_xxx>`. The element `<html>` contains the HTML specification in the relevant language. For example, to provide information in English and German:

```
<xhtml>
    <culture_1033>
        <html>
            <body>
                <h3>Glossary: Application</h3>
                <p>An application is a fully-functional integrated IT
                product that provides functionality to end users
                and/or to other applications. As such, an application
                supports the business to accomplish its mission.
                Applications operate on a platform made up of
                hardware and software components necessary to run the
                application.</p>
            </body>
        </html>
    </culture_1033>
    </culture_1031>
        <html>
```

```
            <body>
                <h3>Glossar: Applikation</h3>
                <p>Eine Applikation ist ein voll funktionsfähiges,
                integriertes IT-Produkt, das Funktionalitäten für
                Endanwender und/oder für andere Applikationen bietet.
                Eine Applikation unterstützt das Unternehmen bei der
                Zielerreichung. Applikationen werden auf einer
                Plattform betrieben, die aus den für die Ausführung
                der Applikation erforderlichen Hardware- und
                Software-Komponenten besteht.</p>
            </body>
        </html>
    </culture_1031>
</xhtml>
```

- Each Alfabet proprietary element `<AlfaHtmlElement>` should be included in a standard HTML tag such as `<body>`, `<td>`, `<span>`, `<div>`, etc. in order to retrieve data from the database. The following Alfabet query language parameters can be used in the `ApplyTo` attribute to define the object whose data is to be displayed:
- `@WIZARDBASE`: to retrieve data about the object that the wizard step references (if the `ShowProps` attribute has been added to the element `<AlfaHtmlElement>` without a child `SqlText` element)
- `@PREVIOUS_STEP`: to retrieve data about the previous wizard step
- `@WIZARD`: to retrieve data about the current wizard
- The attributes `ApplyTo`, `ShowProps`, `PropName`, and `FormatString` can also be used to retrieve and display data. For example, to display the object state of the object targeted by the current step, you would specify `@WIZARDBASE` in the `ApplyTo` attribute and the object class properties `ObjectState` in the `ShowProps` attribute:

```
<span><AlfaHtmlElement ApplyTo="@WIZARDBASE"
ShowProps="Description"/></span>
```

- The attribute `SqlText` may also be included in the element `<AlfaHtmlElement>`. If the attribute `SqlText` is included as a child of the element `<AlfaHtmlElement>`, then the object reference is available via the parameter `@BASE`. This attribute allows you to include an Alfabet query or native SQL query to retrieve data. Please note that if the attribute `SqlText` is included in the element `<AlfaHtmlElement>`, the attribute `ShowProps` will be ignored.

In the example below, multiple application groups will be returned for the query. The `MaxCount` attribute allows you to limit the number of rows (results) displayed. If the number of results is greater than the value in the `MaxCount` attribute, only the first results found in the database will be displayed. If the query includes a sorting instruction (for example, in the query below: `ORDER BY`), the first results found in the sort order will be displayed:

For example:

```
<AlfaHtmlElementMaxCount ="5" ApplyTo="@BASE">
    <SqlText> <![CDATA[
        SELECT appg.REFSTR, appg.Name
        FROM APPLICATIONGROUP appg, RELATIONS rel
```

```
                WHERE rel.FROMREF = appg.REFSTR
                    AND rel.PROPERTY = 'Applications'
                    AND rel.TOREF = @BASE
                ORDER BY appg.NAME
                ]]>
            </SqlText>
        </AlfaHtmlElement>
```

- The attribute `Filter` may be included in the element `<AlfaHtmlElement>`. This attribute allows you to include color instruction to color properties based on a specified value.

For example:

```
<AlfaHtmlElement ApplyTo="@WIZARDBASE"
ShowProps="ObjectState">
    <Filter> <![CDATA[COLORASSIGNMENT(EqualTo, "Active",
    #c0c000, Transparent);]]> </Filter>
    <Filter> <![CDATA[COLORASSIGNMENT(EqualTo, "Retired",
    #00c000, Transparent);]]> </Filter>
    <Filter> <![CDATA[COLORASSIGNMENT(EqualTo, "Draft",
    #c00000, Transparent);]]> </Filter>
</AlfaHtmlElement>
```

3) In the toolbar, click the **Save**  button to save your changes.

Defining Pre-Conditions and Post-Conditions for a Wizard Step

For each wizard step, you may define one or more pre-conditions and post-conditions that must be fulfilled before the wizard step can be entered (pre-condition) or exited (post-condition). Each pre-condition and post-condition require an Alfabet query or native SQL query to be defined that checks whether the pre-/post-condition has been fulfilled. In the case of a post-condition, you can additionally define a message to display information to a user if the post-condition has not been fulfilled. Each wizard step may have multiple pre-conditions and post-conditions defined.

A pre-condition may NOT be configured for the first wizard step NOR for the final wizard step or subordinate wizard step. If you do so and the pre-condition is not fulfilled, an error will occur. In this case, for example, the wizard could stagnate and not advance to the next wizard step. If a pre-condition is required for the last logical step or subordinate wizard step in the wizard, it is recommended that you add another final concluding wizard step with no pre-condition and only static text defined (for example, with a message such as "You have completed the wizard").

The following information is available:

- Defining a Pre-Condition for a Wizard Step
- Defining a Post-Condition for a Wizard Step
- Determining the Sequence of Pre-Conditions and Post-Conditions

Defining a Pre-Condition for a Wizard Step

Pre-conditions can be defined for a wizard step in order to determine if the wizard step should be entered. A pre-condition is based on an Alfabet query or a native SQL query that checks the minimum conditions that should apply for the wizard step to be entered. If certain conditions are not met for a wizard step, then that wizard step will be skipped and the wizard will advance to the next wizard step for which the pre-conditions are met or for which no pre-conditions are defined. Each wizard step may have multiple pre-conditions defined. All pre-conditions must be fulfilled before the wizard step may be entered.

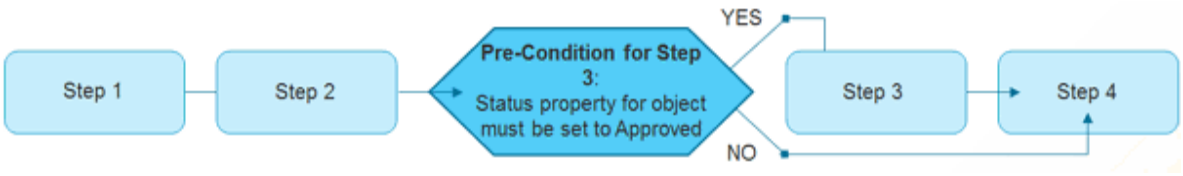

FIGURE: Approval of object is required to enter Step 3

If pre-conditions are not fulfilled for a wizard step, the user may enter the next permissible wizard step. This may be the next wizard step for which the pre-conditions are met or for which no pre-conditions are defined.

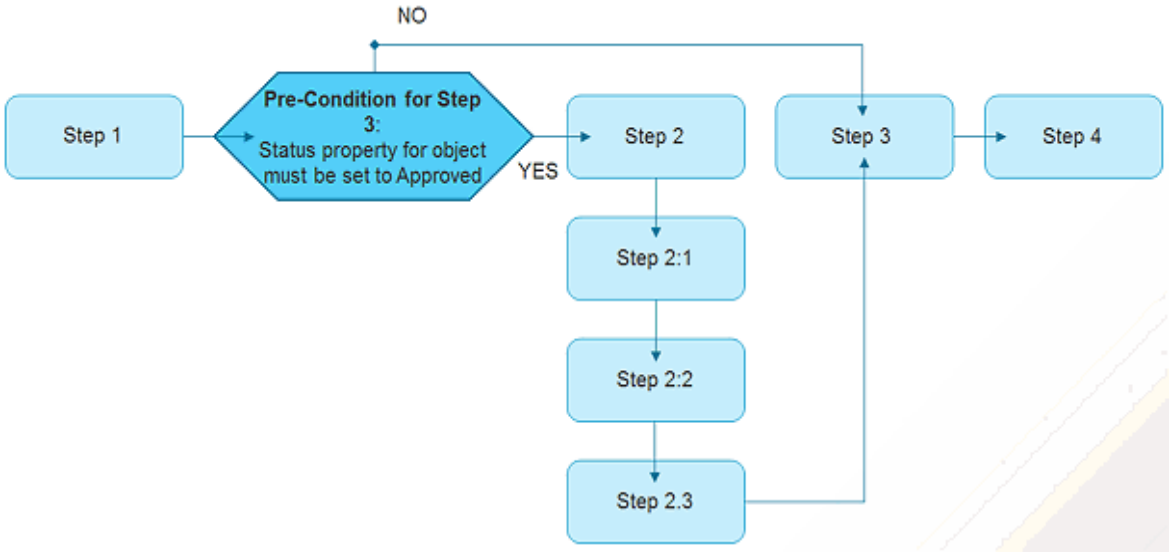

FIGURE: Wizard with a branch of subordinate wizard steps

If subordinate wizard steps are defined for a wizard step, the subordinate wizard steps will only be entered if the pre-conditions are met for the root wizard step, as displayed in the figure above. If the pre-conditions for the root wizard step are not met, the wizard step and its subordinate wizard steps will be skipped and the wizard will advance to the next permissible wizard step.

In the example above, if the pre-condition for wizard step 2 is not fulfilled, the wizard would ignore the wizard step 2 and all subordinate wizard steps and continue to wizard step 3. If the pre-condition is fulfilled, the wizard will enter step 2. The wizard would then advance to the next subordinate wizard step in the branch. When step 2.3 is reached at the leaf-level of the branch, the wizard would advance to wizard step 3.

You can define multiple pre-conditions per wizard step. Once all pre-conditions have been created for a wizard step, the order that they are to be executed should be defined. For more information, see the section Determining the Sequence of Wizard Steps in the Wizard.

A pre-condition may NOT be configured for the first wizard step NOR for the final wizard step or subordinate wizard step. If you do so and the pre-condition is not fulfilled, an error will occur. In this case, for example, the wizard could stagnate and not advance to the next wizard step. If a pre-condition is required for the last logical step or subordinate wizard step in the wizard, it is recommended that you add another final concluding wizard step with no pre-condition and only static text defined (for example, with a message such as "You have completed the wizard").

To define a pre-condition for a selected wizard step or subordinate wizard step:

1) Expand the custom wizard and click the wizard step to open its attribute window.
2) Right-click the **Pre-Conditions** node and select **New Pre-Condition**. You will see the new pre-condition below the relevant node.

A pre-condition can be created based on a copy of an existing condition. To do so, select the pre-condition you want to copy and right click and select **Copy**. Click the wizard step or subordinate wizard step that you want to copy the pre-condition to and select **Paste**. The values define for the pre-condition's attributes are copied and can be modified, as needed.

3) Define its attributes in the attribute window as needed:

- **Technical Name**: Enter a name for the pre-condition.
- **Technical Comment**: Enter any relevant information about the pre-condition.
- Define the query that is executed to ascertain whether the pre-condition has been fulfilled. You can define either an Alfabet query or an SQL query. For information about defining an Alfabet query or SQL query, see the chapter Defining Queries. Define one of the following:
- **Query**: Click the **Browse** button to open the **Alfabet Query Builder** and define an Alfabet query.
- **Query as Text**: Paste in an Alfabet query or native SQL query that you have defined in a text editor.

The following is an example of a pre-condition that specifies that the **Release Status** property of the application must be set to `Approved` in order to enter the subordinate wizard step:

```
ALFABET_QUERY_500
FIND
APPLICATION
WHERE
    (AND
       Application.REFSTR CONTAINS:BASE
       Application.Status LIKE 'Approved'
    )
```

Data update is not allowed in a wizard step pre-condition. If a data update is required, you should define a wizard step action of the type **Action on Exited Step**. For more information, see the section Defining Property Values To Be Automatically Updated When a Wizard Step Is Exited.

- **Check Result Type**: Select either `Positive` or `Negative` to define what constitutes a fulfilled pre-condition.
- `Positive` means that the pre-condition is fulfilled if the query has delivered a result (at least one row.)
- `Negative` means that the pre-condition is fulfilled if the query doesn't deliver any results.
- **Message**: Specify a warning message to display if the pre-condition is not fulfilled. The text should provide the user with information about what is required to fulfill the pre-condition. If no warning message is configured, then the standard warning message preconfigured by Alfabet will be displayed to the user if the pre-condition is not fulfilled.

4) Click the **Save**  button to save your definitions.

Defining a Post-Condition for a Wizard Step

A post-condition is a mechanism that reviews the definition of an object class property for a specified standard object class property or custom object class property for the object being edited in the wizard step. The post-conditions of a wizard step specify the minimum conditions that should apply for the wizard step to be exited. For example, post-conditions might be configured to validate that a specific object class property is defined before proceeding to the next wizard step, or that an object class property is filled with a specified value (for example, a specific release status), or that values are aligned with other values (for example, that start and end dates are aligned with a specified referenced object.)

You can configure whether it is optional or mandatory for the user to fill in the value for the specified standard or custom object class property. If the validation performed on the standard or custom object class property specified in the post-condition fails, a customized prompt message will appear. If the value targeted by the post-condition is optional, the user will be able to continue to the next wizard step without entering the respective object class property. If the value targeted by the post-condition is required, the user cannot continue to the next wizard step until a valid value has been entered for the object class property and the post-condition is validated.

Please consider the following when configuring a post-condition:

- You must ensure that the object class property that is being validated by the post-condition can actually be defined by the user in the wizard step. For example, will the user have the relevant access permission to define or edit the object class property? Or, if the object class property `Status` must be changed, is the release status that is to be modified by the user editable?
- If standard editors are defined for the wizard, the standard object class properties that are preconfigured by Software AG as mandatory properties must be filled in for the user to proceed to the next wizard screen. If any custom object class properties are configured as mandatory for a custom editor, these fields will also display the mandatory red star and must be filled in for the user to proceed.

Please note that you must ensure that the configuration of post-conditions for a wizard step and the configuration of pre-conditions for a subsequent wizard step are not contradictory.

Please note that the post-condition is executed AFTER the database transaction is performed. This is of particular relevance for post-conditions associated with standard or custom editors because the first attempt will be to save the user's data which may fail, for example, due to

mandatory or uniqueness conditions being violated. Once this save has been successful, the post-conditions will be executed.

If the attribute **Execute Post-Conditions on Back Moves** is set to `False`, the post-conditions will not be executed if the user clicks the **Back** button. However, the validation of editor-related constraints such as preconfigured mandatory properties or uniqueness constraints for a set of properties will continue to be performed if the user clicks the **Back** button.

Post-conditions may also be implemented in the Alfabet solution to validate the definition of objects. The following options are possible:

- Post-conditions specified for a wizard step of the type `Editor` will be applied if a user edits a relevant scalar or reference property in-line in an object profile or object cockpit. If a post-condition is not fulfilled after a value has been entered for a permissible property in the object profile or object cockpit, the error message configured for the post-condition will be displayed. Permissibility of inline editing can be specified by your solution designer on the level of an object view, class setting, or GUI scheme. For more information about configuring in-line editing, see the section Configuring Inline Editing of Attributes in the Object View.

  Please note the following regarding the inline editing functionality:

  - Only scalar and reference properties that are editable in the editor/wizard available in the object profile or object cockpit can be edited via inline editing.
  - All unique constraints defined for the class as well as any post-conditions configured for the wizard associated with the object profile/object cockpit will be applied to the data entered.

    Please note that data is saved to the Alfabet database prior to the post-condition being validated. Therefore, data entered via inline editing will be saved even if the post-condition is not fulfilled. This is because the data must be available in the Alfabet database in order to be evaluated for the post-condition. If the data entered does not fulfill the post-condition, the configured warning message will be displayed explaining that the input must be corrected in order to fulfill the post-condition.

  - Inline editing may be limited or prevented if the syntax of the post-condition is not correct. In this case, an error will be displayed if the user tries to open the wizard.

- A section displaying violated wizard post-conditions may be displayed in a **Personal Information** section of the object cockpit. The wizard validations section will display the messages configured for all wizard post-conditions that have been violated for the object displayed in the object cockpit. To include this information, you must add a Value Interface control of sub-type `PersonalInfo` to the flow panel of the object cockpit. For more information about configuring the display of wizard validation information in the object cockpit, see the section Adding Workflow, Assignment, Microsoft Teams Meeting Information and Object Validation Information to the Object Cockpit in the chapter Configuring Object Views.

- Object validation rules based on wizard step post-conditions may be configured. In this context, any object in the object class that the post-condition is associated with is validated when a user accesses the object in the object profile. Violations of the validations rules will be displayed in the object view and the user can then correct the cause of the violations. If the object validation functionality is enabled, all violations of each post-condition will be displayed in the header of the object profile of the currently selected object. The icon and message displayed if the post-condition is not fulfilled will depend on the configuration of the post-condition.

Please note that implementing the execution of the object validation functionality **may significantly impact performance** of the Alfabet solution since each upload to the Alfabet database will trigger the execution of all validation rules. Therefore, it is highly recommended that validation rules are configured for object class properties via a check entry definition in the context of a custom object cockpit. For more information about the configuration of a check entry definition for object validation, see the section Adding a Check Entry to the Object Cockpit in the chapter Configuring Object Views.

To enable validation rules associated with the post-conditions specified for a wizard:

- In order for the validation rules to be executed, one of the following is required:
- The object view must have a custom button for which the **Operation** attribute is set to `WizardEdit` or `Edit` button and the relevant wizard with the post-conditions must be specified in the **View** attribute. For more information about configuring buttons for a custom object view, see the section Configuring Custom Buttons for the Toolbar of a Custom Object View in the chapter Configuring Object Views.
- The wizard with the post-conditions must be specified for the class setting of the base object or object class stereotype. If no wizard is defined for this class setting, the wizard defined for the default class setting of the object class stereotype or base object class will be used. If no post-conditions should be displayed for users accessing the object view, you must ensure that no post-conditions are defined for the wizards specified in the class setting or default class setting specified for the relevant view scheme. For more information about specifying class settings, see the section Configuring Class Settings for Object Classes and Object Class Stereotypes in the chapter Configuring User Profiles for the User Community.
- The specification of an object view with a relevant custom button will have precedence over a wizard assigned to the class settings.
- The user must specify the execution of object validation in his/her user settings by selecting the **Execute Object Validation on Access** checkbox in the **User Settings** editor. For more information about the implementation of this functionality in Alfabet, see the section *Defining Your User Settings in Alfabet* in the reference manual *Getting Started with Alfabet*.

Multiple post-conditions can be configured for a wizard step. Once all post-conditions have been created for a wizard step, the order that they are to be executed should be defined. For more information, see the section Determining the Sequence of Wizard Steps in the Wizard.

To define a post-condition for a selected wizard step:

1) Expand the custom wizard and click the wizard step to open its attribute window.
2) Right-click the **Post-Conditions** node and select **New Post-Condition**. You will see the new post-condition below the relevant node.

A post-condition can be created based on a copy of an existing condition. To do so, select the post-condition you want to copy and right click and select **Copy**. Click the wizard step or subordinate wizard step that you want to copy the post-condition to and select **Paste**. The values define for the post-condition's attributes are copied and can be modified, as needed.

3) Define its attributes in the attribute window as needed:

- **Technical Name**: Enter a name for the post-condition.
- **Technical Comment**: Enter any relevant information about the post-condition.
- **Presence**: Select `Desirable` if a violation of the post-condition triggers a warning message informing the user about the requested property value. In this case, the user must confirm a warning message by clicking either a **Yes** or **No** button. The user can continue to the next wizard step without entering the respective property. Select `Always` if a violation of the post-condition triggers an error message informing the user about the required property value. In this case, the user must confirm the error message by clicking the **OK** button. The user cannot continue to the next wizard step until the required value has been entered for the object class property.
- Define the object class property or set of object class properties targeted by the post-condition:
- If a standard or custom object class property is targeted by the post-condition: In the **Properties** attribute, define the standard or custom object class property that should be validated in the wizard step. Depending on the configuration of the **Presence** attribute, an informational or error message will be displayed. Contact Software AG Support for more information about the object class properties associated with individual views. You should leave this field blank if you have defined an Alfabet query or native SQL query for the post-condition.
- If a referenced property or set of properties is targeted by the post-condition: Define the **Query** or **Query as Text** attribute:
    - **Query**: Define an Alfabet query using the **Alfabet Query Builder** to return a set of object class properties.
    - **Query as Text**: Enter an Alfabet query or a native SQL query to return a set of object class properties. For more information about defining Alfabet queries or about the special conditions that apply to native SQL queries used in Alfabet configurations, see the chapter Defining Queries.

The following is an example of an Alfabet query defined for a post-condition that validates whether an ICT object is assigned to the selected application. The Alfabet query validates that the ICT object's lifecycle is within the timeframe of the application's lifecycle:

```
ALFABET_QUERY_500

FIND

    Application

    InnerJoin ICTObject ON (And
    Application.ICTObject = ICTObject.REFSTR
    Application.StartDate >= ICTObject.StartDate
    Application.EndDate <= ICTObject.EndDate)

WHERE

    Application.REFSTR =:BASE
```

The following is an example of an Alfabet query defined for a post-condition that validates whether the release statuses of the demands associated with a selected project are set to Approved:

```
ALFABET_QUERY_500
FIND
    Project
    InnerJoin Demand ON Demand.AssignedToProject =
    Project.REFSTR
    WHERE
        (AND Project.REFSTR CONTAINS:BASE
        Demand.Status <> 'Approved')
```

- **Check Result Type**: Select either `Positive` or `Negative` to define what constitutes a validated result.
- `Positive` means that the post-condition is fulfilled if the selected property has a value or the query has delivered a result (at least one row.)
- `Negative` means that the post-condition is fulfilled if the selected property has no value or the query doesn't deliver any results.

For example, to validate whether an object class property is set, an Alfabet query is specified that returns the value for the object class property. The post-condition is that the Alfabet query returns a result. In this case, the **Check Result Type** attribute must be set to `Positive`.

On the other hand, to validate that an object class property is not set to a specific value because that value is not allowed in the current environment, an Alfabet query must be specified that searches for the property value. The post-condition is only met if the Alfabet query returns no result. In this case, the **Check Result Type** attribute must be set to `Negative`.

- **Message**: Specify a warning message to display if the post-condition is not fulfilled. The text should provide the user with information about what is required to resolve the post-condition. If no warning message is configured, then the standard warning message preconfigured by Software AG will be displayed to the user if the post-condition is not fulfilled.
- **Apply to Page**: If the wizard step has the **Step Type** attribute set to `Editor` and the **Tab as Separate Step** attribute set to `True`, you must define which editor tab the post-conditions should apply to. To do so, select the relevant tab that should be validated by the post-condition.

Please note that if the **Tab as Separate Step** attribute is set to `False` on the wizard step, the **Apply to Page** attribute must be empty otherwise the post-conditions will NOT be executed.

4) To specify additional behavior for the execution of post-conditions on the level of the wizard, go to the custom wizard  and define the following attributes:

- **Execute Post-Conditions on Back Moves**: Select `True` if post-conditions must be validated for the current wizard step before navigating to a preceding step via the **Back** button or a selected step via the **Go to Step** field. Select `False` if the post-conditions for the current wizard step do not need to be validated in order to navigate to the target wizard step. The default value is `False`.

The **Back** button is automatically displayed in the wizard. The **Go to Step** field is optional and will only be displayed if the **Show Wizard Steps Combo-Box** attribute is set to `True` for the wizard. For more information about configuring the buttons in the wizard, see the section Creating a Wizard.

The **Go to Step** field is only available in the wizard when an existing object is being edited. The field is not available in the first step when a new object is being created. **Please note that data for intermediary steps will not be checked!** For example, if a user goes from Step 2 to Step 4, the post-conditions for Step 2 will be checked and must be fulfilled, but post-conditions for Step 3 are not triggered and must not be fulfilled in order to go to Step 4. a **Go to Step** field can be displayed at the bottom of the wizard in the Alfabet interface.

Please note that the post-condition is executed AFTER the database transaction is performed. This is of particular relevance for post-conditions associated with standard or custom editors because the first attempt will be to save the user's data which may fail, for example, due to mandatory or uniqueness conditions being violated. Once this save has been successful, the post-conditions will be executed.

If the attribute **Execute Post-Conditions on Back Moves** is set to `False`, the post-conditions will not be executed if the user clicks the **Back** button. However, the validation of editor-related constraints such as preconfigured mandatory properties or uniqueness constraints for a set of properties will continue to be performed if the user clicks the **Back** button.

- **Execute Post-Condition in Transaction of Wizard Step**: Wizard step actions performed in an editor may be rolled back in case of failing post-conditions. Set to `True` if the transaction shall be rolled back and the data shall not be saved to the Alfabet database if a configured post-condition for a wizard step of the type `Editor` fails. The wizard will return to the wizard step as it was before the transaction was initiated and the message specified for the failed post-condition will be displayed. Select `False` if the wizard step actions performed in an editor shall not be rolled back in case post-conditions fail for the wizard step.

5) Click the **Save** button to save your definitions.

Determining the Sequence of Pre-Conditions and Post-Conditions

If you define multiple pre-conditions or post-conditions, the conditions will be executed in the order that they are specified for the wizard step. Please keep the following in mind when sequencing the post-conditions:

- Once any preconfigured mandatory properties have been validated as well as mandatory custom object class properties, the post-conditions will be validated in the sequence specified. If multiple post-conditions are violated, the error message for the first violated condition will be displayed when the user attempts to click the **Next** button or close the wizard. Once the error has been corrected and the user attempts to advance to the next wizard step, the error message for the second violated condition will be displayed, etc. The user must proceed to correct all violations in this manner. Once all violations have been corrected, the user will be able to save the current wizard step and advance to the next wizard step or close the wizard without losing data:
- If the wizard is configured to include the **Go to Step** field displayed at the bottom of the wizard view, users will be able to traverse to any step in the wizard process. Any post-conditions configured for

the wizard step that the user is leaving will be checked and, if necessary, required data must be entered in order to conclude the current wizard step. Data for intermediary steps, however, will not be checked. For example, if a user goes from Wizard Step 2 to Wizard Step 4, the post-conditions for Wizard Step 2 will be checked and must be fulfilled, but post-conditions for Wizard Step 3 are not triggered and must not be fulfilled in order to go to Step 4.

Please note that the post-condition is executed AFTER the database transaction is performed. This is of particular relevance for post-conditions associated with standard or custom editors because the first attempt will be to save the user's data which may fail, for example, due to mandatory or uniqueness conditions being violated. Once this save has been successful, the post-conditions will be executed.

If the attribute **Execute Post-Conditions on Back Moves** is set to `False`, the post-conditions will not be executed if the user clicks the **Back** button. However, the validation of editor-related constraints such as preconfigured mandatory properties or uniqueness constraints for a set of properties will continue to be performed if the user clicks the **Back** button.

If the wizard step has post-conditions defined and the **Tab as Separate Step** attribute has been set to `True`, the post-conditions will be checked after the last tab of the standard or custom editor has been reached. In this case, you must ensure that the attribute **Execute Post-Conditions on Back Moves** for the wizard is set to `False`. Otherwise, a situation may occur in which the user cannot navigate forward or backward if a mandatory post-condition has been defined for an object class property that can only be edited on a tab other than the last tab of the editor. For more information about the definition of the attributes associated with post-condition, see the section Defining a Post-Condition for a Wizard Step.

To order the sequence of pre-conditions or post-conditions:

1) To define the sequence of the wizard step actions, do one of the following as needed:

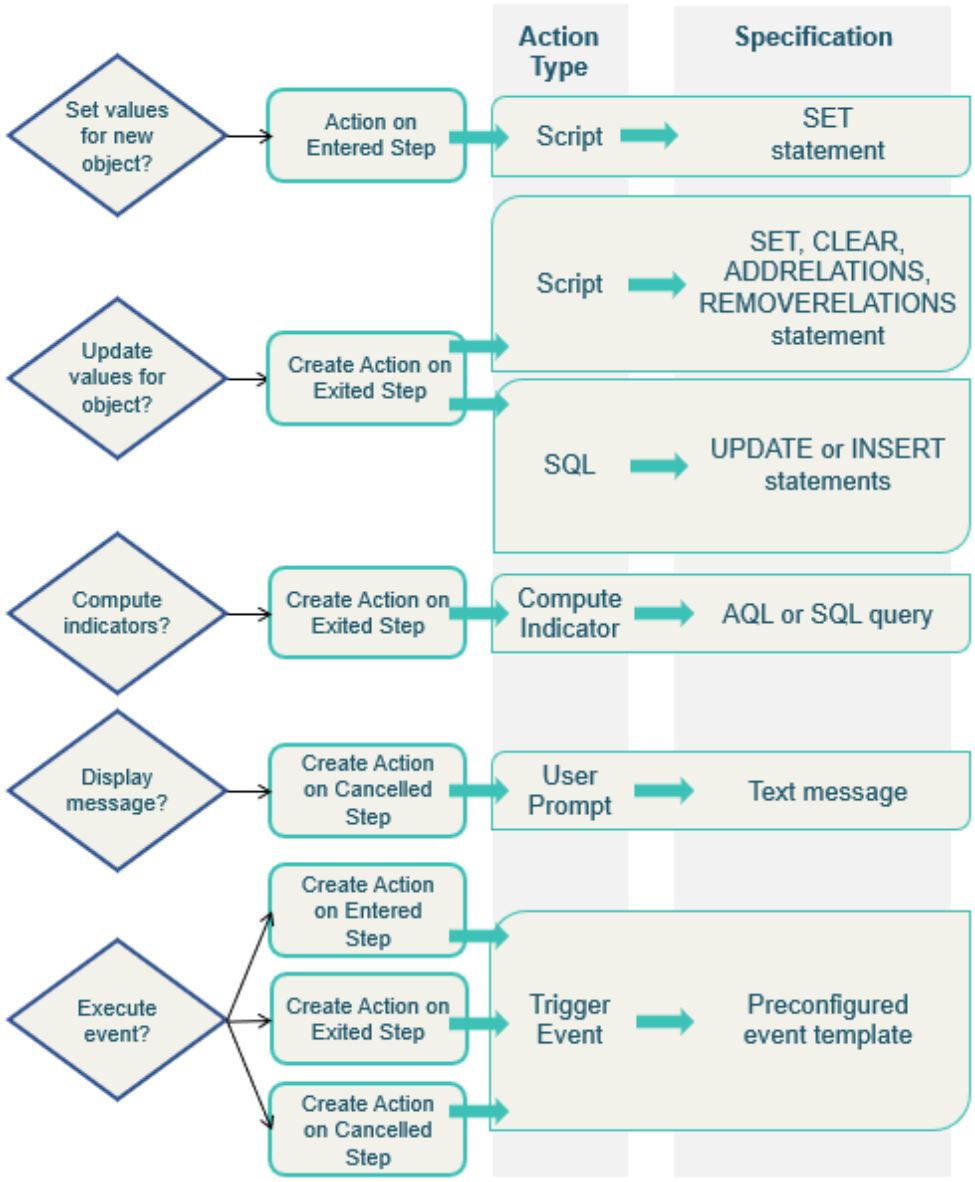
- Click the **Pre-Conditions** node below the relevant wizard step to open its attribute window. In the **Pre-Conditions** field, click the **Browse** button to open the editor and sequence the pre-conditions by clicking the **Up/Down** arrows.
- Click the **Post-Conditions** node below the relevant wizard step to open its attribute window. In the **Post-Conditions** field, click the **Browse** button to open the editor and sequence the post-conditions by clicking the **Up/Down** arrows.

2) In the toolbar, click the **Save** button to save your changes.

If you have completed the definition of the wizard, see Testing the Wizard in the Alfabet User Interface.

Configuring Wizard Step Actions for a Wizard Step

A wizard step action is a configured operation that is automatically executed when a wizard step is entered, exited, or cancelled. You can configure wizard step actions that update property values, create new objects, calculate indicators, or trigger events.



The following can be configured via wizard step actions:

- Automatically enter values for properties for a new object that is created in the context of a first wizard step. For example, you could configure that a status value and start date is automatically set when an object is created in the first wizard step. The command SET must be specified
- Automatically enter or clear properties for an object when a wizard step is exited. In this case, conditions can be specified that describe if the property update shall occur. For example, you could configure that a specified property is cleared when a wizard step is exited. For complex property updates, the SQL statements INSERT and UPDATE may be used.

- Automatically create a new object when a wizard step is exited. Upon creation of the object, you can also automatically enter values for the new object as well as specify references to the wizard in which the object was created.
- Automatically compute indicators for the current object when a wizard step is exited.
- Automatically trigger an event when a wizard step is entered, exited, or cancelled. Events allow for real-time automated updates to external systems as well as to data in Alfabet. Events allow, for example, a configured action to be triggered when a user closes the wizard window in the middle of the wizard process. A configured ADIF scheme will be triggered to process the data.

Wizard step actions are executed each time the wizard step is traversed. If this should not occur, a pre-condition should be configured for the wizard step.

There is no mechanism to verify the syntax or content of the statements. The following syntax is permissible for statements specified for wizard step actions:

- A value for a scalar property or object class property of type `Reference` may be targeted via the commands `SET` and `CLEAR`.
- A value for an object class property of type `ReferenceArray` may be targeted via the commands `ADDRELATIONS` and `REMOVERELATIONS`.
- The object class properties to be updated must be enclosed in parenthesis.
- Each statement must be terminated by a semi-colon.
- The following parameters may be used in the statement:
  - In the specification of the target property to be set:
  - `@BASE` (notation for the object targeted by a wizard step),
  - `@WIZARDBASE` (notation for the base object of the wizard)
  - `@NEW` (notation for a new object created via a `CREATE` statement. `@NEW` refers to the latest created object in the order of the specification.)
  - In the specification of the source property: `@BASE`, `@WIZARDBASE`, `@CURRENT_USER`, `@CURRENT_MANDATE`, `@CURRENT_PROFILE`, `@TODAY`.

The following information is available:

- Defining Property Values To Be Automatically Set for New Objects
- Defining Property Values To Be Automatically Updated When a Wizard Step Is Exited
- Defining a Wizard Step Action of the Action Type Script
- Defining a Wizard Step Action of the Type SQL
- Computing Indicators When a Wizard Step Is Exited
- Creating a New Object When a Wizard Step Is Exited
- Triggering an Event When a Wizard Step Is Exited
- Specifying Wizard Step Actions When a Wizard Step Is Cancelled

- Determining the Sequence of Wizard Step Actions

Defining Property Values To Be Automatically Set for New Objects

When a new object is created in the first wizard step, the object class property fields in the wizard can be pre-populated with default values. A value for a scalar property or object class property of type `Reference` may be specified via the command `SET`. This is only possible for the first wizard step. If multiple statements are required, a separate wizard step action must be created for each statement.

The wizard step action **Action on Entered Step** for which the **Action Type** attribute is set to `Script` may only be specified for the first wizard step. For all other wizard steps, the update of properties must be specified via the wizard step action **Action on Exited Step**. For more information see, Defining Property Values To Be Automatically Updated When a Wizard Step Is Exited.

To define an object class property to be set for a new object created in the context of the first wizard step:

1) Expand the custom wizard and expand the first wizard step .
2) Right-click the **Action on Entered Step** node and select **New Action On Enter Step**.
3) Define the following attributes in the attribute window:

- **Technical Name**. Enter a name for the wizard step action. This name is not displayed in the Alfabet interface.
- **Action Type**: Select `Script`.
- **Technical Comment**: Enter any relevant information about the wizard step action.
- **Statements**: Click the **Browse** button to open the editor. In order to provide an initial value for an object class property when the object is created in the first wizard step, Specify a `SET` statement for the wizard step action. Please note the following:

There is no mechanism to verify the syntax or content of the statements.

- The statement must refer to the class model. Property names must be spelled in accordance with the class model.
- The following syntax is required for the `SET` statement:
  - Specify a value for a scalar property or object class property of type `Reference` that may be targeted.
  - The object class properties to be updated must be enclosed in parenthesis.
  - A statement must be terminated by a semi-colon.
  - The following parameters may be used in the statement:
  - In the specification of the target property to be set: `@BASE` (notation for the object targeted by a wizard step), `@WIZARDBASE`(notation for the base object of the wizard)

- In the specification of the source property: `@BASE`, `@WIZARDBASE`, `@CURRENT_USER`, `@CURRENT_MANDATE`, `@CURRENT_PROFILE`, `@TODAY`.

The following displays the correct syntax to use for statements:

```
SET(PROPERTY_NAME,"Value");
```

For example, to set the `Application Type` property to `Client Server` for new applications:

```
SET(@BASE.SC_ApplicationType, "Client Server");
```

4) Click the **Save**  button to save your definitions.

Defining Property Values To Be Automatically Updated When a Wizard Step Is Exited

You can update property values when a wizard step is exited. To do so, you can either specify an **Action on Exited Step** of type `Script` which allows you to use the commands `SET`, `CLEAR`, `ADDRELATIONS`, and `REMOVERELATIONS`, or of type `SQL` which allows you to specify more complex statements via the commands `UPDATE` and `INSERT`.

If an **Action on Exited Step** wizard step action is a configured for a wizard step of **Type** = `Editor` and the **Tab as Separate Step** attribute for the wizard is set to `True`, the wizard step action will only be executed on the last tab of the editor (which is the last sub-step of the wizard step). Please note that if the user moves backward through the sub-steps of the wizard step via the **Previous** button, for example, the wizard step action will be executed for each sub-step of the wizard step.

The following information is available:

- Defining a Wizard Step Action of the Action Type Script
- Defining a Wizard Step Action of the Type SQL

Defining a Wizard Step Action of the Action Type Script

You can define one or more wizard step actions of the type **Action on Exited Step**. Wizard step actions for which the **Action Type** attribute is set to `Script` can be created and statements using the commands `SET`, `CLEAR`, `ADDRELATIONS`, and `REMOVERELATIONS` can be defined. If multiple statements are required, a separate wizard step action must be created for each statement.

Optionally, you can also define a condition to execute the wizard step action depending on the availability of specific data returned by a query.

To define a wizard step action of the type `Script`:

1) Expand the custom wizard  and expand the first wizard step  .
2) Right-click the **Action on Exited Step** node and select **New Action On Exited Step**.
3) Define the following attributes in the attribute window:

- **Technical Name**. Enter a name for the wizard step action. This name is not displayed in the Alfabet interface.
- **Action Type**: Select `Script`.
- **Technical Comment**: Enter any relevant information about the wizard step action.
- **Statements**: Click the **Browse** button to open the editor. Enter one statement for the wizard step action. Please note the following:

  There is no mechanism to verify the syntax or content of the statements.

- The statement must refer to the class model. Property names must be spelled in accordance with the class model.
- You may use the commands `SET`, `CLEAR`, `ADDRELATIONS`, and `REMOVERELATIONS`. The following syntax is required for statements:
  - `SET` and `CLEAR`: A value for a scalar property or object class property of type `Reference` may be targeted.
  - `ADDRELATIONS` and `REMOVERELATIONS`: A value for an object class property of type `ReferenceArray` may be targeted.
  - The object class properties to be updated must be enclosed in parenthesis.
  - A statement must be terminated by a semi-colon.
  - The following parameters may be used in the statement:

In the specification of the target property to be set: `@BASE`, `@WIZARDBASE`

In the specification of the source property: `@BASE`, `@WIZARDBASE`, `@CURRENT_USER`, `@CURRENT_MANDATE`, `@CURRENT_PROFILE`, `@TODAY`.

The following examples display the correct syntax to use for statements:

```
CLEAR(PROPERTY_NAME);
ADDRELATIONS(Reference.ToProperty,FromReference);
REMOVERELATIONS(Reference.ToProperty,FromReference);
```

If a newly created application that is the base object of the wizard should be added to an application group that is the base object of the current wizard step, the statement would be:

```
ADDRELATIONS(@BASE.Applications,@WIZARDBASE);
```

4) Optionally, you can define a condition to execute the wizard step action depending on the availability of specific data returned by a query. For example, you could specify that the wizard step action may only be executed if a property of the base object of the wizard is set to a specific value. Edit the following attributes in the attribute window to define the condition:

- **Check Query** / **Check Query as Text**: Define a query that will return a result only if a condition is met. The query can be defined either as an Alfabet query in the **Check Query** attribute or as a native SQL query in the **Check Query as Text** attribute.

- **Result Type**: Select `Positive` if the wizard step action shall only be executed if the query returns a result. Select `Negative` if the wizard step action shall only be executed if the query does not return a result.

  For example, a wizard step action to update an application's indicators when a wizard step is exited shall be triggered if the application's release status is set to the value "Approved". The following query will only return a result if the application that is the base application of the wizard step has the correct release status:

  ```
  SELECT REFSTR
  FROM APPLICATION
  WHERE APPLICATION.STATUS = 'Approved'
  AND APPLICATION.REFSTR = @WIZARDBASE
  ```

  The **Result Type** is set to `Positive` so that the wizard step action is only executed if the query returns a result.

5) Click the **Save**  button to save your definitions.

Defining a Wizard Step Action of the Type SQL

You can define one or more wizard step actions of the type **Action on Exited Step**. Wizard step actions for which the **Action Type** attribute is set to `SQL` can be created and the commands `UPDATE` and `INSERT` can be defined.

Please note that the `INSERT` statement is only allowed to insert new relation entries in the `RELATIONS` table. If you attempt to insert new relation entries in class tables, an error will occur because the `GUID` and `REFSTR` are not automatically created and result in a `NULL` value.

Optionally, you can also define a condition to execute the wizard step action depending on the availability of specific data returned by a query.

To define a wizard step action of the type `SQL`:

1) Expand the custom wizard  and expand the wizard step  .
2) Right-click the **Action on Exited Step** node and select **New Action On Exit Step**.
3) Define the following attributes in the attribute window:

- **Technical Name**. Enter a name for the wizard step action. This name is not displayed in the Alfabet interface.
- **Action Type**: Select `SQL`.
- **Technical Comment**: Enter any relevant information about the wizard step action.
- **Statements**: Click the **Browse**  button to open the editor. Enter one statement for the wizard step action. If multiple statements are required, a separate wizard step action must be created for each statement. You may use the commands `UPDATE` or `INSERT`. The parameters `@BASE` (notation for the object targeted by a wizard step) and `@WIZARDBASE` (notation for the base object of the wizard) can be used.

The following examples display the correct syntax to use for statements:

```
UPDATE APPLICATION
SET APPLICATION.APPLICATIONTYPE='Mainframe'
WHERE APPLICATION.REFSTR=@BASE
```

4) Optionally, you can define a condition to execute the wizard step action depending on the availability of specific data returned by a query. For example, you could specify that the wizard step action may only be executed if a property of the base object of the wizard is set to a specific value. Edit the following attributes in the attribute window to define the condition:

- **Check Query** / **Check Query as Text**: Define a query that will return a result only if a condition is met. The query can be defined either as an Alfabet query in the **Check Query** attribute or as a native SQL query in the **Check Query as Text** attribute.
- **Result Type**: Select `Positive` if the wizard step action shall only be executed if the query returns a result. Select `Negative` if the wizard step action shall only be executed if the query does not return a result.

For example, a wizard step action to update an application's indicators when a wizard step is exited shall be triggered if the application's release status is set to the value "Approved". The following query will only return a result if the application that is the base application of the wizard step has the correct release status:

```
SELECT REFSTR
FROM APPLICATION
WHERE APPLICATION.STATUS = 'Approved'
AND APPLICATION.REFSTR = @WIZARDBASE
```

The **Result Type** is set to `Positive` so that the wizard step action is only executed if the query returns a result.

5) Click the **Save** button to save your definitions.

Computing Indicators When a Wizard Step Is Exited

You can configured to automatically compute all indicators for the current object targeted by the wizard step. The indicators will be recalculated when the wizard step is exited. Optionally, you can also define a condition to execute the wizard step action depending on the availability of specific data returned by a query.

For more information about the configuration of evaluation types and indicator types, see the section *Configuring Evaluations, Prioritization Schemes, and Portfolios* in the reference manual *Configuring Evaluation and Reference Data in Alfabet*.

To define a wizard step action of the type `ComputeIndicators`:

1) Expand the custom wizard and expand the wizard step .
2) Right-click the **Action on Exited Step** node and select **New Action on Exited Step**.

3) Define the following attributes in the attribute window:

- **Technical Name**. Enter a name for the wizard step action. This name is not displayed in the Alfabet interface.
- **Action Type**: Select `ComputeIndicators`.
- **Technical Comment**: Enter any relevant information about the wizard step action.

4) Optionally, you can define a condition to execute the wizard step action depending on the availability of specific data returned by a query. For example, you could specify that the wizard step action may only be executed if a property of the base object of the wizard is set to a specific value. Edit the following attributes in the attribute window to define the condition:

- **Check Query** / **Check Query as Text**: Define a query that will return a result only if a condition is met. The query can be defined either as an Alfabet query in the **Check Query** attribute or as a native SQL query in the **Check Query as Text** attribute.
- **Result Type**: Select `Positive` if the wizard step action shall only be executed if the query returns a result. Select `Negative` if the wizard step action shall only be executed if the query does not return a result.

For example, a wizard step action to update an application's indicators when a wizard step is exited shall be triggered if the application's release status is set to the value "Approved". The following query will only return a result if the application that is the base application of the wizard step has the correct release status:

```
SELECT REFSTR
FROM APPLICATION
WHERE APPLICATION.STATUS = 'Approved'
AND APPLICATION.REFSTR = @WIZARDBASE
```

The **Result Type** is set to `Positive` so that the wizard step action is only executed if the query returns a result.

5) Click the **Save**  button to save your definitions.

Creating a New Object When a Wizard Step Is Exited

A new object can be created in the context of a wizard step via the command `CREATE`. The command `ADDRELATIONS` may also be specified in order to specify the base object and add values to the new object. This is of particular relevance when a questionnaire or survey object shall be created in the context of a wizard. The command `SET` may be specified to set property values for the new object.

Optionally, you can also define a condition to execute the wizard step action depending on the availability of specific data returned by a query.

1) Expand the custom wizard  and expand the wizard step  .
2) Right-click the **Action on Exited Step** node and select **New Action On Exited Step**.
3) Define the following attributes in the attribute window:

- **Technical Name**. Enter a name for the wizard step action. This name is not displayed in the Alfabet interface.
- **Action Type**: Select `Script`.
- **Technical Comment**: Enter any relevant information about the wizard step action.
- **Statements**: Click the **Browse** button to open the editor. In order to create a new object, a `CREATE` command should be defined. Enter one statement for the wizard step action. If multiple statements are required, a separate wizard step action must be created for each statement. Please note that wizard step actions of the type `Script` must always refer to the class model and hence property names must be spelled in accordance with the class model.

The following displays the correct syntax to use for statements:

```
CREATE(OBJECTCLASS);
ADDRELATIONS (@NEW.OBJECTCLASSPROPERTY,@WIZARDBASE);
```

For example, to create a new object for the survey class `SC_APP_CSAT` whereby the property `BASEOBJECT` is set to the wizard object:

```
CREATE(SC_APP_CSAT);
ADDRELATIONS(@NEW.BASEOBJECT,@WIZARDBASE);
```

4) Optionally, you can define a condition to execute the wizard step action depending on the availability of specific data returned by a query. For example, you could specify that the wizard step action may only be executed if a property of the base object of the wizard is set to a specific value. Edit the following attributes in the attribute window to define the condition:

- **Check Query** / **Check Query as Text**: Define a query that will return a result only if a condition is met. The query can be defined either as an Alfabet query in the **Check Query** attribute or as a native SQL query in the **Check Query as Text** attribute.
- **Result Type**: Select `Positive` if the wizard step action shall only be executed if the query returns a result. Select `Negative` if the wizard step action shall only be executed if the query does not return a result.

For example, a wizard step action to update an application's indicators when a wizard step is exited shall be triggered if the application's release status is set to the value "Approved". The following query will only return a result if the application that is the base application of the wizard step has the correct release status:

```
SELECT REFSTR
FROM APPLICATION
WHERE APPLICATION.STATUS = 'Approved'
AND APPLICATION.REFSTR = @WIZARDBASE
```

The **Result Type** is set to `Positive` so that the wizard step action is only executed if the query returns a result.

5) Click the **Save** button to save your definitions.

Triggering an Event When a Wizard Step Is Exited

You can configure that an event is triggered when a wizard step is entered, exited, or cancelled. Events allow for real-time automated updates to external systems as well as to data in Alfabet. Events allow, for example, a configured action to be triggered when a user closes the wizard window in the middle of the wizard process. A configured ADIF scheme will be triggered to process the data.

Additional configuration is required in order to trigger events. For more information about the configuration required to implement the event capability, see the chapter Configuring Events.

Optionally, you can also define a condition to execute the wizard step action depending on the availability of specific data returned by a query.

To configure the wizard step to trigger an event:

1) Expand the custom wizard  and expand the wizard step  .
2) Right-click the node of the relevant wizard step action that shall trigger the event and select either **Action on Entered Step**, **Action on Exited Step**, or **Action on Cancelled Step**.
3) Define the following attributes in the attribute window:

- **Technical Name**. Enter a name for the wizard step action. This name is not displayed in the Alfabet interface.
- **Action Type**: Select `TriggerEvent`.
- **Technical Comment**: Enter any relevant information about the wizard step action.
- **Parameter**: Select the relevant event template from the drop-down list.

4) Optionally, you can define a condition to execute the wizard step action depending on the availability of specific data returned by a query. For example, you could specify that the wizard step action may only be executed if a property of the base object of the wizard is set to a specific value. Edit the following attributes in the attribute window to define the condition:

- **Check Query** / **Check Query as Text**: Define a query that will return a result only if a condition is met. The query can be defined either as an Alfabet query in the **Check Query** attribute or as a native SQL query in the **Check Query as Text** attribute.
- **Result Type**: Select `Positive` if the wizard step action shall only be executed if the query returns a result. Select `Negative` if the wizard step action shall only be executed if the query does not return a result.

For example, a wizard step action to update an application's indicators when a wizard step is exited shall be triggered if the application's release status is set to the value "Approved". The following query will only return a result if the application that is the base application of the wizard step has the correct release status:

```
SELECT REFSTR
FROM APPLICATION
WHERE APPLICATION.STATUS = 'Approved'
AND APPLICATION.REFSTR = @WIZARDBASE
```

The **Result Type** is set to `Positive` so that the wizard step action is only executed if the query returns a result.

5) Click the **Save** button to save your definitions.

Specifying Wizard Step Actions When a Wizard Step Is Cancelled

You can configure the action that should occur for a wizard step if a user closes a wizard by clicking the **Close** (X) button at the top of the wizard. You can optionally specify a message in order to intercept the cancel action and allow the user to confirm or negate the impending cancel action.

To configure an event for a cancelled wizard step:

1) Expand the custom wizard and expand the wizard step .
2) Right-click the **Action on Cancelled Step** node and select **New Action on Cancelled Step**.
3) Define the following attributes in the attribute window:

- **Technical Name**. Enter a name for the wizard step action. This name is not displayed in the Alfabet interface.
- **Action Type**: Select `TriggerEvent`.
- **Technical Comment**: Enter any relevant information about the wizard step action.
- **Parameter**: Select the relevant event template from the drop-down list.

4) A message can be configured for wizard step actions of type **Action on Cancelled Step** in order to intercept the cancel action and allow the user to confirm or negate the impending cancel action. To configure a message, create another wizard step action by selecting **New Action on Cancelled Step**. Define the following attributes:

- **Technical Name**. Enter a name for the wizard step action. This name is not displayed in the Alfabet interface.
- **Action Type**: Select `UsePrompt`.
- **Technical Comment**: Enter any relevant information about the wizard step action.
- **Prompt**: Enter the message to display if the user attempts to cancel the wizard step.
- **Cancel Step Message Prompt Buttons**: Select the relevant buttons to show in the message box.

5) Click the **Save** button to save your definitions.

Determining the Sequence of Wizard Step Actions

If you define multiple wizard step actions, the actions will be executed in the order that they are specified for the wizard step.

To order the sequence of actions:

1) To define the sequence of the wizard step actions, do one of the following as needed:

- Click the **Action on Entered Step** node below the relevant wizard step to open its attribute window. In the **Actions on Entered Step** field, click the **Browse** button to open the editor and sequence the actions by clicking the **Up/Down** arrows.
- Click the **Action on Exited Step** node below the relevant wizard step to open its attribute window. In the **Actions on Exited Step** field, click the **Browse** button to open the editor and sequence the actions by clicking the **Up/Down** arrows.
- Click the **Action on Cancelled Step** node below the relevant wizard step to open its attribute window. In the **Actions on Cancelled Step** field, click the **Browse** button to open the editor and sequence the actions by clicking the **Up/Down** arrows.

2) In the toolbar, click the **Save** button to save your changes.

If you have completed the definition of the wizard, see Testing the Wizard in the Alfabet User Interface.

Configuring a Different Target Object for a Wizard Step

When a wizard is created, the wizard designer will specify the object class for which the wizard is configured. The object class is then displayed in the **Class Name** attribute of the wizard. Typically, the wizard will process a single object in the object class that the wizard was created for.

However, it is possible to specify that another object in a different object class must also be processed in the context of capturing the base object of the wizard. To do this, a query must be defined on the wizard step in order to find the related target object.

For example, a wizard has been configured in order to capture application data. The enterprise requires that the ICT object that the application is assigned also be defined at the time that the application data is captured. In this case, you can configure a query to find the object in the object class `ICTObject` that should be defined in the context of the wizard

The query must be entered in the **Base Object Query** field for each relevant wizard step that targets the object found by the query. Therefore, if the object found by the query shall be the target object for multiple wizard steps, the query must be entered in the **Base Object Query** field for each of those wizard steps. If the query is not entered in the **Base Object Query** field of a wizard step, the wizard will return to the original object defined in the wizard.

You must ensure that the object being searched for by the query exists and can be found by the query. If an object cannot be found by the query, an error will occur in the wizard. For example, if an ICT object that the application is assigned to must be found by the query, then you could make the ICT object property a mandatory property that is controlled by a post-condition. Or, you could define a pre-condition for the next wizard step that skips the step if the reference to ICT object does not exist.

To configure a wizard step to find a different target object:

1) Expand the custom wizard and expand the wizard step .

2) In the **Base Object Query** field, enter an Alfabet query or native SQL query to find the relevant object to be processed in the wizard step.

Keep the following in mind when configuring the base object query for a wizard step:

- The query to find the base object for the wizard step is evaluated before the evaluation of other queries associated with the wizard step such as the queries for pre-conditions or wizard step actions. Therefore, when using the parameter `@BASE` in queries related to a wizard step, `@BASE` returns the `REFSTR` of the base object of the wizard step. To refer to the initial base object of the wizard, use the parameter `@WIZARDBASE`.
- The result of the query entered in the **Base Object Query** attribute should have the `REFSTR` of the object which should be used as base object in the first column. Therefore, the `REFSTR` of the object must be defined as the first `SELECT` property in native SQL queries. For Alfabet queries, `SHOW` properties do not need to be defined. The `REFSTR` of the object found by the query is selected automatically as the query result.
- The query should be defined to find only one object. If the query defined in the **Base Object Query** attribute of a wizard step returns several results (rows), then the wizard step will be executed for the first result. If no result is returned by the query, then an error will be displayed stating that no instance has been found.
- If you are implementing an SQL query, the query must be of the type `SELECT`.

The following example illustrates an Alfabet query that searches for the ICT object that the application is assigned to.

```
ALFABET_QUERY_500
FIND
ICTObject
    InnerJoin Application
        ON Application.ICTObject = ICTObject.REFSTR
WHERE
Application.REFSTR CONTAINS:BASE
```

3) Once you have defined the base object query for the selected wizard step, define the **View** attribute as well as the rest of the wizard step attributes as you would for any wizard step as described in the section Creating a Wizard Step.

4) If the object searched for in the query is to be the target object of the next wizard step, then you must also enter the query in the **Base Object Query** attribute for that wizard step. Otherwise, the wizard will return to the original object defined in the wizard.

5) In the toolbar, click the **Save** button to save your changes.

Determining the Sequence of Wizard Steps in the Wizard

Typically, a wizard user will move through the wizard process in a linear manner. In this case, the user starts with the first wizard step and once the required data has been entered, the user can click the **Next** button and advance to the next wizard step.

The order of the wizard steps is determined in the **Steps** attribute of the wizard. Here you must list the wizard steps from top to bottom in the sequence in which they should be processed. Please note the following:

- If you have defined one or more branches of subordinate wizard steps for a particular wizard step, these subordinate wizard steps do not need to be explicitly sequenced since they are created by definition as a hierarchy. For more information about creating a branch of subordinate wizard steps, see the section Defining a Subordinate Wizard Step or a Branch of Subordinate Wizard Steps.
- If the **Tab as Separate Step** attribute is set to `True` for wizard step of the type `Editor`, you cannot change the sequence of the tabbed pages in the editor. In this case, the tabbed pages in an editor are treated as a single unit. The workflow steps based on the editor's tabbed pages will be displayed in the order that they appear in the custom editor. A more granular sequence is not possible. For more information about defining tabbed pages as separate wizard steps, see the section Configuring a Wizard Step to Display a Standard or Custom Editor.

  Alternatively, you could assign the editor to two wizard steps, hide the tabbed pages that are not relevant for each wizard step, and position the two wizard steps as needed in the sequence.

- You can specify the wizard so that users can circumvent the linear process prescribed by the specified sequence. In this case, a **Go to Step** field can be displayed at the bottom of the wizard in the Alfabet interface. This is specified by setting the **Show Wizard Steps Combo-Box** attribute to `True` for wizard. If the **Execute Post- Conditions on Back Moves** attribute is also set to `True` for the wizard, any post-conditions configured for the wizard view that the user is leaving will be checked and, if necessary, the user will be required to provide the missing data in order to conclude the current wizard step. For more information about configuring post-conditions, see the section Defining a Post-Condition for a Wizard Step.

  The completeness of data for intermediary wizard views will not be checked. For example, if a user goes from Wizard Step 2 to Wizard Step 4, the data entry prompts for Wizard Step 2 will be checked and must be fulfilled, but data entry prompts for Step 3 are not triggered and must not be fulfilled in order to go to Wizard Step 4.

A pre-condition may NOT be configured for the first wizard step NOR for the final wizard step or subordinate wizard step. If you do so and the pre-condition is not fulfilled, an error will occur. In this case, for example, the wizard could stagnate and not advance to the next wizard step. If a pre-condition is required for the last logical step or subordinate wizard step in the wizard, it is recommended that you add another final concluding wizard step with no pre-condition and only static text defined (for example, with a message such as "You have completed the wizard").

To define the sequence of the wizard steps:

1) Expand the custom wizard  .
2) Define the following attributes as needed:

- **Steps**: Click the **Browse**  button to open the **Sort Entries** editor to order the wizard steps. You will see all wizard views assigned to the wizard. Subordinate wizard steps defined for a particular wizard

step will not be displayed in the **Sort Entries** editor. To define the sequence of the wizard steps, select a wizard step in the list and click the **Up/Down** button in the upper right corner of the editor to move the view up or down in the list. Repeat this for all wizard steps until they are listed in the correct order. Click **OK** to save the sequence definition.

- **Show Wizard Steps Combo-Box**: Select `True` to display the **Go to Step** field at the bottom of the wizard in order to allow wizard users to go forward or backward to any step in a wizard.

3) If one or more branches of subordinate wizard steps have been specified for a particular wizard step, specify the type of numbering to display in the wizard header for the subordinate wizard steps created for a wizard step. In the **Type** attribute, specify one of the following:

- Select `Tree` to number all subordinate wizard steps so that subordinate wizard step 1, subordinate wizard step 2, and subordinate wizard step 3 that are subordinate to wizard step 1 will be numbered step 1.1, 1.2, and 1.3 in the wizard header. If the **Show Wizard Steps Combo-Box** attribute is set to `True` for the wizard, then the subordinate wizard steps will be displayed in the **Go to Step** field.
- Select `Straight` to number all subordinate wizard steps so that all subordinate wizard step that are subordinate to wizard step 1 will all have the same number as their ascendant wizard step. In this case, subordinate wizard step 1, subordinate wizard step 2, and subordinate wizard step 3 would all be numbered 1 of 7 in the wizard header. Subordinate wizard steps will not be displayed in the **Go to Step** field if the **Type** field is set to `Straight`.

4) In the toolbar, click the **Save** button to save your changes.

Hiding Object Class Properties and Functionalities in the Wizard for a Specific User Profile

The custom wizard will typically have wizard steps in which editors, page views, and configured reports are embedded. Each wizard that you create can be further configured to hide specific data (properties) from users working with the custom wizard. The content of the **Customization Editor** will differ, depending on whether you are configuring an editor, page view, or configured report in the wizard step. If secondary views (data quality widgets) are configured for the wizard, these will also be displayed when you access the Alfabet user interface via the **Configure Wizard** functionality.

Please note the following:

- You can hide specific fields (object class properties) in embedded editors. Additionally, you can specify custom selectors to replace standard selectors for fields in which a reference to an object must be defined.
- You can hide functionalities (for example, create, copy, edit, navigate, etc.) available in the toolbar of page views and configured reports. However, this configuration cannot be done in the context of a wizard, but rather in the context of the user profile configuration. The customization of a page view or configured report is then applied to ALL instances of the page view or report in the configured user profile. In this case, a page view or report cannot be differently configured for specific object views. For more information, see the section Hiding Functionalities in a Page View or Configured Report in the chapter Configuring User Profiles for the User Community.
- You cannot configure the columns in page views and configured reports in the context of a wizard.

The configuration of a custom wizard will apply to all instances of the custom wizard in Alfabet. For example, if you hide object class properties or functionalities in a custom wizard, the object class properties or functionalities will be hidden for all instances of the custom wizard. In other words, a selected wizard cannot be differently configured in the context of different object class stereotypes. The wizard configuration will apply to each object class stereotype that the custom wizard is assigned to. If different configurations are required for a custom wizard, it is recommended that you create a new wizard via the copy functionality and modify the new wizard as needed. Once the wizard is configured, it can be selected in the **Wizard** attribute for the class setting that you create for the object class stereotype.

Please note that if changes are made to a wizard after the **Configure Wizard** functionality has been closed, the settings in the **Configure Wizard** functionality will be lost. Therefore, the following procedure is recommended:

1) Design the wizard
2) Save the design
3) Refine the visibility of tabs, properties, custom selectors in the embedded editors and hide functionalities in embedded page views and configured reports via the **Configure Wizard** functionality
4) Close and reopen the database.

The following information is available:

- Hiding Properties in an Editor Embedded in the Wizard
- Hiding Functionalities in Page Views and Configured Reports Embedded in the Wizard
- Resetting the Configuration of Visibility to the Default Settings

Hiding Properties in an Editor Embedded in the Wizard

You can hide standard or custom object class properties in the editors embedded in a wizard. Please note the following about hiding properties in wizards:

- Any properties that you hide in an editor cannot be defined or edited by users accessing Alfabet with the associated user profile.
- A red star in an editor indicates that the object class property is a mandatory property. It is possible to exclude a mandatory property in an editor or wizard as long as the mandatory property is not part of a class key definition. A class key definition specifies one or a combination of object class properties that must have unique values when the object is created. For more information about the configuration of class keys, see the section Configuring Class Keys for Object Classes in the chapter Configuring the Class Model.
- In conjunction with the task of hiding properties in editors, you can also specify a custom selector that is to be used in place of the standard object selector in editor fields that require a reference to an object to be defined. For more information about the configuration of a custom selector, see the section Configuring a Custom Selector for Search Functionalities.
- Properties that are hidden in an editor embedded in a wizard are excluded in that wizard for all user profiles that the wizard is assigned to.

The configuration of a custom wizard will apply to all instances of the custom wizard in Alfabet. For example, if you hide object class properties or functionalities in a custom wizard, the object class properties or functionalities will be hidden for all instances of the custom wizard. In other words, a selected wizard cannot be differently configured in the context of different object class stereotypes. The wizard configuration will apply to each object class stereotype that the custom wizard is assigned to. If different configurations are required for a custom wizard, it is recommended that you create a new wizard via the copy functionality and modify the new wizard as needed. Once the wizard is configured, it can be selected in the **Wizard** attribute for the class setting that you create for the object class stereotype.

- If the object class properties should not be displayed at all in the Alfabet interface, then you must ensure that they are completely excluded from the view scheme and therefore not displayed in the **Attributes** section of a custom object view, page views, and configured reports.

1) Go to the **Presentations** tab, right-click the custom wizard  and select **Configure Wizard**. The wizard is displayed in the browser.

2) If the wizard step is of the type `Editor`, click the **Configure View**  button in the upper right corner of the first wizard step. The **Customization Editor** opens and displays the relevant interface elements for the view you are working with.

3) In the **Choose One Settings Mode** menu, select **Explicit Settings from Configuration Object**. In the dataset that is displayed, you can configure the visibility of tabs and properties and specify the custom selector in the editor that is embedded in a wizard. The **Customization Editor** displays the following columns for an editor:

- **Name**: Displays the technical name of a tab or object class property in a tab.
- **Caption**: Displays the caption defined for the tab or object class property in a tab.
- **Default Selector**: Displays the name of the default selector used to find objects if an object selector is required to define the object class property. This field will only by filled in if an object selector is actually implemented.
- **Excluded**: Click in the cell to set an X to specify that the respective element shall be hidden in the wizard. Click the X to clear the exclusion setting and make the element visible in the editor.
- **Custom Selector**: Select a custom selector to replace the default selector displayed in the **Default Selector** column. A drop-down menu will display all custom selectors configured for your solution. You must ensure that you select a custom selector relevant to the context for which it will be used. For more information about the configuration of a custom selector, see the section Configuring a Custom Selector for Search Functionalities.

4) Click the **OK** button to save the changes in the **Customization Editor** or click **Cancel** to exit without saving the changes.

5) To view the changes, you must close the wizard and return to Alfabet Expand and click the **Save**  button. When you reopen the wizard, the excluded tabs and properties will no longer be displayed in the editor.

Hiding Functionalities in Page Views and Configured Reports Embedded in the Wizard

In a page view or configured reports that is embedded in a wizard, you can configure the visibility of menus, menu options and action buttons displayed in the toolbar, thus hiding various functionalities in the wizard. Please note that you cannot configure the columns in page views and configured reports in the context of a wizard.

1) Go to the **Presentations** tab, right-click the custom wizard and select **Configure Wizard**. The wizard is displayed in the browser.

2) Click the **Configure View** button in the upper-right corner of the first wizard step. The **Customization Editor** opens and displays the relevant interface elements for the view you are working with.

3) If the wizard step is of the type `View` or `Report` to click the **Configure View** button in the upper right corner of the first wizard step. The **Customization Editor** opens and displays the relevant interface elements for the view you are working with.

4) To specify the visibility of functionalities, select `Toolbar` in the **Select Configuration Object** field.

5) In the **Choose One Settings Mode** menu in the toolbar of the dataset, select **Explicit Settings from Selected Configuration Object** to display a dataset that allows visibility to be explicitly specified for the selected object view.

6) In the **Excluded** column, click in the cell to set an X to specify that the respective menu or action button is hidden in the view.

   If a button includes a drop-down menu providing one or multiple options, you can hide one or more of these functionalities. Please note that if you hide all functionalities available for a button, you must explicitly exclude the parent button in order to ensure that it is hidden from the toolbar.

7) Click the **OK** button to save the changes in the **Customization Editor** or click **Cancel** to exit without saving the changes.

8) To view the changes, you must close the wizard and return to Alfabet Expand and click the **Save** button. When you reopen the wizard, the excluded functionalities will no longer be displayed in the relevant page view or configured report.

Resetting the Configuration of Visibility to the Default Settings

You can reset the configuration to its default setting. You must save your changes by clicking the **Save** button before you can further configure the wizard.

1) Go to the **Presentations** tab, right-click the custom wizard that you want to reset and select **Reset Wizard Configuration**.

2) You must save your changes by clicking the **Save** button before you can further configure the wizard.

Adding Data Quality Widgets to Wizards or Wizard Steps

The completeness of data in a wizard can be displayed in data quality widgets that provide information to the user about the status of data completion in the wizard. Secondary views based on configured data quality widget reports or similar complementary information as represented in Gantt charts or business charts can be assigned to a wizard as a whole or individual wizard steps to provide information to the user such as the completeness of the underlying data of an object and may even provide a link to a view that allows incomplete data to be updated. The secondary views will be attached to the right-hand edge of the wizard view and will stay attached to the wizard if it is resized or repositioned.

A typical use case for quality widgets is a widget report that opens to provide information to the user about the quality of the data in a wizard step. For example, the user could be provided with information about the completeness of the properties or indicators specified for the object in the wizard.

The following additional configuration is required for secondary views:

- The configured reports that are implemented as quality widgets must first be configured before they can be assigned to an object cockpit, wizard, or wizard step. For more information about the configuration of the configured reports, see the section Integration of Quality Widgets in Configured Reports, Object Cockpits and Wizards.
- The visualization of secondary window skins is configured via the **Quality Widget** attributes for a GUI scheme. For more information, see the section Configuring GUI Scheme Definitions for the Alfabet Interface as well as the section *Attributes Displayed in the Grid Section: Secondary Window Skins* in the reference manual *Configuring Alfabet with Alfabet Expand - Appendix*.

To assign a quality widget to an existing object cockpit:

1) Right-click the wizard or wizard step and select **Add Secondary View**. A secondary view is added to the explorer and the attributes of the secondary view are displayed in the attribute window.
2) Define the following attributes of the secondary view:

- **Name**: Enter a unique name for the secondary view. The name is a technical name and shall not contain special characters or whitespaces. The technical name is not displayed in the user interface.
- **Caption**: Enter a caption for the secondary view that shall be displayed in the title bar of the secondary view in the Alfabet user interface and in the tooltip displayed for the icon of the secondary view in the slide-in toolbar. Please note that the caption should be short. It will not be displayed in the title bar if it is too long.
- **Role**: Select `QualityWidget`.
- **View Type**: Select `Report`.

- **View Name**: Select the configured report that shall be displayed as secondary view. The drop-down list displays the names of all available configured reports of the allowed report types widget report, Gantt chart report, and business chart report.
- **Show Automatically**: Select `True` if you would like the secondary view to be fully displayed for a few seconds when the user accesses the object cockpit or configured report that the secondary view is defined for. Select `False` if only the caption of the secondary view shall be displayed in a title bar for a few seconds when the user accesses the object cockpit or configured report that the secondary view is defined for. The secondary view will then open if the user clicks the title bar.
- **Height**: Define the inner height of the quality widget window in pixel. This is the height available for the display of the configured report opened in the window.
- **Width**: Define the inner width of the quality widget window in pixel. This is the width available for the display of the configured report opened in the window.

3) In the toolbar, click the **Save** button.

Deleting a Wizard

Before a wizard is deleted, you should check to see if the wizard is implemented in other configuration objects such as object views or workflow templates. To do so, right-click the wizard and click **Show Usage**. The **Objects Usage** editor will display the configuration objects using the selected wizard. For more information regarding the **Show Usage** functionality, see the section Using the Show Usage Functionality in the chapter Getting Started with Alfabet Expand.

1) Right-click the custom wizard that you want to delete and select **Delete**.
2) Confirm the warning by clicking **Yes**. The wizard is deleted from the explorer.
3) In the toolbar, click the **Save** button to save your changes.

Implementing a Wizard Instead of an Editor to Capture and Define Data

In Alfabet, either standard/custom editors or configured wizards can be implemented to capture data about a new object. The implementation of a configured wizard allows you to standardize the process of data capture. Unlike an editor in which only standard or custom object class properties can be defined upon object creation, a configured wizard allows you to configure a set of views in which reference data can be defined for a new object. Thus, in addition to the editor in which basic data is captured, the wizard can also include views capturing, for example, object indicators, reference documents, and relevant references to other objects in the IT architecture. If a configured wizard is not specified in the class setting, the default editor will be implemented for object creation.

Whether an editor or wizard will be implemented to capture data when creating a new object is configured in the class setting of the relevant object class. The configuration will impact all views in which an object governed by the class setting can be created.

For example, if you want to implement a wizard for the creation of an application, the configured wizard would be available in the **Applications** page view in the **Application Group** object profile, **ICT Object** object profile, and **Domain** object profile, the **Application Variants** page view in the **Application** object profile, and in the **Document Applications** functionality and **Capture Applications** functionality. The wizard would be available to create a new application, a new application variant, a new application version, as well as to edit an existing application.

Please note that some standard page views in Alfabet implement a predefined editor when creating and editing objects. For an overview of the page views with a predefined editor, see the section *Alfabet Page Views with Preconfigured Editing and Navigation Behavior* in the reference manual *Configuring Alfabet with Alfabet Expand - Appendix*.

If object class stereotypes are implemented for an object class, you can determine whether the wizard or editor is implemented for each object class stereotype. In this case, for example, you could specify that a wizard is implemented in all relevant views for the object class stereotype Technical Application and that the conventional editor is used in all relevant views for the object class stereotype Business Applications.

To specify that a standard or custom wizard is to be implemented for object creation, you must do the following:

- Go to the **Presentation** tab, expand the **Class Settings** node, expand the folder for the relevant object class, click the class setting  and define the following attributes:
- **Wizard**: Select the wizard that you want to implement in the class setting.
- **Default Editor Type**: Select `Wizard`.
- Ensure that the relevant class setting is selected for the view scheme that is assigned to the relevant user profile. For more information about user profile configuration, see the chapter Configuring User Profiles for the User Community.

Implementing a Wizard in the Workflow Capability

A wizard can be implemented in the workflow capability to capture the initial data required for a new object or to provide a structured process for the definition of references, cost data, project planning, etc. A wizard that is to be implemented in the workflow capability must first be configured in the **Wizards** node. Once the wizard has been configured and tested, it must be assigned to the relevant workflow step.

If a wizard is only implemented in a workflow, it does NOT need to be assigned to a class setting. For more information about assigning a wizard to a workflow, see the section Defining the View Implemented for a Workflow Step in the chapter Configuring Workflows.

To specify that a wizard is to be implemented in a workflow, go to the **Workflows** tab, expand the relevant workflow template  , click the workflow step  and define the following attributes:

- **Type**: Select `Wizard`.
- **View**: Select the wizard that you want to implement in the workflow step.

Testing the Wizard in the Alfabet User Interface

After you have defined the wizard, you can test the wizard in the Alfabet interface and make it available to the user community. To do this, you must assign the wizard to the relevant class setting, assign the class setting to a view scheme, assign the view scheme to a user profile, and then review the wizard in the Alfabet interface. If a wizard has been configured for the workflow capability, it does not need be assigned to a class setting. For more information about implementing wizards in workflows, see Creating a Workflow Step in the chapter Configuring Workflows.

Once the wizard is assigned to the relevant user profile, it will be available to users accessing Alfabet with the corresponding user profile. For more information about configuring a user profile to access and test the wizard, see the chapter Configuring User Profiles for the User Community:

Chapter 9: Configuring Standard Business Functions and Custom Explorers

The **Functions** tab displays all standard business functions that may be implemented for a user profile as well as all custom explorers that have been configured for your enterprise. Expand the **Business Functions** root node to display the **Standard Business Functions** node and the **Custom Explorers** node.

The **Standard Business Functions** node contains all protected standard business functions and standard explorers that may be assigned to a user profile. The standard business functions and standard explorers are bundled in folders based on their functionality. You can specify a custom help for the standard business functions. The **Custom Explorers** node allows you to create and configure custom explorers that address the specific needs of your enterprise. Custom explorers can be assigned to one or more user profiles.

The following information is available:

- Implementing Standard Business Functions in Your Solution
- Configuring a Custom Explorer
- Defining the XML Def Attribute for a Customized Explorer
- Defining a Name for the Explorer
- Defining the Content of the Explorer Root Node
- Defining the Nodes of the Explorer Tree

Implementing Standard Business Functions in Your Solution

The standard business functions and standard explorers displayed below the **Standard Business Functions** node are bundled in folders based on their functionality. These are protected business functions and can be made available to the user profiles that you configure for your solution configuration. Any of the standard business functions that you see listed here may be made available to a user profile via the configuration of menu items or guide pages/guide views. This is carried out in the **Admin** tab in Alfabet Expand. For more information about making business functions available to the user community, see the section Making Functionalities Accessible to a User Profile.

Configuring a Custom Explorer

An explorer allows users to work with a subset of objects in Alfabet. Via the **Custom Explorers** node, you can build custom explorers and assign them to user profiles as Alfabet functionalities.

The following is important to understand in order to build customized explorers:

- Each explorer has a root node icon. Below the root node, an explorer can display one or multiple levels of nodes.
- Each explorer has a base class. The first node level in the explorer will display only objects in the specified base class.

- An object class stereotype can be configured as the base class of a custom explorer. In this case, the root node level in the explorer will display objects of the specified object class stereotype. By configuring an object class stereotype based on the object class `GenericReferenceData`, it is thus possible to specify multiple root nodes in a custom explorer. Each object based on the object class stereotype created in the **Generic Reference Data** functionality would serve as a root node in the custom explorer. The query specified in the **XML Def** attribute of the custom explorer must be specified to search for the objects that are subordinate to the root nodes.

To specify generic reference data, see the section *Configuring Objects for the Object Class Generic Reference Data* in the reference manual *Configuring Evaluation and Reference Data in Alfabet*.

- Each subordinate level in the explorer may display one or more object classes. For example, stacks and deployments can be child nodes of a node representing an application. Or, applications and application groups can be child nodes of a node representing an application group.
- An object displayed in an explorer must have a defined relationship to the parent object and the subordinate objects in the explorer hierarchy.
- Each node in the explorer except the root node represents an object in the Alfabet database. If you click a node in the explorer, the object view for the object will open.

The object views displayed in Alfabet are configurable in Alfabet Expand. Whether the standard object profile or a customized object view opens when an object in an explorer is clicked is determined by the configuration of the class settings. A user profile can have only one class setting per object class assigned to it. However, multiple class settings can be configured for an object class and each class setting can thus be assigned to a different user profile in your enterprise. Once all class settings that are relevant for a user profile are configured, they must be assigned to the view scheme that is configured for and assigned to a user profile. Regardless of the custom or standard explorer associated with the user profile, the content of the object view that opens when an object in the explorer is clicked will always be determined by the class setting configured for that object class. For more information about configuring class settings and view schemes for a user profile, see the chapter Configuring User Profiles for the User Community.

The following must be included in the configuration of a custom explorer:

- The view that opens in the work area when a user clicks the root node.
- The base class of the explorer that is displayed directly below the root node. If a subordinate node is to be displayed in the explorer hierarchy, the relation to the object class associated with the subordinate level must also be defined.
- All subordinate levels of nodes in the explorer hierarchy and their relation to the parent level and the subordinate level, if relevant.

For an overview of the behavior of standard explorers in Alfabet, see the section *Working with Explorers* in the reference manual *Getting Started with Alfabet*. For an overview regarding the standard page views available for each standard explorer, see *Page Views Assigned to Explorer Root Nodes* in the reference manual *Configuring Alfabet with Alfabet Expand - Appendix*.

To create a new custom explorer:

1) Go to the **Functions** tab, right-click the **Custom Explorers** node and select **New Custom Explorer**. The new custom explorer is displayed in the explorer tree and the attribute window is visible on the right.

2) In the attribute window, define the attributes, as needed:

- **Name**: Enter a name for the custom explorer. This name is not displayed in the Alfabet interface.

  If the **Name** attribute of a business function is changed, the Alfabet Server must be restarted if the **Validate Access** attribute is set to `True`.

  A validation mechanism checks for correct syntax when defining a technical name. The technical name of a configuration object may not begin with an empty space nor include any of the following special characters: **\ / * ? " > < | ':**

  Furthermore, please note that names may not begin with an empty space nor include special characters. For a list of the special characters that are not allowed, see the section Defining Attributes for Configuration Objects in the chapter Getting Started with Alfabet Expand.

  Furthermore, if the technical name of a configuration object is changed, the name will be correctly updated in other configuration objects referencing the changed object during design time. Please note that the name of a changed configuration object will not be updated in guide pages nor if the guide pages reference a configuration object listed in the **Show Usage** functionality. If you plan to change the name of a configuration object, the reference in the guide page should be changed prior to changing the configuration object name.

- **Caption**: Enter the caption to display on the root node of the custom explorer.
- **Comments**: Enter information explaining the purpose of the custom explorer. This information is not displayed on the Alfabet interface.

  The **Tech Info** attribute displays technical information such as the date that the custom explorer was created and last updated as well as who last updated the custom explorer. This information is not displayed on the Alfabet interface.

- **Group**: You can either create a new explorer folder to store the custom explorer in or assign it to an existing explorer folder. To create a new explorer folder, enter the name of the new explorer folder in the field and click the Return key. To assign the explorer to an existing explorer folder, click the drop-down arrow and select an explorer folder to store the custom explorer in. All explorer folders that you have created as well as the standard explorer folders predefined by Software AG will be displayed.
- **Restrict to Administrative User Profiles**: Set to `True` if only users with an administrative user profile may access the custom explorer. Set to `False` if the custom explorer may be accessible to users with relevant access permissions.

  Administrative user profiles are user profiles for which the **Is Administrative User Profile** attribute has been set to `True`. Business functions that are relevant for an administrative user profile must be explicitly added to the user profile. For more information about configuring user profiles, see the section Creating User Profiles for the User Community.

- **Validate Access**: Enter `True` if access permissions should be checked by the system when accessing the custom explorer via a link in a guide page, guide view, express view, etc. If set to `True`, the custom explorer must be assigned to the user profile of the user attempting to access the functionality. Please note that if the **Validate Access** attribute is set to `False` but the **Restrict to Administrative User Profiles** attribute is set to `True`, then only users with an adminstrative access may access the custom explorer.

- **Function Type**: Displays `CustomExplorer`. This attribute cannot be edited.
- **Usage Type**: Displays `Functional`, which specifies the level of complexity relevant for purchasing contracts. This attribute cannot be edited.
- **XML Def**: Click the **Browse** button to open the text editor and define as described below and click **OK** to save your changes. See the section Defining the XML Def Attribute for a Customized Explorer.
- **Automated Assistant URL**: Enter the URL or server variable that targets the content to display in the Assistant assigned to the custom explorer. For more information about configuring the automated assistant capability, see the chapter Providing Custom Online Help to the User Community.
- **Custom Context-Sensitive Help URL**: Enter the URL or server variable that targets the custom context-sensitive help. For more information about configuring a custom context-sensitive help file, see the chapter Providing Custom Online Help to the User Community.
- **Standard Context-Sensitive Help Index**: This field is not relevant for a custom explorer.
- **Standard Context-Sensitive Help Visible**: Select `True` to display both the standard and custom context-sensitive help file in the **Help Selector** Select `False` if the link to the standard context-sensitive help should not be available and should not be displayed in the **Help Selector**.

3) In the toolbar, click the **Save** button to save your changes.

Defining the XML Def Attribute for a Customized Explorer

To define or edit the explorer, you must define the XML object in the **XML Def** attribute of the custom explorer. Please note the following when configuring the XML definition of a custom explorer:

- It is not possible to specify XML elements or XML attributes other than the ones described in the section below. For an overview of the permissible syntax for XML definitions, see the sections Working with XML Objects and Defining Queries in XML Elements.
- XML is case-sensitive.
- You can leave some definitions out if they are not required. For example, it is possible to specify explorers that do not open a view at the root node.

The content and layout of the explorer is defined in the XML element `ExplorerDef`. The following table lists the `ExplorerDef` element and all of its sub-elements that can be configured to specify the content of the report and provides information about the purpose of each sub-element:

XML Element	Required to Configure:	Maximum Number of Elements Allowed
ExplorerDef	General layout of the explorer	1 as top element

XML Element	Required to Configure:	Maximum Number of Elements Allowed
Query	Defines the Alfabet objects that are the content of the explorer's first-level nodes when specified as a subordinate XML element of the XML element ***ExplorerDef***. Defines the Alfabet objects that are the content of the explorer's lower-level nodes when specified as a subordinate element of the XML element ***ClassEntry***.	1 as child of `ExplorerDef` multiple as child of ***ClassEntry***
ClassEntry	Definition of the object classes included in the explorer and their relation to the objects of the subordinate nodes.	Multiple as child of ***ExplorerDef***
AlfaExplorerNode	Definition of the root node of the explorer and definition of the behavior of the object nodes in the explorer tree.	Multiple as child of ***ExplorerDef***

The following example displays a complete explorer specification for an explorer that displays applications for which the current user is the authorized user and all application variants, their stacks as well as the stacks of the application variants and the deployments of the stacks.

On the root node, the Alfabet page view listing all applications for which the current user is the authorized user is displayed.

```
<ExplorerDef>
   <AlfaExplorerNode
      ClassName="CntxExplorerRoot"
      UpdateViews="APP_UserApplicaions"
      NodeView="GraphicView:APP_UserApplicaions"
   />
   <Query

      ClassName="Application"
      Query="ALFABET_QUERY_500 FIND Application
      INNERJOIN Person ON Application.ResponsibleUser=Person.REFSTR
      WHERE
      (AND Person.REFSTR =:CURRENT_USER
      Application.VariantOf IS NULL
      SHOW Application.Name Application.Version
      SORT Application.Name Application.Version" />
   <ClassEntry
```

```
            ClassName="Application"
            ShowProps="Name,Version"
            SortProps="Name,Version" >
            <Query

               ClassName="Application"
               Query="VariantOf CONTAINS:BASE" />
            <Query

               ClassName="Stack"
               Query="(AND Owner CONTAINS:BASE UpgradeFrom IS NULL)" />
         </ClassEntry>
         <ClassEntry

            ClassName="Stack"
            ShowProps="Name,Version"
            SortProps="Name,Version" >
            <Query

               ClassName="Stack"
               Query="UpgradeFrom Contains:BASE" />
            <Query

               ClassName="Deployment"
               Query="Stack CONTAINS:BASE" />
         </ClassEntry>
         <ClassEntry

            ClassName="Deployment"
            ShowProps="Name"
            SortProps="Name" >
         </ClassEntry>
      </ExplorerDef>
```

Defining a Name for the Explorer

You can specify a name for the explorer in the XML element `ExplorerDef` with the XML attribute `Name`. The name is only used for internal identification purposes and is not displayed in the Alfabet interface.

Defining the Content of the Explorer Root Node

The view that opens when clicking the root node of the explorer, is defined in an XML element ***AlfaExplorerNode***. The XML element must contain an XML attribute `ClassName` with the value `CntxExplorerRoot` and a specification of the view displayed when the root node of the explorer is clicked.

Optionally, you can define that the explorer is updated during the current session when a user performs changes in a defined page view or set of page views when the changes impact the objects of one of the object classes displayed in the explorer.

```
<AlfaExplorerNode ClassName="CntxExplorerRoot"
NodeView:"GraphicView:APPG_Root" UpdateViews="APPG_Root"/>
```

The table lists all XML attributes that can be specified for the XML element ***AlfaExplorerNode*** and its child elements.

XML Attribute	Allowed Values or Data Types	Default Values / Mandatory	Description
`ClassName`	`"CntxExplorerRoot"`	Mandatory	The XML attribute `ClassName` must be set to `CntxExplorerRoot` to ensure that the XML attribute specifies the root node of the custom explorer.
`NodeView`	`GraphicView: ViewName` `Report: ViewName`	Mandatory	Specify which page view or configured report you want to add to the root node. Standard page views must be specified as `"GraphicView:"` followed by the **Name** attribute of the page view. For a list of all page views with their name and caption and a short description of the view, see *Page Views Assigned to Explorer Root Nodes* in the reference manual *Configuring Alfabet with Alfabet Expand - Appendix*. Configured reports must be specified as `"Report:"` followed by the **Name** attribute of the configured report. **NOTE:** If the custom explorer is configured to display workflow activities (as an alternative to **Workflow Activities Explorer** (`WFS_Explorer`), then you must specifiy `NodeView="GraphicView:CustomExplorerHtmlView"` in order to call the relevant view required to display the configured HTML templates for the workflow

XML Attribute	Allowed Values or Data Types	Default Values / Mandatory	Description
			activites. For more information, see the section Specifying the Customized Workflow Activities Explorer (WFS_Explorer) or a Custom Explorer.
`UpdateViews`	*ViewName,ViewName*	Mandatory	Enter the **Name** attribute of the graphic view to trigger the update of the explorer tree. If changes are made in the view by creating, deleting, or editing objects of the object classes displayed in the explorer, the explorer tree will be updated to reflect the current changes. Multiple views can be defined in a comma-separated list. Only standard Alfabet views can be specified as the update view.

Defining the Nodes of the Explorer Tree

Each level of nodes in the explorer displays objects of one or multiple object classes that are related to the object class of the parent node.

The objects will be displayed in the explorer with their relevant icon. Please note that if a custom icon has been defined for an object displayed in the custom explorer, the custom icon will be displayed. If the object in the custom explorer is based on an object class stereotype, the custom icon will have precedence over the icon defined for the object class stereotype. If no custom icon or object class stereotype icon has been defined, the standard icon will be displayed for the object class.

For each node, the objects in the node must be specified by an XML element ***ClassEntry*** that specifies the object class and the default display of the nodes for the object class. The child XML element ***Query*** of the XML element ***ClassEntry*** specifies the relation of the object in the node to objects in child nodes.

The following must be taken into account when defining explorer nodes:

- To define which objects are displayed as top level explorer nodes, an XML element ***Query*** is specified directly as child element of the ***ExplorerDef*** element because this node level does not have a parent node that can contain the XML element ***Query***.
- The XML element ***ClassEntry*** for the leaf level does not contain a child XML element ***Query*** because no objects for a next layer may be specified. Nevertheless, the ***ClassEntry*** element must be specified for the leaf level of all explorer nodes.
- The XML element ***ClassEntry*** can contain multiple child XML elements ***Query***. This allows to display nodes for multiple different object classes under the same parent node.

- Only one ***ClassEntry*** element can be specified for an object class but the object class can be referenced multiple times by different XML elements ***Query*** in any ***Class Entry*** element in the explorer definition.
- A XML element ***ClassEntry*** can contain a XML element ***Query*** that references the same XML element ***ClassEntry***. For example, the XML element ***ClassEntry*** of the class `Application` can contain an Alfabet query with applications as a base class. The same XML elements `ClassEntry` and `Query` are then evaluated at each level of the explorer tree. This specifies that the explorer will display a hierarchy of parent and child objects.
- When building the explorer tree, Alfabet starts evaluating the Alfabet query defined directly in the XML element ***ExplorerDef*** and displays all objects of the base class of the Alfabet query that match the search criteria in the first level of explorer nodes. The mechanism then searches for the XML element ***ClassEntry*** of that class and reads the information from the child XML elements ***Query*** of that class regarding which objects to display. For the next level of nodes, the XML elements ***Query*** in the XML element ***ClassEntry*** of the classes displayed in the second level are evaluated. This means that the order of processing the specification is not necessarily the order written in the XML definition. For example, the first level displays applications, and the XML elements ***Query*** in the XML element ***ClassEntry*** for the class Application specify that application variants and local components are displayed on the second level. In the XML element ***ClassEntry*** for application variants, local components are allowed as third level elements. The XML element ***ClassEntry*** used for local components on the third level is the same as the one for local components in the second level. If a ***Query*** child element is defined in the local component's XML element ***ClassEntry***, objects found by the defined Alfabet query are displayed as child elements in the third and fourth level nodes under local components.
- A XML element ***ClassEntry*** can have XML elements ***Query*** that searches for the same class. This allows a hierarchy of parent and child elements to be constructed. For example, an explorer can be constructed with application groups that have no parent application group on the first level. In this case, the XML element ***ClassEntry*** for application groups has a XML elements ***Query*** with an Alfabet query searching for application groups that are assigned to the current application group. The same XML element ***ClassEntry*** is evaluated for each node level in the explorer until no more child elements are found for an application group.

The table below lists all available attributes in the XML element ***ClassEntry*** and XML element ***Query***.

XML Elements (Bold) and Attributes	Allowed Values or Data Types	Default Values / Mandatory	Description
ClassEntry			
`ClassName`	Name of Alfabet object class	**MANDATORY**	Defines the object class specified in this XML element ***Query***. For the object classes that allow stereotype specifications (for example `Project` and `Domain`), the XML attribute `ClassName` can specify an object of a specific stereotype. To define an XML element

XML Elements (Bold) and Attributes	Allowed Values or Data Types	Default Values / Mandatory	Description
			Query for a stereotype, the XML attribute `ClassName` must be *`ClassName:StereotypeName`* For example: *`Project:StatementOfWork`*

`ShowProps`	Name of a property of the object class	**MANDATORY**	Defines the text displayed in the explorer on an explorer node. The content of the selected property for the object is displayed in the explorer. Multiple properties can be selected in comma separated format. A typical specification of `ShowProps` is or
			`ShowProps="Name"`
			`ShowProps="Name, Version"`

`SortProps`	Name of a property of the object class	Optional	Defines the sort order of explorer nodes in a node level. The content if the selected property is used for sorting in ascending alphanumerical order. Multiple properties can be selected in comma separated format. Sorting is then performed in the order of specification of the properties.
Query			
`ClassName`	Name of Alfabet object class	Class specified in the Alfabet query	Defines the object class for the node level below the current level. This attribute is mandatory in case the XML attribute ***Query*** contains a `WHERE` clause only.
`Query`	Valid Alfabet query or `WHERE` statement of Alfabet query language	**MANDATORY**	Defines the content and number of the objects in the next node level. Either a valid Alfabet query or a `WHERE` statement has to be written into the parameter that finds the relevant objects.

Take the following into account when defining the Alfabet query in the XML element ***Query***:

Basic knowledge about how to define a valid Alfabet query is assumed in this description. If you are not familiar with alfabet queries, see the chapter Defining Queries.

- The Alfabet query to define subordinate node levels must include a `WHERE` statement that contains the parameter `:BASE`. This parameter specifies the object in the current level.

  The use of the `:BASE` parameter is not allowed for the root node objects.

- Show and sort properties are not allowed in the Alfabet query. The show and sort properties for an explorer node are read from the attributes of the XML element ***ClassEntry*** of the object class of the node.
- `JOINS` can be specified if the `WHERE` conditions require comparisons with objects of other classes. For example, a `WHERE` condition can specify that only applications that offer business services are displayed. This requires a `JOIN` to the class `Business Service`.
- The `FIND` statement is optional, because the base class for the Alfabet query is defined separately in the XML element ***Query*** with the XML attribute `ClassName`. Therefore, if no `JOINS` are required to specify the `WHERE` conditions, you can write a `WHERE` statement into the XML attribute ***Query*** instead of a complete Alfabet query.
- When the query contains special characters (for example, a greater then (>) or lesser then (<) symbol) in the `WHERE` clause, you have to replace it with the HTML code for angle brackets:
- `>` for >
- `<` for <
- `&quot;` for "
- `&#091;` for [
- `&#093;` for]
- The instruction `SetRowsStereotypeIndex` can be used in the query to display stereotype-specific icons for objects in the explorer. The query must return one column in the dataset that finds the object class stereotype of the objects. The row is used by the instruction to evaluate which object icon shall be displayed for each object in the explorer. The `RemoveColumns` instruction can be used to hide the stereotype information from display in the object information in the explorer.

Specifying the Content of Explorer Nodes and the Update of Explorer Content

Optionally, you can define the following for a node view:

- The automatic update of relevant objects in the explorer during the current session if a user performs changes in a defined page view or set of page views.
- The automatic display of a defined view in the working area when the user clicks a node in the explorer. By default, the object profile of the object represented by the explorer node is displayed. When multiple object profiles and object cockpits are defined for an object class, the object profile/object cockpit that opens when the node is clicked will depend on the view scheme assigned to the user profile that the user is logged in with when working with the explorer. The explorer nodes can be configured to ignore the view scheme definition and display a defined graphic view or object view. This can be useful, for example, in order to configure an explorer focused on a defined task only. For example, the explorer might only display the **Business Support Map** page view of

applications in order to provide a functionality that is limited to editing business support for applications.

An XML element ***AlfaExplorerNode*** must be added for each object class node in the explorer tree that is to be updated. The XML element must contain an XML attribute `ClassName` identical to the XML attribute `ClassName` of the XML element ***ClassEntry*** defining the explorer nodes for the object class. The XML element can contain a definition of the graphic view that is to trigger the update of the explorer tree content on the current node level and/or a definition of the view that opens when a user clicks the node.

```
<AlfaExplorerNode ClassName="Application"
NodeView="ObjectView:APP_ObjectView_Customized"
UpdateViews:"GraphicView:APPG_Applications" />
```

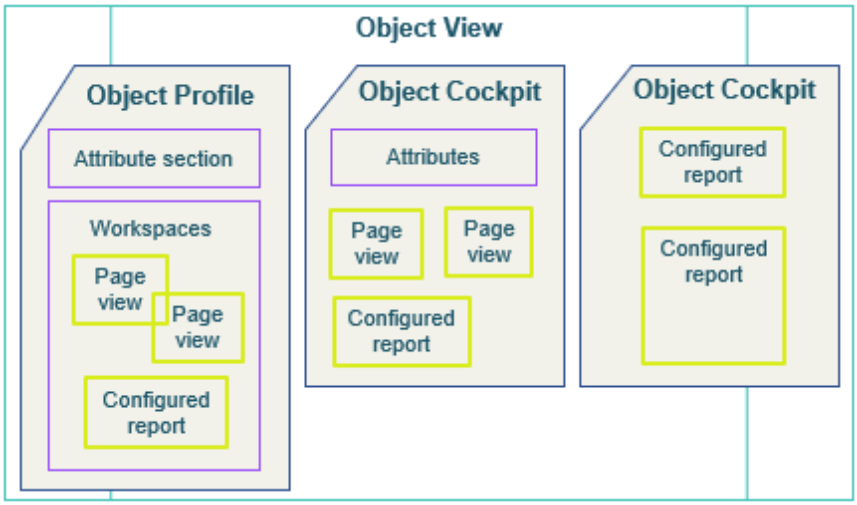
The table lists all attributes of the XML element ***AlfaExplorerNode*** and its child elements.

XML Attribute	Allowed Values or Data Types	Default Values / Mandatory	Description
`ClassName`	*ClassName*	Mandatory	The XML attribute `ClassName` must be identical to the XML attribute `ClassName` of the XML element ***ClassEntry*** defining the explorer nodes that shall be updated.
`UpdateViews`	*ViewName,ViewName*	Optional	Enter the **Name** attribute of the graphic view that is to trigger the update of the explorer tree. If changes are made in the view by creating, deleting, or editing objects of the object class defined in the XML attribute `ClassName`, the explorer tree will be updated to reflect the current changes. Multiple views can be defined in a comma-separated list. **NOTE:** Only a standard Alfabet view can be specified as the update view.

`NodeView`	`GraphicView: ViewName`
	
	`ObjectView: ObjectViewName`
		Optional	Specify which view you want to add to the class node. Page views and object views can be added to a class node. Standard page views must be specified as `"GraphicView:"` followed by the **Name** attribute of the page view. For a list of all page views with their name, caption, and a short description of the view, see *Page Views Assigned to Explorer Root Nodes* in the reference manual *Configuring Alfabet with Alfabet Expand - Appendix*. Object views must be specified as `"ObjectView:"` followed by the **Name** attribute of the object view.

Chapter 10: Configuring Object Views

An object view is the configuration object that typically consists of an object profile as well as any object cockpits that have been configured for the object view.



A standard object view is available for all object classes that require an object profile. The object profile is a standard overview that displays the basic information about an object with topical workspaces grouping all standard page views available for the object class. Object cockpits are not available in standard object views. Multiple custom object views may be configured for an object class or object class stereotype, whereby only one object view can be assigned per class setting per user profile.

The solution design can specify which standard and custom object class properties, page views, configured reports, and object cockpits should be visible or hidden for a custom object view. Each custom object view may include the standard object profile or a customized object profile as well as multiple configured object cockpits. The object cockpit is typically a focused and abbreviated set of data for a particular topic that includes pertinent attribute information as well as a few relevant page views or configured reports that are embedded in the object cockpit.

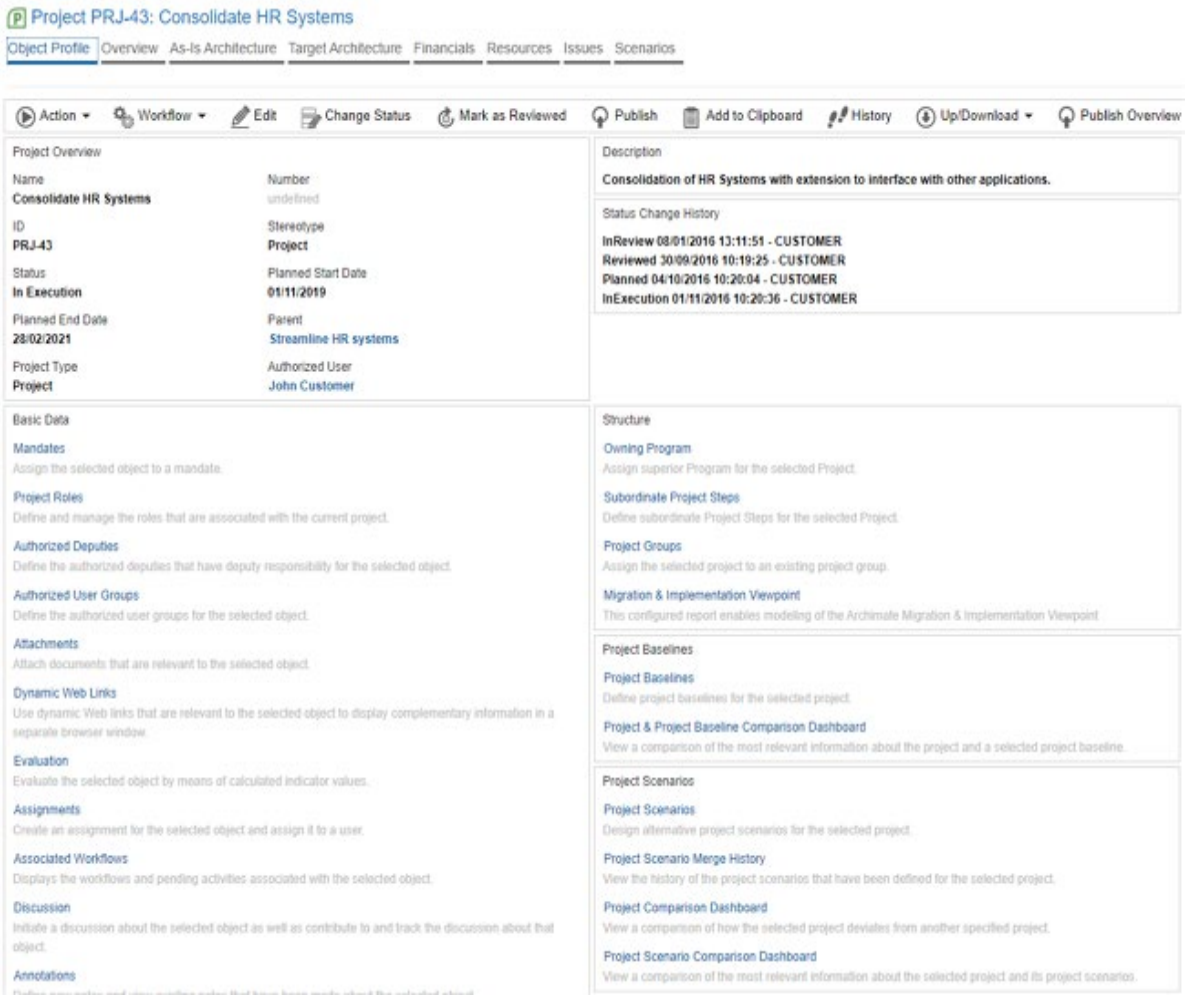


FIGURE: Object view configured for a project stereotype

The object profile and associated object cockpits are accessible via tabs in the header of the object view in the Alfabet user interface. The tabs of the object profile and object cockpits are displayed below the object header and the user can switch back and forth as needed. The caption of the object view is displayed on the object profile tab and the captions of the object cockpits are displayed on the cockpit tabs. The object profile can be hidden in the Alfabet user interface, if necessary.

The display of standard attributes and page views available for a standard object view is determined by Software AG.

A custom object view should be created and made available to a user profile if any of the following is relevant:

- Object class stereotypes have been configured for a relevant class.
- The standard object profile must be modified. The following is possible:
  - Specify a customized **Attributes Section** that includes custom properties
  - Specify a customized **Attributes Section** that regroups or hides standard properties
  - Rename or resequence workspaces that group page views
  - Remove individual page views or entire workspaces with their page views

- Include configured reports
- One or more object cockpits are required. An object cockpit provides users with an immediate and transparent overview of data for the selected object. It is an abbreviated and focused presentation of object data, typically from a particular perspective such as an architecture, technology, or strategy perspective. The display of data in an object cockpit can be highly customized. The following is possible:
- Add attributes with custom captions organized in group boxes.
- Specify that an attribute is highlighted with color or displayed as an icon based on its value.
- Display a URL or document link or properties that are fetched via a query.
- Embed views or configured reports directly in the object cockpit so that users can immediately see data without having to navigate to another page. In the case of views with a significant amount of data, you can include a placeholder that allows the user to navigate to a full display of the page view or configured report.
- Specify conditional restraints that control the information displayed in the object cockpit based on the value of an attribute.
- Customized context-sensitive help or an automated assistant providing specific help for the custom object view.

An overview of the workflow to configure custom object views is displayed in the section Conceptualizing the Object View.

Please keep the following in mind when conceptualizing the object views, class settings, and view schemes that you plan to implement in the user profiles you configure for your user community:

- Multiple custom object views can be defined for an object class, but only one object view can be assigned to a class setting.
- Multiple class settings can be defined for an object class, but only one class setting can be assigned per object class to a view scheme.
- Only one view scheme can be assigned to a user profile.

The following information is available:

- Understanding the Object View Node
- Conceptualizing the Object View
- Creating a New Custom Object View
- Creating a Custom Object View Based on an Existing Object View
- Creating a Custom Object View for an Object Class Stereotype
- Creating a New Custom Object View for a Custom Object Class
- Configuring an Object Profile for a Custom Object View
- Configuring the Attributes Section of the Object Profile
- Adding Standard or Custom Properties to the Attributes Section

Understanding the Object View Node

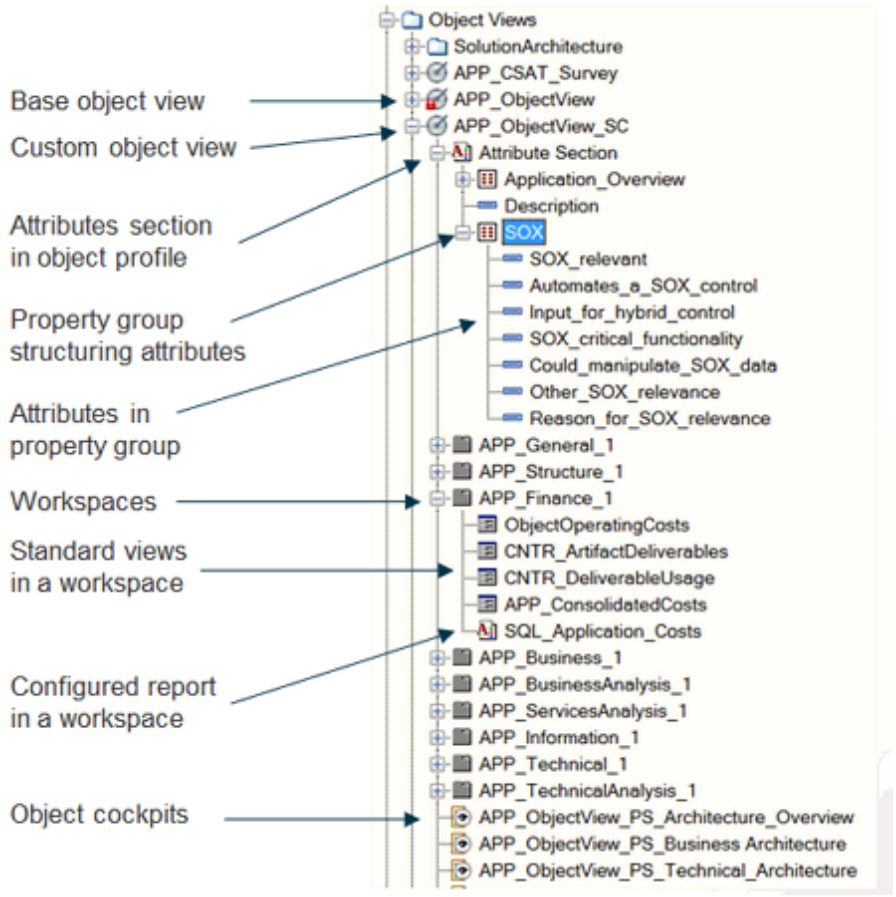

FIGURE: Object Views node with the objects relevant for the configuration of an object view

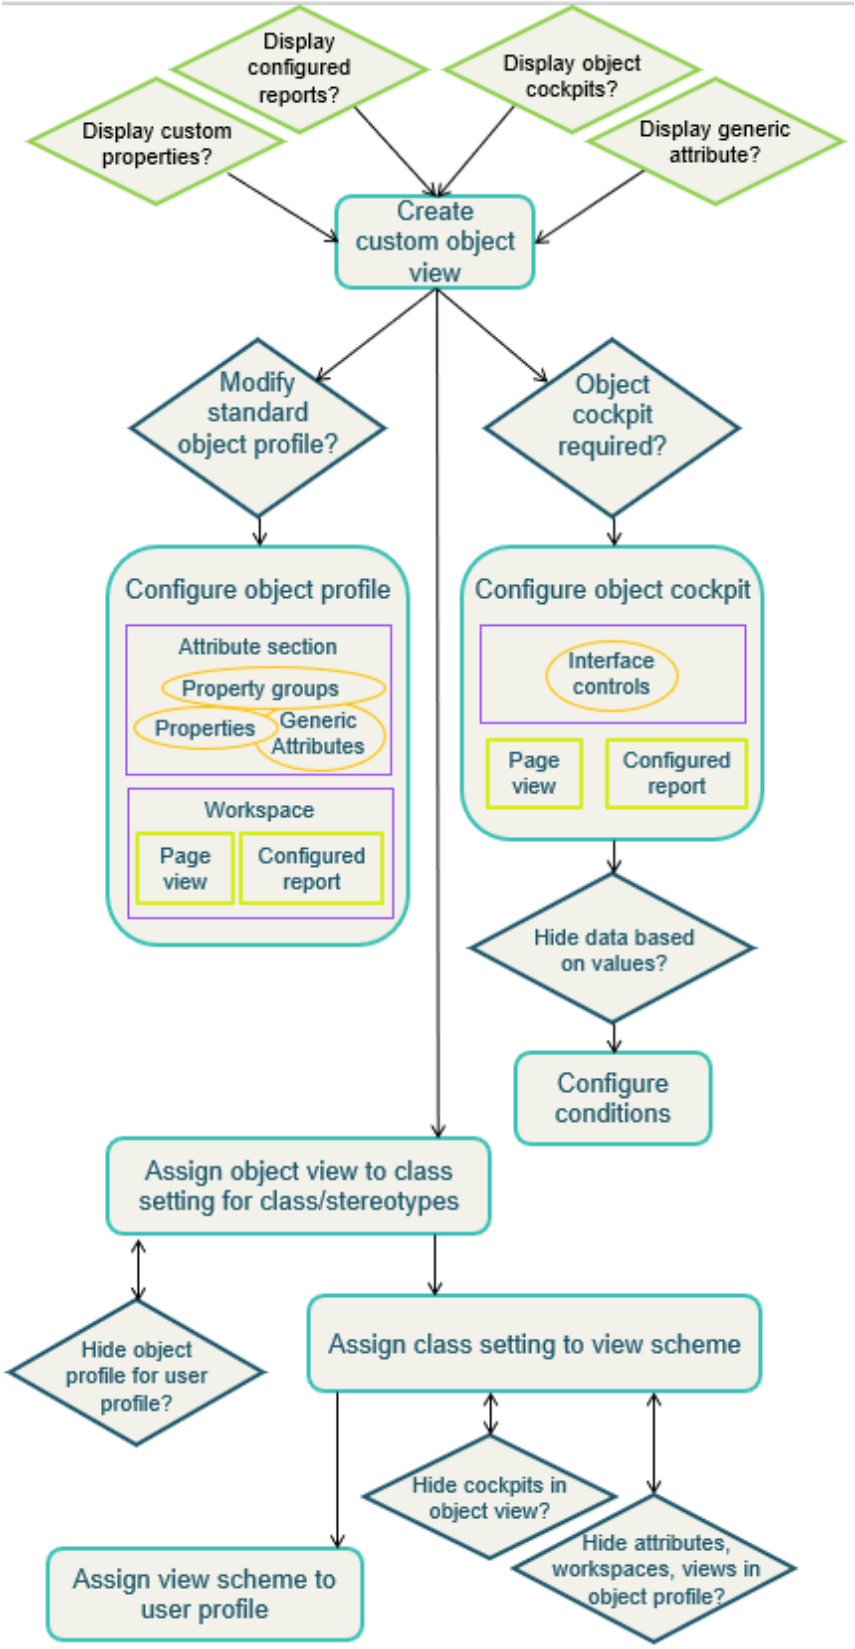
To view existing standard object views that have been preconfigured by Software AG, go to the **Presentation** tab and expand the **Object Views** node. You may see any of the following:

- Standard private object views hat can be used as the base object view to create and configure custom object views. Private object views cannot be edited and are only available as a template. They can be copied to create a custom object view.
- Standard protected object views that can be edited in a limited way. Protected object views typically include object views that require controlled user access.
- Public (custom) object views that have been created by your enterprise.

Conceptualizing the Object View

The following image illustrates the steps to configure an object view:



Creating a New Custom Object View

An object view is the configuration object that typically consists of an object profile as well as any object cockpits that have been configured for the object view. A standard object view is available for all object classes that require an object profile. The object profile is a standard overview that displays the basic information about an object with topical workspaces grouping all standard page views available for the object class. Object cockpits are not available in standard object views. Multiple custom object views may be configured for an object class or object class stereotype, whereby only one object view can be assigned per class setting per user profile.

The solution design can specify which standard and custom object class properties, page views, configured reports, and object cockpits should be visible or hidden for a custom object view. Each custom object view may include the standard object profile or a customized object profile as well as multiple configured object cockpits. The object cockpit is typically a focused and abbreviated set of data for a particular topic that includes pertinent attribute information as well as a few relevant page views or configured reports that are embedded in the object cockpit.

The following information is available:

- Creating a Custom Object View Based on an Existing Object View
- Creating a Custom Object View for an Object Class Stereotype
- Creating a New Custom Object View for a Custom Object Class

Creating a Custom Object View Based on an Existing Object View

You can create a new custom object view by copying either a private object view (a preconfigured standard Alfabet object view) or an existing custom object view that has already been configured by your enterprise. The copied object view can be modified as needed. For example, you could add or remove properties in the **Attributes** section, rename or remove workspaces, add or remove page views in the workspaces, and configure one or more object cockpits.

A few protected object views are available for limited configuration (`USERG_RO_ObjectView`, `USER_RO_ObjectView` and <ObjectClass>`_LE_ObjectView`). These object views require controlled user access and are thus preconfigured by Software AG to have limited access permissions. Please note the following:

- The name of the protected object view cannot be changed. You can create a custom object view based on one of the protected object views but the custom object view will not be available in the Alfabet functionalities where the base protected object view is typically implemented.
- New workspaces, page views and configured reports can be added to protected object views.
- Visibility can be configured for the standard workspaces and page views included in the protected object view.
- Inline-editing in not possible in read-only object views.

- Future changes by Software AG to standard protected object views must be manually updated to modified or customized protected object views for each future release. **Customized protected object views will not be migrated to future releases of Alfabet and must be manually reconfigured in such cases**.

Click the + symbol to expand a private object view in order to view the attributes, workspaces, and page views that have been preconfigured for the object view.

To create a new custom object view based on a copy of an existing object view:

1) Go to the **Object Views** folder, right-click the private object view or custom object view that you want to base the custom object view on and select **New Custom Object View as Copy**. The new custom object view is displayed in the explorer. The new object view has an underscore and automatically generated number appended to the name. The **Attributes** section including its properties as well as the preconfigured workspaces with their page views have been copied to the new object view.

   Please note that if a new custom object view based on an existing custom object view is created via the copy and paste functionalities, the workspaces configured for the source custom object view will be reused. If a reused workspace in the source or new custom object view is deleted, the reused workspace will be deleted from all other object views in the same database.

2) Right-click the new custom object view to activate its attribute window. The **Class Name** attribute displays the object class for which the custom object view was created. Define the following attributes, as needed:

- **Name**: Enter a name for the object view. This name is not displayed in the Alfabet interface.

  A validation mechanism checks for correct syntax when defining a technical name. The technical name of a configuration object may not begin with an empty space nor include any of the following special characters: **\ / * ? " > < | ':**

  Furthermore, please note that names may not begin with an empty space nor include special characters. For a list of the special characters that are not allowed, see the section Defining Attributes for Configuration Objects in the chapter Getting Started with Alfabet Expand.

  Furthermore, if the technical name of a configuration object is changed, the name will be correctly updated in other configuration objects referencing the changed object during design time. Please note that the name of a changed configuration object will not be updated in guide pages nor if the guide pages reference a configuration object listed in the **Show Usage** functionality. If you plan to change the name of a configuration object, the reference in the guide page should be changed prior to changing the configuration object name.

- **Caption**: Enter the caption to display on the object profile tab in the user interface.
- **Format String**: Specify the standard and custom properties to display in the header of the object view. The **Name** property will be displayed per default if no value is defined. The properties must be listed comma-separated on the first line. The formatting of the properties is specified as variables enclosed in curly brackets. For example, for the object class stereotype **Banking Application**, the following definition in the text editor displays the following results in the object profile in the Alfabet interface.

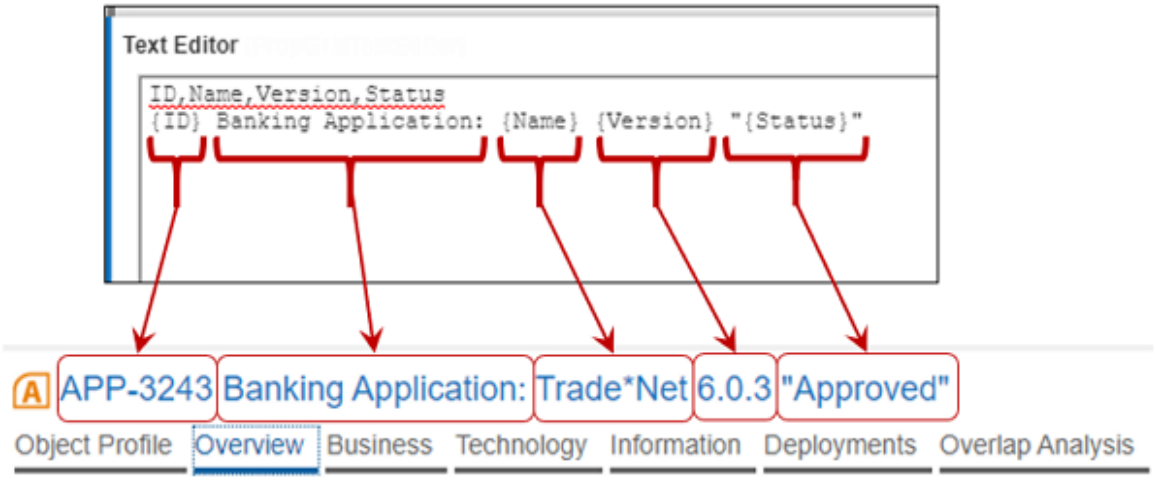


FIGURE: Format string for an application stereotype

If the **Format String** attribute is not defined for the object view, the **Format String** attribute for the class setting that the object view is assigned to will be displayed. The **Format String** attribute for an object view will have precedence over the **Format String** attribute for the class setting. If a **Format String** attribute is not specified for neither the object view nor the class setting, the following will be displayed: `<Object.Class.Caption|Object.Stereotype.Caption + Object.ID + ":" + Object.ClassSetting.ImageProps>`. If no image properties are defined in the class setting, the **Name** property will be used. If neither image properties nor the **Name** property are defined in the class setting, the header will be defined as follows: `<Object.Class.Caption|Object.Stereotype.Caption + Object.ID + ":">`.

- **Can Create Bookmark**: Select `True` if bookmarks can be created for the object view, or select `False` if bookmarks cannot be created for the object view. Please note that the custom object view may only be added to a user's splash screen if the **Can Create Bookmark** attribute is set to `True` for the respective object view. For more information about the splash screen capability, see the chapter *Creating a Splash Screen As Your Start Page* in the reference manual *Getting Started with Alfabet*.
- **Can Create Express View**: Select `True` if express views can be created for the object view, or select `False` if express views cannot be created for the object view.
- **Prevent Inline Editing in Object Views**: You must specify whether inline editing is permissible for scalar and reference properties in the selected object view. Select `True` if inline editing shall be prevented in the object view. Select `False` if inline editing shall be allowed in the object view. If no value is selected, inline editing shall be allowed per default (= `False`). For more information about the configuration required to allow inline editing of scalar and reference properties, see the section Configuring Inline Editing of Attributes in the Object View.
- **Comments**: Enter information explaining the purpose of the object view. This information is not displayed on the Alfabet interface.

The **Tech Info** attribute displays technical information such as the date that the object view was created and last updated as well as who last updated the object view. This information is not displayed on the Alfabet interface.

3) In the toolbar, click the **Save** button to save your changes.

Creating a Custom Object View for an Object Class Stereotype

Custom object views for object class stereotypes are created via the base class as described in the section Creating a Custom Object View Based on an Existing Object View. Multiple custom object views may be created per object class stereotype. The custom object view must be assigned to the relevant class setting defined for the object class stereotype. For more information about creating a class setting for an object class stereotype, see the section Configuring Class Settings for Object Classes and Object Class Stereotypes.

Creating a New Custom Object View for a Custom Object Class

If you have configured a custom object class, you must explicitly create an object view for that object class. To do so, right-click the **Object Views** folder and select **New Object View** in the context menu. In the **Select Class** editor, select the custom object class that you want to create the object view for and click **OK**. A new object view will be added to the **Object Views** folder. Define the object view as described in the section Creating a Custom Object View Based on an Existing Object View.

Please note that if custom object views required for a survey class are created for the survey in the Surveys tab, additional configuration is required. For more information about working with surveys, see the chapter Configuring Surveys for Data Capture Campaigns.

Configuring an Object Profile for a Custom Object View

The object profile summarizes information that is relevant to a selected object. The object profile typically displays object class properties and their values for the object as well as workspaces with views and reports relevant to the selected object. Users can open the available views and define or edit the data about the selected object.

Typically, object profiles are configured specifically for the needs of the user community. Thus, various object profiles with different data and functionality may be available for the same object class, depending on the user profile with which users access Alfabet. Each object profile may have multiple object cockpits associated with it that have been configured to visualize a specific set of data about the object.

The object profile can be configured in the context of a custom object view. It is possible to hide the object profile in the context of the view scheme configuration. In this case, only the object cockpits visible for the view scheme will be available to the associated user profile.

When a new custom object view is created, the standard object profile associated with the private, protected, or public object view that the new object view is based on will be automatically copied to the new object view. The object profile can be modified or hidden in the Alfabet user interface, if necessary.

Consider the following in the configuration of a custom object view:

- If `SYS_VIEW_CustomRelationsManagement` (*Custom Relation Page View*) is included in a custom object view that is created as a copy of an existing object view, you must ensure that `SYS_VIEW_CustomRelationsManagement` is placed in a separate workspace that contains no other views. If `SYS_VIEW_CustomRelationsManagement` is in a workspace with other views, these views will no longer be visible in the object view at runtime.

- If `ObjectReportsDataSet` (*Configured Reports Page View*) is included in a custom object view, you must ensure that `ObjectReportsDataSet` is placed in a separate workspace that contains no other views. If `ObjectReportsDataSet` is in a workspace with other views, these views will no longer be visible in the object view at runtime.
- If these views are **NOT** put in their own workspace and there are other views in the workspace, all other views in the workspace or the entire workspace may be hidden if the visibility constraints for `ObjectReportsDataSet` / `SYS_View_CustomRelationsMgmt` are not fulfilled.
- Only ReadOnly versions of configured reports of the type `Custom` that are based on the template `EvaluationReport` should be implemented in a custom object view. You should not implement a ReadWrite version of these reports in the custom object view.

Please note that the font, hyperlink colors, and other style issues displayed in the object profile are determined by the configuration of the GUI schemes implemented in your enterprise. For more information, see the section Configuring GUI Scheme Definitions for the Alfabet Interface.

The following information is available:

Configuring the Attributes Section of the Object Profile

Once a new custom object view has been created, you can configure the **Attributes Section** of the object view. The **Attributes Section** preconfigured for the base object view will be copied to the new object view and any exiting property groups or properties will be displayed below the **Attributes Section** node.

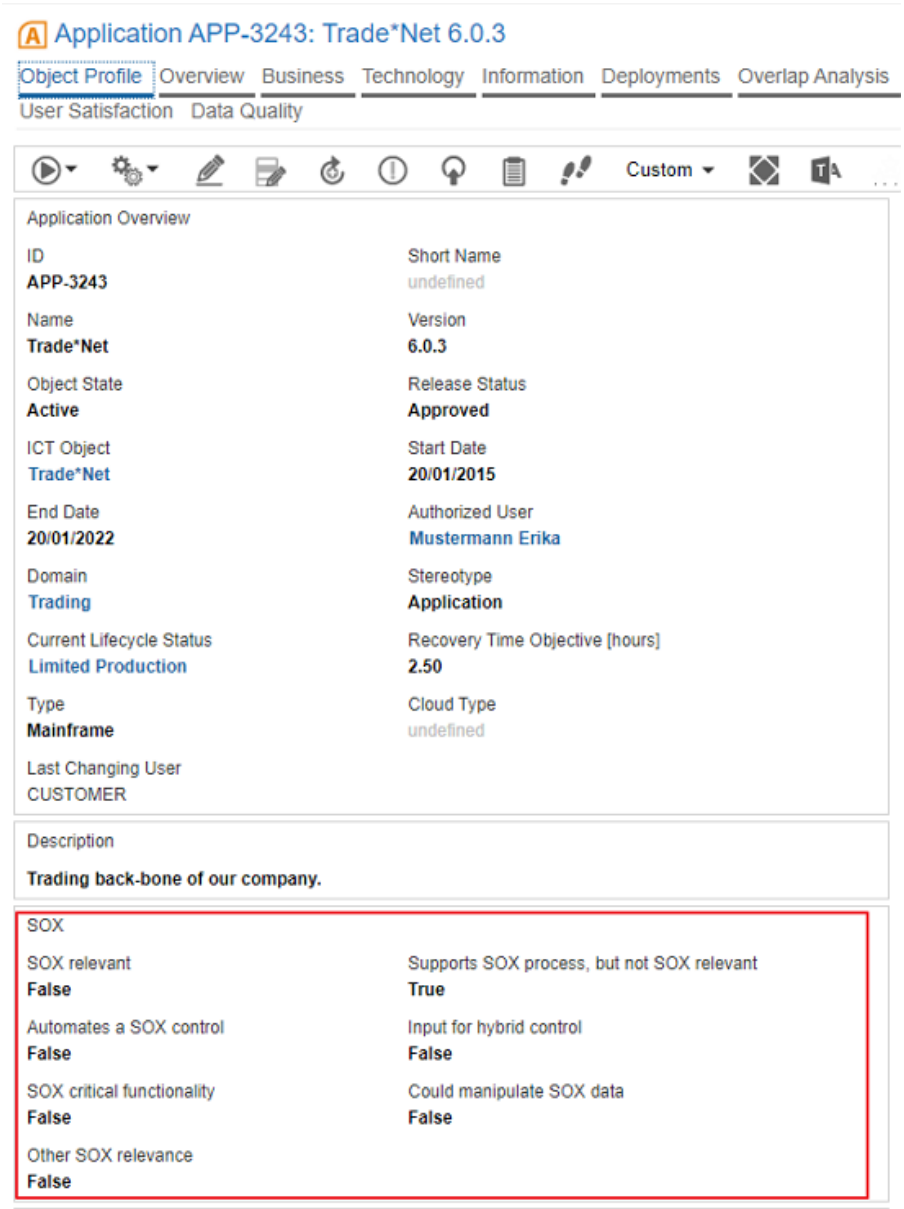

FIGURE: Attributes section in a custom object view

The following is possible in terms of the configuration of the **Attributes Section**:

- You can display the properties in the **Attributes Section** as a flat list or you can group sets of properties in subordinate property groups. Each property group can have a caption that is displayed as a heading for the group.

- You can add any standard or custom properties configured for the associated object class directly to the **Attributes Section** or to a property group defined for the **Attributes Section**. If you add a custom object class property of the type `URL`, the URL defined by the user in the relevant custom editor will be displayed as a hyperlink in the **Attributes Section**.
- You can add a property that is not a standard or custom object class property of the associated object class. Such properties require the configuration of an Alfabet query.
- You can remove any unwanted standard or custom properties that were copied to the custom object view from the base object view.
- You can display important page views or configured reports directly above or below of the **Attributes Section** so that they are easily accessible to the user community.

Please consider the following:

- Inline editing of scalar and reference properties may be configured so that users can edit data directly in the object profiles and object cockpits. If inline editing is supported, users can edit scalar attributes for an existing object directly in the **Attributes** section of an object profile or in an object cockpit without needing to open the object's editor or wizard. For more information about configuring inline editing, see the section Configuring Inline Editing of Attributes in the Object View.
- Users can determine whether only properties that have a value defined are displayed in the **Attributes Section** or whether properties that have no value defined are included in the **Attributes Section**. This setting is defined by a user in the **Show Empty Values in Object Profile** attribute in the **User Settings** editor in Alfabet.

Please note that if a scalar or reference property is displayed in an object profile/object cockpit and is editable in the user's wizard/editor for the associated object class/object class stereotype and the **Show Empty Values in Object Profile** attribute is set to `False` in the **User Settings** editor in Alfabet, the setting will be ignored so that the user can edit the property and provide a value using in-place editing. For more information about how a user can define the display of properties with no value defined, see the section *Defining Your User Settings in Alfabet* in the reference manual *Getting Started with Alfabet*.

The following information is available:

- Adding Standard or Custom Properties to the Attributes Section
- Copying and Pasting Properties to the Attributes Section
- Configuring Property Groups to Bundle a Set of Properties in the Attributes Section
- Adding a Generic Attribute to the Attributes Section
- Determining the Sequence of the Information Displayed in the Attributes Section

Adding Standard or Custom Properties to the Attributes Section

1) Depending on where you want to place the new property, do one of the following:

- To add properties to a property group, right-click the property group  and select **New Property**.

- To add a property directly to the **Attributes Section** without placing it in a subordinate grouping, right click the **Attributes Section** node  in the explorer and select **New Property.**

2) Click the new property to open the attribute window. Define the following:

- **Property**: Select the standard or custom object class property that you want to display.

Please note that if the property that you are defining is of the type `Reference`, you must specify the **Show Properties** otherwise a defined value for the property will not be displayed in the **Attributes** section.

If you want to add one or more properties that are not standard or custom properties of the associated object class, then you should leave the **Property** attribute empty and specify an Alfabet query or native SQL query. To do so, in the **SQL Type** field, select either `Query` to specify an Alfabet Query

or `NativeSql` to specific a native SQL query. Select `None` if no query will be defined. Enter the relevant query in the **Query** attribute. You will also need to define the **Show Properties** and **Sort Properties** attributes in order to determine what will be displayed in the **Attributes Section**. If the display of properties in the **Attributes Section** is determined via a query, the exclusion of properties configured for a class setting will not be applied.

- **Caption**: Enter the caption for the object class property selected in the object class property attribute. If no value is entered here, then the object class property will not be displayed in the **Attributes** section.
- **Mark as Mandatory**: Select `True` if a mandatory property should be marked with a red star as a mandatory property in the **Attributes Section**. Select `False` if no red star should be displayed next to the object class property in the **Attributes Section**.
- **Enable Data Translation**: Select `True` if the caption should be available in the vocabulary for translation.
- **Enable HTML Content**: If the **HTML Content** attribute is set to `True` for the Memo interface control in the editor where the property is defined, the attribute will be automatically set to `True` and the HTML formatting for the property will be displayed in the object profile. The HTML editor will also be available to edit the property directly in the user interface of the object profile. The **Enble HTML Content** attribute can be set to `False` if HTML format shall not be displayed.
- **Navigate**: Select `True` if the object class property is a reference to another object and the user should be able to navigate to that referenced object. In this case, the object class property will be displayed as a blue hyperlink that the user can click to navigate. Select `False` if the user should not be able to navigate to the referenced object.
- **Show in Foreign Mandates**: Specify `True` if the property should be shown when the object view is displayed for a user that does not have mandate rights on the current object.

3) Continue this procedure to add all properties to the **Attributes Section** as required.

4) In the toolbar, click the **Save**  button to save your changes.

Copying and Pasting Properties to the Attributes Section

You can copy a property or an entire property group configured in one object view and paste it to another object view.

1) Right-click the object class property or property group that you want to copy and select **Copy**.
2) Right-click the node in the object view that should be the ascendant object of the object class property or property group you are adding and select Paste.

For example, if the object class property is to be placed in a property group, you must select the object class property group node and click **Paste**. If the object class property is to be placed directly in the **Attributes Section**, click the **Attributes Section** node and click **Paste**.

3) Remove any unnecessary properties by right-clicking the object class property and selecting **Delete**.
4) In the toolbar, click the **Save**  button to save your changes.

Configuring Property Groups to Bundle a Set of Properties in the Attributes Section

You can display the properties in the **Attributes Section** as a flat list or you can group sets of properties in subordinate property groups. Each property group can have a caption that is displayed as a heading for the group.

1) Right-click the **Attributes Section** node  in the explorer and select **New Property Group**. A new property group  is added below the **Attributes Section** node.
2) Click the object class property group  to activate the attribute window. Define the following:

- **Caption**: Enter a caption for the header of the object class property group.
- **Attribute Sequence**: To order the sequence of properties in a property group, click the object class property group node and click the **Browse**  button. The **Sort Entries** editor opens. To define the sequence of the data, select an object in the list and click the up/down arrows in the upper right corner of the dialog. Repeat this for all properties until they are listed in the correct order. Click **OK** to close the editor.
- **Show in Foreign Mandates**: Specify `True` if the property group should be shown when the object view is displayed for a user that does not have mandate rights on the current object.

3) In the toolbar, click the **Save**  button to save your changes.

Adding a Generic Attribute to the Attributes Section

This section is only relevant for object profiles configured for the object classes `Application`, `Component`, `Deployment`, `Deployment Element`, `Standard Platform`, `Standard Platform Element`, `Stack`, `Stack Element`, and `Stack Item`.

If generic attributes have been created for an object in the *Generic Attributes Page View* (`ObjectGenericAttributes`), you can configure the **Attributes** section of the object profile to display the generic attributes and their values. For more information about working with generic attributes, see the section Implementing the Generic Attribute Concept Instead of Custom Properties in the chapter Configuring the Class Model.

To display generic attributes in the object profile:

1) Depending on where you want to place the generic attribute, do one of the following:

- Add a property to a property group by right-clicking the property group and selecting **New Property**.
- Add a property directly to the **Attributes Section** without placing it in a subordinate grouping by right-clicking the **Attributes Section** node in the explorer and selecting **New Property.**

2) Click the new property to open the attribute window. Define the following:

- **SQL Type**: Select `AttributeQuery`.
- **Query**: Enter a query to find the generic attributes for the object class. The query should be specified for the class `GenericAttribute` and return the relevant `SHOW` and `SORT` properties.

The following example displays an Alfabet query specified to display generic attributes for a configured object profile:

```
ALFABET_QUERY_500
FIND GenericAttribute
WHERE(AND GenericAttribute.Owner CONTAINS:BASE)
QUERY_XML
   <QueryDef></QueryDef>
      <ShowProperty Type="Property"
      ClassName="GenericAttribute" Name="Name" />
      <ShowProperty Type="Property"
      ClassName="GenericAttribute" Name="Value" />
      <ShowProperty Type="Property"
      ClassName="GenericAttribute" Name="Type" />
      <SortProperty Type="Property"
      ClassName="GenericAttribute" Name="Name" />
```

3) In the toolbar, click the **Save** button to save your changes.

Determining the Sequence of the Information Displayed in the Attributes Section

Once you have defined the content to display in the object profile, you can determine the order of the information that is displayed. You will be able to define the sequence of any page views, configured reports, individual properties, and property groups displayed in the **Attributes Section**. By default, properties in a property group are listed in two columns.

1) Click the new custom object view and define the following:

- To order the sequence of all property groups as well as any individual properties not grouped in a property group, configured reports, and page views displayed in the **Attributes Section**, click the **Attribute Section** node and click the **Browse** button in the **Attribute Sequence** attribute.
- To order the sequence of properties in a property group, click the object class property group node and click the **Browse** button in the **Attribute Sequence** attribute.

2) In the **Sort Entries** editor, select an object in the list and click the up/down arrows in the upper right corner of the dialog. Repeat this for all elements assigned to the **Attributes Section** until they are listed in the correct sequence. Select the **Sort Lexicographically** checkbox if the object class property groups and individual properties should be sorted alphabetically. Click **OK** to close the editor.

3) In the toolbar, click the **Save** button to save your changes.

Adding Configured Reports to the Object Profile Independent of a Workspace

You may decide that particular configured reports have data that is significant to users accessing the object profile and that you therefore want the reports to be easily and immediately accessible to the user community. In this case, you can add one or more configured reports directly to the object profile. This allows you to display them independent of a workspace and thus sequence them to be available at the top of the object profile after the **Attributes Section**.

Configured reports can also be assigned to a workspace. For more information, see the section Configuring Workspaces for an Object Profile.

Keep the following in mind when assigning configured reports to custom object views:

- Only configured reports of the type `Query` or `Custom` can be assigned to custom object views.
- A configured report with the **Report State** attribute set to `Planned` or `Retired` will be displayed in the custom object view, but an error message will be displayed if the user attempts to open the configured report.
- The text entered in the **Caption** attribute of the configured report is displayed as the title of the configured report in the configured report itself and as the default caption for the configured report in the object view. The report caption displayed in the object view can be overwritten by defining the **Caption** attribute for the respective report object assigned to the object view. This has no effect on the caption displayed in the configured report itself. Therefore, the caption can be different for the object view and the configured report itself.
- The text entered in the **Description** attribute of the configured report is displayed as the page view description in the object view of the report.
- You can provide customized context-sensitive help to your user community in order to understand the content of a configured report that you have configured. The Help file is stored externally and the URL of the help file is defined in the configured report. When the

user views the configured report in the Alfabet interface, he/she can click the **Help** button that opens the Alfabet online Help. The context-sensitive help screen that provides access to the context-sensitive online Help will display an option that can be clicked to open the hyperlinked help document.

- The **Can Create Bookmark** and **Can Create Express View** attributes are configured for configured reports in the context of the report configuration in the **Reports** tab. Please note that a configured report may only be added to a user's splash screen if the **Can Create Bookmark** attribute is set to `True` for the respective report. For more information about the splash screen capability, see the chapter *Creating a Splash Screen As Your Start Page* in the reference manual *Getting Started with Alfabet*.

For more information about configuring a configured report, see the chapter Configuring Reports.

To add a configured report to the object profile of a custom object view:

1) Right-click the new custom object view and select **Add Report**. The **Select Report** editor opens.
2) Select one or more configured reports that you would like to add to the object profile and click **OK**. Simultaneously select multiple configured report by holding down the CTRL key while you select the reports.
3) To sequence the configured reports (and page views), click the object view to activate its attribute window. In the **Workspace Sequence** attribute, click the **Browse** button to open the **Sort Entries** editor. In the **Sort Entries** editor, select a report in the list and click the up/down arrows in the upper right corner of the dialog. Repeat this for all reports until they are listed in the correct sequence. Select the **Sort Lexicographically** checkbox if the reports should be sorted alphabetically. Click **OK** to close the editor.

   Please note that the **Attributes Section** is not listed in the editor. The **Attributes Section** is always the first item in the object view. Therefore, the first item listed in the **Sort Entries** editor will be the first page view/configured report/workspace to follow the **Attributes Section**.

4) In the toolbar, click the **Save** button to save your changes.

Adding Page Views to the Object Profile Independent of a Workspace

You may decide that particular page views have data that is significant to users accessing the object profile and that you therefore want the page view to be easily and immediately accessible to the user community. In this case, you can add one or more page views directly to the object profile. This allows you to display them independent of a workspace and thus sequence them to be available at the top of the object profile after the **Attributes Section**.

Captions defined for page views in object profiles and object cockpits may only be changed via the localization method described in the section Modifying the Original Strings Provided by Software AG . in the chapter Localization and Multi-Language Support for the Alfabet Interface.

Page views can also be assigned to a workspace. For more information, see the section Configuring Workspaces for an Object Profile.

To add a page view to the object profile:

1) Right-click the new custom object view and select **Add View**. The **Select View** editor opens. All permissible page views not yet added to the object view will be displayed.
2) Select one or more page views that you would like to add to the object profile and click **OK**. Simultaneously select multiple configured report by holding down the CTRL key while you select the page views.
3) To sequence the page views (and configured reports), click the object view to activate its attribute window. In the **View Sequence** attribute, click the **Browse** button to open the **Sort Entries** editor. In the **Sort Entries** editor, select a page view in the list and click the up/down arrows in the upper right corner of the dialog. Repeat this for all page views until they are listed in the correct sequence. Select the **Sort Lexicographically** checkbox if the reports should be sorted alphabetically. Click **OK** to close the editor.

   Please note that the **Attributes Section** is not listed in the editor. The **Attributes Section** is always the first item in the object view. Therefore, the first item listed in the **Sort Entries** editor will be the first page view/configured report/workspace to follow the **Attributes Section**.

4) In the toolbar, click the **Save** button to save your changes.

Configuring Workspaces for an Object Profile

When you configure the workspaces for an object profile, all of the workspaces associated with the standard object profile will typically be included in the creation of the new custom object view. These workspaces can be modified, as needed, by adding and removing page views.

Once a custom workspace has been configured, you can copy that workspace and reuse it in other custom object views for the same object class. The copied workspace can then be further modified by adding and removing page views.

Consider the following in the configuration of a custom object view:

- If `SYS_VIEW_CustomRelationsManagement` (*Custom Relation Page View*) is included in a custom object view that is created as a copy of an existing object view, you must ensure that `SYS_VIEW_CustomRelationsManagement` is placed in a separate workspace that contains no other views. If `SYS_VIEW_CustomRelationsManagement` is in a workspace with other views, these views will no longer be visible in the object view at runtime.
- If `ObjectReportsDataSet` (*Configured Reports Page View*) is included in a custom object view, you must ensure that `ObjectReportsDataSet` is placed in a separate workspace that contains no other views. If `ObjectReportsDataSet` is in a workspace with other views, these views will no longer be visible in the object view at runtime.
- If these views are **NOT** put in their own workspace and there are other views in the workspace, all other views in the workspace or the entire workspace may be hidden if the visibility constraints for `ObjectReportsDataSet` / `SYS_View_CustomRelationsMgmt` are not fulfilled.
- Only ReadOnly versions of configured reports of the type `Custom` that are based on the template `EvaluationReport` should be implemented in a custom object view. You should not implement a ReadWrite version of these reports in the custom object view.

The following information is available:

- Creating a New Workspace for an Object Profile
- Adding Page Views to an Object Profile
- Configuring a Custom Caption and Description for a Page View
- Adding Configured Reports to a Workspace
- Deleting a Page View or Configured Report from a Workspace or Object Profile
- Sequencing the Order of the Workspaces and Configured Reports in the Object Profile

Creating a New Workspace for an Object Profile

When you configure the workspaces for an object profile in a custom object view, all of the workspaces associated with the standard custom view are typically included in the creation of the new custom object view. These workspaces can be modified, as needed, by adding and removing page views.

Once a custom workspace has been configured, you can copy that workspace and reuse it in other custom object views for the same object class. The copied workspace can then be further modified by adding and removing page views.

To create a new workspace in an object profile of a custom object view

1) Right-click the new custom object view  and select **New Workspace**. The new workspace  is displayed below the custom object view node.
2) Define the following attributes, if needed:

- **Caption**: Enter a title to change the caption of the workspace.

- **Visible** attribute. Set to `False` if the workspace should not be displayed in the object profile. This may be useful if you are reusing a custom object view and would like to configure different visibility settings for common workspaces in different custom object views.

3) In the toolbar, click the **Save** button to save your changes. You can now add or remove page views to the custom view.

The following information is available:

Adding Page Views to an Object Profile

You may decide that particular page views have data that is significant to users accessing the object profile and that you therefore want the page view to be easily and immediately accessible to the user community. In this case, you can add one or more page views to the **Attributes Section** of the object profile. Page views can also be assigned directly to the object profile rather than grouped in a workspace. For more information, see the section Adding Page Views to the Object Profile Independent of a Workspace.

To add a page view to a workspace:

1) Right-click the custom workspace and select **Add View**. The **Select View** editor opens. All relevant and permissible page views not yet added to the object view will be displayed. The **Comments** attribute provides a general description about the purpose of the view.

   As an alternative to the **Add View** functionality, you can also right-click an individual page view in a workspace and select **Copy View**. The page view can be pasted to another workspace by right-clicking the workspace and selecting **Paste**.

2) Select one or more page views that you want to display in the workspace and click **OK**. You can simultaneously select multiple page views by holding down the CTRL key while you select views. Repeat this procedure to add all necessary page views to the selected workspace.

3) The page views are added to the workspace. For each page view, you can specify whether a bookmark or express view may be created for the view. In the explorer, click the page view to activate its attribute window and define the following, as needed:

   The **Can Create Bookmark** and **Can Create Express View** attributes will be automatically set to `False` and disabled for views for which bookmarks or express views cannot be set. For example, bookmarks cannot be created for functionalities used for administrative purposes that are available via an administrative user profile or configuration functionalities that are not associated with objects governed by access permissions. Also, some views cannot be bookmarked because they are only accessible via other views. This is the case, for example, with the *Map Objects Page View* (`ITMPM_MapObjectsReport`), which can only be opened from the *Business Support Map Page View* (`ITMPM_Matrix`) or *Business Support Map Report* (`ITMPM_MatrixReport`) for a master plan map.

- **Can Create Bookmark**: Select `True` if a bookmark may be created for the view. Select `False` if a bookmark may not be created for the view. The definition you make here is applicable to all instances in which this view is implemented in Alfabet, regardless of the object class or object class stereotype for which the view is implemented.

Please note that a page view may only be added to a user's splash screen if the **Can Create Bookmark** attribute is set to `True` for the respective view. For more information about the splash screen capability, see the chapter *Creating a Splash Screen As Your Start Page* in the reference manual *Getting Started with Alfabet*.

- **Can Create Express View**: Select `True` if an express view may be created for the view. Select `False` if an express view may not be created for the view. The definition you make here is applicable to all instances in which this view is implemented in Alfabet, regardless of the object class or object class stereotype for which the view is implemented.

4) To sequence the page views and configured reports, click the object view to activate its attribute window. In the **View Sequence** attribute, click the **Browse** button to open the **Sort Entries** editor. In the **Sort Entries** editor, select a page view or configured report in the list and click the up/down arrows in the upper right corner of the dialog. Repeat this for all page views and configured reports until they are listed in the correct sequence. Select the **Sort Alphabetically** checkbox if the page views and configured reports should be sorted alphabetically. Click **OK** to close the editor.

   Please note that the **Attributes Section** is not listed in the editor. The **Attributes Section** is always the first item in the object view. Therefore, the first item listed in the **Sort Entries** editor will be the first page view/configured report/workspace to follow the **Attributes Section**.

5) In the toolbar, click the **Save** button to save your changes.

Configuring a Custom Caption and Description for a Page View

Captions and descriptions may be customized for page views assigned to the protected or custom object view. This is particularly useful for page views targeting object class stereotypes where the names deviate from the standard class names. The custom caption and custom description can be defined for either a selected object class or for all object classes in the context of a specified view scheme. The custom page view captions and descriptions can be translated via the localization capabilities available in Alfabet Expand. For more information about manually or automatically translating the custom strings in the solution configuration, see the section Modifying, Translating and Managing the Vocabularies.

To define a custom caption or description for a page view:

1) Right-click the object view that the page view is assigned to and select **Show Usage** in order to understand which view schemes the object view is assigned to. This is helpful if the object view is assigned to multiple view schemes so that you know which view schemes to define the custom caption/description for.

2) Right-click the page view and select **Specify Caption and Description**. The **Caption and Description for <Page View Name>** editor opens displaying all view schemes configured for your enterprise.

3) In the **Select Class** field, select one of the following:

- If the custom caption or description is relevant to the page view regardless of the object class for which it is configured, select <`Class Independent`>. For example, if you want to configure a custom caption for the *Attachments Page View* (`ObjectAttachments`) that should be displayed for all object

classes in the view schemes you specify, you should select <Class Independent>. In this case, the page view caption and description will be changed for all instances of the page view for the specified class.

- If the configuration should only be relevant for a specific object class in the view scheme, select the relevant object class. If the caption and description is not explicitly specified for an object class stereotype, the caption and description will be applied to all object class stereotypes based on the object class.
- If the configuration should only be relevant for a specific object class stereotype in the view scheme, select the relevant object class stereotype.

4) In the row of the view scheme that is relevant for the object view that you are configuring, enter the custom caption in the **Caption** cell and/or a description in the **Description** cell.

5) Click **OK** to save the changes or click **Cancel** to exit without saving.

6) In the toolbar, click the **Save**  button to save your changes.

Adding Configured Reports to a Workspace

You can add configured reports to a custom workspace. In this case, the report will be available in a manner similar to a page view. The caption of the configured report will be displayed in the interface and users can select the configured report in a workspace as they would a standard Alfabet page view.

Keep the following in mind when assigning configured reports to custom object views:

- Only configured reports of the type `Query` or `Custom` can be assigned to custom object views.
- A configured report with the **Report State** attribute set to `Planned` or `Retired` will be displayed in the custom object view, but an error message will be displayed if the user attempts to open the configured report.
- The text entered in the **Caption** attribute of the configured report is displayed as the title of the configured report in the configured report itself and as the default caption for the configured report in the object view. The report caption displayed in the object view can be overwritten by defining the **Caption** attribute for the respective report object assigned to the object view. This has no effect on the caption displayed in the configured report itself. Therefore, the caption can be different for the object view and the configured report itself.
- The text entered in the **Description** attribute of the configured report is displayed as the page view description in the object view of the report.
- You can provide customized context-sensitive help to your user community in order to understand the content of a configured report that you have configured. The Help file is stored externally and the URL of the help file is defined in the configured report. When the user views the configured report in the Alfabet interface, he/she can click the **Help** button that opens the Alfabet online Help. The context-sensitive help screen that provides access to the context-sensitive online Help will display an option that can be clicked to open the hyperlinked help document.

- The **Can Create Bookmark** and **Can Create Express View** attributes are configured for configured reports in the context of the report configuration in the **Reports** tab. Please note that a configured report may only be added to a user's splash screen if the **Can Create Bookmark** attribute is set to `True` for the respective report. For more information about the splash screen capability, see the chapter *Creating a Splash Screen As Your Start Page* in the reference manual *Getting Started with Alfabet*.

For more information about configuring a configured report, see the chapter Configuring Reports.

Configured reports can also be assigned directly to the object view rather than grouped in a workspace.

To add one or more configured reports to a workspace.

1) Right-click the custom workspace and select **Add Report**. The **Select Report** editor opens.
2) Select one or more configured reports you would like to add to the workspace and click **OK**. You can simultaneously select multiple configured reports by holding down the CTRL key while you select reports.
3) The configured reports are added to the workspace. Repeat this procedure to add all necessary configured reports to the selected workspace.
4) To sequence the page views and configured reports in the workspace, click the workspace to activate its attribute window. In the **View Sequence** attribute, click the **Browse** button to open the **Sort Entries** editor.
5) Select a page view or configured report and place it in the correct sequence by clicking the up/down arrows in the editor. Click **OK** to close the editor and save the definition.
6) Sequence any other relevant reports or page views
7) In the toolbar, click the **Save** button to save your changes.

Deleting a Page View or Configured Report from a Workspace or Object Profile

To delete a page view or configured report from a workspace or object view, right-click the page view or configured report and select **Delete**.

Sequencing the Order of the Workspaces and Configured Reports in the Object Profile

To define the order that the workspaces should appear in the object view, click the object view to activate the attribute window. In the attribute window, click the **Browse** button in the **Attribute Sequence** attribute to open the editor. Move the workspaces and configured reports up and down and place them in the correct sequence by clicking the up/down arrows in the editor. Click **OK** to close the editor and save the definition.

Configuring Conditional Constraints for an Object Profile

Specifying condition constraints in object profiles can provide a more dynamic user experience and ensure that users are seeing and defining the data that is pertinent to the task at hand. The display of the data can be suppressed based on the definition of a value for a property of the associated class. For example, if the **Is SOX Relevant** attribute is set to `True` for the application, then you might want to display the **Business Analysis** workspace in the object profile, but not display if in the application is not SOX-relevant. In this case, you would assign a visibility condition to the workspace.

The following steps are required to configure a visibility condition for an object profile:

- Define a configured report of the type `Query` or `NativeSQL`. The query should search the Alfabet database and return at least one row as a result to fulfill the condition if the **Check Result Type** attribute of the condition is set to `Positive`. When the **Check Result Type** attribute of the condition is set to `Negative` the query return no records. For more information about configuring reports of the type `Query` or `NativeSQL`, see the chapter Configuring Reports.
- Set the **Category** attribute of the report to the relevant category name specified for conditions in the XML object ***UseCaseCategories***. Definition of the XML object ***UseCaseCategories*** is explained in the section Assigning a Category for Specific Functional Use to a Configured Report.
- Create the condition and specify the configured report with the query as described below in the section Creating Conditions to Implement in an Object Profile.
- Specify the visibility of the interface control targeted by the condition is visible via the **Visibility Condition** attribute as described below in the section Assigning Conditions to Interface Controls in the Object Profile.

- Creating Conditions to Implement in an Object Profile
- Assigning Conditions to Interface Controls in the Object Profile

Creating Conditions to Implement in an Object Profile

Conditions can be used in the context of custom editors, object cockpits, and filters in configured reports and can be reused as needed. Conditions for the interface controls in object profiles must be based on queries defined in configured reports. The condition state must be set to `Active` in order to make the condition available in the **Visibility Condition** attribute for interface controls.

To create a condition:

1) Go to the **Presentation** tab and right-click the **Conditions** folder and select **New Condition**. The condition state will be set to `Plan` per default for the new condition.
2) Click the new condition  and define the following in the attribute window:

- **Technical Name**: Enter a name for the condition. It is recommended that the name indicates the meaning of the condition. All active conditions will be displayed in drop-down lists for the **Visibility Condition** attribute.

- **Group**: Enter the name of a new condition folder that you want to store the condition in or select an existing condition folder.

3) In the **Type** field, select `Report` to specify a configured report for the condition. The configured report should already be configured and should be of the type `Query` or `NativeSQL`. The query should search the database and return one row as a result to fulfill the condition. The report is only selectable for conditions if the **Category** attribute of the report is set to `Condition`. Define the following attributes:

- **Report**: Select the configured report that should be executed for the condition. The query should search the Alfabet database and return at least one row as a result to fulfill the condition if the **Check Result Type** attribute is set to `Positive`. When the **Check Result Type** attribute is set to `Negative` the query return no records.
- **Check Result Type**: Select either `Positive` or `Negative` to define what constitutes a fulfilled condition.
- `Positive` means that the condition is fulfilled if the query associated with the configured report delivers a result.
- `Negative` means that the condition is fulfilled if the query associated with the configured report delivers no result.

4) Once the condition is complete and ready to be implemented, the condition state must be set to `Active`. To do so, right-click the condition and select **Set Condition State to 'Active'**. The active condition will be available in the **Visibility Condition**, **Presence Condition**, and **Read-Only Condition** attributes for custom editor fields, filter fields in configured reports, object cockpits, and object profiles.

5) In the toolbar, click the **Save** button to save your changes.

Assigning Conditions to Interface Controls in the Object Profile

You can specify that a workspace or page view is visible or not visible based on whether a condition is fulfilled.

To define conditions for object profiles:

1) Go to the **Presentations** tab and navigate to the object profile that you want to define.
2) Click the workspace, page view, or configured report that you want to apply a visibility condition to.
3) Expand the **Local Settings** section of the attribute window. In the **Visibility Condition** field, click the **Browse** button. In the **Visibility Condition** editor select the configured report in the **Use** column. Click **OK** to save the definition and close the editor.
4) In the toolbar, click the **Save** button to save your changes.

Configuring Object Cockpits for a Custom Object View

An object cockpit provides users with an immediate and transparent overview of data for a selected object. It is as an abbreviated and focused presentation of object data, typically from a particular perspective such as an architecture perspective or a strategy perspective.

Multiple object cockpits can be available per object profile. For example, one object cockpit for the object class Application might display data relevant for understanding the application in the as-is architecture, another cockpit might display data relevant to master planning issues, and a third cockpit might display relevant data for cost and budget issues. The object cockpit is a configuration that is available in addition to the more comprehensive object profile.

An object cockpit can be created and configured in the context of a custom object view. Although an object view may have multiple object cockpits defined, it is possible to hide object cockpits in the context of the view scheme configuration. In this case, only the object cockpits visible for the view scheme will be available to the associated user profile.

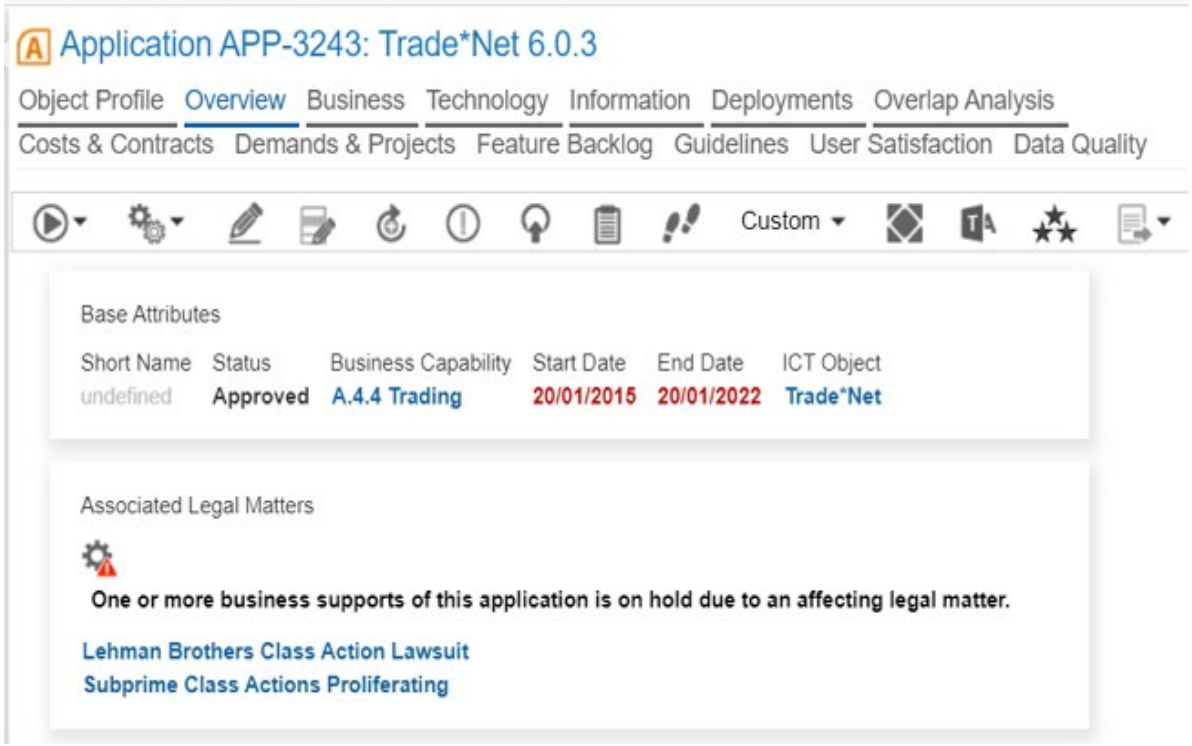

FIGURE: Object profile and multiple object cockpits

There are two possibilities when configuring object cockpits:

- You can use the configuration possibilities available that leverage the browser's layout capability in HTML 5. This configuration is based on a flow panel. This configuration is recommended, and it ensures that object cockpits are not squeezed, stretched, or truncated when the interface is resized. When resizing the interface, the content displayed in object cockpits will be redistributed in the available space and the content will not be cut-off. The flow panel ensures that a configured view or set of views will be bumped down and placed below the preceding view or set of views. Business graphics embedded in an object cockpit will be automatically scaled down in size to fit in the available screen space of the device the user is using. Pictures and icons can be implemented as placeholders that link to views or reports. This is especially useful for large reports for which only a

portion of the report is displayed in the object cockpit. This method is described in the section Configuring the Object Cockpit By Means of a Flow Panel.

- You can use the configuration possibilities that were available in releases of Alfabet prior to the introduction of HTML 5-based user interface and user interactions. This configuration is based on a table layout panel. This method is available for reasons of backward compatibility. However, the table layout method is not recommended because the data in the object cockpit may be squeezed, stretched, or truncated when the interface is resized. This method is described in the section Configuring the Object Cockpit By Means of a Table Grid.

Object cockpits can also be implemented in a configured report. In this case, a filter field is displayed in the configured report that allows the user to select an object in order to view its data in an object cockpit. Please note that the object cockpits available in a configured report will depend on the view scheme configuration associated with the user profile that the user is accessing the configured report with. For more information about implementing an object cockpit in a configured report, see the Creating a Configured Report Displaying an Object Profile or Object Cockpit in the chapter Configuring Reports.

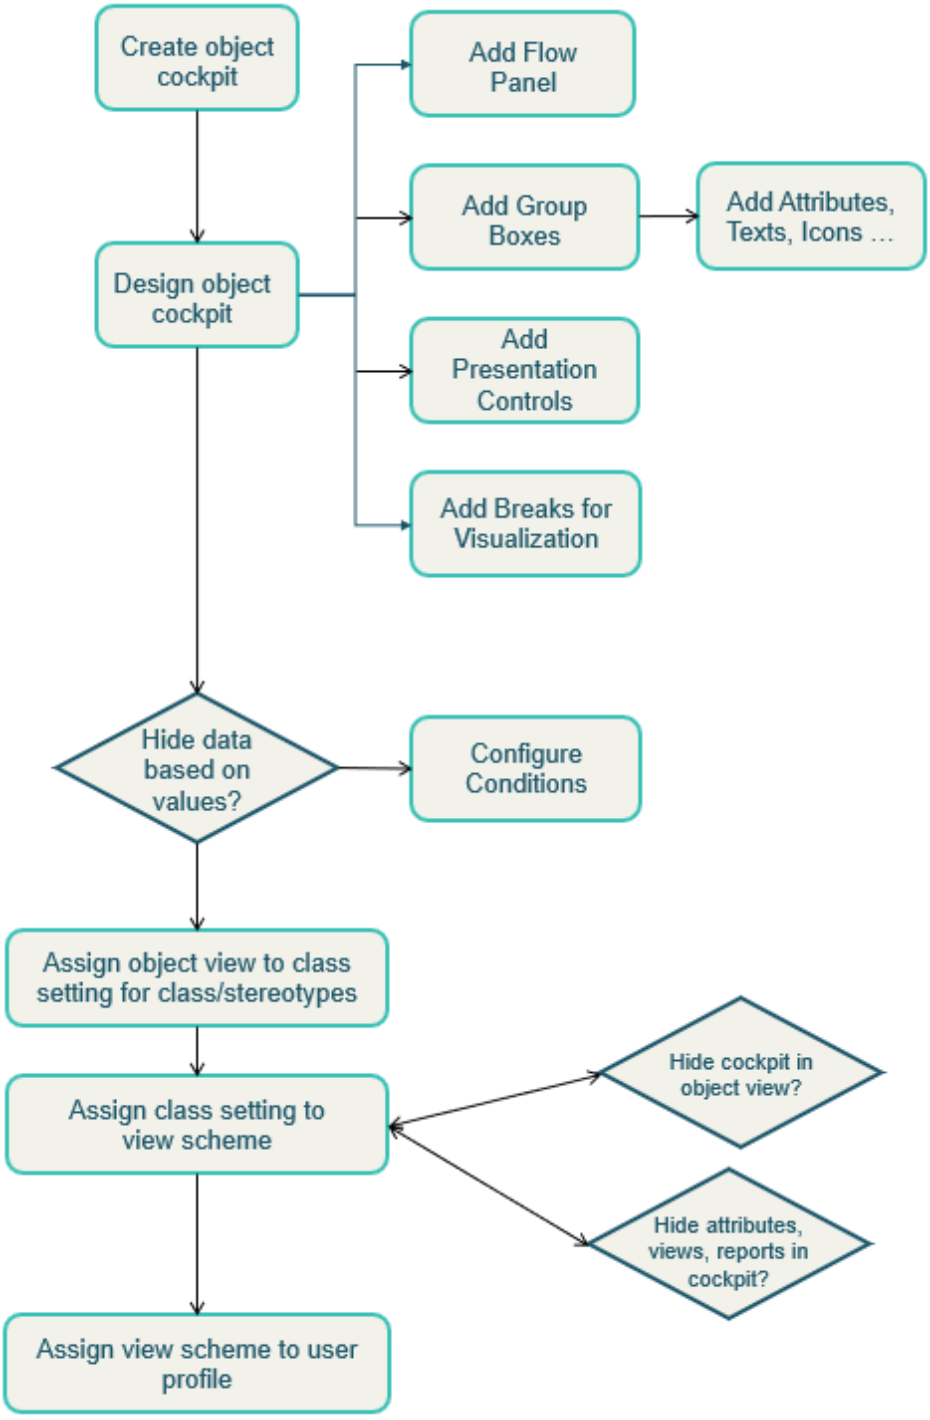
The following information is available:

- Conceptualizing the Object Cockpit
- Creating an Object Cockpit
- Configuring the Object Cockpit By Means of a Flow Panel
- Adding Group Boxes to Display Attributes
- Adding Static Text to the Object Cockpit
- Adding a Property to the Object Cockpit
- Adding a Generic Attribute to the Object Cockpit
- Adding an Indicator to the Object Cockpit
- Adding a Check Entry to the Object Cockpit
- Adding a Query to the Object Cockpit
- Adding a URL to the Object Cockpit
- Adding a Dynamic Web Link to the Object Cockpit
- Adding Presentation Objects to Display Page Views and Configured Reports
- Adding a Floating Group Box to Contain Presentation Objects
- Adding a Floating Group Box as a Filter Panel for Reports
- Adding a Presentation Object for a Different Target Object
- Adding Placeholders for Page Views and Configured Reports
- Adding Workflow, Assignment, Microsoft Teams Meeting Information and Object Validation Information to the Object Cockpit
- Adding Icons to the Object Cockpit
- Adding Embedded HTML to the Object Cockpit

Conceptualizing the Object Cockpit

Before you begin to define the object cockpit, you should conceptualize what information should be displayed in the object cockpit. You can define multiple object cockpits for a protected or custom object view. Each object cockpit can be configured to be relevant to a specific perspective (for example, a business perspective, technical perspective, financial perspective, etc.). This allows you to create object cockpits with a manageable amount of data that users can quickly and easily comprehend.

The following image illustrates the steps to configure an object cockpit:



Because the custom object view may be implemented in multiple class settings, you may have many object cockpits that are relevant for the custom object view. During the context of configuring a view scheme, you can specify which of the object cockpits should be relevant for the class setting implemented in the user profile. Furthermore, if you only want users to view the object cockpits you have configured, you can hide the standard or custom object profile from the user interface.

To conceptualize the object cockpit, you should consider the following questions in order to develop a general idea of the data that should be available to users working with the object cockpit:

- Which object class properties should be displayed in the object cockpit? Which of these properties are particularly important and require special highlighting to attract the user's attention? Options included providing captions, changing the font size or color of a cell caption, adding borders to table cells, or configuring color or picture instructions that add color or icons to a table cell based on the object class property value.
- Should check entries be included to control the value defined for a property? Check entries are based on queries configured to find and flag data with a message and/or icon. For example, a check entry could be configured to ensure that the object class property `ICT Object` for the object class `Application` has a value defined. If no ICT object is defined, a warning symbol or message can be displayed informing the user that this data is missing for the application.
- Should referenced properties be displayed that must be fetched via a query? For example, a query could be defined to display all projects for which an application has been defined in the as-is architecture.
- Should indicators be displayed in the object cockpit?
- Should static HTML be displayed in the object cockpit? Should each property displayed in the overview section have a corresponding table cell displaying a caption or explanatory text? Any static HTML code can be included in the object cockpit including, for example, images, links, and forms.
- Should the object cockpit display standard Alfabet views and configured reports? If so, which views and reports should be included in the object cockpit? Should users be able to navigate to the views or perhaps to other views that might be relevant to the user's context? Please note that in order to make the amount of data in the object cockpit manageable, it is recommended that you not include more than 10 views in an object cockpit.
- Should the data in the page views and configured reports be displayed or should an icon be displayed that allows the user to navigate to the full-view of the page view or report. Please note that a variety of icons are available that symbolize the content of the page view or configured report are available. For example, icons are available with a diagram symbol, matrix symbol, portfolio symbol, etc.

Creating an Object Cockpit

You can create multiple object cockpits for a protected object view or a custom object view. Each object cockpit can be differently designed, as needed.

Please note that new object cockpits will typically be created with a Flow Panel interface control rather than a Table Layout interface control. This is determined via the XML attribute `UseGUISchemeStyleForNewCockpits` in the XML object ***SolutionOptions***, which is set to `False` per default. When set to `False`, a new cockpit is created with a flow panel and the **Ignore GUI Scheme Common Container Skin** attribute of the flow panel is automatically set to `True`.

To create a new object cockpit:

1) Navigate to the protected object view or custom object view that you want to create an object cockpit for. Right-click the object view and select **Create Object Cockpit**. The new object cockpit s displayed below the selected object view node.

You can copy an existing object cockpit as the basis to create a new one and paste it to the object view of another object view configured for the same object class. To create a new object cockpit based on a copy of an existing object cockpit, right-click the protected or custom object view and select **Create Object Cockpit**. Right-click the existing object cockpit that you want to copy and select **Copy**. Right-click the new object cockpit and select **Paste**. You can modify the copied object cockpit as needed.

2) Click the new object cockpit below the object view node. The attribute window is displayed in the right pane. The **Class Name** attribute displays the object class that the object cockpit is based on. Define the following attributes, as needed:

- **Name**: Edit the automatically-generated technical name, if necessary. This name is not displayed in the Alfabet interface.

A validation mechanism checks for correct syntax when defining a technical name. The technical name of a configuration object may not begin with an empty space nor include any of the following special characters: **\ / * ? " > < | ':**

Furthermore, please note that names may not begin with an empty space nor include special characters. For a list of the special characters that are not allowed, see the section Defining Attributes for Configuration Objects in the chapter Getting Started with Alfabet Expand.

Furthermore, if the technical name of a configuration object is changed, the name will be correctly updated in other configuration objects referencing the changed object during design time. Please note that the name of a changed configuration object will not be updated in guide pages nor if the guide pages reference a configuration object listed in the **Show Usage** functionality. If you plan to change the name of a configuration object, the reference in the guide page should be changed prior to changing the configuration object name.

- **Caption**: Enter the caption to display on the object cockpit tab in the user interface.
- **Show Toolbar**: Define the visibility of the standard toolbar for the selected object cockpit. The standard toolbar will allow users to access basic functionalities available via such buttons as the **Mark as Reviewed** button and **Notify Authorized User** button. Depending on the object class that you are working with, other buttons such as the **Edit** button, **Change Object State** button, **Workflow** button, etc. may be available. Select `True` if the standard toolbar should be displayed for the object cockpit. Select `False` if the standard toolbar should not be displayed for the object cockpit.

Please note that the same toolbar is used in both the object profile and all object cockpits defined for the object class for which **Show Toolbar** is set to `True`.

3) Right-click the object cockpit and select **Design Object Cockpit**. The design editor is displayed in the center pane. The new object cockpit is automatically filled with the Flow Panel interface control.

4) Click anywhere in the Flow Panel interface control to activate the attribute window. If the flow panel is selected, its handles will be displayed.

5) Set the **Dock** attribute to `Fill` to ensure that the flow panel is docked in the object cockpit. You can now add group boxes containing attributes, presentation objects containing page views or configured reports, and breaks to structure the content:

A validation mechanism checks for inconsistencies in the layout and docking definition of interface controls in guide views, configured reports, and other configured views. Please note that an error message will be displayed when the user attempts to open an incorrectly configured view if two or more interface controls have no docking defined in the view. The error message will provide detailed information about the faulty configuration.

The **Height** and **Width** attributes are irrelevant for the configuration of the object cockpit. The object cockpit will be automatically sized to fill the available space in the user interface.

6) Click the  button to save the new object cockpit. You must first add group boxes or presentation objects to the flow panel in order to view the object cockpit in the Alfabet Web interface. You can now add interface controls to the new object cockpit.

Configuring the Object Cockpit By Means of a Flow Panel

You can use the configuration possibilities available that leverage the browser's layout capability in HTML 5. This configuration is based on a flow panel and has the advantage that object cockpits are not squeezed, stretched, or truncated when the interface is resized. Group boxes containing attributes and presentation objects (views and reports) will be dynamically positioned according to the current width of the Alfabet Web interface. When resizing the interface, the content displayed in object cockpits will be redistributed in the available space and the content will not be cut-off. The flow panel ensures that a configured view or set of views will be bumped down and placed below the preceding view or set of views. Business graphics embedded in an object cockpit will be automatically scaled down in size to fit in the available screen space of the device the user is using. Pictures and icons can be implemented as a placeholder that link to views or reports. This is especially useful for large reports for which only a portion of the report is displayed in the object cockpit.

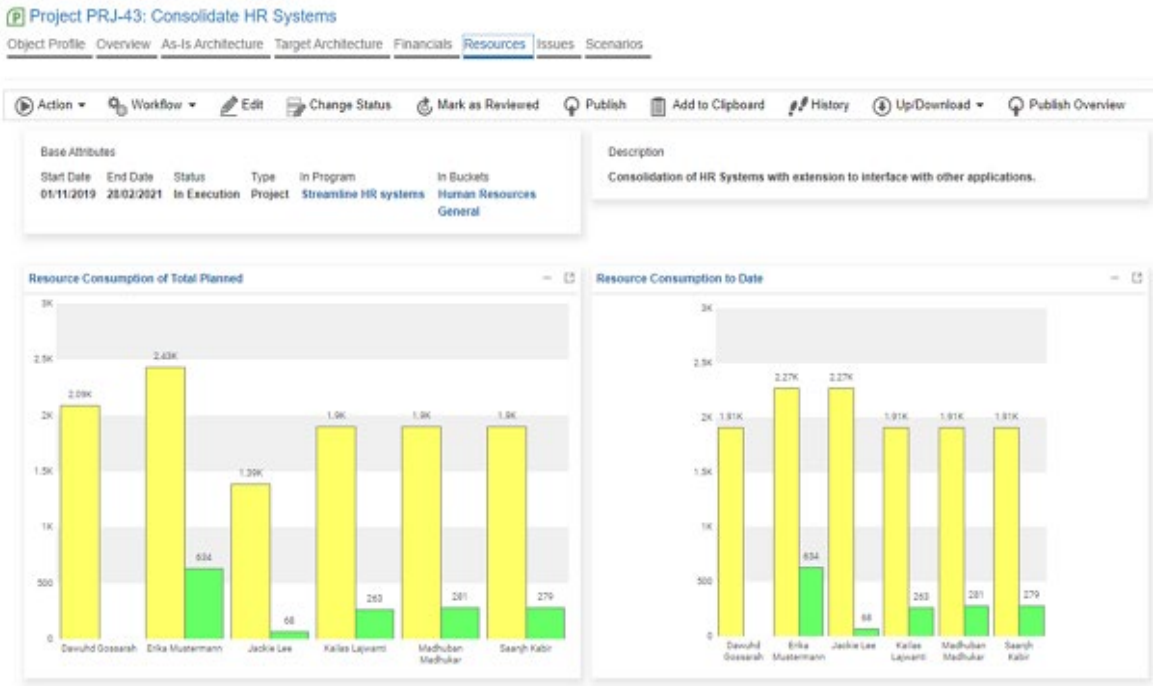


FIGURE: Object cockpit based on a flow panel

The placement of the interface controls in the object cockpit designer as well as their alignment and spacing horizontally is not relevant to the displayed output. The actual display in the Alfabet interface at runtime will be determined by the sequence and linebreaks that you define in the object cockpit configuration. However, it is recommended that you position the interface controls in the object cockpit designer in the order that you want them to be displayed in order to make the conceptualization and design of the object cockpit easier.

Please note that font and hyperlink colors displayed in the object cockpit are determined by the configuration of the GUI schemes implemented in your enterprise. For more information, see the section Configuring GUI Scheme Definitions for the Alfabet Interface.

When you design the layout of the object cockpit, you must consider the following factors:

- **The order in which you want information to be displayed on the interface.** All interface controls that you place in the object cockpit must be sequenced in order to determine their order from left to right and top to bottom on the interface. The interface controls are assigned a tab order in the last step of the design process but it is useful to have a general idea of what this order will be when you begin to configure the object cockpit.
- **The width in pixel of the individual interface controls (group boxes and presentation objects).** It is recommended that Group Box and Presentation Object interface controls have a base width of either 400, 600, or1200 pixel. The sum of the width of multiple interface controls (group boxes and presentation objects) that shall be displayed in one row should not exceed 1200 pixel. For example, if you want to display three reports in the same row, you could define each presentation object to have a width of 400 pixel and conclude the row with a break <`break`> element. If the screen size is smaller than 1200 pixel or the user manually reduces the width of the screen is less than 1200 pixel, the last report preceding the break <`break`> element that doesn't fit in the user interface will be bumped down to the next row. If an interface control (group box or presentation object) is wider than the available screen space, the content will be truncated.

- **The height in pixel of the individual group boxes.** You can either define a static height for a group box or allow the height to be automatically sized based on the content in the group box. If you define a static height, the group box will retain the defined size regardless of the amount of content in it and a scrollbar will be added to the group box if the content exceeds the height. If you want the group box to automatically adjust its height based on the amount of content, then you must set the Automatic Sizing `True`. In this case, any height definition will be ignored. Please note, however, that if you specify that the height of one group box in a row is greater than the height of the other group boxes (or you define some but not all group boxes to be automatically sized), empty space may result in the row. This is because the bottom edge of the largest group box will be used to determine the top edge of the next row of interface controls.
- **The height in pixel of the individual presentation objects.** All Presentation Object interface controls (reports or page views) require a defined height and width. The height of a presentation object may be configured to be automatically sized based on its content. A zoom functionality will be available automatically for views with business graphics.

The following provides best practice recommendations to configure object cockpits optimized for a resolution of1920 x 1080 (full HD) down to 1200 x 786 (HD ready) which is common for current monitors, projectors, and laptops.

- A Flow Panel interface control is automatically placed in a new object cockpit. The Flow Panel interface control allows the resizing mechanisms in the browser to be leveraged and is required in order to configure an object cockpit that is optimized for HTML 5. A Flow Panel interface control should be the base of the object cockpit. The **Dock** attribute should be set to `Fill`. A validation mechanism checks for inconsistencies in the layout and docking definition of interface controls in object cockpits, configured reports, and other configured views. Please note that an error message will be displayed when the user attempts to open an incorrectly configured view if two or more interface controls have no docking defined in the view. The error message will provide detailed information about the faulty configuration.

  

  A validation mechanism checks for inconsistencies in the layout and docking definition of interface controls in guide views, configured reports, and other configured views. Please note that an error message will be displayed when the user attempts to open an incorrectly configured view if two or more interface controls have no docking defined in the view. The error message will provide detailed information about the faulty configuration.

- Static Text, Icon, and HTML Content and Value Control interface controls (properties, indicators, check entries, queries, URLs,etc.) can be added to the Flow Panel interface control or Group Box interface control. It is recommended to group such interface controls in group boxes in order to better control the visual layout.
- Multiple Group Box interface controls can be added to the flow panel to visually structure the data. The content placed inside a group box is arranged by the browser vertically. The size of the interface controls inside the group box will be honored. If the content in the group box does not fit in the space available, scroll bars will be automatically added.
- Linebreaks should be configured to create a linefeed in the layout in order to visually separate attribute groups from presentation objects (page views and reports) or to thematically structure views in sections. The content before each linebreak should have the same height. Otherwise the content will not be horizontally aligned.
- You can define color and styles for all interface controls. Styles can be configured for all object cockpits via various GUI scheme attributes in order to create a coherent look-and-feel for your

enterprise. Please note that color definition will be ignored if the interface control represents a referenced property (hyperlink) that can be clicked in order to navigate. In this case, the color will be displayed as a blue hyperlink. For more information about configuring styles in the object cockpit, see the section Configuring Styles and GUI Scheme Settings for Object Cockpits.

- You can copy existing configurations of interface controls (such as group boxes, value controls, or presentation objects from an existing object cockpit to the one you are currently designing.

The following information is available:

- Adding Group Boxes to Display Attributes
- Adding Static Text to the Object Cockpit
- Adding a Property to the Object Cockpit
- Adding a Generic Attribute to the Object Cockpit
- Adding an Indicator to the Object Cockpit
- Adding a Check Entry to the Object Cockpit
- Adding a Query to the Object Cockpit
- Adding a URL to the Object Cockpit
- Adding a Dynamic Web Link to the Object Cockpit
- Adding Presentation Objects to Display Page Views and Configured Reports
- Adding a Floating Group Box to Contain Presentation Objects
- Adding a Floating Group Box as a Filter Panel for Reports
- Adding a Presentation Object for a Different Target Object
- Adding Placeholders for Page Views and Configured Reports
- Adding Workflow, Assignment, Microsoft Teams Meeting Information and Object Validation Information to the Object Cockpit
- Adding Icons to the Object Cockpit
- Adding Embedded HTML to the Object Cockpit
- Configuring Conditional Restraints in the Object Cockpit
- Creating Conditions to Implement in an Object Cockpit
- Assigning Conditions to Interface Controls in the Object Cockpit
- Adding Linebreaks to Visually Structure the Information in the Object Cockpit
- Configuring Styles and GUI Scheme Settings for Object Cockpits
- Sequencing the Content in the Flow Panel
- Configuring Drill-Down Navigation in the Object Cockpit

Adding Group Boxes to Display Attributes

A Group Box interface control allows you to structure and display attributes that shall be contained in the group box. You can create one Group Box interface control that contains all attributes that you want to display, or you can create multiple Group Box interface controls with different sets of attributes.

A Group Box interface control can be used in other contexts:

- As a collapsible container to group two or more Presentation Object interface controls such as a set of widget reports. For more information, see Adding a Floating Group Box to Contain Presentation Objects.
- As a collapsible container to group a set of filters targeting Presentation object interface controls that implement configured reports. In this case, the filter settings will be applied to all relevant configured reports in the object cockpit. For more information, see the section Adding a Floating Group Box as a Filter Panel for Reports.

The content placed inside a group box is arranged by the browser vertically. The attribute data is structured vertically as two columns, one containing the attribute caption and the other, the attribute value.The size of the interface controls inside the group box will be honored. If the content in the group box does not fit in the space available, scroll bars will be automatically added. The user can collapse the group box by clicking the collapse (-) symbol and expand the group box by clicking the expand (+) symbol. The collapsed group box will reduce to the width and height of the group box caption.

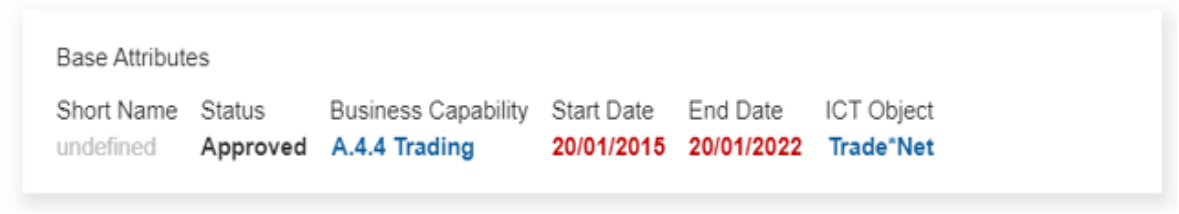

FIGURE: Group box with attributes

Please consider the following when conceptualizing the group box and the data that shall be displayed in it:

- The width that you define for a Group Box interface control will influence the number of Group Box interface controls that may be displayed horizontally in a row. Therefore, you should consider how many Group Box interface controls you would ideally like to display horizontally in a row and the width of each. It is recommended that Group Box interface controls have a base width of either 400, 600, or 1200 pixel. The sum of the width of multiple interface controls (group boxes and presentation objects) that shall be displayed in one row should not exceed 1200 pixel. For example, if you want to display three group boxes in the same row, you could define each group box to have a width of 400 pixel and conclude the row with a break <`break`> element. If the screen size is smaller than 1200 pixel or the user manually reduces the width of the screen is less than 1200 pixel, the last group box preceding the break <`break`> element that doesn't fit in the user interface will be bumped down to the next row. If an interface control (group box or presentation object) is wider than the available screen space, the content will be truncated.
- The height of a group box can be automatically sized based on the content in the group box or you can specify a static height for the group box. If the content of the group box exceeds the maximum height definition, a scrollbar will be added so that the user can scroll to see the complete content in the group box. In order to better control the visual layout and ensure an object cockpit with reduced white space, it is recommended that you configured a maximum height for group boxes.

- If multiple group boxes shall be visualized in the object cockpit:

- Break elements (<break>) may be configured to create a linefeed between multiple group boxes in order to visually structure the group boxes in sections. For example, if 4 group boxes are displayed in the object cockpit, you may configure all of them to have a width of 600 pixel and place a line break between the second and third group box. This would result in the first and second group boxes being horizontally aligned in a row and the third and fourth group box being horizontally aligned on the next row.

- The height that you define for a Group Box interface control will influence the horizontal alignment of the group boxes. If multiple group boxes shall be visualized in the object cockpit, all Group Box interface controls located before a line break should have the same height, otherwise the content will not be horizontally aligned and there will be excessive white space in the object cockpit.

- It is recommended that multiple Group Box interface controls have the same width. If Group Box interface controls have different widths (600 pixel and 1200 pixel), line wrapping may be an issue. If different widths cannot be avoided, all Group Box interface controls located before a line break should be sequenced based on their size as follows: 200 pixel, 600 pixel, 600 pixel, 1200 pixel. This provides an adequate display on both, high and low resolution cockpits.

- Static Text, Icon, and HTML Content and Value Control interface controls (properties, indicators, check entries, queries, URLs,etc.) can be added to the Group Box interface control. The attribute data is structured vertically as two columns, one containing the attribute caption and the other, the attribute value. Please consider the following if a high number of interface controls are added to a group box:

- Multiple Group Box interface controls should be configured if a high number of interface controls shall be included in the object cockpit. The content should be structured to make it easy for the user to understand how the content is organized.

- Attributes which are guaranteed to have one line maximum should not be mixed up with multi-line attributes in one Group Box interface control. The attributes that are guaranteed to consist of only one line should be grouped in one Group Box interface control and attributes that require multiple lines of text should be grouped in another Group Box interface control.

- Break elements (<break>) can be used in the group box to create a linefeed and separator line to improve the layout of data in the group box. For example, you could group a set of attributes with basic information in the group box, add a break element (<break>) after the basic data attributes, and add another set of attributes about risk assessment to follow the break. The **Tab Index** attribute must specify the correct sequence for all attributes and breaks in the group box.

When an object cockpit is published to a DOC or PDF file, the user can select which group boxes and page views to include in the DOC or PDF file as well as the orientation of the each group box and view in the **Object Document** editor. During the publication process, group boxes will be converted to tables, thus providing a structured visualization of the data in the DOC and PDF file. Linebreaks in group boxes will be removed from the file when an object cockpit is published to a DOC or PDF file. For more information about publishing an object cockpit to a PDF or DOC file, see the section *Exporting Data* in the reference manual *Getting Started with Alfabet*.

To add a Group Box interface control to the object cockpit:

1) In the toolbar of the object cockpit designer, click the **Group Box** button and click in the flow panel. You can add multiple Group Box interface controls. If you only define one Group Box

interface control and it is configured to be very wide, its display may be truncated if the width of the object cockpit is smaller than anticipated or is decreased by the user.

2) Click the Group Box interface control to ensure that its attribute window is open. Define the following attributes, as needed:

- **Sub-Type**: Select `Attributes`.
- **Caption**: Define a caption for the group box. This attribute may not be left empty.

The font color and font style of the caption of group boxes is specified via the **Attributes Group Caption Font** attribute of the GUI scheme. For more information about defining the styling of the object cockpit, see the sections Configuring Styles and GUI Scheme Settings for Object Cockpits.

3) Specify the height of the group box:

- To specify that the height of the group box automatically adjusts to the size of its contents, set the **Automatic Sizing** attribute to `True`. Please consider the following:
- The **Automatic Sizing** attribute is only visible in the attribute window if the **Use Height as Max. Height** attribute is set to `False`.
- If the Group Box interface control contains a Static Text interface control, the **Automatic Sizing** attribute should also be set to `True` for the Static Text interface control.
- To specify that the height of the group box maintains a static size, regardless of the content of the group box, specify in pixel the size of the group box in the **Height** attribute. If the content of the group box exceeds the maximum height definition, a scrollbar will be added so that the user can scroll to see the complete content in the group box.
- **Use Height as Max. Height**: Select `True` if the maximum height of the group box shall not exceed the defined height. If the content of the group box exceeds the maximum height definition, a scrollbar will be added so that the user can scroll to see the complete content in the group box. If the **Automatic Sizing** attribute is set to `True`, the **Use Height as Max. Height** attribute will be ignored and the height will be automatically sized.

4) Specify the width of the group box:

- **Width**: Define the width in pixel for the group box. Any group box with a defined width that is greater than the defined width of the object cockpit will be truncated and not all content will be visible.
- **Item Max. Width**: Enter the maximum width of the interface controls in the group box. Enter -1 if there shall be no limitation on the maximum width.
- **Item Min. Width**: Enter the minimum width of the interface controls in the group box. Enter -1 if there shall be no limitation on the minimum width.

5) Specify the placement of the group box. You can do this via drag-and-drop of the attribute box or by entering values in pixel in the **Top** and **Left** attributes.

6) Click the **Save**  button to save the new group box.

7) Add the relevant Static Text, Icon, and HTML Content and Value Control interface controls to the group box as described in the following sections.

8) Add a break (<break>) element between groups of attributes in the group box to add a linefeed and separator, as needed. For more information about configuring a linebreak, see the section Adding Linebreaks to Visually Structure the Information in the Object Cockpit.

9) Define the styling of the group box as needed. For more information, see the section Configuring Styles and GUI Scheme Settings for Object Cockpits.

10) Specify the **Tab Index** attribute for all Static Text, Icon, and HTML Content and Value Control interface controls and break elements (<break>) in the Group Box interface control in order to specify the correct sequence and layout in the group box. The sequence should begin with 1. The sequence that you specify is the order in which the interface controls and break elements are displayed as well as the order to navigate through the group box via the TAB key.

Adding Static Text to the Object Cockpit

A Static Text interface control can be add to the Flow Panel interface control or Group Box interface control to visualize text such as instruction or guidelines to provide the user community with specific information.

To add and configure a Static Text interface control:

1) In the toolbar of the object cockpit designer, click the **Static Text** button and click in the Flow Panel interface control or Group Box interface control.

2) Click the Static Text interface control to activate its attribute window. Define the following attributes as needed: The **Control Type** attribute is automatically set to StaticText.

- **Control Type**: This attribute is automatically set to StaticText.
- **Caption**: Enter the text that should be displayed for the Static Text interface control. This could be a short text such as a property caption or comprehensive information.

3) To specify styles such as the font and color for the Static Text interface control, set the **User Style** attribute to True. Expand the **Style** section of the attribute window and specify the relevant styles as needed.

4) In the toolbar, click the **Save** button to save your changes.

Adding a Property to the Object Cockpit

The Value Control interface control allows you to add standard or custom properties that have been configured for the object class that the object cockpit has been created for. If a property should be highlighted with a color or icon if it has a specified value, then you can configure color or picture instructions for the Value Control interface control.

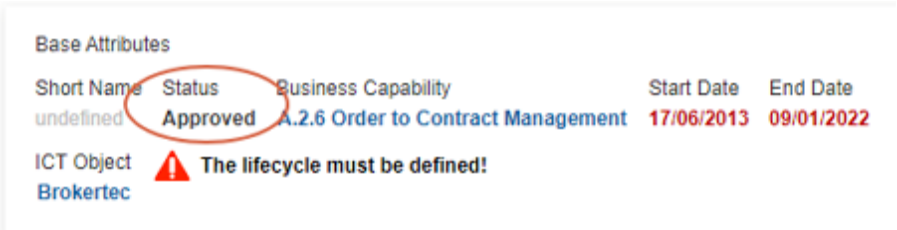

FIGURE: Status property in a group box

To add a standard or custom object class property via a Value Control interface control to the object cockpit:

1) In the toolbar of the object cockpit designer, click the **Value Control** button and click in the Group Box interface control.
2) Click the Value Control interface control to activate its attribute window. The **Control Type** attribute is automatically set to `ValueControl`. Define the following properties, as needed:

- **Sub-Type**: Select `Property`.
- **Property** attribute (in the **Value Definition** section): Select the standard or custom object class property that should be associated with the Value Control interface control.

  Please note that if the property that you are defining is of the type `Reference`, you must specify the **Show Properties** attribute in the **Value Definition** section, otherwise a defined value for the property will not be displayed in the object cockpit.

- **Caption**: Define a caption for the Value Control interface control.
- **Inline Navigation**: Select `True` if users should be able to navigate to an object referenced by the object class property. The object class property will be displayed as a blue hyperlink.
- **Filters** attribute (in the **Value Definition** section): Optional. Define picture instructions or color instructions to highlight the object class property with a specified color or icon based on the object class property value. If picture instructions or color instructions are to be defined for the object class property, enter the instructions for the filter. For picture instructions, the icon specified first must be imported to the icon gallery. The icon can be 22x22, 30x30, or an icon in the free size icon gallery. For more information about defining instructions, see the section Using Instructions to Format the Results of an Alfabet or Native SQL Query in the chapter Defining Queries.
- The picture can be defined by writing the following instruction to the **Filters** attribute: `PictureAssignment(ConditionString,"Argument", IconName);` For example, to define picture instructions for a `Boolean` value for a property, you might enter the following instructions:

  ```
  PictureAssignment(EqualTo,False,Bubble_Red);
  PictureAssignment(EqualTo,True,Bubble_Green);
  ```

- The coloring can be defined by adding the following instruction to the Alfabet query: `ColorAssignment(ConditionString,"Argument",TextColor,CellColor);` For example, to define a color filter for object state values, you might enter the following instructions:

  ```
  ColorAssignment(EqualTo,Plan,Black,Silver);
  ColorAssignment(EqualTo,Active,Yellow,Green);
  ColorAssignment(EqualTo,Retired,White,Red);
  ```

- **Hint**: Optional. Enter text for a tooltip. The tooltip will be displayed when the user points to the attribute in the object cockpit.
- **Enable HTML Content**: If the **HTML Content** attribute is set to `True` for the Memo interface control in the editor where the property is defined, the attribute will be automatically set to `True` and the HTML formatting for the property will be displayed in the object cockpit. If the **Read-Only** attribute is set to `True` for the Value Control interface control, the HTML editor will also be available to edit the property directly in the user interface of the object cockpit. The **Enable HTML Content** attribute can be set to `False` if HTML format shall not be displayed.

- **Read-Only**: Set to `True` if inline editing shall be disabled for the property in the context of the object cockpit. Set to `False` if inline editing shall be permissible for the property in the context of the object cockpit. For more information about the configuration required to allow Inline editing of scalar and reference properties, see the section Configuring Inline Editing of Attributes in the Object View.

  

  Please note the following regarding the inline editing functionality:

  - Only scalar and reference properties that are editable in the editor/wizard available in the object profile or object cockpit can be edited via inline editing.
  - All unique constraints defined for the class as well as any post-conditions configured for the wizard associated with the object profile/object cockpit will be applied to the data entered.

    

    Please note that data is saved to the Alfabet database prior to the post-condition being validated. Therefore, data entered via inline editing will be saved even if the post-condition is not fulfilled. This is because the data must be available in the Alfabet database in order to be evaluated for the post-condition. If the data entered does not fulfill the post-condition, the configured warning message will be displayed explaining that the input must be corrected in order to fulfill the post-condition.

  - Inline editing may be limited or prevented if the syntax of the post-condition is not correct. In this case, an error will be displayed if the user tries to open the wizard.

3) To specify styles such as the background color, borders, padding, margins, and font of the value displayed for the Value Control interface control, set the **Use Style** attribute to `True`. Expand the **Style** section of the attribute window and specify the relevant styles as needed.

   

   The font color and font style of the caption of Value Control interface control is specified via the **Value Control Caption Font** attribute of the GUI scheme. For more information about defining the styling of the object cockpit, see the sections Configuring Styles and GUI Scheme Settings for Object Cockpits.

4) In the toolbar, click the **Save**  button to save your changes.

Adding a Generic Attribute to the Object Cockpit

This section is only relevant for object cockpits configured for the object classes `Application`, `Component`, `Deployment`, `Deployment Element`, `Standard Platform`, `Standard Platform Element`, `Stack`, `Stack Element`, and `Stack Item`.

If generic attributes have been created for an object in the *Generic Attributes Page View* (`ObjectGenericAttributes`), you can configure the object cockpit to display the generic attributes and their values. For more information about working with generic attributes, see the section Implementing the Generic Attribute Concept Instead of Custom Properties in the chapter Configuring the Class Model.

To display generic attributes in the object cockpit:

1) In the toolbar of the object cockpit designer, click the **Value Control** button and click in the Group Box interface control.

2) Click the Value Control interface control to activate its attribute window. The **Control Type** attribute is automatically set to `ValueControl`. Define the following properties, as needed:

- **Sub-Type**: Select `AttributeQuery`.
- **Query**: Enter a query to find the generic attributes for the object class. The query should be specified for the class `GenericAttribute` and return the relevant `SHOW` and `SORT` properties.

The following example displays an Alfabet query specified to display generic attributes for a configured object profile/object cockpit:

```
ALFABET_QUERY_500

FIND GenericAttribute

WHERE(AND GenericAttribute.Owner CONTAINS:BASE)

QUERY_XML

   <QueryDef></QueryDef>

      <ShowProperty Type="Property"
      ClassName="GenericAttribute" Name="Name" />

      <ShowProperty Type="Property"
      ClassName="GenericAttribute" Name="Value" />

      <ShowProperty Type="Property"
      ClassName="GenericAttribute" Name="Type" />

      <SortProperty Type="Property"
      ClassName="GenericAttribute" Name="Name" />
```

- **Hint**: Optional. Enter text for a tooltip. The tooltip will be displayed when the user points to the attribute in the object cockpit.
- **Caption**: Not relevant for a Value Control interface control of the sub-type `AttributeQuery`.

3) To specify styles such as the background color, borders, padding, margins, and font of the value displayed for the Value Control interface control, set the **Use Style** attribute to `True`. Expand the **Style** section of the attribute window and specify the relevant styles as needed.

4) In the toolbar, click the **Save** button to save your changes.

Adding an Indicator to the Object Cockpit

An indicator type/evaluation type can be configured for a Value Control interface control. If the indicator type has been evaluated for the object, the indicator will be displayed in the object cockpit. You can configure the display of the numeric value and/or an icon for the indicator.

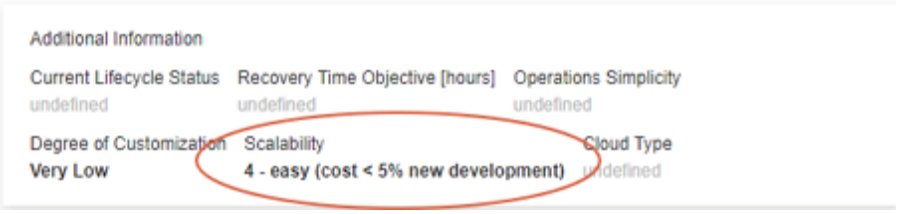

FIGURE: Numeric indicator in a group box

Evaluation types and their indicator types must first be configured in the **Evaluations and Portfolios** functionality in the **Configuration** module in order to see results in this report. The evaluation types must be assigned to the respective object class in the **Class Configuration** functionality in the **Configuration** module. For more information about the configuration of evaluation types, see the chapter *Configuring Evaluations, Prioritization Schemes, and Portfolios* in the reference manual *Configuring Evaluation and Reference Data in Alfabet*.

Please note that the indicators configured for project evaluation types are not stored in the Alfabet database and therefore cannot be displayed in object cockpits. If project indicators need to be displayed in the object cockpit, please configure a Value Control interface control with the **Sub-Type** attribute set to `ValueByQuery` to fetch the relevant data. For more information about configuring a query, see the section Adding a Query to the Object Cockpit. For more information regarding project evaluation types, see the section *Configuring Reference and Evaluation Data Required for Project Management* in the reference manual *Configuring Evaluation and Reference Data in Alfabet*.

To add an indicator via a Value Control interface control to the object cockpit:

1) In the toolbar of the object cockpit designer, click the **Value Control** button and click in the Flow Panel or Group Box interface control.
2) Click the Value Control interface control to activate its attribute window. The **Control Type** attribute is automatically set to `ValueControl`. Define the following attributes, as needed:

- **Sub-Type** attribute, select `Indicator`.
- **Indicator** attribute´(in the **Value Definition** section); Enter the name of the evaluation type that the indicator type is assigned to and the name of the indicator type. You should use the syntax: `<EvaluationType>/<IndicatorType>`. Please note that the names of the evaluation type and indicator type must be spelled correctly.
- **Display Style**: Select one of the following to determine how the indicator is displayed:
- `Default`: Displays the default visualization for the indicator.
- `Text`: Displays the semantic value of the indicator. If the indicator's semantic value is empty, the numeric value will be displayed.
- `Icon`: Displays the icon representing the indicator.
- `IconAndText`: Displays first, the icon representing the indicator and second, the semantic value of the indicator. If the indicator's semantic value is empty, the numeric value will be displayed.
- `TextAndIcon`: Displays first, the semantic value of the indicator and second, the icon representing the indicator. If the indicator's semantic value is empty, the numeric value will be displayed.
- **Caption**: Define a caption for the Value Control interface control.

- **Hint**: Optional. Enter text for a tooltip. The tooltip will be displayed when the user points to the attribute in the object cockpit.

3) To specify styles such as the background color, borders, padding, margins, and font of the value displayed for the Value Control interface control, set the **Use Style** attribute to `True`. Expand the **Style** section of the attribute window and specify the relevant styles as needed.

The font color and font style of the caption of Value Control interface control is specified via the **Value Control Caption Font** attribute of the GUI scheme. For more information about defining the styling of the object cockpit, see the sections Configuring Styles and GUI Scheme Settings for Object Cockpits.

4) In the toolbar, click the **Save**  button to save your changes.

Adding a Check Entry to the Object Cockpit

A check entry is a mechanism based on an Alfabet query or native SQL query that reviews the definition of a property for a specified standard or custom object class property for the object displayed in the object cockpit. If the query finds results, a configured icon and message can be displayed providing the user with information about the check.

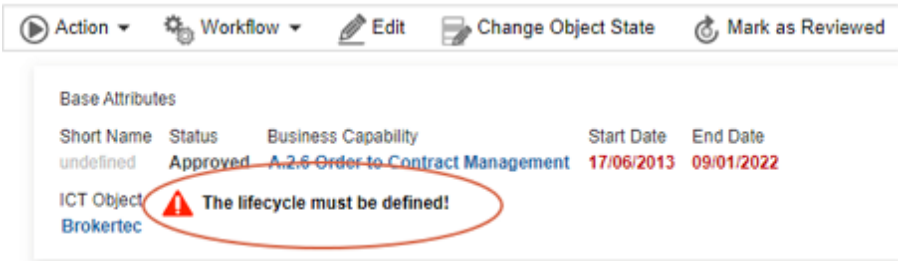

FIGURE: Check entry for lifecycle definition in a group box

To add a check entry via a Value Control interface control to the object cockpit:

1) In the toolbar of the object cockpit designer, click the **Value Control**  button and click in the group box.

2) Click the Value Control interface control to activate its attribute window. The **Control Type** attribute is automatically set to `ValueControl`. Define the following attributes, as needed:

- **Sub-Type**: Select `CheckEntry`.
- **Query** attribute (in the **Value Definition** section): Define an Alfabet query or a native SQL query to return a set of properties. For more information about the special conditions that apply to native SQL queries used in Alfabet configurations, see the section Defining Native SQL Queries in the chapter Defining Queries.

The following is an example of an Alfabet query defined to validate whether a lifecycle has been defined for the selected application:

```
ALFABET_QUERY_500

FIND
```

```
    Application
    InnerJoin TimeStatus ON TimeStatus.Owner =
    Application.RefStr
WHERE
    Application.REFSTR =:BASE
```

The following is an example of an Alfabet query defined to validate that a role has been defined for the selected application:

```
ALFABET_QUERY_500
FIND
    Application
    InnerJoin Role ON Role.Object = Application.RefStr
    InnerJoin RoleType ON Role.RoleType = RoleType.RefStr
WHERE
    (AND
    RoleType.Name = 'Architect'
    Application.RefStr =:BASE
    )
```

- **Check Result Type**: Select one of the following to define what constitutes a validated check:
- `Positive` means that the condition is fulfilled if the selected property has a value or the query has delivered a result (at least one row.)
- `Negative` means that the condition is fulfilled if the selected property has no value or the query doesn't deliver any results.

For example, to validate whether a property is set, an Alfabet query is specified that returns the value for the object class property. The condition is that the Alfabet query returns a result. In this case, the **Check Result Type** attribute must be set to `Positive`.

On the other hand, to validate that a property is not set to a specific value because that value is not allowed in the current environment, an Alfabet query must be specified that searches for the object class property value. The condition is only met if the Alfabet query returns no result. In this case, the **Check Result Type** attribute must be set to `Negative`.

- **Message** attribute. Enter the text to display if the check entry is fulfilled. This text should provide the user with information about what is required to resolve the check entry.
- **Icon**: Select the icon to display if the check entry is fulfilled. Any icon that you want to add to the object cockpit first must be imported to the icon gallery. For more information, see the section Adding and Maintaining Icons for the Alfabet Interface.
- **Display Style**: Select one of the following to determine how the icon and message are displayed:
- `Default`: Displays the icon defined in the **Icon** attribute and message defined in the **Message** attribute.
- `Text`: Displays the message defined in the **Message** attribute.

- `Icon`: Displays the icon defined in the **Icon** attribute.
- `IconAndText`: Displays first the icon and second the message.
- `TextAndIcon`: Displays first the text and second the icon.
- **Caption**: Not relevant for a Value Control interface control of the sub-type `CheckEntry`.
- **Hint**: Optional. Enter text for a tooltip. The tooltip will be displayed when the user points to the attribute in the object cockpit.

3) To specify styles such as the background color, borders, padding, margins, and font of the value displayed for the Value Control interface control, set the **Use Style** attribute to `True`. Expand the **Style** section of the attribute window and specify the relevant styles as needed.

The font color and font style of the caption of Value Control interface control is specified via the **Value Control Caption Font** attribute of the GUI scheme. For more information about defining the styling of the object cockpit, see the sections Configuring Styles and GUI Scheme Settings for Object Cockpits.

4) In the toolbar, click the **Save**  button to save your changes.

Adding a Query to the Object Cockpit

A query can be specified in order to find specific objects to display in the object cockpit. Be defining `Query` as the **Sub-Type** attribute for the Value Control interface control, you can configure a query to find a set of results that should be displayed. By defining `ValueByQuery` as the **Sub-Type** attribute for the Value Control interface control, you can configure a query whereby only the first row of the result is displayed. The Value Control interface control will be displayed in the Alfabet interface in the size that you define, even though during design time it may be distorted to show the entire query.

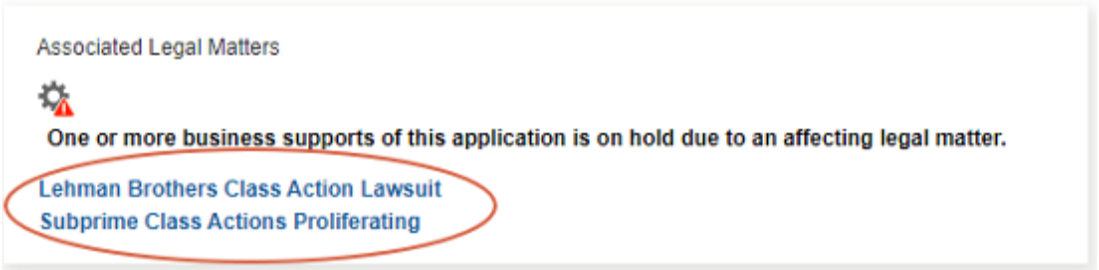

FIGURE: Query returning policy stereotypes

To add an Alfabet query or a native SQL query via a Value Control interface control to the object cockpit:

1) In the toolbar of the object cockpit designer, click the **Value Control**  button and click in the Group Box interface control.
2) Click the Value Control interface control to activate its attribute window. The **Control Type** attribute is automatically set to `ValueControl`. Define the following attributes, as needed:

- **Sub-Type**: Select one of the following:

- `Query` to configure an Alfabet or native SQL query to find a set of results that will be displayed (The subtype `Query` returns a scalar value), or
- `ValueByQuery` to configure a query to display only the first row of the result set the subtype `ValueByQuery` returns an Alfabet object). Ideally, the result set should return only one result. However, if a set of results is found, only the first row will be displayed and all other rows will be ignored.

If the **Sub-Type** attribute for the Value Control interface control is set to `ValueByQuery` and the query is a native SQL query, the instruction `SETCOLUMNFORMAT` must be included in the query, otherwise the formatting of dates displayed in the object cockpit may be incorrect.

It may be that the length of the data in the returned dataset is longer than the width of the cell. In this case, if the returned dataset contains one result, the value will be line-wrapped if the name is long. However, if multiple entries are displayed, the lines will not be wrapped in order to ensure that the individual results are recognizable and immediately usable for navigation.

- **Query**: (in the **Value Definition** section) Define an Alfabet query or a native SQL query to return a set of properties. For more information about the special conditions that apply to native SQL queries used in Alfabet configurations, see the section Defining Native SQL Queries in the chapter Defining Queries.

The following is an example of an Alfabet query of the type `Query` defined to find all projects whereby the selected application is defined in the project's as-is architecture:

```
ALFABET_QUERY_500

FIND

    Project

    InnerJoin ProjectArch ON ProjectArch.Project =
    Project.REFSTR

    InnerJoin Application ON ProjectArch.Object =
    Application.REFSTR

WHERE

    Application.REFSTR CONTAINS:BASE

    AUTODSINFO

    QUERY_XML

    <QueryDef>

    <ShowProperty Type="Property" ClassName="Project"
    Name="Name" />

    </QueryDef>
```

For value controls of the sub-type `ValueByQuery` that do not have a string defined via the attribute **Format String**, coloring and picture assignment can be assigned via Alfabet query language instructions. Only a subset of the available formatting options is available for this context:

- The `RowColorAssignment` and `ColorAssignment` instructions can both be used to change text and background color based on a condition. Please note

however that the value control returns the content of all cells of the dataset in a single string and therefore the whole text will be colored, even if a `ColorAssignment` instruction to color a single cell in a row is used.

- The `PictureAssignment` instruction can be used to return a value as an icon instead of a text or icon plus text. Only one of the values in the returned dataset can be converted to an icon. If the dataset returns cells containing text and a cell returning an icon, the icon will be displayed in front of the text string that is concatenated from the texts in all cells returning text, independent of the position of the icon in the dataset. If the picture assignment defines that both text and picture shall be displayed in the column, the text will be displayed within the concatenated text string in the correct position of the column it is defined for. If the `PictureAssignment` instruction specifies that the icon shall be displayed first, the icon will be displayed in front of the complete text string. If the `PictureAssignment` instruction specifies that the icon shall be displayed last, the icon will be displayed behind the complete text string. If an `ALT` text is defined in the picture assignment, it will be displayed as tooltip on the icon. Legend text specifications will be ignored in this context.

- **Format String** attribute (in the **Value Definition** section): If properties other than the `Name` property of the referenced object should be displayed in the object cockpit, specify which properties of the referenced object(s) to display in the table. The properties are specified as variables and must always be enclosed in curly brackets. For example, to display the name and status of a reference object, you would enter `{Name} Status={Status}`. Please note that any variable used in the **Format String** attribute must first be defined in the **Show Properties** attribute.

- **Inline Navigation**: Select `True` if users should be able to navigate to an object referenced by the object class property. The object class property will be displayed as a blue hyperlink. Please note that drill-down navigation is only possible if the **Sub-Type** attribute is set to `Query`. It is not possible if the **Sub-Type** attribute is set to `ValueByQuery`.

- **Hint**: Optional. Enter text for a tooltip. The tooltip will be displayed when the user points to the attribute in the object cockpit.

3) To specify styles such as the background color, borders, padding, margins, and font of the value displayed for the Value Control interface control, set the **Use Style** attribute to `True`. Expand the **Style** section of the attribute window and specify the relevant styles as needed.

The font color and font style of the caption of Value Control interface control is specified via the **Value Control Caption Font** attribute of the GUI scheme. For more information about defining the styling of the object cockpit, see the sections Configuring Styles and GUI Scheme Settings for Object Cockpits.

4) In the toolbar, click the **Save**  button to save your changes.

Adding a URL to the Object Cockpit

You can define a URL (a static Web link) in the object cockpit.

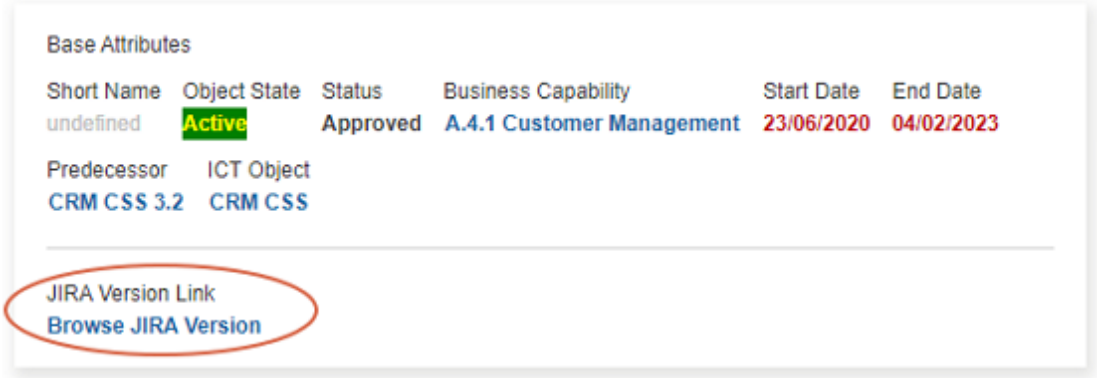

FIGURE: URL link in a group box

There are two different ways to make links accessible to users in the object cockpit:

- Display one link that requires a single click in the object cockpit. The link may either be an ALFI_URI object defined as a web link in the **Attachments** page view for the object or the link may be specified as a static link. When clicked, the target link opens in a new tab in the user's standard browser.

  If multiple links are defined in the **Attachments** page view, the most recently created link will be displayed.

- Display multiple links. The links must be ALFI_URI objects defined as web links in the **Attachments** page view. When the user clicks the link, a preview will open with an **Open Link** button. When clicked, the target link opens in a new tab in the user's standard browser.

An URL can alternatively be displayed in the object cockpit by means of a custom object class property of the type URL. To add a custom object class property of the type URL, see the section Adding a Property to the Object Cockpit.

The static web links will be automatically displayed in dark blue with an underline to indicate that it is a hyperlink.

To add a URL via a Value Control interface control to the object cockpit:

1) In the toolbar of the object cockpit designer, click the **Value Control** button and click in the Group Box interface control.
2) Click the Value Control interface control to activate its attribute window. The **Control Type** attribute is automatically set to `ValueControl`. Define the following attributes, as needed:

- To display one link that requires a single click in the object cockpit, set the **Sub-Type** attribute to `AlfaUriLink`.
- To display multiple links, set the **Sub-Type** attribute to `Query`. The query returns a scalar value.

3) In the **Query** attribute (in the **Value Definition** section), define an Alfabet query or a native SQL query to return the URL defined for the `ALFA_URI.OBJECT`. For more information about defining queries, see the chapter Defining Queries.

The following is an example of an Alfabet query defined to find the URL specified for the object displayed in a selected object cockpit.

```
ALFABET_QUERY_500
    FIND ALFA_URI
    WHERE ALFA_URI.OBJECT CONTAINS:BASE
    QUERY_XML
        <QueryDef>
            <ShowProperty Type="Property" ClassName="ALFA_URI"
            Name="NAME" />
        </QueryDef>
```

For a value control with the **Sub-Type** attribute set to `AlfaUriLink`, you can alternatively specify a static link. For example:

```
SELECT 'https://softwareag.com' AS LINK
```

4) In the toolbar, click the **Save** button to save your changes.

Adding a Dynamic Web Link to the Object Cockpit

Dynamic web links can be specified in value controls in object cockpits. Dynamic web links reference applications that are accessible via a URL. The dynamic web link references a specific location in the application, allowing you to access information in the application that is relevant to the object that the user is currently working with in Alfabet. The dynamic web links will be automatically displayed in dark blue with an underline to indicate that it is a hyperlink.

FIGURE: Dynamic web link in a group box

The relevant dynamic web links must first be configured for the relevant object class in the XML object ***WebViewManager***. At runtime, the dynamic web link will only be displayed if the object class and object class stereotype match the definition in the XML object ***WebViewManager***. For more information about configuring the XML object ***WebViewManager***, see the section Configuring Dynamic Web Links That Users Can Access.

The following is an example of an XML definition for dynamic web links in the XML object ***WebViewManager***:

```
<WebViewDef
    Caption = "Cumulocity Links"
    ClassNames = "Device:Cumulocity Device">
        <WebLinkDef Caption = "Cumulocity Device Link"
        HRef="https://alfabet.cumulocity.com/apps/devicemanagement/ind
```

```
                ex.html#/device/ {SC_CumulocityID} /info"
                PropNames="SC_CumulocityID" Target="Search"/>
        </WebViewDef>
```

To add a dynamic web link via a Value Control interface control to the object cockpit:

1) In the toolbar of the object cockpit designer, click the **Value Control** button and click in the Group Box interface control.
2) Click the Value Control interface control to activate its attribute window. The **Control Type** attribute is automatically set to `ValueControl`. Define the following attributes, as needed:

- **Sub-Type**: Select `DynamicWebLink`.
- **Web Link** attribute (in the **Value Definition** section): The selector displays all configured dynamic web links that have been defined for the relevant object class in the XML object ***WebViewManager***. Select the dynamic web link to display in the object cockpit.
- **Caption**: Define a caption for the dynamic web link. If no caption is defined for the value control, the caption defined in the XML object ***WebViewManager*** will be displayed.

3) In the toolbar, click the **Save** button to save your changes.

Adding Presentation Objects to Display Page Views and Configured Reports

You can add multiple Presentation Object interface controls in order to display page views and configured reports in the object cockpit. All views embedded in the object cockpit are ReadOnly and users will not be able to edit data in the context of the object cockpit. However, if users may need to edit data, you can provide a means for the user to navigate to the view from the object cockpit. For each view or configured report that you display in the object cockpit, you can specify a drill-down navigation that opens the page view/configured report in the object cockpit. The navigation can also be specified to open a page view/configured report other than that displayed in the object cockpit that would be relevant for the user context. If a configured report is embedded in the object cockpit and that report does not have the **Report State** attribute set to `Active` (perhaps because the report designer has changed the state in order to modify the configured report), a message will be displayed in the object cockpit where the report is embedded explaining that the report is currently under construction.

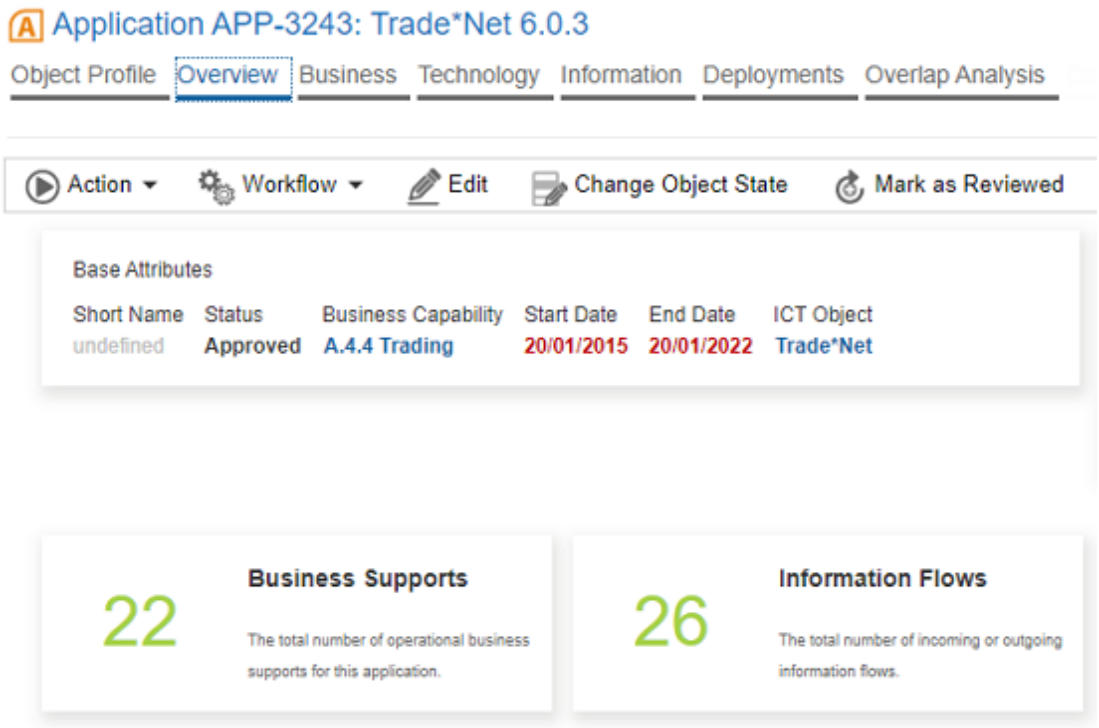

FIGURE: Two presentation objects based on widget reports

In some cases, you may want the object cockpit to consist only of one or more configured reports.

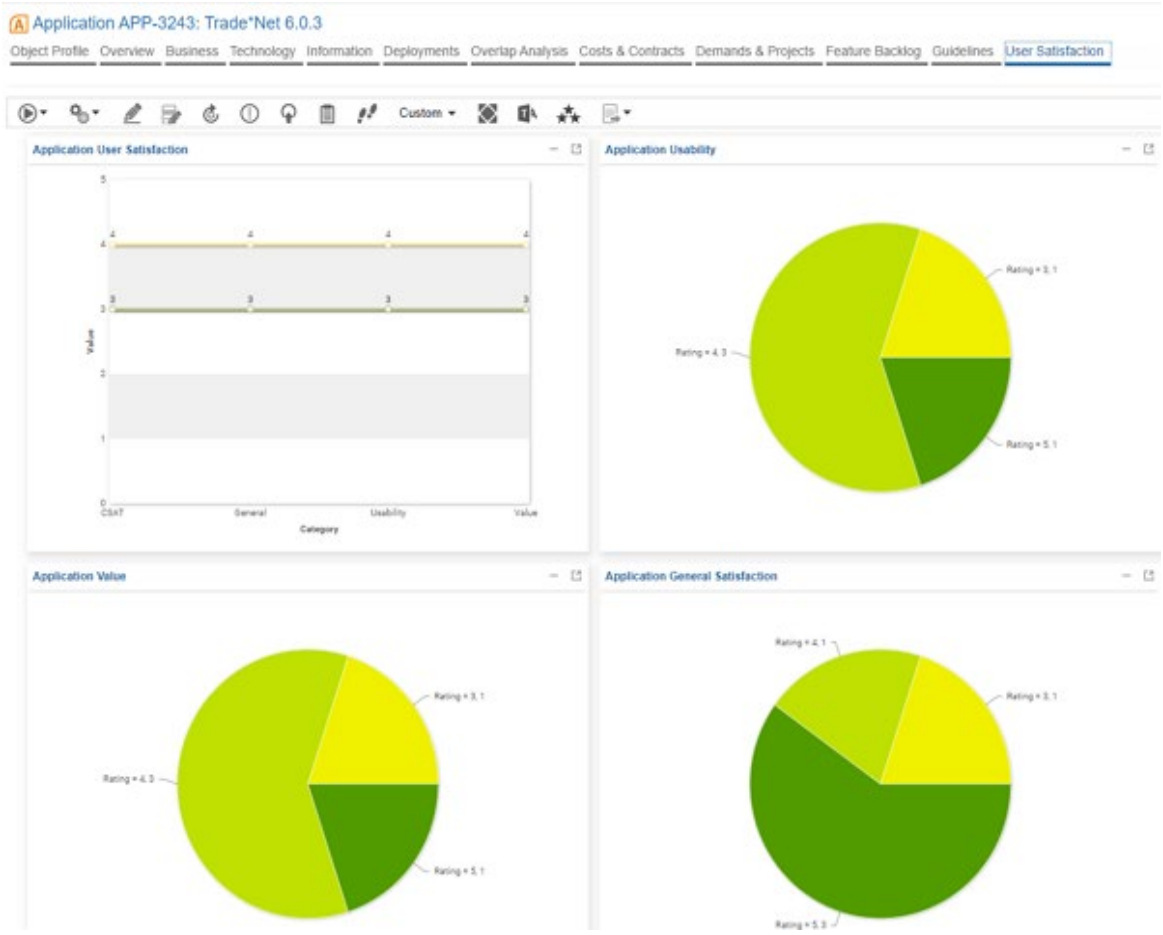

FIGURE: Object cockpit with four configured reports

The width that you define for a Presentation Object interface control will influence the number of Presentation Object interface controls that may be displayed horizontally in a row. Therefore, you should consider how many Presentation Object interface controls you would ideally like to display horizontally in a row and the width of each. It is recommended that Presentation Object interface controls have a base width of either 400, 600, or 1200 pixel. The sum of the width of multiple interface controls (group boxes and presentation objects) that shall be displayed in one row should not exceed 1200 pixel. For example, if you want to display three reports in the same row, you could define each presentation object to have a width of 400 pixel and conclude the row with a break <break> element. If the screen size is smaller than 1200 pixel or the user manually reduces the width of the screen is less than 1200 pixel, the last report preceding the break <break> element that doesn't fit in the user interface will be bumped down to the next row. If the data displayed in the Presentation Object interface control is dense (as in a diagram or business support map, for example), you might want the width of the Presentation Object interface control to be 1200 pixel. If an presentation object is wider than the available screen space, the content will be truncated.

For more information about adding break <break> elements to structure presentation objects and attribute boxes in the flow panel, see the section Adding Linebreaks to Visually Structure the Information in the Object Cockpit.

A height must be defined for the presentation objects, although it is possible to configure that the height is automatically reduced based on the content in the presentation object in order to avoid excessive white space in the object cockpit. Presentation objects with no available data will display the text **No data provided...**. Users can also collapse and expand the presentation objects in order to optimize the use of space and reduce the amount of scrolling required. A collapse button (−) will be displayed in the right corner header of the embedded view/report. When clicked, the view/report will collapse to show only the header bar with the caption of the view/report. The contents will be automatically rearranged in the object cockpit when the view/report is collapsed. The user can click the expand button (+) in the view/report header to expand the view. This setting will be stored in the user context settings. A zoom functionality will also be available automatically for views with business graphics.

Furthermore, a navigation button has been added to the header bar of embedded views and reports. When clicked, the view or report will open to fit the full screen. The user can also navigate to the view or report by clicking the hyperlinked caption of the view or report in the header bar.

As an alternative to displaying the data for a page view or configured report directly in the object cockpit, you can implement placeholders which act like links to open the relevant page view or configured report. For more information, see the section Adding Placeholders for Page Views and Configured Reports.

The **Add to Clipboard** button available in the toolbar of page views and relevant configured reports can be used in the context of the object cockpit without explicitly opening the embedded view/report. The functionality will also be available in the **Preview** window when opened in the context of the embedded view or report.

To add a standard page view or configured report via a Presentation Object interface control to the object cockpit

1) In the toolbar of the object cockpit designer, click the **Presentation** button and click in the Flow Panel interface control. The Presentation Object interface control is displayed in the Flow

Panel interface control and should be selected. The **Control Type** attribute is automatically set to `Presentation`. Define the following attributes, as needed:

- **Sub-Type**: Select `View`.
- **Source**: Click the **Browse** button and in the **Select Source** editor that opens, select either `Configured Reports` or `Page Views`. If you select `Page Views`, all relevant and permissible page views that have not yet been added to the object view will be displayed in the **Select Source** editor. If you select `configured Reports`, all configured reports will be displayed in the **Select Source** editor. Select the relevant view/configured report in the drop-down field and click **OK**.

  Offline executed reports cannot be embedded in object cockpits and therefore will not be displayed in the drop-down list in the **Source** attribute.

- **Caption**: Enter a caption for the view/report. This attribute must be filled in if you want to configure the page view/configured report so that the user may navigate to it. The caption may differ from the actual name of the view/report. Please note that the caption specified for configured reports displaying business graphics will not be displayed in the context of the object cockpit. Instead, the caption specified in the **Caption** attribute of the presentation object embedded in the object cockpit will be displayed.
- **Inline Navigation**: Select `True` to configure the page view/configured report so that users can navigate to it. The caption will be displayed as a blue hyperlink that the user can click to open the view/report.
- **Width**: Define the width in pixel for the presentation object. Any presentation object with a defined width that is greater than the defined width of the object cockpit will be truncated and not all content will be visible. Because the presentation object's typically contain lots of information, it is recommended that they not be smaller than 400 pixel in width.
- **Height**: Define the height in pixel for the presentation object. Please note that if you specify that the height of one presentation object in a row is greater than the height of the other presentation objects, empty space may result in the row. This is because the bottom edge of the largest presentation object will be used to determine the top edge of the next row. It is recommended that all presentation objects in a row preceding a break <`break`> element have the same height.

  You can configure the height of a Presentation Object interface control to be automatically reduced based on the content in the view. This ensures that the data is dense and excessive white space is not displayed. In order to specify that the height of presentation objects shall be automatically reduced based on their content, see the section Configuring Styles and GUI Scheme Settings for Object Cockpits.

- **Hint**: Optional. Enter text for a tooltip. The hint will be displayed when the user points to the embedded view in the object cockpit.
- **Can Print**: Set to `False` if the **Print** button displayed in the floating toolbar of the embedded page view/configured report should be disabled. The attribute is set to `True` per default.

2) To add a caption for the view or report, click the **Static Text** button in the design editor and place the Static Text interface control directly above the presentation object. In the **Caption** attribute for the static text, enter a caption for the view. For more information about how to create static text, see the section Adding Static Text to the Object Cockpit.

3) To add padding to the view or report, define the **Style** > **Margin** attributes for each presentation object in the object cockpit and set the **Use Style** attribute to `True`. For example, enter 2 in the **All** attribute in the **Margin** section of the attribute window

4) In the toolbar, click the **Save**  button to save your changes.

Adding a Floating Group Box to Contain Presentation Objects

Two or more Presentation Object interface controls can be placed inside a collapsible group box, thus allowing the set of views to be hidden or expanded in the object cockpit as needed. For example, a set of widget reports might be placed inside such a group box in order use the space in the object cockpit more efficiently. The user can collapse the group box by clicking the collapse (-) symbol and expand the group box by clicking the expand (+) symbol. The collapsed group box will reduce to the width and height of the group box caption. For general information about positioning group boxes in the object cockpit, see the section Adding Group Boxes to Display Attributes.

To add a Group Box interface control containing Presentation Object interface controls to the object cockpit:

1) In the toolbar of the object cockpit designer, click the **Group Box**  button and click in the flow panel.

2) Click the Group Box interface control to ensure that its attribute window is open. Define the following attributes, as needed:

- **Sub-Type**: Select `Floating`.
- **Caption**: Define a caption for the group box. This attribute may not be left empty.

The font color and font style of the caption of group boxes is specified via the **Attributes Group Caption Font** attribute of the GUI scheme. For more information about defining the styling of the object cockpit, see the sections Configuring Styles and GUI Scheme Settings for Object Cockpits.

3) Specify the height of the group box in pixel in the **Height** attribute. Please note that the height you define will depend on the height of the presentation objects you place inside the group box. The height of the group box should be larger than the height of the presentation objects so that they can be adequately displayed.

4) Specify the width of the group box:

- **Width**: Define the width in pixel for the group box. Any group box with a defined width that is greater than the defined width of the object cockpit will be truncated and not all content will be visible.
- **Item Max. Width**: Enter the maximum width of the interface controls in the group box. Enter -1 if there shall be no limitation on the maximum width.
- **Item Min. Width**: Enter the minimum width of the interface controls in the group box. Enter -1 if there shall be no limitation on the minimum width.

5) Specify the placement of the group box. You can do this via drag-and-drop of the attribute box or by entering values in pixel in the **Top** and **Left** attributes.

6) Click the **Save**  button to save the new group box.

7) Add the relevant Presentation Object interface controls to the group box as described in the following section Adding Presentation Objects to Display Page Views and Configured Reports.

8) Add a break (`<break>`) element between groups of attributes in the group box to add a linefeed and separator, as needed. For more information about configuring a linebreak, see the section Adding Linebreaks to Visually Structure the Information in the Object Cockpit.

9) Specify the **Tab Index** attribute for all interface controls and break elements (`<break>`) in the Group Box interface control in order to specify the correct sequence and layout in the group box. The sequence should begin with 1. The sequence that you specify is the order in which the interface controls and break elements are displayed as well as the order to navigate through the group box via the TAB key.

Adding a Floating Group Box as a Filter Panel for Reports

Report filters available in the configured reports that are embedded in the object cockpit can be placed inside the group box of type `Floating`. This includes filters based on Checked List Box and Combo Box interface controls. The user can set the report filters, which are applied to all relevant reports displayed in the object cockpit. This supports a "what-if analysis" whereby the end user could change the filter settings to immediately display different results across multiple dimensions.

To add a Group Box interface control containing report filters to the object cockpit:

1) In the toolbar of the object cockpit designer, click the **Group Box**  button and click in the flow panel.

2) Click the Group Box interface control to ensure that its attribute window is open. Define the following attributes, as needed:

- **Sub-Type**: Select `Floating`.
- **Caption**: Define a caption for the group box. This attribute may not be left empty.

The font color and font style of the caption of group boxes is specified via the **Attributes Group Caption Font** attribute of the GUI scheme. For more information about defining the styling of the object cockpit, see the sections Configuring Styles and GUI Scheme Settings for Object Cockpits.

3) Specify the height of the group box in pixel in the **Height** attribute. Please note that the height you define will depend on the height of the interface controls you place inside the group box. The height of the group box should be larger than the height of the interface controls so that they can be adequately displayed.

4) Specify the width of the group box:

- **Width**: Define the width in pixel for the group box. Any group box with a defined width that is greater than the defined width of the object cockpit will be truncated and not all content will be visible.
- **Item Max. Width**: Enter the maximum width of the interface controls in the group box. Enter -1 if there shall be no limitation on the maximum width.

- **Item Min. Width**: Enter the minimum width of the interface controls in the group box. Enter -1 if there shall be no limitation on the minimum width.

5) Specify the placement of the group box. You can do this via drag-and-drop of the attribute box or by entering values in pixel in the **Top** and **Left** attributes.

6) Click the **Save** button to save the new group box.

7) Add the relevant report filters that are configured for the reports embedded in the object cockpit directly to the Group Box interface control. It is easiest to simply copy the report filter in the report and paste it to the Group Box interface control. For more information about configuring report filters, see the section Defining Filters for Configured Reports and Selectors in the chapter Configuring Reports in the chapter Defining Queries.

8) For each report embedded in the object cockpit that the filters shall apply to, set the **Refresh on Submit** attribute to `True`.

9) Create a button to execute the filters and place it in the Group Box interface control. The **Submit** attribute must be set to `True` for the button. For more information about creating a submit button, see the section Configuring the Submit Button in the chapter Defining Queries.

10) The new **Save Context** attribute has been added to the attribute grid for the object cockpit. This attribute should be set to `True` so that the user context settings for the filters can be saved.

11) Specify the **Tab Index** attribute for all interface controls and break elements (`<break>`) in the Group Box interface control in order to specify the correct sequence and layout in the group box. The sequence should begin with 1. The sequence that you specify is the order in which the interface controls and break elements are displayed as well as the order to navigate through the group box via the TAB key.

Adding a Presentation Object for a Different Target Object

A view can be displayed in an object cockpit for an object that is not the target object of the object cockpit. For example, a workflow diagram could be displayed in the context of the object that it is associated with or the **LIfecycle** page view could be displayed for the ICT object that owns the application that is the target object of the object cockpit.

You can define either an Alfabet query or native SQL query. The query should be defined to find only a single object. The object returned by the query will be the base object of the view displayed in the object cockpit.

You must ensure that the object being searched for by the query exists and can be found by the query. If an object cannot be found by the query, the message **No data provided...** will be displayed for the view.

To configure the object cockpit to display a view for a different target object:

1) In the toolbar of the object cockpit designer, click the **Presentation** button and click in the Flow Panel interface control. The Presentation Object interface control is displayed in the Flow Panel interface control and should be selected. The **Control Type** attribute is automatically set to `Presentation`. Define one of the following attributes, as needed:

- **Base Object via Alfabet Query**: Specify an Alfabet query via the **Alfabet Query Builder** to find the relevant object. The result of the query should have the `REFSTR` of the object which should be used as

base object in the first column. For Alfabet queries, `SHOW` properties do not need to be defined. The `REFSTR` of the object found by the query is selected automatically as the query result.

The following example illustrates an Alfabet query that searches for the ICT object that the application is assigned to.

```
ALFABET_QUERY_500
FIND
ICTObject
  InnerJoin Application
        ON Application.ICTObject = ICTObject.REFSTR

WHERE
Application.REFSTR CONTAINS  :BASE
```

- **Base Object via SQL Query**: Enter a native SQL query to find the relevant object. The query must be of the type `SELECT`. The result of the query should have the `REFSTR` of the object which should be used as base object in the first column. Therefore, the `REFSTR` of the object must be defined as the first `SELECT` property in the native SQL query.
- **Base Object via Query as Text**: Enter a native SQL query or Alfabet query to find the relevant object.

2) Once you have defined the base object query for the Presentation Object interface control, specify the view to open for the object found by the base object query. To do so, click the **Browse** button available for the **Source** attribute. In the **Select Source** editor that opens, select `Configured Reports`. All configured reports will be displayed in the **Select Source** editor. Select the relevant configured report in the drop-down field and click **OK**.

3) In the toolbar, click the **Save**  button to save your changes.

Adding Placeholders for Page Views and Configured Reports

As an alternative to displaying the data for a page view or configured report directly in the object cockpit, you can implement placeholders via an Icon interface control. The placeholders are icons that are displayed instead of the page view or configured report. This is especially useful for complex views or large reports for which only a portion of the report is displayed in the object cockpit. Users can click the icon and open the relevant page view or configured report. Alfabet provides a number of icons that represent various view and report types including, for example, diagrams, Gantt charts, gauge reports, matrix reports, portfolio reports, etc. However, you can use any of your enterprise's icons that have been added to the icon gallery. For more information, see the section Adding and Maintaining Icons for the Alfabet Interface.

FIGURE: Placeholder for report in object cockpit

To add a placeholder to a page view or configured report via an Icon interface control:

1) In the toolbar of the object cockpit designer, click the `Icon` button and click in the flow panel. An empty box displays the undefined icon in the object cockpit. The **Control Type** attribute is automatically set to `Icon`. Define the following attributes, as needed:

- **Source**: Select either `Reports` or `Views` and select the relevant page view/configured report in the drop-down field and click **OK**.
- **Caption**: Enter the text to display below the placeholder. For example, this could be the name of the page view/configured report or other text that may be relevant.
- **Sub-Type**: Select `IconFree` to add one of the standard icons provided by Alfabet to represent the specified page view/configured report. You can also select `Icon` to add an icon sized 22x22 pixel or `IconLarge` to add an icon sized 30x30 that is available in the icon gallery.
- **Icon**: Select the icon that you want to display for the specified page view/configured report.

2) Click the **Save** button to save the new break.

Adding Workflow, Assignment, Microsoft Teams Meeting Information and Object Validation Information to the Object Cockpit

The number of open assignments and open workflow activities as well as the number of Microsoft Teams meetings scheduled today for the current user about the current object can be displayed in object cockpits. The relevant number will be automatically generated at runtime and the respective link will open when the user clicks the text. Additionally, a wizard validations section will display all wizard post-conditions that have been violated for the object displayed in the object cockpit.

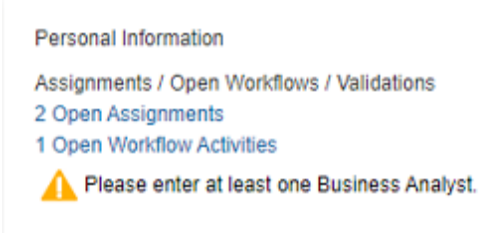

FIGURE: Personal Info section shows open assignments, workflows, and violated post-conditions

To include this information, you must add a Value Interface control of sub-type `PersonalInfo` to the flow panel. You can specify individually whether assignment, workflow, and wizard validation information shall be displayed in the object cockpit. In the user interface, a personal information box will be added to the object profile displaying the caption **Assignments** / **Open Workflows** / **Validations**. The following will be displayed:

- **Assignments**: A link showing the number of open assignments will be displayed. When the user clicks the link, the **My Assignments** page view will open displaying the pending assignments for the object.
- **Open Workflows**: A link showing the number of open workflows will be displayed. When the user clicks the link, the **Workflow Activities Explorer** will open displaying the active workflow steps that the user is responsible for.

  Instead of displaying the default **Workflow Activities Explorer**, a custom explorer can be configured to open instead. The custom explorer must be specified in the **Custom Workflow Activities Explorer** attribute of the relevant user profile. For more information about configuring custom explorers, see the chapter Configuring a Custom Selector for Search Functionalities, and for more information about specify the custom explorer for a user profile, see the chapter Creating User Profiles for the User Community.

- **Validations**: Each wizard post-condition that has been violated will be displayed. The message configured for the wizard post-condition will be displayed as information about why the validation failed. For more information about the configuration of wizard post-conditions, see the section Defining a Post-Condition for a Wizard Step.

To add the personal information box to the object cockpit:

1) In the toolbar of the object cockpit designer, click the **Value Control** button and click in the Flow Panel interface control.
2) Click the Value Control interface control to activate its attribute window. The **Control Type** attribute is automatically set to `ValueControl`. Define the following attributes, as needed:

- **Sub-Type**: Select `PersonalInfo`.
- **Caption**: Define a caption for the personal information box.
- **Value Definition**: Expand this section and specify the following as needed:
- **Assignments**: Set to `True` to include the number of assignments and the respective link to access the **My Assignments** page view.
- **Workflow**: Set to `True` to include the number of open workflow activities and the respective link to access the **My Workflow Activities Explorer**.
- **Wizard Validations**: Set to `True` to include violated wizard post-conditions and the message configured for the wizard post-condition

3) To specify styles such as the background color, borders, padding, margins, and font of the value displayed for the Value Control interface control, set the **Use Style** attribute to `True`. Expand the **Style** section of the attribute window and specify the relevant styles as needed.

   The font color and font style of the caption of Value Control interface control is specified via the **Value Control Caption Font** attribute of the GUI scheme. For more

information about defining the styling of the object cockpit, see the sections Configuring Styles and GUI Scheme Settings for Object Cockpits.

4) In the toolbar, click the **Save** button to save your changes.

Adding Icons to the Object Cockpit

You can add graphic images to a Group Box interface control or Flow Panel interface control that are available in the icon gallery in Alfabet Expand. Any icon that you want to add to the object cockpit first must be imported to the icon gallery. For more information, see the section Adding and Maintaining Icons for the Alfabet Interface.

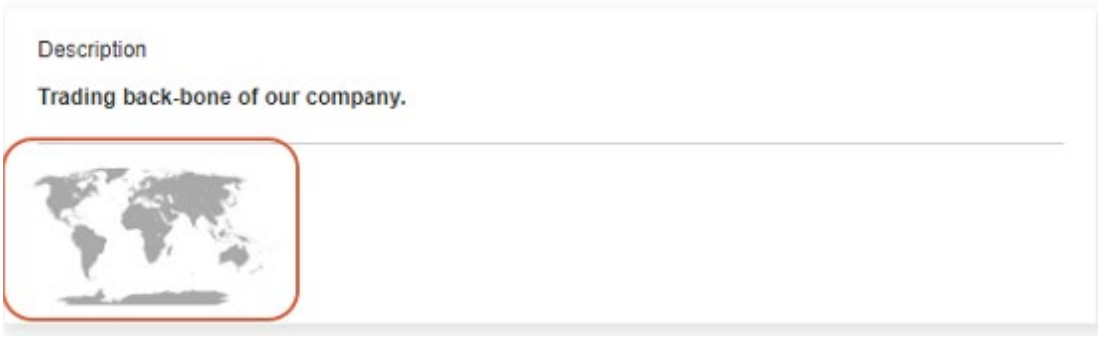

FIGURE: Icon displaying global map

To add an Icon interface control to the object cockpit:

1) In the toolbar of the object cockpit designer, click the **Icon** button and click in the Flow Panel interface control or Group Box interface control. An empty box displays the undefined icon in the object cockpit. The **Control Type** attribute is automatically set to `Icon`. Define the following attributes, as needed:

- **Sub-Type**: Select the relevant option based on the size of the icon that you want to add:
- `Icon`: To add an icon that is 22x22 pixel in size.
- `IconLarge`: To add an icon that is 30x30 pixel in size.
- `IconFree`: To add an icon that has an arbitrary size.
- **Icon**: Select the relevant icon that you want to display in the object cockpit. The icons that you can choose from are based on the value you selected in the **Sub-Type** attribute.

2) To change the size of the icon, adjust the values in the **Height** and **Width** attributes as needed.

3) In the toolbar, click the **Save** button to save your changes.

Adding Embedded HTML to the Object Cockpit

The HTML Content interface control allows you to display text with HTML formatting (font and color) as well as images, links to external URLs, and HTML forms. Variables such as @BASE may be used in the URL link to specify content for static links or server variables.

Please note that the HTML Content interface control should not be added to a Group Box interface control. The HTML Content interface control should only be placed in a Flow Panel interface control or a Table Layout Panel interface control

Please note that if the object cockpit is published via the **Publish** button, the HTML content will not be included in the DOC or PDF file.

To add an HTML Content interface control to an object cockpit:

1) In the toolbar of the object cockpit designer, click the **HTML Content** button and click in the Flow Panel interface control.
2) Click the HTML element to activate its attribute window. The **Control Type** attribute is automatically set to `Html`. Define the following attributes, as needed:

- **Sub-Type**: Select `EmbeddedHTML`.
- **HTML Source**: Enter the HTML code. Please keep the following in mind:
- The HTML must be compliant with XHTML, XML-conform HTML, compliant with HTML 5, and use standard HTML tags. The HTML header implements standard HTML elements.
- The code must start with an `<xhtml>` tag and end with `</xhtml>`. Standard HTML elements must be written in lower-case letters in order to be correctly parsed: `<xhtml>`, `<html>`, `<head>`, `<body>`, and `<culture_>`. The definition of `<head>`, `<body>`, and `<culture_>` is optional.
- The formatting of the HTML can either be written explicitly in the `<body>` element or can be specified via a stylesheet that is stored in the **Internal Document Selector**. In this case, the HTML must refer to the target CSS file in a `<link>` element. The CSS file should contain all necessary styles to display the content of the HTML. Please note that the CSS file may not be stored in the root folder of the **IDOC** explorer. The CSS file stored in the **Internal Document Selector** must be located in a document folder that is subordinate to the root folder of the **IDOC** explorer. To upload a file to the **Internal Document Selector**, see the section *Uploading Documents and Managing User Permissions to Document Folders in the Internal Document Selector* in the reference manual *User and Solution Administration*. For example:

```
<xhtml>
    <culture_1033>
        <html>
        <body
        style="margin:4px;background:#3d4b60;overflow:hidden;">
            <link type="text/css" rel="stylesheet"
            href="IDOC:\CSS\my_style_file.css"></link>
            <p>This is the content for the header of the wizard
            step.</p>
            ...
```

```
        </body>
        </html>
    </culture_1033>
</xhtml>
```

- All CSS formatting instructions must end with `!important` to ensure that they are processed by the Alfabet application. For example:

```
<xhtml>
    <culture_1033>
        <html>
        <body style="margin:4px !important;background:#3d4b60
        !important;overflow:hidden !important;">
            <style type="text/css">
                p.header
                {
                    font-family:verdana !important;
                    font-size:18px !important;
                    color:#ff0000 !important;
                    text-align: Left !important;
                }
            </style>
            <p class="header">This is the content for the header of
            the wizard step.</p>
            ...
        </body>
        </html>
    </culture_1033>
</xhtml>
```

- If translation to a secondary language is required, you must provide the translation in the HTML specification. Please note that HTML texts cannot be translated via the **Translation Editor** available in Alfabet Expand. Please consider the following:
    - If the HTML description is required in additional languages, each language text must be defined within language elements (For example, `<culture_1031>` for English, `<culture_1033>` for German, etc.)
    - The element `<culture_xxx>` must be specified as a child of the root element `<xhtml>`. The element `<html>` must be specified as a child of the element `<culture_xxx>`. The element `<html>` contains the HTML specification in the relevant language. For example, to provide information in English and German:

```
<xhtml>
    <culture_1033>
        <html>
            <body>
```

```
                    <h3>Glossary: Application</h3>
                    <p>An application is a fully-functional integrated
                    IT product that provides functionality to end
                    users and/or to other applications. As such, an
                    application supports the business to accomplish
                    its mission. Applications operate on a platform
                    made up of hardware and software components
                    necessary to run the application.</p>
                </body>
            </html>
        </culture_1033>
        </culture_1031>
            <html>
                <body>
                    <h3>Glossar: Applikation</h3>
                    <p>Eine Applikation ist ein voll funktionsfähiges,
                    integriertes IT-Produkt, das Funktionalitäten für
                    Endanwender und/oder für andere Applikationen
                    bietet. Eine Applikation unterstützt das
                    Unternehmen bei der Zielerreichung. Applikationen
                    werden auf einer Plattform betrieben, die aus den
                    für die Ausführung der Applikation erforderlichen
                    Hardware- und Software-Komponenten besteht.</p>
                </body>
            </html>
        </culture_1031>
    </xhtml>
```

3) In the toolbar, click the **Save** button to save your changes.

Configuring Conditional Restraints in the Object Cockpit

Specifying conditional constraints in object cockpits can provide a more dynamic user experience and ensure that users are seeing and defining the data that is pertinent to the task at hand. The display of data in the object cockpit that isn't relevant to the context at hand can be suppressed based on the definition of a value for a property of the associated class. You can specify that interface controls such as Value Query or Presentation Object are visible/not visible based on whether one or more conditions are fulfilled. If all visibility conditions fail for an interface control, the visibility will be revoked for that interface control.

For example, if the **Is SOX Relevant** attribute is set to `True` for the application, then you would want to display the **Business Support Map Report** embedded in the object cockpit. In this case, you would assign a visibility condition to the Presentation Object interface control specifying the **Business Support Map Report** and map the variables in the condition to the **Is SOX Relevant** attribute that the variable references.

The following steps are required to configure a visibility condition for a Presentation Object or constraints for interface controls in object cockpits:

- Define a configured report of the type `Query` or `NativeSQL` and set the **Category** attribute of the report to a category name defined in the XML object ***UseCaseCategories*** for the use case `Conditions`. The query should search the Alfabet database and return at least one row as a result to fulfill the condition if the **Check Result Type** attribute is set to `Positive`. When the **Check Result Type** attribute is set to `Negative` the query return no records. For more information about configuring reports of the type `Query` or `NativeSQL`, see the chapter Configuring Reports.
- Create the condition and specify the configured report with the query.
- To specify that the interface control targeted by the condition is visible, specify the **Visibility Condition** attribute.

The following information is available:

- Creating Conditions to Implement in an Object Cockpit
- Assigning Conditions to Interface Controls in the Object Cockpit

Creating Conditions to Implement in an Object Cockpit

Conditions can be used in the context of custom editors, object cockpits, and filters in configured reports and can be reused as needed. Conditions for the interface controls in object cockpits can be based on either expressions or queries defined in configured reports. The condition state must be set to `Active` in order to make the condition available in the **Visibility Condition** attribute for interface controls.

To create a condition:

1) Go to the **Presentation** tab and right-click the **Conditions** folder and select **New Condition**. The condition state will be set to `Plan` per default for the new condition.
2) Click the new condition  and define the following in the attribute window:

- **Technical Name**: Enter a name for the condition. It is recommended that the name indicates the meaning of the condition. All active conditions will be displayed in drop-down lists for the **Visibility Condition** attribute.
- **Group**: Enter the name of a new condition folder that you want to store the condition in or select an existing condition folder.

3) Conditions for the interface controls in object cockpits can be based on either expressions or queries defined in configured reports. Please note the following:

- In the **Type** field, select `Report` to specify a configured report for the condition. The configured report should already be configured and should be of the type `Query` or `NativeSQL`. The query should search the Alfabet database and return at least one row as a result to fulfill the condition if the **Check Result Type** attribute is set to `Positive`. When the **Check Result Type** attribute is set to `Negative` the query return no records. The report is only selectable for conditions if the **Category** attribute of the report is set to `AEMF`. Define the following attributes:
- **Report**: Select the configured report that should be executed for the condition.
- **Check Result Type**: Select either `Positive` or `Negative` to define what constitutes a fulfilled condition.

- `Positive` means that the condition is fulfilled if the query associated with the configured report delivers a result.
- `Negative` means that the condition is fulfilled if the query associated with the configured report delivers no result.

- In the **Type** field, select `Expression` to specify an expression for the condition. Define the following attributes:
- **Expression**: Click the **Browse**  button to open the editor and enter the expression that shall be evaluated for the condition. Multiple expressions may be specified, whereby individual expressions must be placed in parenthesis. Values must be placed in single quotes. For example: `(@InterfaceControl_1 == 'True') I ((@InterfaceControl_2 == 'True') & (@InterfaceControl_3 == 'False'))`. The following operators and conditions may be used in the expression:

equals	@Param == 'STRING' (or 'True' and 'False' for Boolean values)
does not equal	@Param != 'STRING'
in	@Param IN ['STRING', 'STRING', 'STRING'] (used when the value is a list)

- **Check Result Type**: Select either `Positive` or `Negative` to define what constitutes a fulfilled condition.
    - `Positive` means that the condition is fulfilled if the variable targeted by the expression has a value.
    - `Negative` means that the condition is fulfilled if the variable targeted by the expression has no value.
- Once the condition, has been written, you can test the condition. To do so, right-click the condition and select **Test Condition**. In the editor, enter a valid value in the **Parameter Value** field and click **OK**. The message box will indicate if the condition is valid based on the value entered or if an error has occurred.

4) Once the condition is complete and ready to be implemented, the condition state must be set to `Active`. To do so, right-click the condition and select **Set Condition State to 'Active'**. The condition will be available in the **Visibility Condition**, **Presence Condition**, and **Read-Only Condition** attributes for custom editor fields, filter fields in configured reports, object cockpits, and object profiles.

5) In the toolbar, click the **Save**  button to save your changes.

Assigning Conditions to Interface Controls in the Object Cockpit

You can specify that an interface control is visible/not visible based on whether a condition is fulfilled.

To define conditions for object cockpits:

1) Go to the **Presentations** tab and navigate to the object cockpit that you want to define.
2) Right-click the object cockpit  that you want to define and select **Design Object Cockpit**. The object cockpit is displayed in the editor in the center pane.
3) Click the interface control that is the target of the condition and define the following attributes:

- **Visibility Condition**: Click the **Browse**  button and in the **Visibility Condition** editor select the configured report or expression in the **Select Condition** field. If the condition is based on an expression, define the following:
- **Parameter Name**: Displays the variables used in the condition.
- **Parameter Value**: This column is not relevant for object cockpits.
- **Parameter Value Reference**: Select the interface control that shall be visible if the variable in the **Parameter Name** column to the source interface control (Interface Control 1) of the condition.

For example, in the case of example about the **SOX Relevance** attribute and the **Business Support Map Report** embedded in the object cockpit in the **Application** object cockpit: the `SimpleBooleanOnTrue` condition has been created with the expression `@VALUE == 'True'`. You would define the attributes for the **Visibility Condition** as follows:

- **Select Condition**: Select `SimpleBooleanOnTrue`.
- **Parameter Name**: Displays `VALUE`.
- **Parameter Value Reference**: Select `SOXRelevant`. This parameter represents the variable to be evaluated for the parameter in the **Parameter Name** column.

Therefore, if the **SOX Relevance** interface control is set to `True`, then the `SimpleBooleanOnTrue` condition is fulfilled and the **Business Support Map Report** interface control will be visible.

- Click **OK** to save the definition and close the editor.

4) In the toolbar, click the **Save**  button to save your changes.

Adding Linebreaks to Visually Structure the Information in the Object Cockpit

You can add multiple linebreaks to create separators in the layout. Adding a break `<break>` element to the object cockpit forces the interface control following the break to bump to the next row. In this way, you can add visual space and structure the layout of interface controls. This might be useful, for example, to visually separate attribute boxes from page views or to thematically structure page views in sections.

A break `<break>` element can be added to the flow panel to structure Group Box interface controls and Presentation Object interface controls. For example, if you want to display three reports in the same row, you could define each presentation object to have a width of 400 pixel and conclude the row with a break `<break>` element. If the screen size is smaller than 1200 pixel or the user manually reduces the width of the screen is less than 1200 pixel, the last report preceding the break `<break>` element that doesn't fit in the user interface will be bumped down to the next row. If an interface control (group box or presentation object) is wider than the available screen space, the content will be truncated.

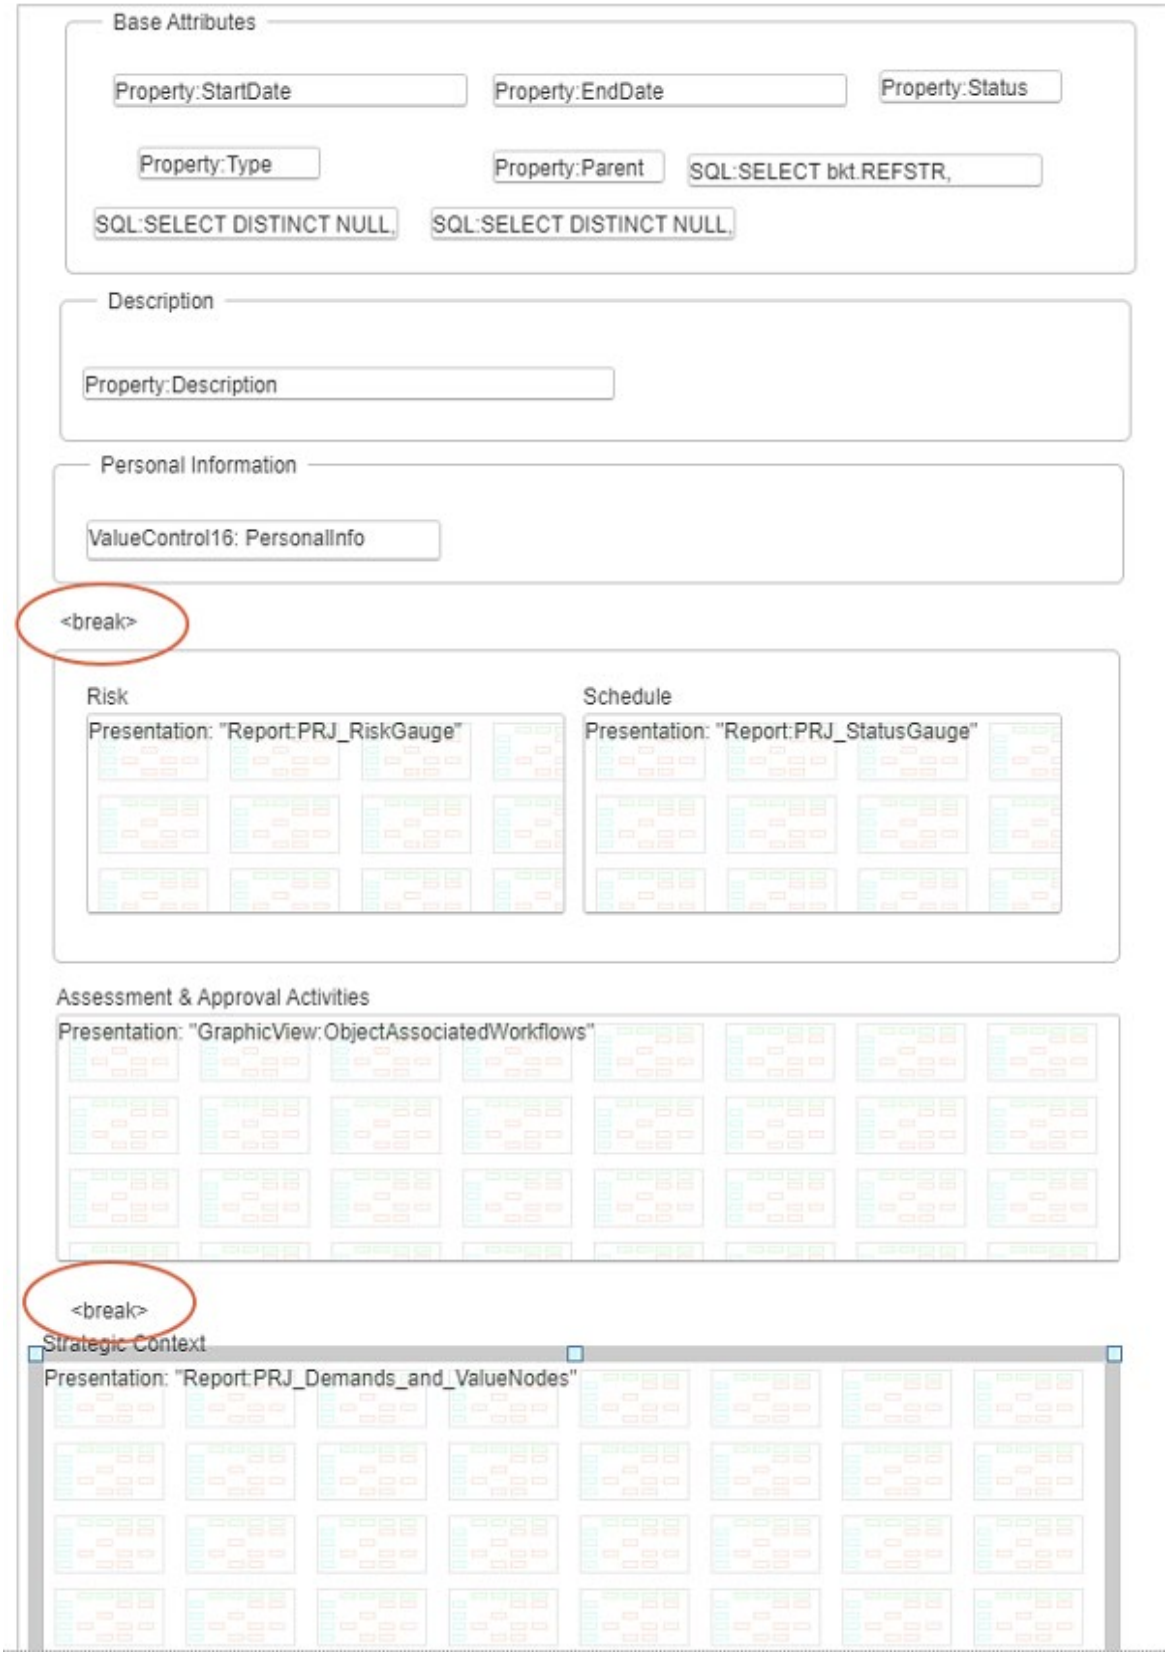

FIGURE: Configuration of line breaks

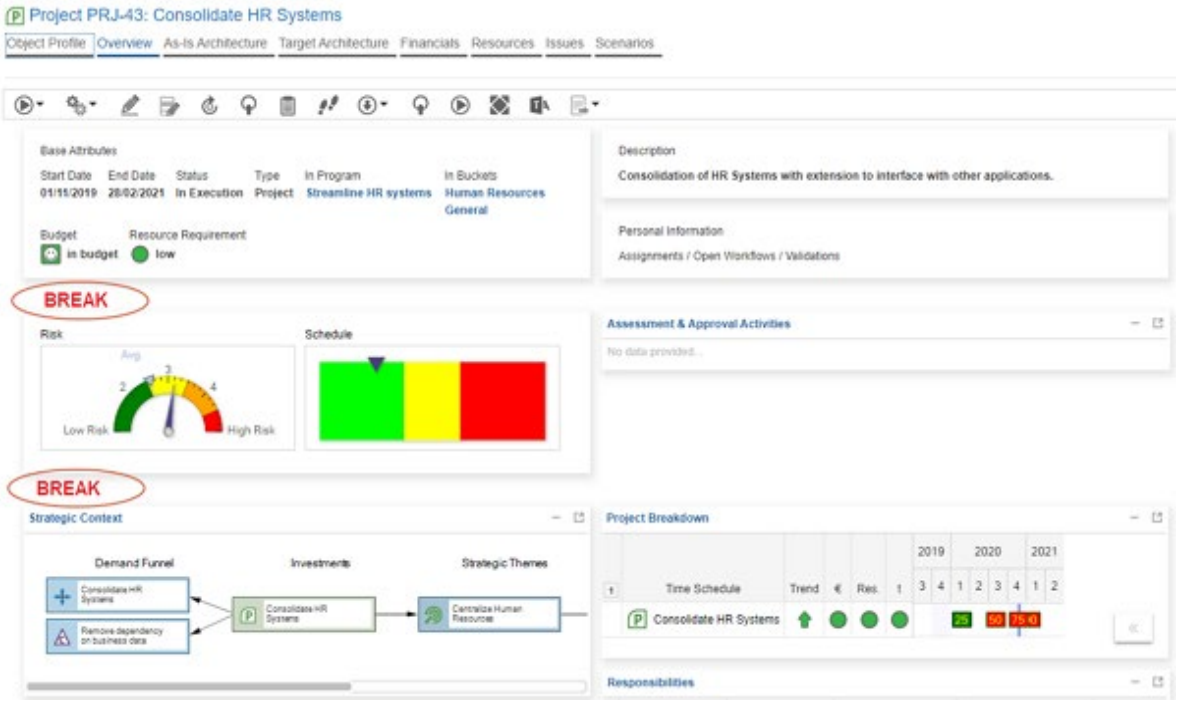

FIGURE: Result of configuration of line breaks

A break `<break>` element can be added in the context of a Group Box interface control to structure the various interface controls in the group box. In this case, the break `<break>` element causes a linebreak and adds a separator line in the group box. The linebreak with separator line is only displayed in a Group Box interface control for which the **Sub-Type** attribute is set to `Attributes`. The functionality of the break `<break>` element remains unchanged otherwise.

To add a break `<break>` element to the object cockpit:

1) In the toolbar of the object cockpit designer, click the **Static Text** button and click in the Flow Panel interface control. The Static Text interface control is displayed in the Flow Panel interface control.
2) In the **Caption** attribute, enter `<break>`. Be sure to include the angle brackets.
3) Repeat this throughout the object cockpit to structure its layout.
4) Specify the **Tab Index** attribute to specify the break element (`<break>`) in the sequence of interface controls. The sequence that you specify is the order in which the interface controls and break elements are displayed.
5) Click the **Save** button to save the new linebreak.

Configuring Styles and GUI Scheme Settings for Object Cockpits

You can specify the styling of Flow Panel, Group Box, Presentation Object, and Value Control interface controls embedded in object cockpits:

- Flow Panel interface controls: To specify the skin style of the flow panels (margins, padding, foreground color, and font color) embedded in all object cockpits, specify the **Common View Control Skins** attribute for the relevant GUI scheme. To do so, do the following:

- Expand the **Global Control Skins** section of the attribute window of the relevant GUI scheme, go to the **Common Control Skins** attribute and specify the margins, padding, foreground color, and font color for flow panels as needed. The styling specified in the **Common Control Skins** attribute specified for a GUI scheme will be applied to flow panels in splash screens, guide views, and console reports. Please note that styles cannot be defined for individual Flow Panel interface controls.

- Apply the skin style defined in the GUI scheme to all flow panels in all object cockpits as well as all splash screens, guide views, and console reports. To do so, right-click the **Object Views** node in the **Presentation** tab and select **Turn GUI Scheme Common Container Skin On for All Flow Panel Cockpits**. The **Ignore GUI Scheme Container Skin** will be set to `False` for the Flow Panel interface control for all object cockpits and the GUI scheme settings will apply to the object cockpit.

- Attribute Group interface controls: To specify the font color and font style of the captions of attribute groups displayed in object cockpits, define the **Attributes Group Caption Font** attribute for the relevant GUI scheme. To do so, expand the **Captions Styling** section of the attribute window of the relevant GUI scheme and specify the **Font Color** and **Font Style** attributes as needed.

- Presentation Object interface controls:

- To specify the font color and font style for the captions of the Presentation Object interface controls embedded in flow panels in the object cockpit and guide views, specify the **Flow Panel Presentation Object Caption Font** attribute for the relevant GUI scheme. Please note that this configuration will only be applied to the captions of presentation objects if the **Inline Navigation** attribute has been set to `False` for the Presentation Object interface control. To do so, expand the **Captions Styling** section of the attribute window of the relevant GUI scheme and specify the **Font Color** and **Font Style** attributes as needed.

- To specify the automatic sizing of the heights of Presentation Object interface controls based on their content displayed, specify the following attributes in the relevant GUI scheme. Go to the **Cockpits** section in the attribute window of the GUI scheme, expand the **Cockpit Contained Objects Behavior** section, and specify the following:

- **Automatically Reduce Height**: Set to `True` to ensure that views with no data are shrunk and that minimal white space is displayed in the object cockpit.

- **Height Difference Threshold**: Enter a percentage value to specify the minimal height difference if the content in page views and configured reports embedded in object cockpits has different values. This improves the visualization in that views with marginally different values are stretched so that they are consistent in their layout. A minimum height difference of 20% is recommended.

- To improve the layout of multiple presentation objects embedded in an object cockpit, adjust the padding of the presentation objects. To do so, define the relevant attributes in the **Margin** section in the attribute window of the Presentation Object interface control. For example, set the **All** attribute to 2 to add 2 pixels to the bottom, top, left, and right margins of the presentation object. Set the **Use Style** attribute to `True` for the presentation object.

- Value Control interface controls:

- To specify the font color and font style for the captions of the Value Control interface controls embedded in flow panels of the object cockpits associated with the GUI scheme, specify the **Value Control Caption Font** attribute for the relevant GUI scheme. To do so, expand the **Captions Styling**

section of the attribute window of the relevant GUI scheme and specify the **Font Color** and **Font Style** attributes as needed.

- To specify styles such as the background color, borders, padding, margins, and font of the value displayed for the Value Control interface control, set the **User Style** attribute to `True` in the attribute window of the value control. Expand the **Style** section of the attribute window and specify the relevant styles as needed. Please note that it may not make sense to specify styles for all sub-types available for Value Control interface controls.

For more information about configuring the GUI scheme for a user profile, see the section Configuring GUI Scheme Definitions for the Alfabet Interface in the chapter Configuring the Visualization of the Alfabet Interface as well as a detailed documentation of all GUI scheme attributes in the chapter *Overview of GUI Scheme Attributes* in reference manual *Configuring Alfabet with Alfabet Expand - Appendix*.

Sequencing the Content in the Flow Panel

Once you have added all interface controls to the object cockpit, you can specify their sequence. The definition of an explicit tab order informs the browser to position the group boxes in a specified sequence and layout. This is also relevant for users working in the Alfabet interface using keyboard shortcuts. The tab order also determines the order of the content when exported via the **Publish** capability.

The content can be sequenced in two ways.

1) Define the sequence via the **Define Tab Order** functionality: Click in the object cockpit and click the **Format** menu that appears in the top toolbar. Select **Define Tab Order** in the drop-down menu. Blue boxes with numbers will appear on all interface controls starting with the flow panel. The flow panel will have the number 00. The following interface control shall be assigned the number 00,01 then next one 00,02, etc. If a group box has the number 00,02, for example, then the interface controls in the group box shall be assigned the numbers 00,02,01, 00,02,02, 00,02,03, etc. To define the tab order, click in each blue box for each interface control sequentially to set its tab order. Click the **Save** button to save the tab order. You must hide the tab order in order to make any further changes to the configuration of the object cockpit. To do this, reselect **Format** > **Define Tab Order**.

FIGURE: Sequencing interface controls in flow panel

2) Define the sequence of the interface controls via the **Tab Index** attribute on each interface control: Click each interface control in the object cockpit to activate its attribute window. In the **Tab Index** attribute, entering the sequence number to define the interface control's place in the tab sequence. Click the **Save** button to save the number for the interface control. Continue this procedure for all interface controls.

FIGURE: Sequencing interface controls in group box

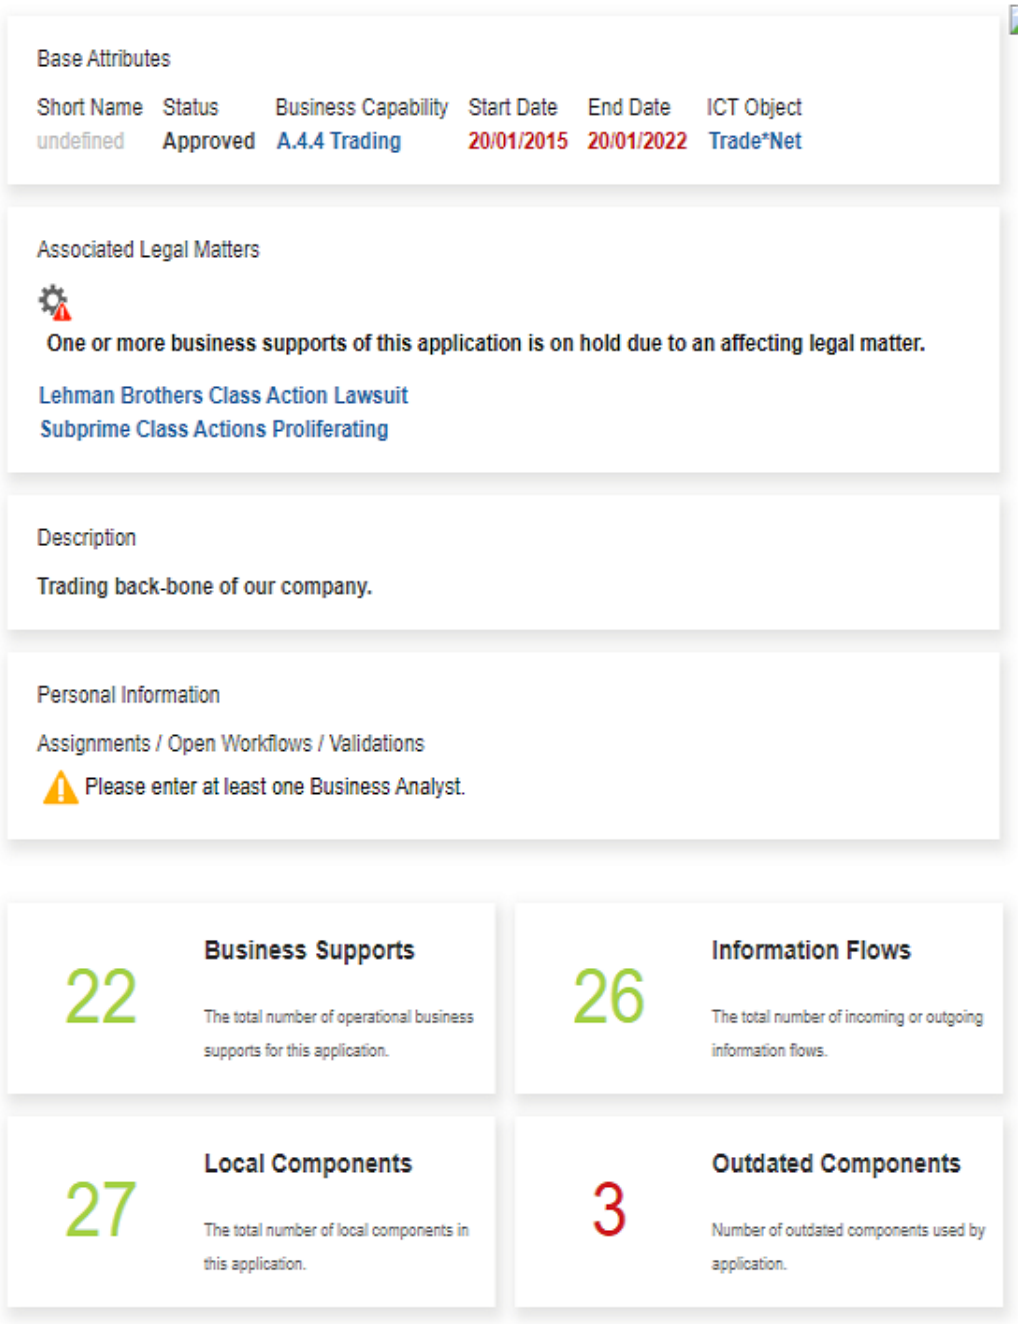

FIGURE: Result of sequenced group box and flow panel

Configuring Drill-Down Navigation in the Object Cockpit

Drill-down navigation can be defined for any of the following:

- An object referenced via a Value Control interface control of the type `Property` or `Query`.
- A page view or configured report specified in the **Source** attribute for a Presentation Object interface control.
- A page view or configured report specified in the **Source** attribute for a Static Text interface control.

If users should be able to navigate via one of the above options, select the interface control in the group box or flow panel and set the **Inline Navigation** attribute to `True` in the attribute window. Click the **Save** button to save your changes. The icon indicating that drill-down navigation is possible will be automatically added to the upper-right corner of the interface control embedded in the object cockpit.

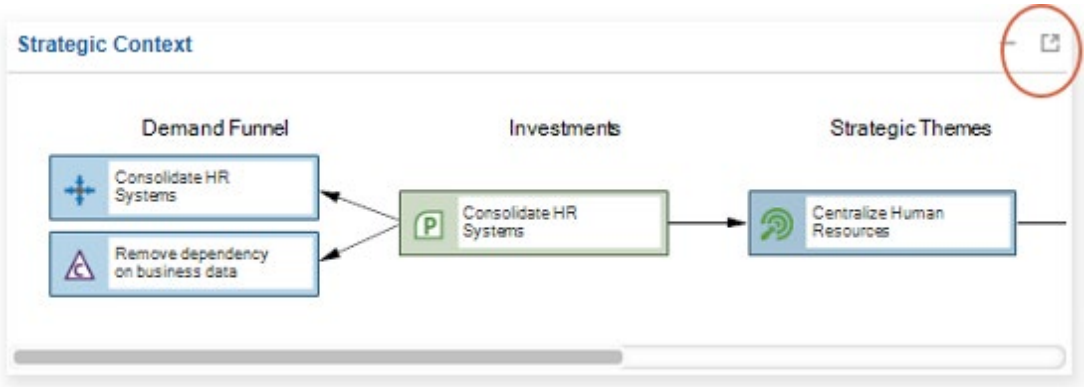

FIGURE: Icon for drill-down navigation

Configuring the Object Cockpit By Means of a Table Grid

The following information describes the configuration possibilities that were available in releases of Alfabet prior to the introduction of HTML 5-based user interface and user interactions. This configuration is based on a Table Layout Panel interface control. Object cockpits rendered in HTML 4 are configured in a static Table Layout Panel interface control that does not allow for dynamic positioning of the interface controls based on the width of the software interface. This method is available for reasons of backward compatibility however it is not recommended to use the Table Layout Panel interface control because the data in the object cockpit may be squeezed, stretched, or truncated when the interface is resized.

Instead, it is recommended that you base the object cockpit on a Flow Panel interface control in order to leverage the browser's layout capability in HTML5. This configuration is recommended and it ensures that object cockpits are not squeezed, stretched, or truncated when the interface is resized. The configuration for object cockpits rendered in HTML 5 ensures that group boxes containing attributes and presentation objects (views and reports) are dynamically positioned according to the current width of the Alfabet Web interface. When resizing the interface, the content displayed in the Flow Panel interface control will be redistributed in the available space and the content will not be cut-off. The Flow Panel interface control ensures that a configured view or set of views will be bumped down and placed below the preceding view or set of views. Business graphics embedded in an object cockpit will be automatically scaled down in size to fit in the available screen space of the device the user is using. Pictures and icons can be implemented as a placeholder that link to views or reports. This is especially useful for large reports for which only a portion

of the report is displayed in the object cockpit. This method is described in the section Configuring the Object Cockpit By Means of a Flow Panel.

Please note that font and hyperlink colors displayed in the object cockpit are determined by the configuration of the GUI schemes implemented in your enterprise. For more information, see the section Configuring GUI Scheme Definitions for the Alfabet Interface.

For more information about specifying the content of the table layout panel, see the relevant information in the section Configuring the Object Cockpit By Means of a Flow Panel:

The following information is available:

- Adding the Table Layout Panel to the Object Cockpit
- Configuring the Header Panel of the Table

Adding the Table Layout Panel to the Object Cockpit

The default size of the Table Layout Panel interface control is 2000 pixel in height and 800 pixel in width. At run time, the object cockpit will be automatically sized to the needs of the content of the object cockpit. However, it may be necessary to resize the object cockpit for the design process if an excessive number of controls must be configured and added to the object cockpit. In order to ensure that business graphics can be adequately viewed on a variety of devices, it is recommended that object cockpits are designed for a lower screen resolution (such as 1280 x 800 or 1280 x 1024). Furthermore, the graphic views embedded in the Table Layout Panel interface control should be vertically positioned rather than horizontally for small display sizes. The object cockpit will be automatically sized to fill the available space in the user interface.

Each table cell in the Table Layout Panel interface control serves as a frame in which you can add content to the object cockpit. The content can either be a static text, property, check entry, indicator, query, icon, page view, configured report, HTML text, URL, or link to a document in the **Internal Document Selector**. The content is added to the table cell via the respective toolbar buttons in the object cockpit designer. Once content has been placed in the table cell, the size of the table cell can be modified, as needed.

Please note that the tab sequence for the cells in the Table Layout Panel interface control is from left-to-right and top-to-bottom. The **Tab Index** attribute defined for the interface controls in each table cell will be ignored. This ensures a consistent navigation in the case of user profiles configured for barrier-free accessibility.

1) Remove the Flow Panel interface control that was automatically included in the object cockpit when it was first created. To do so, click anywhere in the object cockpit and click the **Delete** button in the toolbar.
2) To add a Table Layout Panel interface control to the object cockpit, click the **Table Layout Panel** button and click in the object cockpit designer pane.
3) The default Table Layout Panel interface control is made up of 3 rows and 3 columns. The first row is a header panel that straddles the 3 columns. Click in the Table Layout Panel interface control to activate the attribute window. The **Table Layout** attribute displays the value 3x3 (3 rows x 3 columns). You can edit the **Table Layout** attribute, as needed, and click the **Save** button to save your changes.

The **Height** and **Width** attributes are irrelevant for the configuration of the object cockpit. The object cockpit will be automatically sized to fill the available space in the user interface.

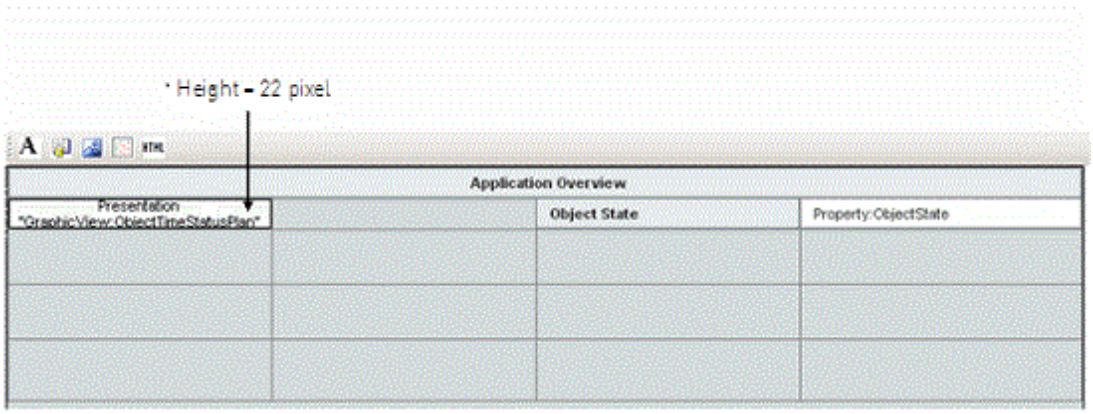
4) You can do any of the following:

- Add content to the table cell in the Table Layout Panel interface control and copy the table cell or adjust its size. To add content to the table cell, click the relevant button in the toolbar and click in the table cell that you want to place it. The following can be added by means of the toolbar in the object cockpit designer pane:
- **Static Text** : Use to add a caption or other instructional text to the table cell. All text in a Static Text interface control in a Table Layout Panel interface control will be displayed in upper-case letters in the Alfabet interface, regardless of its definition in Alfabet Expand.
- **Value Control** : Use to add a property, check entry, indicator, or query to the table cell.
- **Icon** : Use to add an icon to the table cell.
- **Presentation Object** : Use to add a standard page view or configured report to the table cell.
- **HTML Content** : Use to display any static HTML code including, for example, images, links, and forms. The HTML must be XML-conform HTML, compliant with HTML 5, and use standard HTML tags.
- Edit the column span or row span of a table cell containing content. To do so, click the element to open its attribute window. Adjust the values in the **Column Span** and **Row Span** attributes, as needed. You may not enter a number less than 1 nor greater than the corresponding column or row definition in the table's **Table Layout** attribute.
- Copy a table cell containing content and paste it to an empty table cell. This allows you to copy elements that have already been adjusted to have the correct size. To do so, right-click the element you want to copy and select **Copy** in the context menu and right-click the empty table cell and select **Paste**. The copied element can be modified, as needed. The key operations CTRL + C and CTRL + V can be used to copy and paste cockpit elements.
- Change the table layout value to add an estimated total number of rows and columns. To do so, click the table to view the attribute window in the right pane. The **Table Layout** attribute will display the maximum number of defined rows and columns in the syntax <rows>x<columns>. The default value is 3x4. Edit this value, as needed. Please note that additional columns and rows can later be added ad-hoc. The **Table Layout** attribute will be automatically updated as the table is built.

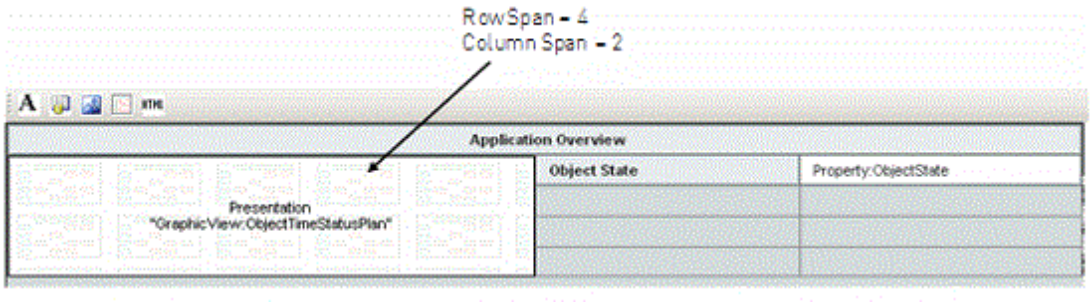
5) Once you have modified the table, click the **Save** button to save your changes.

To create an object cockpit with table cells that span over several rows or columns of the table like that displayed above, you would proceed as follows:

1) Add the relevant content (for example, a presentation object) to the relevant cell. In this case, the cell in the first row and column. Set the **Height** attribute to a small value such as 22 pixel.

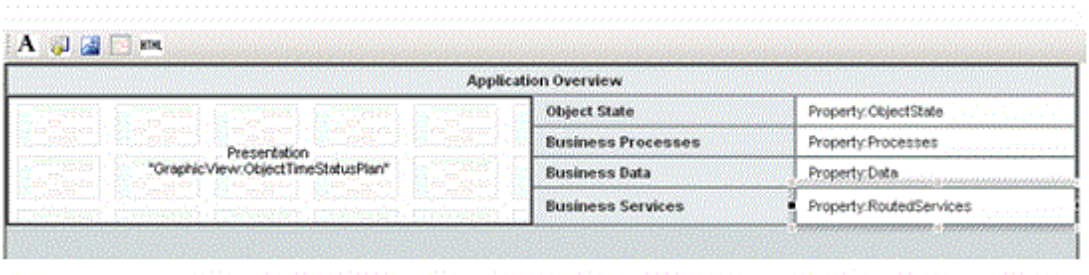


2) Add additional content to the remaining columns in the first row. The **Height** attributes will automatically be set to 22 pixel.



3) Next, define the **Row Span** attribute of the table cell that should span one or more rows. In the example, the **Row Span** attribute has been defined as 4 and the **Column Span** attribute has been set to 2. Remember that the total value of all **Row Span** attributes of all rows may not exceed the number of rows in the **Table Layout** attribute of the object cockpit. In this case, the table layout is 5 x 4, whereby the first row displays a caption for the object cockpit.

Please note that the configured row span and column span is ignored for a page view displaying a diagram when the object cockpit is published to a DOC or PDF file. In this case, the size of the diagram will be decreased in the publication.



4) Configure the remaining cells in the object cockpit accordingly. All cells must be filled with content and no cell may remain empty.

5) In the toolbar, click the **Save**  button to save your changes.

Configuring the Header Panel of the Table

The default table that is automatically generated includes a header panel for the first row. This row contains a Static Text interface control, per default.

If the number of columns of the default table has been modified, you can adjust the size of the header panel. Furthermore, you can adjust the height of the row and specify a caption to display in the header row of the object cockpit.

1) Click the Static Text interface control in the table to activate its attribute window. Define the following attributes, as needed.

- **Caption**: Enter the text that should be displayed as the title of the object cockpit: The caption will be displayed in upper-case letters in the user interface, regardless of their definition in Alfabet Expand.
- **Automatic Sizing**: Select `False` if you want to adjust the height of the row. This allows you to define a distinct size for the table cell containing the static text element.
- **Height**: Enter a pixel value for the height of the header panel.
- **Column Span**: Enter the total number of columns if the number of columns has changed and you want the header panel to straddle all columns.
- Expand the **Style** section to define the style and formatting of the text, as needed.

2) In the toolbar, click the **Save** button to save your changes.

Defining the Default Object Cockpit for a Custom Object View

If multiple object cockpits have been defined for a custom object view, you can define a default object for a specified view scheme.

To define a default object cockpit:

1) Right-click the custom object view and select **Configure Object View**. The **View Configuration** editor opens. The selected object view is displayed in the **Select Object** field.
2) In the **Select View Scheme** field, select the relevant view scheme that you are configuring the object view for.
3) If you are working with an object class for which object class stereotypes have been defined, select the relevant object class stereotype in the **Select Base Class** field.
4) In the table, scroll down to the table section labeled **Cockpits** and in the drop-down menu in the **Default Cockpit** column, select the object cockpit that should be displayed as the default for the selected view scheme. Click the **OK** button to save your changes and close the editor.
5) In the toolbar, click the **Save** button to save your changes.

For additional information about configuring the object view, see the sections Defining the Visibility of Object Class Properties, Workspaces, Page Views/Configured Reports, and Object Cockpits in an Object View and Hiding Functionalities in an Object View in the chapter Configuring User Profiles for the User Community.

Adding Data Quality Widgets to Object Cockpits

Additional information about data in a object cockpit can be provided via a quality widget in a pop-up window. The quality widget is either a configured report or a standard Alfabet view that can be assigned to multiple object cockpits as well as configured reports. When the user opens or loads the object cockpit that the quality widget is assigned to, the quality widget will be displayed in a separate pop-up window that opens for a short time. The quality widget pop-up window opens by default in the upper right corner of the Alfabet user interface below the main menu. This position is configurable. Depending on the configuration of the primary configured report, either the complete quality widget will be displayed or only the caption will be displayed in a title bar and the user can click the title to open the quality widget.

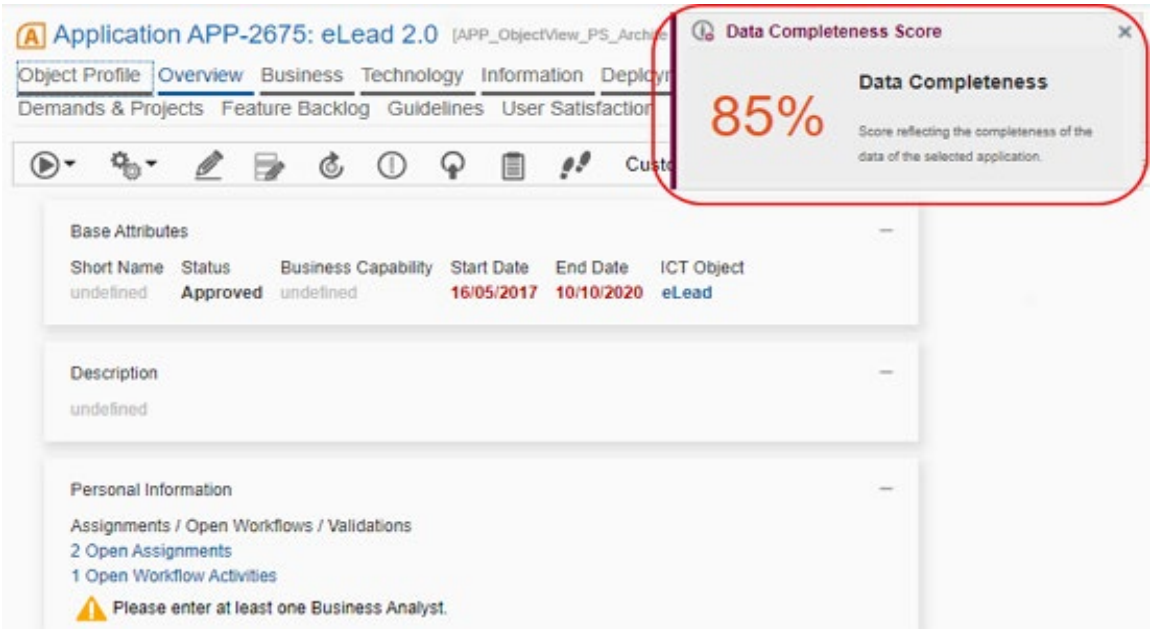


FIGURE: Secondary view displaying quality widget based on a configured report

A typical use case for quality widgets is a widget report that opens to provide information to the user about the quality of the data in a object cockpit. For example, the user could be provided with information about the completeness of the indicators specified for the object in the object cockpit. A configured link available in the quality widget could then open a view that allows the user to provide the missing data and thus correct the issue. When the user clicks the link available in the quality widget report, the view will open in a new tab. The user can then define the relevant indicators, return to the original tab, refresh the view and view the configured report with the updated data.

The following additional configuration is required for secondary views:

- The configured reports that are implemented as quality widgets must first be configured before they can be assigned to an object cockpit, wizard, or wizard step. For more information about the configuration of the configured reports, see the section Integration of Quality Widgets in Configured Reports, Object Cockpits and Wizards.
- The visualization of secondary window skins is configured via the **Quality Widget** attributes for a GUI scheme. For more information, see the section Configuring GUI Scheme Definitions for the Alfabet Interface as well as the section *Attributes Displayed in the Grid Section: Secondary Window Skins* in the reference manual *Configuring Alfabet with Alfabet Expand - Appendix*.

To assign a quality widget to an existing object cockpit:

1) Right-click the object cockpit and select **Add Secondary View**. A secondary view is added to the explorer and the attributes of the secondary view are displayed in the attribute window.
2) Define the following attributes of the secondary view:

- **Name**: Enter a unique name for the secondary view. The name is a technical name and shall not contain special characters or whitespaces. The technical name is not displayed in the user interface.
- **Caption**: Enter a caption for the secondary view that shall be displayed in the title bar of the secondary view in the Alfabet user interface and in the tooltip displayed for the icon of the secondary view in the slide-in toolbar. Please note that the caption should be short. It will not be displayed in the title bar if it is too long.
- **Role**: Select `QualityWidget`.
- **View Type**: Select `Report`.
- **View Name**: Select the configured report that shall be displayed as secondary view. The drop-down list displays the names of all available configured reports of the allowed report types widget report, gantt chart report, and business chart report.
- **Show Automatically**: Select `True` if you would like the secondary view to be fully displayed for a few seconds when the user accesses the object cockpit or configured report that the secondary view is defined for. Select `False` if only the caption of the secondary view shall be displayed in a title bar for a few seconds when the user accesses the object cockpit or configured report that the secondary view is defined for. The secondary view will then open if the user clicks the title bar.
- **Position**: Select the position of the open quality widget on the Alfabet user interface. The quality widget window can be placed in the center of the Alfabet user interface or in one of the corners of the user interface beneath the main toolbar. The quality widget pop-up window opens by default in the upper-right corner of the Alfabet user interface below the main menu.
- **Height**: Define the inner height of the quality widget window in pixel. This is the height available for the display of the configured report opened in the window.
- **Width**: Define the inner width of the quality widget window in pixel. This is the width available for the display of the configured report opened in the window.

3) In the toolbar, click the **Save** button.

Configuring Inline Editing of Attributes in the Object View

Inline editing of scalar and reference properties may be configured so that users can edit data directly in the object profile and object cockpit. If inline editing is supported, users can edit scalar attributes for an existing object directly in the **Attributes** section of an object profile or in an object cockpit without needing to open the object's editor or wizard.

Please note the following regarding the inline editing functionality:

- Only scalar and reference properties that are editable in the editor/wizard available in the object profile or object cockpit can be edited via inline editing.
- All unique constraints defined for the class as well as any post-conditions configured for the wizard associated with the object profile/object cockpit will be applied to the data entered.

  Please note that data is saved to the Alfabet database prior to the post-condition being validated. Therefore, data entered via inline editing will be saved even if the post-condition is not fulfilled. This is because the data must be available in the Alfabet database in order to be evaluated for the post-condition. If the data entered does not fulfill the post-condition, the configured warning message will be displayed explaining that the input must be corrected in order to fulfill the post-condition.

- Inline editing may be limited or prevented if the syntax of the post-condition is not correct. In this case, an error will be displayed if the user tries to open the wizard.

For more information about configuring post-conditions for wizard steps, see the section Defining a Post-Condition for a Wizard Step.

When the user points to the relevant interface control, the **Edit**  icon will be displayed next to the attribute to indicate the object can be edited inline. Users can click in the field and depending on the type of field, define text, select a value in a drop-down list, or specify a date. Upon completion, the user can then click the **Save**  button to save the definition to the Alfabet database or click the **Cancel**  button to remove the definition.

Permissibility of inline editing can be specified by your solution designer on the level of an object view, class setting, or GUI scheme. If the **Prevent Inline Editing in Object Views** is not explicitly defined, the default value `False` will be applied. Please note the following:

- If the GUI scheme attribute **Prevent Inline Editing in Object Views** is set to `True`, then inline editing is not permissible for all object profiles and object cockpits in all object views relevant for the user profile that the GUI scheme is assigned to.
- If the GUI scheme attribute **Prevent Inline Editing in Object Views** is set to `False`, then inline editing is permissible for all object profiles and object cockpits in all object views relevant for the user profile that the GUI scheme is assigned to. This setting can be overruled for an individual class or object view. Please consider the following if the GUI scheme attribute **Prevent Inline Editing in Object Views** is set to `False`:

- If you set the class setting attribute **Prevent Inline Editing in Object Views** to `True`, then inline editing will not be permissible for the relevant object class.
- If you set the class setting attribute **Prevent Inline Editing in Object Views** to `False` and set the object view attribute **Prevent Inline Editing in Object Views** attribute to `True` for an object view of the relevant class, then inline editing will not be permissible in the object view.
- If the **Prevent Inline Editing in Object Views** attribute is set to `False` for the GUI scheme, class setting, and object view, you can specify that an individual Value Control interface control is not permissible by setting the **Read-Only** attribute of the interface control to `True`.

- If **Prevent Inline Editing in Object Views** is set to `False`, inline editing may be disabled for an interface control in an object cockpit if the **Read-Only** attribute is set to `True` for the interface control.

Inline editing is not possible in object views in which the **Edit** button has been excluded for the view scheme. For more information about hiding buttons, see the section Hiding Functionalities in an Object View.

For more information about configuring GUI schemes, see the section Configuring GUI Scheme Definitions for the Alfabet Interface in the chapter Configuring the Visualization of the Alfabet Interface as well as a detailed documentation of all GUI scheme attributes in the chapter *Overview of GUI Scheme Attributes* in reference manual *Configuring Alfabet with Alfabet Expand - Appendix*.

Configuring the Toolbar of the Object View

Various aspects of the object view toolbar can be configured. Standard toolbar buttons can be hidden in the context of a user profile as described in the section Hiding Functionalities in an Object View in the chapter *Configuring User Profiles for the User Community*.

Furthermore, styles can be configured for the toolbar in all object views relevant to a user profile. Additionally, custom buttons that will open a specified editor, wizard, standard Alfabet view, or configured report can be configured to be displayed in a toolbar of a custom object view.

The following information is available:

- Configuring Styles for the Toolbar in an Object View
- Configuring Custom Buttons for the Toolbar of a Custom Object View

Configuring Styles for the Toolbar in an Object View

You can specify the borders, background color, and grey scaling of images for the toolbar displayed in object views via the **Object Profile Toolbar Style** attribute in the GUI scheme.

To do so, expand the **GUI Schemes** node in the **Presentation** tab and select the relevant GUI scheme you want to define. Expand the Toolbars section and then expand the **Object Profile Toolbar Style** attribute to specify the **Background Color**, **Border Color**, **Border Width**, and **Render Images in Grey Scale** attribute attributes, as needed. Please note that the **Render Images in Grey Scale** attribute will not apply to Microsoft Internet Explorer.

For more information, see the section Configuring GUI Scheme Definitions for the Alfabet Interface in the chapter Configuring the Visualization of the Alfabet Interface as well as a detailed documentation of all GUI scheme attributes in the chapter *Overview of GUI Scheme Attributes* in reference manual *Configuring Alfabet with Alfabet Expand - Appendix*.

Configuring Custom Buttons for the Toolbar of a Custom Object View

You can create a button to display in the toolbar of the custom object view that will open a specified editor, wizard, standard Alfabet view, or configured report.

One of the use cases for the custom button is to provide configured audit information to users accessing the custom object view. Because the **Object Audit** view displayed for a selected object displays all information about the object independent of the access permission available to the user viewing the audit information, you may want to consider configuring a configured report to display audit information in accordance with the visibility rules of the associated user profile(s). Please note the following configuration requirements.

- Create a native SQL-based configured reports to extract specific information from the audit history such as the changes made to the object by a specific user or specific types of changes made to the object (for example, new information flows added to an application). For information about the structure of the database table for auditing and how to configure such a report, see the section Defining Audit Management Related Configured Reports in the chapter Configuring Reports. Once the report is configured, you must make it available in the relevant custom object view by configuring a custom button for the relevant custom object view, as described below.
- The standard **Audit Trail**  button can be hidden from the relevant custom object view in the context of the user profile configuration. For more information, see the section Hiding Functionalities in an Object View in the chapter Configuring User Profiles for the User Community.
- For general information about how to make the auditing capability available for an object class, see the section Specifying History Tracking for an Object Class in the chapter Configuring the Class Model.

To create a new button for a custom object view

1) Right-click the new custom object view  and select **Create Button**. The new button is displayed below the custom object view node.
2) Click the new button to activate the attribute window and define the following attributes, as needed:

- **Button Type**: Select `Action`. When a user clicks the button displayed in the object view, the specified editor, wizard, view or configured report will open.
- **Name**: Enter a unique name for the button. Special characters are not allowed. This value is displayed in the solution interface if the **Caption** attribute has not been defined.
- **Caption**: Enter the caption that should be displayed on the button. If no caption is defined, the value in the **Name** attribute will be displayed on the button.
- **Extract Caption for Translation**: Set to `True` if the button caption shall be extracted to the Meta-Model vocabulary for translation. Set to `False` if the button caption shall not be extracted to the Meta-Model vocabulary for translation.
- To specify the editor, wizard, standard Alfabet view, or configured report that will open when the button is clicked:
- *For editors*:

- **Operation**: Select `Edit` to specify that a standard editor should be linked to the custom button.
- **View**: Select the standard editor that should open when the button is clicked by a user:

- *For wizards*:
  - **Operation**: Select `WizardEdit` to specify that a standard or custom wizard should be linked to the custom button.
  - **View**: Enter `Wizard`:<NameOfConfiguredWizard>. You must spell the name of the wizard exactly as it is spelled in the **Name** attribute of the custom wizard.
- *For standard Alfabet views*:
  - **Operation**: Select `Navigate` to specify that a standard Alfabet view should be linked to the custom button.
  - **View**: Select the relevant view in the drop-down list.
- *For configured reports:*
  - **Operation**: Select `Navigate` to specify that a configured report should be linked to the custom button.
  - **View**: Enter `Report`:<NameOfConfiguredReport>. You must spell the name of the report exactly as it is spelled in the **Name** attribute of the configured report.
- **Apply Operation To**: Select `Base Instance` to specify that the data in the element specified in the **View** attribute is for the object that the user is currently working with.
- **Disable In Show Mode**: Select `True` if the button should only be available to the users with ReadWrite access permissions to the object. Select `False` if the button should be available to any user accessing the object's object profile.
- **View Mode**: Select `Edit` if the user opening the view or configured report should have Read/Write access permissions to the view or select `ReadOnly` if the user should have Read/Only access permissions to the view.
- **Icon**: Select an icon to display on the button. The icon should not be larger than 22 x 22 pixel.
- **Hint**: Enter text for a tooltip. The tooltip will be displayed when the user points to the button.

3) To sort the order of the buttons created for the object profile, click the object view  that the buttons have been created for to activate the attribute window. In the **Buttons** attribute, click the **Browse**  button. An editor opens that allows the sequence of the buttons in the toolbar to be defined via the **Up/Down**  button. Sort the buttons and click O **K** to close the editor.

4) In the toolbar, click the **Save**  button to save your changes. You can now add or remove page views to the custom view.

Making the Custom Object View Available to the User Community

Once the custom object view and, if relevant, its object cockpits, have been configured, it can be implemented in a user profile. To do so, the following must be carried out:

- The object view must be assigned to a class setting that will be implemented in the user profile. This is described in the section Configuring Class Settings for Object Classes and Object Class Stereotypes in the chapter Configuring User Profiles for the User Community.
- The class setting must then be assigned to a view scheme. This is described in the section Configuring a View Scheme for a User Profile in the chapter Configuring User Profiles for the User Community.
- The object view can then be further configured in the context of the view scheme it is assigned to. At this point, you can choose to hide the visibility of object class properties, page views, configured reports and entire workspaces. This is described in the section Modifying the Object View for Implementation in Multiple User Profiles. You an also hide functionalities available in the toolbar of the object view. This is described in the section Hiding Functionalities in an Object View in the chapter Configuring User Profiles for the User Community.
- Finally, the view scheme that the object view is associated with must be assigned to a user profile to make it available to the Alfabet user community. This is described in the section Assigning the View Scheme to a User Profile in the chapter Configuring User Profiles for the User Community.

Modifying the Object View for Implementation in Multiple User Profiles

Once the object profile and object cockpits have been configured for the custom object view, you can modify the custom object view so that it can be reused in various view schemes that are assigned to different user profiles. The object view can be individually modified for each view scheme in which it will be implemented. For each view scheme, you can specify which workspaces, page views, configured reports, attributes, etc. should be displayed in the custom object view. In this way, a custom object view can be very broadly configured and refined for the user profile context in which it will be implemented.

The following is possible:

- Refine the visibility of various elements of the custom object view for multiple view schemes. The configuration possibilities include:
- Hide standard or custom object class properties assigned to the **Attributes** section of the object profile
- Hide individual page views and configured reports.
- Hide an entire workspace. When you hide an entire workspace, all page views assigned to the workspace will also be hidden.
- Hide individual object cockpits
- Specify an object cockpit as the default object cockpit that is displayed when the user navigates to the object view. The user can switch to another cockpit, as needed.

- Specify which functionalities are available in the toolbar of the object view/object cockpit. This is described in the section Hiding Functionalities in an Object View in the chapter Configuring User Profiles for the User Community.
- Hide the object profile in a custom object view. This is configured on the level of the class setting.
- Specify which workspaces, page views, configured reports, or object cockpits should be hidden in a custom object view when the current object is based on the value defined for a specified standard or custom property. For example, if a custom object view is configured for the object class `Device`, you could specify that different object cockpits are hidden when accessing the object view for the object class stereotype Physical Device vs. Virtual Device.

Visibility for interface controls in object profiles and object cockpits can also be configured via conditional constraints. This is described in detail in the sections Configuring Conditional Constraints for an Object Profile and Configuring Conditional Restraints in the Object Cockpit.

The following information is available:

- Configuring Visibility Issues of the Custom Object View for a View Scheme
- Excluding the Object Profile from a Custom Object View
- Hiding Aspects of a Custom Object View Based on Standard or Custom Properties

Configuring Visibility Issues of the Custom Object View for a View Scheme

The visibility of object class properties, workspaces, page views, and configured reports can be specified for a standard object view or custom object view. Additionally, you can specify which object cockpits are visible for the user profile as well as which object cockpit is the default object cockpit that the user will navigate to the first time in the user session.

Please note that the first time that a user navigates to an object view for a specific object class, the object cockpit configured as the default cockpit will be displayed. If no object cockpit is specified as the default for the user profile, the user will automatically navigate to the first object cockpit in the list of object cockpits in the **Default** field in the **View Configuration** editor available via a user profile. If no default object cockpit has been configured, the object profile will be displayed per default.

Please note that this configuration is done at the level of the individual object view. Each relevant object view must be explicitly configured. For each view scheme assigned to a user profile, the following should be configured:

- Hide standard or custom object class properties assigned to the **Attributes** section of the object profile
- Hide individual page views and configured reports.
- Hide an entire workspace. When you hide an entire workspace, all page views assigned to the workspace will also be hidden.
- Hide individual object cockpits

- Specify an object cockpit as the default object cockpit that is displayed when the user navigates to the object view. The user can switch to another cockpit, as needed.
- Specify which functionalities are available in the toolbar of the object view/object cockpit. This is described in the section Hiding Functionalities in an Object View.

To configure the visibility of object class properties, page views, configured reports, workspaces, and object cockpits in an object view:

1) Open the Alfabet interface by right-clicking the relevant user profile and selecting **Configure User Profile**.
2) Navigate to the object view that you want to configure and click the **Configure View**  button in the upper right corner of the view. The **Customization Editor** opens.
3) Define the following as needed:

- **Select Configuration Object**: Displays the current configuration object that is being configured.
- **Select View Scheme**: Select the view scheme that the configuration is relevant for.
- **Select Hierarchy Level**. Select the hierarchy level for which the configuration is being defined. The levels are listed in the order of the hierarchy, starting with **All Classes**, followed by the object class and then the object class stereotypes.
- **Currently Applied Settings**: Displays the inherited configuration that is applied to the selected configuration object if the option **Inherited Settings from Parent Configuration Object** is selected in the **Choose One Settings Mode** menu. This field will be empty if settings have not been inherited.
- Select the relevant option in the **Choose One Settings Mode** menu in the toolbar of the dataset. The options available will depend on the configuration object that you are working with:
- **Explicit Settings from Selected Configuration Object**: Select to display a dataset that allows visibility to be explicitly specified for the relevant aspects of the selected configuration object displayed in the **Select Configuration Object** field.
- **Inherited Settings from Parent Configuration Object**: Select if the selected configuration object shall inherit the exclusion settings configured for the relevant parent configuration object. The **Currently Applied Settings** field will display the inherited configuration that is applied to the selected configuration object if the option **Inherited Settings from Parent Configuration Object** is selected in the **Choose One Settings Mode** menu.
- **No Explicit Settings from Configuration Object**: Select to display the current settings for the selected configuration object. This dataset allows no explicit settings to be configured. The **No Explicit Settings from Configuration Object** option is displayed instead of the **Inherited Settings from Parent Configuration Object** option if no settings can be inherited.

4) If **Explicit Settings from Selected Configuration Object** has been selected in the **Choose One Settings Mode** menu, you can configure the visibility of the **Attribute Section**, a section for each workspace, and a **Cockpits** section. Expand the section of the table in order to display the respective attributes, views, or cockpits that you want to configure by clicking the + symbol. If necessary, navigate to the next page in the **View Configuration** editor. The **View Configuration** editor displays the following columns:

- **Name**: Displays the name of the interface element in the object view (**Attribute** section, attributes, reports, workspaces, views, etc.) in the object view.

- **Caption**: Displays the caption defined for the interface element in the object view.
- **Type**: Displays the type of interface element in the object view (`Attribute`, `Report`, `Workspace`, `Cockpit`, etc.)
- **Excluded**: Click in the cell to set an X to specify that the respective interface element in the object view should be hidden. For example, to hide an object cockpit, scroll to the **Cockpits** section of the table and set an X in the **Excluded** column for the object cockpit that you want to hide for the selected view scheme.
- **Default Cockpit**: Click in the cell to set an X to specify that the object cockpit is the default view. The first time that a user navigates to an object view for a specific object class, the default object cockpit configured will be displayed. The user can switch to another object cockpit as needed. If no object cockpit is specified as the default for the user profile, the user will automatically navigate to the first object cockpit in the list of object cockpits in the **Default** field in the **View Configuration** editor of the user profile. If no object cockpits have been configured, the object profile will be displayed per default.
- **Usage Type**: Displays the specification of the user type that the view is intended for (`All`, `Viewer`, `Data Entry`, `Functional`, `Expert`).

5) Click the **OK** button to save the changes in the **Customization Editor** editor or click **Cancel** to exit without saving the changes.

To configure the visibility of object class properties, page views, configured reports, workspaces, and object cockpits in an object view:

1) Right-click the new custom object view  and select **Configure Object View**. The **View Configuration** editor opens.
2) In the **Select View Scheme** field, select the view scheme that the configuration is relevant for.
3) In the **Choose One Settings Mode** menu, select the **Explicit Settings from Selected Configuration Object** option to configure the visibility of the **Attribute Section**, a section for each workspace, and a **Cockpits** section.
4) Expand the section of the table in order to display the respective attributes, views, or cockpits that you want to configure by clicking the + symbol. If necessary, navigate to the next page in the **View Configuration** editor. The **View Configuration** editor displays the following columns:

- **Name**: Displays the name of the interface element in the object view (**Attribute** section, attributes, reports, workspaces, views, etc.) in the object view.
- **Caption**: Displays the caption defined for the interface element in the object view.
- **Type**: Displays the type of interface element in the object view (`Attribute`, `Report`, `Workspace`, `Cockpit`, etc.)
- **Excluded**: Click in the cell to set an X to specify that the respective interface element in the object view should be hidden. For example, to hide an object cockpit, scroll to the **Cockpits** section of the table and set an X in the **Excluded** column for the object cockpit that you want to hide for the selected view scheme.
- **Default Cockpit**: Click in the cell to set an X to specify that the object cockpit is the default view. The first time that a user navigates to an object view for a specific object class, the default object cockpit configured will be displayed. The user can switch to another object cockpit as needed. If no object cockpit is specified as the default for the user profile, the user will automatically navigate to the first object cockpit in the list of object cockpits in the **Default** field in the **View Configuration** editor of the user profile. If no object cockpits have been configured, the object profile will be displayed per default.

- **Usage Type**: Displays the specification of the user type that the view is intended for (`All`, `Viewer`, `Data Entry`, `Functional`, `Expert`).

5) Click the **OK** button to save the changes in the **View Configuration** editor or click **Cancel** to exit without saving the changes.

Excluding the Object Profile from a Custom Object View

You can exclude the object profile for a relevant class setting so that it is not displayed in the Alfabet user interface when a user with the user profile accesses the custom object view: To hide the object profile, navigate to the relevant class setting assigned to the view scheme of the relevant user profile. In the attribute window of the class setting, set the **Suppress Object Profile** attribute to `True`. In this case, the object profile will be hidden and only the object cockpits will be displayed. For more information about defining class settings, see the section Configuring Class Settings for Object Classes and Object Class Stereotypes.

Hiding Aspects of a Custom Object View Based on Standard or Custom Properties

The XML object ***ObjectViewCustomFilters*** allows you to explicitly specify which workspaces, page views, configured reports, or object cockpits should be hidden in a custom object view when the current object is based on the value defined for a specified standard or custom property. For example, the following is possible:

- If a custom object view is configured for the object class `Device`, you could specify that different object cockpits are hidden when accessing the object view for the object class stereotype Physical Device vs. Virtual Device.
- If a custom object view is configured for an object class stereotype Business Application, you could specify that different workspaces are hidden when accessing the business applications with the object state set to Active vs. business applications with the object state set to Retired.

Please note that the XML object ***ObjectViewCustomFilters*** is a blacklist that allows you to specify the content that shall **not** be available when users access custom object views for the specified object class stereotype.

To edit the XML object ***ObjectViewCustomFilters***:

1) Go to the **Presentations** tab, expand the **XML Objects** folder, and expand the **SolutionManagers** folder.
2) Right-click the XML object ***ObjectViewCustomFilters*** and select **Edit XML**. The XML editor is displayed in the center pane. For general information about editing XML objects in Alfabet Expand, see the section Working with XML Objects.
3) In the XML attribute ***ObjectViewFilter***, specify the following XML attributes for each object class stereotype relevant for the project scenario configuration:

For example, to hide an object cockpit displaying information about virtual devices:

```
<ObjectViewFilter ClassName="Device" Property="Stereotype"
Value="PhysicalDevice" >
```

```
<Item Type="Cockpit"
Name="DVC_ObjectView_VitualDevice_Overview" />

</ObjectViewFilter>
```

- `ClassName`: Enter the name of the object class.
- `Stereotype`: If you specifying the custom object view configured for an object class stereotype, enter the name of the object class stereotype.
- `Property`: Enter the name of the object class property upon which the filtering should be based. For example, you might specify the `Stereotype` property for an object class, or you might specify another standard or custom property such as `State` or `Status` that might be relevant for an object class or object class stereotype.
- `Value`: Enter the value of the property for which the content specified in the XML attribute `Type` should be hidden.

4) Add a child XML element ***Item*** for each workspace, page view, configured report, or object cockpit that should be hidden for the specified object class/object class stereotype:

- `Type`: Enter any of the following:
- "`WS`" to specify a workspace that should be hidden.
- "`View`" to specify a page view or configured report that should be hidden.
- "`Cockpit`" to specify an object cockpit that should be hidden.
- `Name`: Enter the technical name of the relevant workspace, page view, configured report, or object cockpit that should be hidden.

5) In the toolbar, click the **Save**  button to save the XML definition.

Providing Custom Online Help for an Object View

You can provide custom context-sensitive help for any custom object view or object cockpit configured by your solution designer. You can specify only one custom context-sensitive help link per object view and only one custom context-sensitive help link per object cockpit. Users will be able to access the context-sensitive help for the object profile or object cockpit that is currently displayed in the Alfabet user interface.

The custom context-sensitive help that you provide for your user community must be available via a URL that can be viewed in a browser. For each custom object view, you can decide whether custom context-sensitive help should be displayed and whether the standard context-sensitive help should or should not be displayed. If you specify that both the standard context-sensitive help and the custom context-sensitive help are to be displayed, the link for the standard context-sensitive help will be listed first in the **Help Selector**, followed by the custom context-sensitive help link. The links will be displayed in the **Help Selector** with the syntax **Custom Help on<Object View Caption>** or **Custom Help on<Object Cockpit Caption>**. For general information about the standard and custom context-sensitive help, see the section Understanding the Context-Sensitive Help.

Furthermore, you can specify content for the automated help assistant and make it available to a selected object view and/or object cockpit. The automated help assistant will be displayed in a fly-in element in the

upper-right corner of the user interface when the user accesses the object view or object cockpit in the Alfabet user interface. The automated help assistant can be closed, whereby it will drop into the slide-in toolbar and can be opened for the current view at another time. For general information about the automated help assistant capability, see the section Understanding the Automated Help Assistant.

Server variables can be used in the **Custom Context-Sensitive Help URL** attribute and the **Automated Assistant URL** attribute to specify the custom help links. Server variables allow you to define all or part of the URL definition in the alias server setting instead of directly defining it in the configuration in Alfabet Expand. Use of server variables is, for example, useful in order to change a Web server name defined in multiple URL definitions in Alfabet Expand. Instead of changing all URL definitions, only the variable value in the alias server setting must be updated. For more information about defining server variables for custom online help, see the section Configuring Server Variables for the Custom Help.

For more information about defining tooltips for the custom and protected properties that are displayed in the **Attributes** section of an object view, see the section Providing Custom Tooltips for Custom and Protected Object Class Properties.

To specify custom help for a custom object view or object cockpit:

1) Go to the **Presentation** tab, expand the **Object Views** explorer node and navigate either to the standard object vie w or object cockpit that you want to define a custom help for.
2) Define the following attributes, as needed.

- **Automated Assistant URL**: Enter the URL or server variable that targets the content to display in the automated help assistant assigned to the object view or object cockpit.

  The size of the automated help assistant, its header color and position in the Alfabet user interface, and the notch in the slide-in toolbar are configured for each configuration object type in the GUI scheme. For more information about defining GUI schemes, see the section Configuring GUI Scheme Definitions for the Alfabet Interface. For details about the individual GUI scheme attributes that are relevant for the automated help assistant, see the section *Overview of GUI Scheme Attributes* in the reference manual *Configuring Alfabet with Alfabet Expand - Appendix*.

- **Custom Context-Sensitive Help URL**: Enter the URL or server variable that targets the custom context-sensitive help.
- **Standard Context-Sensitive Help Index**: Displays the HTML file that is available as the standard context-sensitive help for the object view.

  The **Standard Context-Sensitive Help Index** attribute can be edited for a custom object view for purposes of backward compatibility. Prior to release 10.1, users specified the location of the external help file using the following syntax: `CUSTOM_HELP:<URL>` (For example: `CUSTOM_HELP:http://helphost/objectview1.html`). The link to the external help file will be displayed in the **Help Selector**. Server variables can be used in the help links. It is recommended that you specify your custom help by means of the **Custom Context-Sensitive Help URL** attribute.

- **Standard Context-Sensitive Help Visible**: Select `True` to display both the standard and custom context-sensitive help file in the **Help Selector** Select `False` if the link to the standard context-sensitive help should not be available and should not be displayed in the **Help Selector**.

3) In the toolbar, click the **Save** button to save your changes.

Managing Custom Object Views in Object View Groups

Custom object views can be assigned to and managed in object view groups. This allows you to structure and organized your enterprise's custom object views according to your enterprise's need. For example, you could organize custom object views according to the user profiles they are assigned to. You can create multiple object view groups, as needed.

To create a new object view group:

1) Go to the **Object Views** folder, click a custom object view that you want to assign to a new object view group. The attribute window is displayed in the right pane.
2) In the **Group** attribute, enter the name of the new object view group and click the Return key. The new object view group is displayed in the below the **Object Views** node. The custom object view has been removed from its position in the object view explorer and is now displayed below the new object view group.
3) In the toolbar, click the **Save** button to save your changes.

Deleting an Object View

Before an object view is deleted, you should check to see if the object view is implemented in other configurations. The custom object view will be irrevocably deleted from the Alfabet database.

To delete a custom object view:

1) Right-click the custom object view and click **Show Usage** and ensure that the object view is not implemented in other critical configuration objects. Click the **Close** button to close the **Objects Usage** editor.
2) Right-click the custom object view that you want to delete and select **Delete**.
3) Confirm the warning by clicking **Yes**. The object view is deleted from the Alfabet database.

Chapter 11: Configuring User Profiles for the User Community

Alfabet Expand enables you to create and configure user profiles that allow the appropriate users in the user community to access the set of functionalities that are relevant to their tasks and responsibilities. For example, a data entry user profile might provide access to such functionalities as **Capture Applications**, **Capture Peripherals**, **Capture Components**, etc., or a strategic planning user profile might provide access to such functionalities as **View As-Is Architecture**, **Plan Target Architecture**, **Manage Master Plans**, etc.

User profiles are the basis of user administration in Alfabet and serve as the entry point when accessing Alfabet. Every user must log in with a user profile that has been assigned to him/her by a user administrator. Therefore, all users accessing Alfabet must be assigned at least one user profile. However, users may possess multiple user profiles in accordance with their responsibilities in the user community and in the enterprise as a whole. A user can switch to another permissible user profile at any point during a user session.

A user profile specifies the Alfabet functionalities available to a user, the visibility and editability of object classes and object class attributes, as well as the availability of associated capabilities including, for example, wizards and workflows.

Each user profile must have one view scheme assigned to it that bundles various class settings. The user profile may have only one class setting defined per object class.

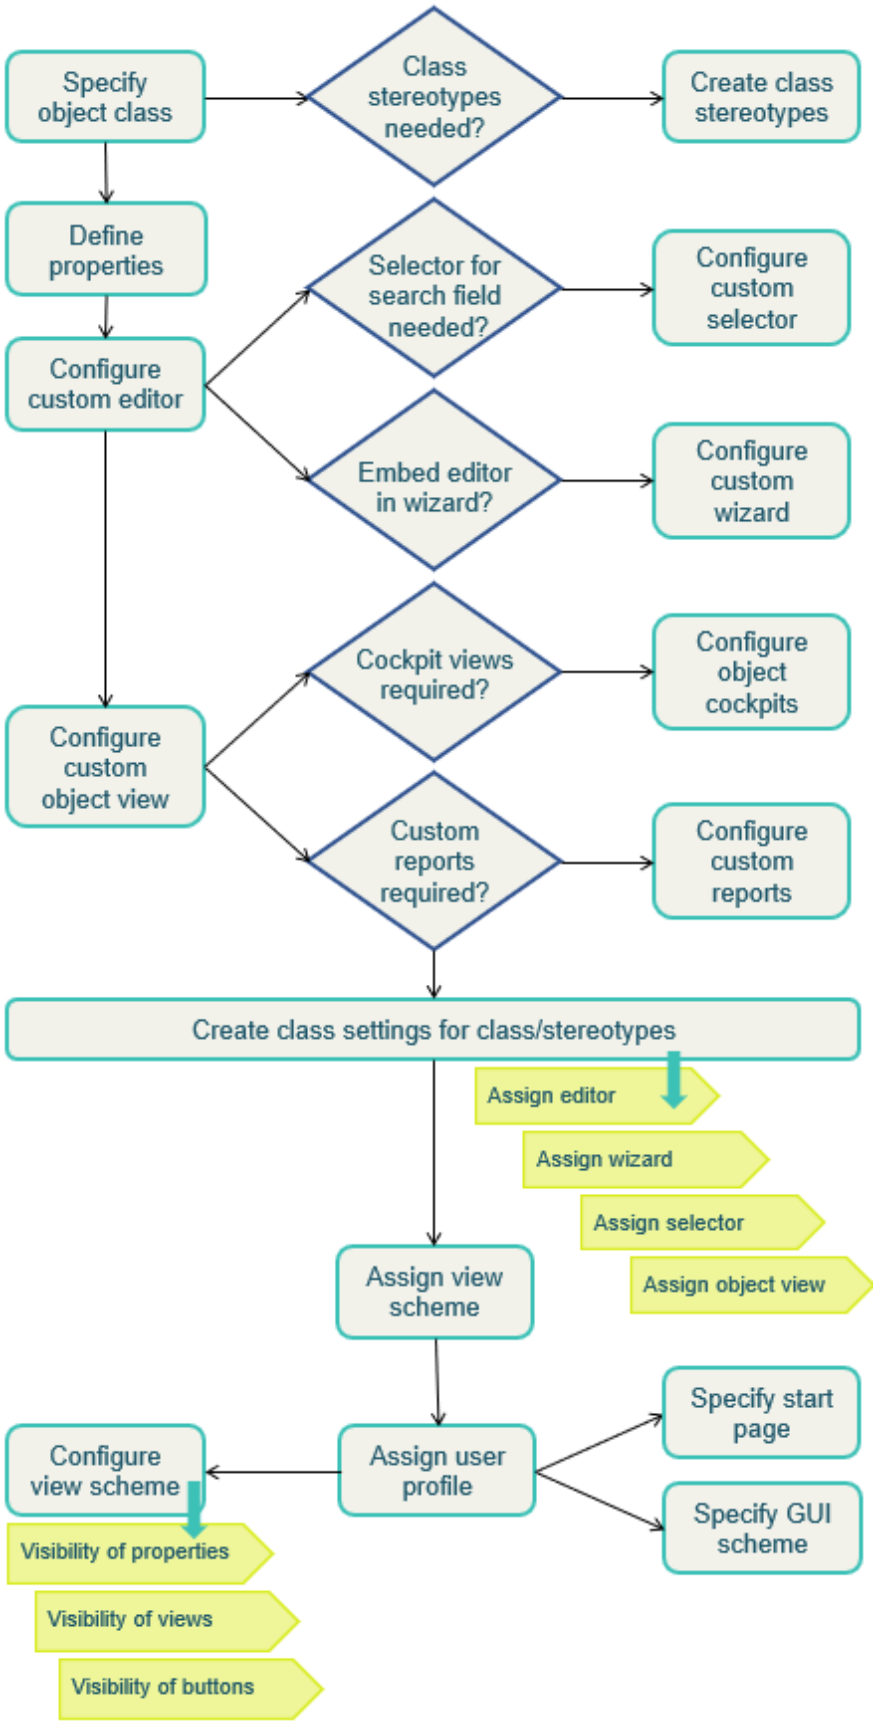

FIGURE: Overview of user profile configuration

Typically, the creation of custom object class properties, custom editors, custom wizards, and custom object views should be complete before beginning the task of configuring class settings for the view scheme that will be assigned to the user profile. The configuration of class settings and their assignment to view schemes are an essential part of the configuration of the user profile. Either a standard class setting or a custom class setting must be available for each object class that users will work with via the user profile. Once custom object class properties, custom editors, custom wizards, and custom object views have been configured, you can begin the following steps which constitute the actual task of user profile configuration.

- Configure class settings for all object classes relevant to the user profile.

A class setting is a specification about an object class or object class stereotype. A class setting is associated with a view scheme which is assigned to a user profile. The class setting therefore specifies what the user can see and do with an object class in the context of the user profile that he/she uses to access Alfabet. The class setting includes such information as which standard or custom object view is displayed, whether users will enter data in a standard or custom editor vs. a standard or custom wizard, whether a standard or custom selector will be used to find objects in the object class, and which standard and custom object class properties will be hidden from view.

Multiple settings can be defined for an object class. However, only one class setting per object class can be assigned to a view scheme so that only one class setting will be available for an object class in a given user profile. Please keep the following in mind when conceptualizing the object views, class settings, and view schemes that you plan to implement in the user profiles you configure for your user community:

- Multiple custom object views can be defined for an object class, but only one object view can be assigned to a class setting.
- Multiple class settings can be defined for an object class, but only one class setting can be assigned per object class to a view scheme.
- Only one view scheme can be assigned to a user profile.

- Assign the relevant class settings to a view scheme and specify the visibility of data and functionality for the view scheme.

A view scheme is associated with a user profile and groups a set of class settings that describe the visibility of objects in the associated object classes. Only one class setting per object class may be assigned to a view scheme.

The view scheme also contains the definition about the functionalities available in the object views accessible via the view scheme. For each standard and configured object view available to the view scheme, workspaces, page views, and toolbar buttons that allow object data to be created, edited, and deleted, for example, can be hidden.

The view scheme thus determines the object classes that are visible to the user. Once a standard class setting or custom class setting has been specified for each relevant object class, the class settings must be assigned to a view scheme.

- Assign the view scheme to a user profile and define access to functionalities via a Alfabet menu bar or navigation pages.

In addition to the configuration of the class settings and the assignment of a view scheme to a user profile, the solution designer must also specify whether the user profile allows Read/Write or ReadOnly permissions. Finally, the means that users use to access the Alfabet functionalities once they log in with the user

profile must be configured. The solution designer can choose to define access to the functionalities via guide pages with hyperlinks or via drop-down menu items displayed in the top toolbar.

User profiles are typically created by a user administrator in the Alfabet interface via the **User Profiles Administration** functionality that can be accessed via the `Admin` user profile or by a solution designer in Alfabet Expand. Users can then be assigned to a user profile in the Alfabet interface via either the **Users Administration** functionality or **User Profiles Administration** functionality that can be accessed via the `Admin` user profile. For more information, see the sections *Assigning User Profiles to a Selected User* or *Assigning Users to a User Profile* in the reference manual *User and Solution Administration*.

- Refine visibility issues for the user profile

For each object profile available in the user profile, the solution designer can further refine the visibility of object class properties and availability of functionality in various parts of the interface. Thus, data and functionality that would be inappropriate for the users assigned to the user profile can be hidden from view. The following can be specified for a view scheme assigned to a user profile:

- Visibility of standard and custom object class properties in standard editors, custom editors, and custom wizards
- Visibility of object class properties (in the **Attributes** section), page views and configured reports in standard and custom object views
- Visibility of standard and custom object class properties in page views and configured reports
- Functionality available via toolbar buttons in object views, object cockpits, page views, and configured reports (for example, create, copy, edit, navigate, etc).

The following information is available:

- Creating User Profiles for the User Community
- Making Functionalities Accessible to a User Profile
- Defining Access to the Functionalities via a Guide Page
- Defining Access to the Functionalities via the Menu Bar
- Specifying the Type of Device That the User Profile Will Access
- Configuring Class Settings for Object Classes and Object Class Stereotypes
- Conceptualizing a Class Setting
- About the Templates Available for Class Settings
- Creating a Custom Class Setting for a Protected Object Class or Object Class Stereotype
- Creating a Class Setting for a Custom Object Class
- Configuring a View Scheme for a User Profile
- Regulating Access Permissions via Class Settings
- Creating a View Scheme and Assigning Class Settings
- Assigning the View Scheme to a User Profile

Creating User Profiles for the User Community

User profiles are the basis of user administration in Alfabet and serve as the entry point when accessing Alfabet. Every user must log in with a user profile that has been assigned to him/her by a user administrator. Therefore, all users accessing Alfabet must be assigned at least one user profile. However, users may possess multiple user profiles in accordance with their responsibilities in the user community and in the enterprise as a whole. A user can switch to another permissible user profile at any point during a user session.

A user profile specifies the Alfabet functionalities available to a user, the visibility and editability of object classes and object class attributes, as well as the availability of associated capabilities including, for example, wizards and workflows.

Each user profile must have one view scheme assigned to it that bundles various class settings. The user profile may have only one class setting defined per object class.

User profiles are typically created by a user administrator in your enterprise. A user profile can have multiple functionalities assigned to it and a functionality can be assigned to multiple user profiles.

The **User Profiles** node in the **Admin** tab in Alfabet Expand allows you to view and edit all existing user profiles as well as create new user profiles. For more information about configuring the attributes relevant for the self-administration capability for a user profile, see the section Configuring User Profile Request or Assignment for the User Community

Please note that user profiles can also be created in the **User Profiles Administration** functionality in Alfabet that can be accessed via the `Admin` user profile. Consider the following:

- If your enterprise is working with an external repository (for example, LDAP), the external ID can be captured for user profiles via the alternative editor `UserProfileWithExternalID_Editor`. This editor should be specified in the **Edit View** attribute for a custom class setting for the class `ALFA_USERPROFILE`.
- Users are assigned to a user profile in the **User Profiles Administration** functionality accessible via the `Admin` user profile. For more information, see the section *Assigning Users to a User Profile* in the reference manual *User and Solution Administration*. Users are created in the **Users Administration** functionality accessible via the `Admin` user profile. For more information, see the section *Defining and Managing Users* in the reference manual *User and Solution Administration*.

To create a user profile:

1) Go to the **Admin** tab, right-click the **User Profiles** node and select **New User Profile**. A new user profile  is displayed in the explorer.
2) In the attribute window, define the following attributes:

- **Name**: Enter a caption for the user profile. This is the name of the user profile that users will see when logging in to Alfabet.

  The names of user profiles will be available in the `METAMODEL` vocabulary and can be translated in the context of the vocabularies. The translated user profile name will be displayed in the masthead of the Alfabet user interface as well as in the **Change User Profile** menu in the <Alfabet User Name> menu in the main toolbar. Please note however that the translation of the user profile name will not be displayed in the **User Profiles Administration** and **User Administration** functionalities in the Alfabet user interface as well as the **User Profiles** node in Alfabet Expand. For more information about translating strings in the vocabularies, see the section Modifying, Translating and Managing the Vocabularies in the reference manual *Configuring Alfabet with Alfabet Expand*.

- **Type**: If the user profile should have editing permissions, select `Read/Write`. If the user profile should only have viewing permissions, select `ReadOnly`.
- **Device Type**: Specify which type of device may be accessed by the user profile. Select `Browser` to indicate that Alfabet may only be accessed by the user profile in a Web-based browser, `App` to indicate that Alfabet may only be accessed by the user profile in the Alfabet Mobile Portfolio Manager which is available for mobile devices or `Unspecified` to indicate that Alfabet may be accessed by the user profile in both a Web-based browser an the Alfabet Mobile Portfolio Manager. Please note that if the user profile will be accessed Alfabet on mobile devices, it is recommended that the visual layout of the object cockpits, guide pages/guide views, etc. is optimized for mobile devices.
- **GUI Scheme**: The drop-down menu displays all GUI schemes configured by your enterprise. Select the GUI scheme that should be used to visualize the Alfabet interface. The configuration of GUI schemes is described in the section Configuring GUI Scheme Definitions for the Alfabet Interface in the chapter Configuring the Visualization of the Alfabet Interface. For more information about configuring user profiles for barrier-free accessibility, see the section Configuring Barrier-Free User Profiles.
- **Guide Page**: Select an existing guide page or guide view from the drop-down list to assign it to the user profile. A guide page/guide view is the start page that is displayed when Alfabet is accessed with the user profile. The guide page/guide view contains links to Alfabet functionalities, thus defining the scope of access to functionalities for the user logged in with the user profile. Guide pages and guide views are configured with the tool Guide Pages Designer and must be uploaded to the Alfabet database

in order to be available in the drop-down list in the **User Profile** editor. For more information about how to create, edit, and upload guide pages and guide views, see the reference manual *Designing Guide Pages for Alfabet*. For more information about whether to assign a guide page/guide view to the user profile or whether to configure access via menus, see the section Making Functionalities Accessible to a User Profile.

- **Enable Feedback Bot**: Select `True` if the user profile may access the Feedback Bot configured for your enterprise. The Feedback Bot allows users to provide feedback for a view, configured report, object cockpit, guide view, etc. For more information about the configuration of the Feedback Bot, see the section Configuring the Feedback Bot.
- **Enable Feedback for View**: Select `True` to activate the **Feedback for Current View** capability. This is relevant for user profiles responsible for reviewing and responding to feedback provided via the Feedback Bot.

Feedback that has been provided for a view or report via the Feedback Bot can be displayed in the Alfabet user interface in a seconday view for those users responsible for reviewing and responding to the feedback. This allows the responsible users to navigate the Alfabet user interface and see the feedback for the relevant view where they currently are. A secondary view with the caption **Feedback for Current View** will be displayed with a link if feedback has been provided for the view, configured report, object cockpit, guide view, etc. Clicking the link will open the *Feedback Review Functionality* in a new browser tab which displays all feedback in detail for the view. To implement the **Feedback for Current View** capability, the **Enable Feedback for View** checkbox must be selected in the **User Profile** editor for the relevant user profile and the **Enable Check Feedback for View** checkbox must be selected for the relevant user in the **User Settings** editor.

- **Enable User Self-Administration**: Select `True` if all named users can assign a permissible user profile to themselves via the **Assign User Profile** option in the < **Alfabet User Name** > menu available in the Alfabet interface. For more information about configuration the user self-administration, see the section Configuring User Profile Request or Assignment for the User Community. Please note that the **Workflow Template** attribute is also only relevant for the self-administration capability.
- **Is Administrative User Profile**: Select `True` if the user profile is an administrative user profile. An administrative user profile has access to all objects, document folders, configured reports and standard views including those specified as administrative. If the checkmark is not set, users will only have access to object and document folders for which they have access permissions and will not have access to any standard views or configured reports that are specified to be administrative. The **Is Administrative User Profile** attribute will be set to `False` by default for all user profiles except the administrative user profiles.

Business functions that are relevant for an administrative user profile must be explicitly added to the user profile. For an overview of all views that are specified as administrative views, see the section *Standard Views Accessible via Administrative User Profiles* in the reference manual *Configuring Alfabet with Alfabet Expand - Appendix*.

Please note that for any standard or custom business functions assigned to an administrative user profile, the **Restrict to Administrative User Profiles** must be set to `True` for a standard business function or custom explorer if only users with an administrative user profile may access the business function. For more information about configuring standard business functions and custom explorers, see the chapter Configuring Standard Business Functions and Custom Explorers.

It is recommended that express views are not sent via administrative user profiles. Per default, the XML attribute `EnableExpressViewForAdminProfiles` in the XML object ***SolutionOptions*** is set to "false" and therefore express views will not be sent via user profiles for which the **Is Administrative User Profile** attribute is set to `True`.

If your enterprise wants express views to be sent via administrative user profiles, the XML attribute `EnableExpressViewForAdminProfiles` must be set to "true".

- **Use for Anonymous Users**: If the user profile should be used as the default user profile that persons defined as anonymous users should use to access Alfabet with, select `True`. You can only select `True` for this attribute if you have defined the value `ReadOnly` for the **Type** attribute.

  

  If you attempt to define a user profile of the type `Read/Write` as the default user profile for anonymous users, the definition will be ignored. If you define more than one user profile as the default user profile for anonymous users, the first user profile in the alphabetical order of user profiles will be used as the default user profile for anonymous users. All other definitions will be ignored.

  Please consider that a user of the type `Anonymous` typically accesses Alfabet infrequently and therefore, will only have `ReadOnly` access. Only one user profile may be defined as the default user profile that anonymous users use to access Alfabet.

  A user of the type `NamedUser` may be assigned to a user profile configured with either Read/Write or ReadOnly access. A named user may be assigned multiple user profiles (including the user profile that is the default for anonymous users). For information about how to define a Alfabet user as a user of the type `NamedUser` or `Anonymous`, see the section *Defining and Managing Users* in the reference manual *User and Solution Administration*.

- **View Scheme**: Click the **Drop-Down**  button to select the relevant view scheme that applies to the user profile when accessed by an external application or via a hyperlink in an email notification. For more information about configuring a view scheme, see the section Configuring a View Scheme for a User Profile.

- **Use WAI-ARIA**: Set to `True` if the WAI ARIA specification should be implemented for barrier-free accessibility. For more information about the configuration of barrier-free user profiles, see the section Configuring Barrier-Free User Profiles.

- **Automated Assistant Enabled**: Set to `True` if the automated assistant capability should be enabled for the user profile. Set to `False` if all assistants available for the user profile shall be disabled. It is recommended that the **Enable Automated Assistant** attribute is set to `False` for user profiles requiring barrier-free accessibility as well as administrative user profiles or super users providing help desk services, for example. For more information about configuring the automated assistant capability, see the chapter Providing Custom Online Help to the User Community.

- **Automated Assistant URL**: Enter the URL or server variable that targets the content to display in the assistant assigned to the user profile.

- **Custom Context-Sensitive Help URL**: Enter the URL or server variable that targets the custom context-sensitive help for the user profile. For more information about configuring custom context-sensitive help, see the chapter Providing Custom Online Help to the User Community.

- **Standard Context-Sensitive Help Index**: Displays the HTML file that is available as the standard context-sensitive help for this user profile. A standard context-sensitive help is only available for administrative user profiles. The standard online help provides information about the user

administration and solution administration functionalities available that can be accessed in the Alfabet user interface via administrative user profiles.

- **Standard Context-Sensitive Help Visible**: Select `True` to display both the standard and custom context-sensitive help file in the **Help Selector** Select `False` if the link to the standard context-sensitive help should not be available to the user profile and should not be displayed in the **Help Selector**.
- **Workflow Activities Explorer**: The configuration of guide views and guide pages may contain a hyperlinked text or button displaying the number of workflow steps that the user is responsible for and that when clicked opens the **Workflow Activities Explorer**. Instead of displaying the default **Workflow Activities Explorer**, a custom explorer can be configured to open instead. Select the custom explorer that should be opened in the context of the guide view/guide page configuration for the selected user profile. For more information about configuring the hyperlinked text or button displaying the number of workflow steps that the user is responsible for in guide views/guide pages, see the section *Adding Workflow, Assignment, Collaboration, and Microsoft Teams Meeting Links to the Guide View* in the reference manual *Designing Guide Pages for Alfabet*. For more information about configuring custom explorers, see the chapter Configuring Standard Business Functions and Custom Explorers.

3) In the toolbar, click the **Save** button to save your changes.

Making Functionalities Accessible to a User Profile

Once a user profile has been created, you must configure a means for users to open the Alfabet functionalities with the user profile that they are logging on with. You can either configure a navigation page providing hyperlinks to the functionalities with optional text describing the functionalities, or you can configure a top menu bar containing drop-down menus that allow users to select the functionality they want to open.

Please be aware that the `Admin` user profile as well as any other user profile specified to be an administrative user profile grant Read/Write permissions to all objects accessed via the user profile. Therefore, users with an administrative user profile should typically be able to access those functionalities that provide them with access to the objects that they may need to edit. Typically, this includes the user administration functionalities, solution configuration functionalities, and search functionalities. Business functions that are relevant for an administrative user profile must be explicitly added to the user profile.

Please note that for any standard or custom business functions assigned to an administrative user profile, the **Restrict to Administrative User Profiles** must be set to `True` for a standard business function or custom explorer if only users with an administrative user profile may access the business function. For more information about configuring standard business functions and custom explorers, see the chapter Configuring Standard Business Functions and Custom Explorers.

There are a number of functionalities that must be configured before they can be implemented in the Alfabet software. The following functionalities require configuration before implementation:

- For more information regarding the business function `ComplianceConfiguration` and `ComplianceInstances`, and `Home_ComplianceObjects`, see Configuring the Compliance Management Capability

- For more information regarding the business function `PRJ_Management`, see the section Configuring the Project Management Capability.
- For more information regarding the business function `VM_StrategyDeduction`, see the section Configuring the Strategy Deduction Capability.
- For more information regarding the business functions `InitiateWorkflow`, `WF_Activites`, `WF_Administration`, and `Workflows`, see the section Configuring Workflows.
- For information regarding the configuration of the following data capture functionalities, see the section Configuring Standard Data Capture Environments.

  - `APP_CaptureApplication`
  - `APP_UserApplications`
  - `COM_CaptureComponents`
  - `COM_UserComponents`
  - `DEM_CaptureDemands`
  - `DVC_CaptureDevices`
  - `DVC_UserDevices`
  - `ICTO_CaptureICTObjects`
  - `ICTO_UserICTObjects`
  - `ITMPM_CaptureMaps`
  - `PRF_CapturePeripherals`
  - `PRF_UserPeripherals`
  - `PRJ_CaptureProjects`
  - `PRJ_SubProjects`

The following information is available:

- Defining Access to the Functionalities via a Guide Page
- Defining Access to the Functionalities via the Menu Bar
- Specifying the Type of Device That the User Profile Will Access

Defining Access to the Functionalities via a Guide Page

A guide page serves as the start page for a user profile. A guide page is a customized HTML file with hyperlinks that provide users access to the software and support them in their work. A guide page could include, for example, informational text or images about enterprise-specific workflows in the Alfabet solution, links to specific functionalities in Alfabet, URL links to internal documents or the Web, or hyperlinks to other guide pages.

Software AG provides a standard set of HTML-based guide pages with the standard Alfabet product that serve as an example of how guide pages can be configured. You can access the sample guide pages using the `FullAccess` user profile.

The configuration of guide pages is carried out in the tool Guide Pages Designer. For detailed information about how to configure guide pages for the user profiles in your user community, see the reference manual *Designing Guide Pages for Alfabet*.

You must assign a guide page to a user profile to display it in the Alfabet interface.

To assign the guide pages to a user profile:

1) Go to the **Admin** tab, expand the **User Profiles** explorer node and click the user profile that you want to assign a guide page to.

2) In the **Guide Page** attribute, click the arrow to select the guide page in your guide page project. The guide page names will be listed in the drop-down list without the file extension.

Please note that if you specify that the user profile is to be used in mobile devices, (**Device Type** = `App`), it is recommended that the visual layout of the selected guide page is associated with a user profile should be optimized for such mobile devices.

3) In the toolbar, click the **Save** button to save your changes.

Defining Access to the Functionalities via the Menu Bar

To configure access to the functionalities via the menu bar at the top of the Alfabet interface, you can create drop-down menus containing menu items that allow users to select the functionality that they want to work with. Please keep in mind that if a high number of drop-down menus are configured for a user profile and users are working with Alfabet on a small display, it is possible that the captions of the menus may be truncated.

Custom explorers can also be configured for your Alfabet solution. A custom explorer is considered a functionality and can be made accessible to the Alfabet interface via the menu bar or a guide page. The following information assumes that any necessary custom explorers have already been configured. For more information, see the section Configuring Standard Business Functions and Custom Explorers.

Please note that if you create menu items to make functionalities available via the menu bar, the **Guide Page** attribute may not be defined for the user profile. If a guide page is selected in the **Guide Page** attribute, the guide page definition will take precedence and the menu items configured for the user profile will not be applied. For more information about how to assign a guide page to the user profile, see Defining Access to the Functionalities via a Guide Page.

For an overview of the technical names of the business functions, their caption displayed in the solution interface, and any addressable sub-functions, see the chapter *Business Functions and Their Sub-Functionalities* in the reference manual *Configuring Alfabet with Alfabet Expand - Appendix*.

To configure the menu bar to display drop-down menus listing one or more functionalities:

1) Go to the **Admin** tab, expand the **User Profiles** node, right-click the user profile that you want to define and select **Create Menu Item**. A menu item labeled **New Menu Item** will be added below the user profile node. This menu item is the top-level menu item.

The top-level menu item will be displayed as a button in the toolbar. No functionality should be assigned to this menu item. Please note that if you want to provide access to only one functionality, you must still create a top-level menu item with a subordinate menu item to which the functionality is assigned. A top-level menu item cannot provide access to a functionality.

2) Click the new menu item in the explorer to open the attribute window. Define the following attributes, as needed.

3) In the **Caption** attribute, enter the text that should be displayed on the button in the Alfabet menu bar.

The ampersand (&) is not allowed in the caption of a menu item.

4) To add a functionality to the drop-down the menu, right-click the top-level menu item and select **Add Business Function**. In the **Select Business Functions** editor, select one or more functionalities that you want to add to the menu. If your enterprise has configured custom explorers, these will also be displayed in the drop-down menu. Click **OK** to add the functionalities to the selected menu item. The menu items (functionalities) are displayed below the selected top-level menu item .

Keep the following in mind when selecting functionalities in the editor:

- **CTRL + mouse-click** allows you to select one or more functionalities.
- **CTRL + Shift + mouse-click** to select a block of objects

5) Click a menu item (functionality) to further define its attributes:

- **Caption**: Enter the text that should be displayed for the functionality in the Alfabet menu bar. If you do not explicitly define this attribute, the default caption will be displayed for the functionality.
- **Arguments**: If you have selected any of the functionalities listed below, you must specify arguments to define the link target. The syntax for this entry is `ContextArgs=` *<Type of Argument>:<Value of Argument>* (for example: `ContextArgs=Explorer:COMG_Explorer` or `ContextArgs=Class:Application`):
- **Simple Search** functionalities (`GenericSearch`, `Simple_Search`, `Browse`):
  - If the search functionality should be limited to a set of object classes, specify the object class names in a comma-separated format with the argument `ContextArgs=` *<ObjectClassName>*. For example, to search for an object in the object classes `Application`, `Component`, and `ICTObject`, enter the following: `ContextArgs=Class:Application,Component,ICTObject`.
  - If the search functionality should be limited to a set of object classes and object class stereotypes, specify the object class stereotype in the comma-separated list as: *<ObjectClassName>:<ObjectClassStereotypeName>*. For example, to include the application stereotypes `BusinessApplication` and `TechnicalApplication` in the list, enter: `ContextArgs=Class:Application:BusinessApplication,Application:TechnicalApplication,Component,ICTObject`.
- **Capture Projects** functionalities (`PRJ_CaptureProjects` and `PRJ_CaptureProjects_Ex`): If the functionalities should open with the filter preset to a defined project stereotype. You must specify the project stereotype with the entry `ContextArgs=` *<ProjectStereotypeName>*. For example, `ContextArgs=ProjectStep`.
- **Generic Object Viewer** functionality (`GenericObjectViewer`): You must provide information about which object class can be searched via the Edit Search interface control. You must specify the object class name with the entry `ContextArgs=Class:` *<ObjectClassName>*. For example, `ContextArgs=Class:Application`.

- If you set a link to a functionality that includes sub-functionalities (for example, the functionalities **Define Business Standards** (`Business_Standards`) and **Define IT Standards** (`IT_Standards`), you must specify which sub-functionality should be accessed. If no sub-functionality is assessed, the default sub-functionality will be automatically displayed. In the case of the functionalities **Define Business Standards** (`Business_Standards`), this would be `BO_Explorer`. In the case of **Define IT Standards** (`IT_Standards`), this would be `COM_Explorer`. The syntax to specify the sub-functionality is *<Type of Argument>=<Value of Argument>*. For example, for the functionality `CostManagement`, you could specify either `ContextArgs=Explorer:COSTCG_Explorer` or `ContextArgs=GraphicView:COSTC_Overview`: To determine which functionalities have sub-functionalities, see the chapter *Business Functions and Their Sub-Functionalities* in the reference manual *Configuring Alfabet with Alfabet Expand - Appendix*.

6) In the toolbar, click the **Save** button to save your changes to the menu item.

7) Click the top-level menu item to define the sequence of the functionalities in the drop-down menu. In the **Sub-Items** attribute, click the **Browse** button. In the editor, click the **Up/Down** arrows to sequence the functionalities in the drop-down menu. The top of the list represents at the top of the drop-down menu. Click **OK** to close the editor and save the sequence of the menu items.

8) In the toolbar, click the **Save** button to save your changes.

9) Repeat this procedure to add all top-level menu items and their respective functionalities that should be accessible to the selected user profile.

10) Click the user profile to define the sequence of the top-level menu items in the drop-down menu. In the **Sub-Items** attribute, click the **Browse** button. In the editor, click the **Up/Down** arrows to sequence the top-level menu items. The top of the list represents the menu items furthest to the left on the menu bar. Click **OK** to close the editor and save the sequence of the menu items.

11) In the toolbar, click the **Save** button to save your changes.

Specifying the Type of Device That the User Profile Will Access

When defining the user profile, you can specify whether the user profile should be used to access Alfabet in a Web-based browser or in the Alfabet Mobile Portfolio Manager, which is available for mobile devices. Please note that if you the user profile will be used to view Alfabet on mobile devices, it is recommended that the visual layout of the object cockpits, guide pages, etc. associated with a user profile should be optimized for such mobile devices.

To specify which type of device may be accessed by the user profile, define the **Device Type** attribute available in the attribute window for the user profile. Select `Browser` to indicate that Alfabet may only be accessed by the user profile in a Web-based browser, `App` to indicate that Alfabet may only be accessed by the user profile in the Alfabet Mobile Portfolio Manager, or `Unspecified` to indicate that Alfabet may be accessed by the user profile in both a Web-based browser and the Alfabet Mobile Portfolio Manager.

Configuring Class Settings for Object Classes and Object Class Stereotypes

A class setting is a specification about an object class or object class stereotype. A class setting is associated with a view scheme which is assigned to a user profile. The class setting therefore specifies what the user can see and do with an object class in the context of the user profile that he/she uses to access Alfabet. The class setting includes such information as which standard or custom object view is displayed, whether users will enter data in a standard or custom editor vs. a standard or custom wizard, whether a standard or custom selector will be used to find objects in the object class, and which standard and custom object class properties will be hidden from view.

Multiple settings can be defined for an object class. However, only one class setting per object class can be assigned to a view scheme so that only one class setting will be available for an object class in a given user profile.

You must configure a custom class setting for a custom object class, protected object class, or object class stereotype if any of the following is required for the respective user profile:

- custom object view
- custom editor
- custom wizard
- exclusion of standard object class properties
- object class stereotypes
- custom icon for object class

Please note that the object class stereotypes, custom editor, custom wizard, and custom object view must be configured before you can define the class setting. The following information is available:

- Conceptualizing a Class Setting
- About the Templates Available for Class Settings
- Creating a Custom Class Setting for a Protected Object Class or Object Class Stereotype
- Creating a Class Setting for a Custom Object Class

Conceptualizing a Class Setting

Class settings determine technical information about an object class or object class stereotype (such as the object view, wizard, editor, and preview properties to display) as well as your specific class setting configuration. A class setting must be created for a set of configuration objects available to a user profile.

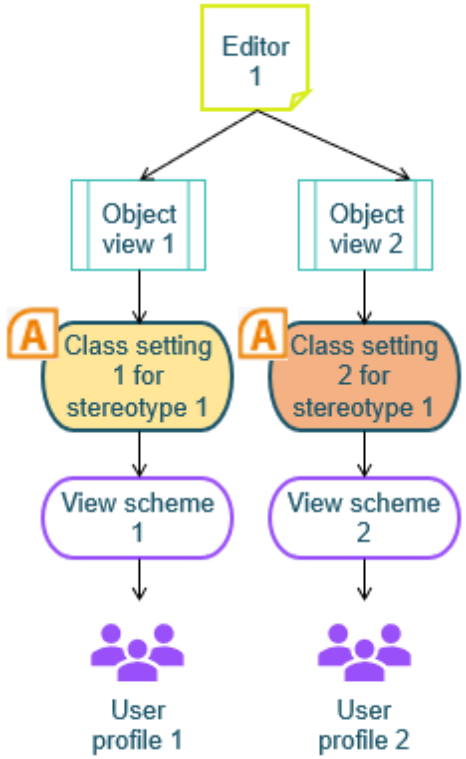

FIGURE: Example configuration for a stereotype for the class Application

Please keep the following in mind when conceptualizing the object views, class settings, and view schemes that you plan to implement in the user profiles you configure for your user community:

- Multiple custom object views can be defined for an object class, but only one object view can be assigned to a class setting.
- Multiple class settings can be defined for an object class, but only one class setting can be assigned per object class to a view scheme.
- Only one view scheme can be assigned to a user profile.

Typically, a class setting should be defined for each wizard available for an object class, since each wizard is usually accessed in a different user context (via a view scheme assigned to a user profile).

This does not apply to wizards that have been defined for the workflow capability. Wizards defined for workflows are not assigned to a class setting but rather are assigned to a workflow template. For details about defining a workflow, see Configuring Workflows.

The issues that you can specify in a class setting for an object class are:

- Which object profile should be displayed for the object class. Should the standard object view be used or has a custom object view been configured? (Standard object views are typically implemented for object classes such as `Person` or `UserGroup`, for example.)
- Should configured object cockpits should be displayed for the object class? If object cockpits have been configured, should the object profile be hidden?
- Which wizard, if any, should be associated with the class setting?

- Which custom editor, if any, should be associated with the class setting?
- Which properties should be displayed in the preview available for objects in the object class?
- Should this class setting be the default class setting for the object class? Alfabet Expand provides a default class setting for every protected object class in the meta-model so you are not required to define a class setting for every object class. If you do not explicitly define this class setting as the default (**Default** = `True`), the default class setting template provided by Software AG will be used.
- Which protected object class properties and custom object class properties should be hidden from the Alfabet interface for this class setting?
- Should this object class be searchable?
- Should a custom icon be displayed in explorers for this object class? Should custom foreground and background colors be displayed?
- Should objects of this object class be displayed in the Alfabet views available to display new and changed objects or recently used objects? (These views are: `New_Objects`, `Recent_Objects`, and `New_Recent_Objects` which displays a view with a table for new objects and a table for recent objects. These views must be explicitly assigned to the relevant user profile.)
- Should an **Add Misssing <ObjectClass>** button be added to the standard or custom object selectors specified in the **Selector Definition** attribute allowing an object of the object class/object class stereotype to be created if it is not in the inventory?

You can define multiple class settings for each class. Each class setting should have a unique name. Only one class setting can be assigned per object class to a view scheme.

Before a class setting is deleted, you should check to see if the class setting is implemented in other configuration objects such as view schemes or workflow templates. To do so, right-click the class setting and click **Show Usage**. A window will be displayed showing the configuration objects using the selected class setting. For more information regarding the **Show Usage** functionality, see the section Reviewing the Usage of a User Profile.

Alfabet provides an **Archive Manager** functionality that allows objects to be archived. The **Archive Object** symbol displayed in the table below indicates that the page view may potentially be archived for the object class. The set of information that is archived for an object class is determined by the class setting configured for the user profile of the user archiving the object. The **Archive Manager** functionality is only accessible to users accessing Alfabet with an administrative user profile. For more information about the **Archive Manager** functionality, see the section *Deleting and Archiving Alfabet Objects* in the reference manual *User and Solution Administration*.

About the Templates Available for Class Settings

Alfabet Expand has a number of class setting templates that should be used when configuring the class settings for your enterprise. The **Class Settings** folder is available in the **Presentation** tab and contains sub-folders for all Alfabet object classes that are potentially available to users in the Alfabet interface. For each object class, one or more class settings may be available that can be copied in order to define class settings specific to the needs of your enterprise. In each object class folder, you may see one or all of the following class setting templates.

- <ObjectClass>_Standard: This standard template will be used for most class setting definitions. This template is available for all object classes available in the **Class Settings** node. It contains the basic information for the respective class setting including, for example, the assigned object view, search properties, and selector definition. This template also allows you to configure visibility in the custom wizards that you have created for your enterprise. Standard class settings cannot be deleted.

  

  If a class setting is not explicitly assigned to a view scheme, then the standard template <ObjectClass>_Standard will be assigned per default tot he view scheme.

- <ObjectClass>_Example: This template is available for object classes for which standard custom editors and standard wizards have been configured by Software AG. These classes include: Application, Component, Demand, Device, ICTObject, ITMasterPlanMap, Peripheral, StandardPlatform. You should use this template when you want to define the visibility for the standard Alfabet wizards provided for the above classes.

  

  Software AG provides a number of data maintenance functionalities that are driven by wizards. The wizards implemented in the **Capture** <ObjectClass> functionalities are determined by the wizard definition for the respective class setting assigned to a view scheme. These data maintenance functionalities include **Capture ICT Objects**, **Capture Applications**, **Capture Components**, **Capture Devices**, **Capture Peripherals**, **Capture Demands**, and **Capture Master Plan Maps**. For more information about configuring these functionalities, see the section Configuring Standard Data Capture Environments.

- <ObjectClass>_RM: This template is available for object classes relevant to the **Release Management** functionality. These object classes include Application, Component, and StandardPlatform. You should use this template if you want to define class settings for the above classes in the context of the **Release Management** functionalities.

- <ObjectClass>_ReadOnly: This template is available for a specific set of object classes for which a ReadOnly view is required to control accessibility. These classes include, for example, CostCenterType, CostType, EvaluationType, IncomeType, IndicatorType, IndicatorTypeComputationRule, INDLUT_ReadOnly, Portfolio, Person, RISKTMPL_ReadOnly, RISKSET_ReadOnly, RISKCLS_ReadOnly, RoleType, Skill, UserGroup. These classes are typically used to configure or administrate your Alfabet solution. Therefore, it is recommended that the <ObjectClass>_ReadOnly class setting should be used for user profiles that have no configuration or administration responsibilities.

  

  In addition to the class setting templates USER_ReadOnly and USER_Standard*, the class Person also has a class setting template USER_LimitedEditability which allows users to edit custom object class properties only.

  If the editability of user information should be limited, then you must explicitly define either the USER_ReadOnly class setting or USER_LimitedEditability class setting. Otherwise, the default template USER_Standard* will apply. The USER_Standard* class setting grants all users with accessibility to an object in the relevant object class to edit all user information.

  If your enterprise is working with an external repository (for example, LDAP), the external ID can be captured for user profiles via the alternative editor UserProfileWithExternalID_Editor. This editor should be specified in the **Edit View** attribute for a custom class setting for the class ALFA_USERPROFILE.

Creating a Custom Class Setting for a Protected Object Class or Object Class Stereotype

You can create multiple class settings for an object class or object class stereotype.

The following information describes the configuration of class settings for general use in Alfabet. The attributes **Allow Read via Rest API**, **Allow Write via Rest API**, and **Allow Update from External Reference Data Service** are for special import functionalities and are not explained in this section. They are described in the context of the import functionalities in the section Importing Objects of Configuration Relevant Object Classes from a Master Database in this reference manual and in the reference manual *Alfabet RESTful API*.

To create a custom class setting:

1) Go to the **Presentation** tab and expand the **Class Settings** node.
2) In the **Class Settings** folder, navigate to the folder for the object class that you want to define class settings for and right-click the public or private class setting template  that you want to copy. Select either:

- **New Class Settings as Copy** to create a new class setting for the selected object class. A copy of the class settings template is added to the class setting folder.
- **New Class Settings for Stereotype as Copy** to create a class setting for an object class stereotype. In the dialog that opens, select the object class stereotype and click **OK**. A new class setting folder will be created for the object class stereotype which will contain the new class setting for the object class stereotype. The naming convention of the class setting folder and class setting is: <ObjectClass:ObjectClassStereotype>. The class setting for the object class stereotype can be configured in the same manner as class settings for conventional object classes. Additional class settings can be created for the object class stereotype via the **New Class Settings as Copy** functionality.

For additional details about defining a class setting for an object class stereotype based on the class `Project`, see the section Configuring the Project Management Capability.

3) All attributes specified for the class setting that you copied will also be copied to the new class setting. These attributes can be edited, as needed. Click the new class setting template to open the attribute window and enter a technical name for the class setting in the **Name** attribute.

It is recommended that the name of the class setting indicates the view scheme that it is being defined for and the name of the view scheme indicates the user profile it is assigned to. In other words, the name of the class setting should thus indicate the user profile that it is associated with.

A validation mechanism checks for correct syntax when defining a technical name. For a list of the special characters that are not allowed, see the section Defining Attributes for Configuration Objects in the chapter Getting Started with Alfabet Expand.

4) Define the following attributes, as needed:

- **Default**: Set to `True` if this class setting should be the default class setting for this object class. Set to `False` if this class setting should not be the default class setting for this object class. If no value is defined, the class setting template `<ObjectClass>_Standard*` provided by Software AG will automatically be used as the default.

- **Searchable**: If the object class should be searchable in the Alfabet search functionalities, select `True`. Select `False` if the object class should not be searchable in the Alfabet search functionalities.

  Please note the following regarding the implementation of searchability in class settings:

  - Not all object classes are searchable. For an overview of the object classes that are searchable per default in the standard Alfabet search functionality, see the chapter *Overview of Configurable Features for Object Classes* in the reference manual *Configuring Alfabet with Alfabet Expand - Appendix*.
  - If object class stereotypes have been defined for the object class, you can specify searchability on the level of the object class and/or object class stereotype:
    - If an object class stereotype is to be searchable, set the **Searchable** attribute to `True` for each relevant class setting for the object class stereotype. The object class stereotype will be displayed in the **Search for** filter in the search functionality.
    - If the entire class is to be searchable irrespective of the object class stereotype, set the **Searchable** attribute to `True`. The name of the object class will be displayed in the **Search for** filter in the search functionality.
  - If you set the **Searchable** attribute to `True`, you can implement a custom selector for the selected object class in the *Simple Search Functionality* (`GenericSearch`, `Simple_Search`). To implement a custom selector, select a custom selector that is relevant for the object class. All custom selectors that have been configured for your solution will be displayed. You must ensure that you select a custom selector that is meaningful for the view and defined for the relevant object class. For more information about configuring custom selectors, see the section Configuring a Custom Selector for Search Functionalities.
  - If you set the **Searchable** attribute to `True`, you can define and sequence the object class properties that should be used to sort the objects in this object class when found via search functionalities. In the **Sort Properties** attribute, select the object class properties in the list to use to order the object class properties and determine their sequence by using the **Up/Down** buttons.

- **Selector Definition**: Specify a custom selector to replace the standard selector for the object class. Custom selectors assigned to a class setting will globally replace the standard selector in all cases where the selector is implemented except in cases where a hard-coded selector is required or a custom selector is explicitly specified in the **Customization Editor** used when configuring the associated user profile. For more information, see the section Hiding Functionalities in an Object View.

  Please note that new objects may be created in the context of class-based standard and custom object selectors with a minimal amount of navigation required. When ad-hoc adding of new objects is enabled, the **Add Missing <Class.Caption>** button will be available in the selector and uses can create objects needed to define a reference in the context of the selector. When the user clicks the **Add Missing <Class.Caption>** button, the configured functionality/explorer, configured report, or standard view in which the user can create the new object will open in a separate browser tab. Once the missing object has been created, the user can return to the original browser tab with the object selector and search in the selector for the new

object. If the **Add Missing <Class.Caption>** button shall be available in the standard object selector or the custom selector specified in the **Selector Definition** attribute, you must enable the button by specifing the view that shall open to add the missing objects. This must be specfied in the **View for Missing Object Button** available in the **Views** section of the attribute window as described below.

- **Object View**: Select the standard or custom object view that should be displayed for this class setting. Please keep the following in mind regarding the object view setting:
- An object view can be reused for multiple class settings.
- If you select a custom object view, all object cockpits configured for a custom object view will also be included. However, you can hide the object cockpits that you consider to not be relevant for the users that will be working with this class setting. Further visibility issues can also be refined for a custom object view in the context of the view scheme it is assigned to. For example, you can hide functionalities and aspects of the object profile. For more information, see the section Hiding Functionalities in an Object View.
- Set the **Suppress Object Profile** attribute to `True` if you want only the configured object cockpits to be displayed and the standard or custom object profile to be hidden from the user interface.
- The **Graphic View** attribute allows a single page view to be displayed rather than an object view in the Alfabet interface. This attribute is typically used for diagram page views that can only be accessed via another page view (for example, `ApplicationDiagramStatusLink`). This attribute is configured in some private class settings available in the standard Alfabet product. It is highly recommended that the **Graphic View** attribute is not configured for custom class settings. Please note that if the **Object View** attribute is defined for the class setting, it will override the **Graphic View** definition and the selected object view will be displayed.
- **Prevent In-Line Editing in Object Views**: Specify whether in-line editing is permissible in the object view specified in the **Object View** field. Specify `True` if in-line editing shall be prevented in the object view assigned to the class setting. Select `False` if in-line editing shall be allowed in the object view assigned to the class setting If no value is selected, in-line editing shall be allowed per default (= `False`).

  Please note that the definition of the **Prevent In-Line Editing in Object Views** attribute for a class setting will override the setting of the **Prevent In-Line Editing in Object Views** attribute for the associated GUI scheme. However, the definition of the **Prevent In-Line Editing in Object Views** attribute for an object view will override the setting of the **Prevent In-Line Editing in Object Views** attribute for the associated class setting.

- **Default Editor Type**: Define whether the standard/custom editor or a configured wizard should open when the user clicks the **Edit** button in a relevant page view or object view. If no value is set for the **Default Editor Type** attribute, the specification of the **Default Editor Type** attribute in the default class setting for the object class will be applied. Specify one of the following:
- To implement an editor: Select `SimpleEditor` in the **Default Editor Type** attribute if an editor should be implemented for views in which an object of this object class can be created. Define the following attributes, as needed if you have specified `SimpleEditor`:
  - **Edit View**: If you do not want to display the conventional standard Alfabet editor when users click the **Edit** button, select a different Alfabet editor that should be implemented.

- **Custom Editor**: If you want to implement a custom editor that has been configured for the object class in addition to the Alfabet editor, select the custom editor. If no custom editor is specified, only the standard Alfabet editor will be implemented. If you specify a custom editor in the **Custom Editor** attribute, the class settings will determine the visibility of the custom object class properties that may potentially be displayed in the custom editor. You may only select one custom editor per class setting. For more information about defining a custom editor, see Configuring Custom Editors.

- To implement a configured wizard: Select `Wizard` in the **Default Editor Type** attribute if a configured wizard should be implemented for views in which an object of this object class can be created. Specify which wizard to implement in the **Wizard** attribute. If you specify a wizard in the **Wizard** attribute, the class settings will determine the visibility of the standard and custom object class properties that may potentially be displayed in the wizard. You may only select one wizard per class setting. For more information about defining a custom editor, see Configuring Wizards.

  

  A wizard cannot be implemented for the following views:

  - **Assignments** page view (`ObjectAssignments`)
  - **Check In Inventory** page view (`PRJ_CheckInReport`
  - **To-Be Architecture** page view (`PRJ_NewArchitecture`)
  - **Service Levels** page view (`BMSVC_ServiceLevels`)
  - **Evaluations by Objects** page view (`CMPL_UserEvaluationsByObjects`)
  - **Evaluations by Controls** page view (`CMPL_UserEvaluationsByObjects`)

  

  The configuration of a custom wizard will apply to all instances of the custom wizard in Alfabet. For example, if you hide object class properties or functionalities in a custom wizard, the object class properties or functionalities will be hidden for all instances of the custom wizard. In other words, a selected wizard cannot be differently configured in the context of different object class stereotypes. The wizard configuration will apply to each object class stereotype that the custom wizard is assigned to. If different configurations are required for a custom wizard, it is recommended that you create a new wizard via the copy functionality and modify the new wizard as needed. Once the wizard is configured, it can be selected in the **Wizard** attribute for the class setting that you create for the object class stereotype.

- **Editor Rendering Options**. You must specify the rendering style of the interface controls in the custom editor. Two options are possible and the method you choose will determine how you go about designing the custom editor. You can choose the traditional rendering style, which reflects the explicit layout of all interface controls in the custom editor as designed by the solution designer, or the stack rendering style which automatically positions the visible interface controls in a one- or two-column linear list. Editor rendering may also be specified on the level of a class setting, thus allowing the editors to be differentiated on a class-by-class basis for a user profile. For an overview of configuring the rendering styles of standard and custom editors, see the section Specifying the Rendering Definition of the Custom Editor. Expand the **Editor Rendering Options** section and define the following:

- **Rendering Style**: Select either `Traditional` to display standard and custom editors as the have been explicitly designed or select `Stack` to display standard and custom editors as a one- or two-columnar linear list. If you select `Stack`, define the attributes listed below.
- **Stack Layout Type**: If **Stack** has been selected for the **Rendering Style** attribute: Select `OneColumn` if the captions and interface controls shall be displayed as a single left-aligned column in the editor. Select `TwoColumns` if the captions and interface controls shall be displayed as two left-aligned columns in the editor. Please note that the sequence of the interface controls is determined by the **Tab Index** attribute defined for each interface control.
- **Preserve Layout in Group Boxes**: Select `True` if the position of interface controls in a Group Box interface control should follow a traditional rendering style and not be changed to have a stack rendering style. Select `False` if the interface controls in a Group Box interface control should have a stack rendering style.
- **Show Hint In-Line**: Select `True` if the help texts defined via the **Hint** attribute of the interface controls shall be displayed in the editor below the editor field. The hint icon specified in the **Interface Control Hint Icon** attribute will not be displayed if the **Show Hint In-Line** attribute is set to `True`. Select `False` if the help texts should not be displayed below the editor field.
- **Override GUI Scheme Settings**: Select `True` if the class setting shall override the GUI scheme setting of the editor rendering options. Select `False` if the class setting shall not override the GUI scheme definition of the editor rendering options.
- **View for Missing Object Button**: This attribute allows the **Add Missing <Class.Caption>** button to be available in the standard object selector or the custom selector specified in the **Selector Definition** attribute. The **Add Missing <Class.Caption>** button enables users to create objects needed to define a reference in the context of the selector that has been opened in a page view, search field in an editor/wizard, or a filter field in a view. The caption on the button will specify the caption of the relevant class or object class stereotype that the class setting is specified for. By clicking the **Add Missing <Class.Caption>** button, the specified functionality/explorer, configured report or standard view in which the user can create the new object will open in a separate browser window. Once the missing object has been created, the user can return to the original browser tab displaying the object selector and search in the selector for the new object.

  

  Please note that the **Add Missing <Class.Caption>** button capability is not supported in the Search functionalities (`SRCH_GenericSearchWraper`).

To add the **Add Missing <Class.Caption>** button to the standard selector or custom object selector specified in the **Selector Definition** field, click the **Browse**  button to open the **Select View** editor. Define the following fields as needed:

- In the **View Type** pane, select the relevant radio button to specify whether a functionality/explorer, configured report, or standard view should open in which the new object should be created.
- In the **View** field, select the respective functionality/explorer, configured report, or standard view that should open so that the user can create the new object.
- **Properties in Preview**: Define which standard and custom properties are displayed in the preview window that opens via a click-and-hold action on an object in a tabular dataset or business graphic. To define the preview properties for the class setting, click the **Browse**  button to open the editor. Set a checkmark for all properties that should be displayed in the preview. You can define the order of the object class properties displayed in the preview by using the **Up/Down**  buttons. Please note the following:

- The object class properties are displayed in two columns sequenced from left to right and top to bottom.
- If the **Properties in Preview** attribute is not defined, the `Name`, `Description`, and, if applicable, `Stereotype` properties will be displayed per default.
- Any standard and custom properties of the type `Reference` that are defined in the **Properties in Preview** attribute can be visualized as a link that allows navigation to the object profile/object cockpit of the referenced object. The properties displayed for an object referenced by the standard or custom property will be visualized as defined in the **Image Properties** attribute of the class setting defined for the referenced object class/object class stereotype.

  

  For example, if you include the property `Domain` in the **Properties in Preview** attribute for the class setting for the class `Application`, then the **Image Property** attributes defined for the class setting for the class `Domain` will be displayed for the **Primary Domain** attribute in the preview window for applications.

- **Image Properties**: The image properties are typically used to represent objects in a condensed form in the Alfabet user interface. Image properties may be used, for example, for objects displayed in the preview window, auto-fill function in editors and filter fields, full-text searches, log files, etc. To define the image properties for the class setting, click the **Browse**  button to open the editor. Set a checkmark for all properties that should be displayed for objects in the object class/object class stereotype associated with the class setting. You can define the order of the object class properties by using the **Up/Down**  buttons.

  

  For most classes, this may simply be the property `Name`. However, for the class `Application` you might want `Name` and `Version` to be displayed or for the class `Domain` you might want `LevelID` and `Name` to be displayed.

- **Consider in New Objects**: Define whether objects in this object class that have been added by the user with the last seven days should be displayed in the **New Objects** functionality (`New_Objects`) and **New or Recent Objects** functionality (`New_Recent_Objects`). These functionalities display a list of objects in Alfabet that have been added or modified during the last seven days. This list is dynamically generated via the `LAST_UPDATE` field in the database table of the relevant artifact class. Select `True` if objects of this object class should be displayed in the **New Objects** functionality (`New_Objects`) and **New or Recent Objects** functionality (`New_Recent_Objects`) available in the relevant user profile. Select `False` if objects should not be displayed. If no value is defined, the default value `False` will apply and no objects will be displayed for the object class.

  

  Please note the following additional configuration requirements:

  - The functionalities `New_Objects` or `New_Recent_Objects` must be explicitly assigned to the relevant user profile. For more information, see the section Making Functionalities Accessible to a User Profile.
  - This functionality must be explicitly activated for Alfabet as a whole via the `SaveRecentObjects` parameter in the server alias configuration. For more information, see the section *Configuration Attributes for the Alfabet Components* in the reference manual *System Administration* or contact your system administrator.

- **Consider in Recent Objects**: Define whether objects in this object class that have been accessed or edited by the user with the last seven days should be displayed in the **Recent Objects** functionality (`Recent_Objects`) and **New or Recent Objects** functionality (`New_Recent_Objects`). These functionalities display a list of objects in Alfabet that have been accessed during the last seven days. This is a user-specific list. Data is stored in the database table `ALFA_RECENTOBJECTS`. Select `True` if objects of this object class should be displayed in the **Recently Used Objects** functionalities available in the relevant user profile. Select `False` if objects should not be displayed. If no value is defined, the default value `False` will apply and no objects will be displayed for the object class.

- **Format String**: Configure the standard and custom object class properties to display in the header of the page views configured for the object views that are assigned to the class setting. The **Format String** value for the class setting will also be displayed in the header of the associated object view if no **Format String** attribute is explicitly defined for that object view. The object class properties must be listed comma-separated on the first line. The formatting of the object class properties is specified as variables enclosed in curly brackets.

  

  If the **Format String** attribute is not defined for the object view, the **Format String** attribute for the class setting that the object view is assigned to will be displayed. The **Format String** attribute for an object view will have precedence over the **Format String** attribute for the class setting. If a **Format String** attribute is not specified for neither the object view nor the class setting, the following will be displayed: `<Object.Class.Caption|Object.Stereotype.Caption + Object.ID + ":" + Object.ClassSetting.ImageProps>`. If no image properties are defined in the class setting, the **Name** property will be used. If neither image properties nor the **Name** property are defined in the class setting, the header will be defined as follows: `<Object.Class.Caption|Object.Stereotype.Caption + Object.ID + ":">`.

  

  The **Format String** attribute can be translated. For more information about defining custom translations, see the section Modifying, Translating and Managing the Vocabularies in the chapter Localization and Multi-Language Support for the Alfabet Interface.

- **Icon**: You can optionally replace the default icon displayed for the object class in the Alfabet user interface. To do so, select the icon in the drop-down menu.

- **Foreground Color** and **Background Color**: (Optional) Select a color in the color picker to define the foreground and background colors when displaying an object in standard Alfabet views and configured reports with business graphics (for example, portfolios and bar charts).

  

  Please note the following:

  - If colors have been explicitly defined for configured reports, the specification in the configured report will have precedence over the class setting definition. For more information about the definition of configured reports, see Creating a Graphic Report.
  - If color rules are specified for the display of objects in map views and diagram views, the color rules will have precedence over the class setting definition. For more information about color rules, see the section *Configuring Color Rules for Map Views and Diagram Views* in the reference manual *Configuring Evaluation and Reference Data in Alfabet*.
  - If a color selector is configured in a custom editor, the custom color will have precedence over the class setting definition. For more information about

configuring the color selector for a custom editor, see the section Adding a Color Selector to the Custom Editor in the chapter Configuring Custom Editors in the reference manual *Configuring Alfabet with Alfabet Expand*.

- Users may also explicitly specify a color for objects in object classes that have a ***Color*** property and that the user has access permissions to. This is carried out via the **Colors**  button which is available in standard Alfabet views and configured reports with business graphics (for example, portfolios and bar charts) in the Alfabet user interface. Please note that if the user changes the color of an object, the selected color is used for the object in all views and reports for all Alfabet users. This capability is typically used for demonstration purposes and it is highly recommended that the **Colors**  button is hidden from Alfabet views and configured reports in order to prevent users from changing object colors across the user community. The **Colors**  button may be globally hidden via the **Allow Edit Object Colors** attribute in the server alias or may be hidden on a per-view basis. For more information about globally hiding the **Colors**  button via the server alias, see the section *Allowing Users to Change the Color Assigned to Objects in Business Graphics* in the reference manual *System Administration*.

- **Report Collection**: Configured reports selected in this attribute will be accessible via tabs in tabular configured reports and automatically generated reports returning objects of the object class or object class stereotype. This feature requires pre-configuration. Configured reports must explicitly be configured to provide meaningful information about the objects listed in the tabular dataset they are accessible from. The attribute should only be used as part of the complete configuration described in the section Integration of Configured Reports as Report Collection Into Tabular Configured Reports.

5) In the toolbar, click the **Save**  button to save your changes.

Creating a Class Setting for a Custom Object Class

If you have configured a custom object class, you must explicitly create a class setting for that object class. To do so, right-click the **Class Settings** folder and select **New Class Settings** in the context menu. In the **Select Class** editor, select the custom object class that you want to create the class setting for and click **OK**. A new class setting folder with the name of the selected custom object class will be added to the **Class Settings** folder and below the folder node the new class setting will be displayed. Define the class setting as described in the section Creating a Custom Class Setting for a Protected Object Class or Object Class Stereotype.

Configuring a View Scheme for a User Profile

A view scheme captures the information about which class settings are applied to the object classes that are implemented in the associated user profile. When you define the view scheme, you must clarify which class setting should be implemented for the relevant object classes that will be accessed via the view scheme. Only one class setting can be defined per object class for a view scheme. The class setting determines the object view to use as well as which custom editor or wizard should open when the **Edit** button is clicked in the toolbar of a page view or object view. If no class setting is explicitly defined for a view scheme, the default class setting (<ObjectClass>_Standard*) will be automatically applied to the view scheme definition. For more information about defining a class setting, see the section Configuring Class Settings for Object Classes and Object Class Stereotypes.

Once the relevant class settings have been assigned to the view scheme, you can access the view scheme in the Alfabet interface and further refine the view scheme by hiding various elements from the Alfabet interface. In this phase of configuration, you can determine which standard and custom object class properties to exclude from editors, which functionalities (toolbar buttons) to exclude from the toolbars of object views and page views, and which page views to exclude from the explorer root node and object view.

Although it is possible to reuse a view scheme and assign it to multiple user profiles, it is recommended that only one view scheme be configured per user profile.

It is recommended that all views associated with administrative functions such as those typically accessible via the `Admin` user profile are explicitly excluded from the view schemes of all user profiles that are not authorized to perform administrative tasks. For on overview of these functionalities and the tasks that can be performed with them, see the reference manual *User and Solution Administration*.

It is advised that you contact Software AG Support before excluding an object class from a view scheme in order to avoid inadvertently hiding dependent views. Please note that if you exclude an object class, you will hide the object class from the **Search** functionality, relevant explorer trees, and any views in the Alfabet solution that are dependent on that object class. As an alternative to excluding an object class, you can hide entire workspaces or individual page views available for an object class and thus avoid interfering with dependent object classes. The following examples illustrate the impact of excluding an object class:

- If the object class `MarketProduct` is excluded from a view scheme, all page views relevant for the object class `BusinessSupport` will also be inaccessible in the context of other object classes. This is because the object class is one possible class that can be used in the definition of a business support. Therefore, any users accessing an organization, business process, or master plan map with a user profile that the view scheme is assigned to would not see the **Business Support Map** page views (for example, `ITMPM_Matrix`, `ITSM_Matrix`, or `ITMPM_MatrixReport` or any other page views displaying business supports.
- If the object class `BusinessFunction` is excluded from a view scheme, all page views relevant for the object class `BusinessService` will also be inaccessible in the context of other object classes. For example, any users accessing an application with a user profile that the view scheme is assigned to would not see the **Business Services** page view (`APP_ProvidedServices`) and **Services Matrix** page view (`APP_ProvidedServicesMatrix`).

The following information is available:

- Regulating Access Permissions via Class Settings

- Creating a View Scheme and Assigning Class Settings
- Assigning the View Scheme to a User Profile

Regulating Access Permissions via Class Settings

In some cases, you may want users to see data but have only limited or no permissions to edit particular information such as, for example, data about other users, reference data for costs or indicators, or the enterprise's master plans and IT strategies. The following table provides important information about which class settings should be assigned to the view schemes that are configured for specific types of user profiles. The recommendations should be implemented so that access permissions may be correctly executed in your Alfabet solution. Once you have defined which class settings are relevant for the selected view scheme, you will be able to refine the visibility issues for the functionalities, object views, editors, and page views assigned to the view scheme. This is explained in the section Refining Visibility Issues in the View Scheme.

Type of User Profile to Configure:	Recommendation:
For the `Admin` user profile. For on overview of the administrative functionalities that can be accessed via the `Admin` user profile, see the reference manual *User and Solution Administration*.	**A user logged on with the Admin user profile has edit permissions to all objects at all times, regardless of the user authorization definition or the release status assigned to an object. Therefore, it is critical that only users who may change such data are assigned the Admin user profile!** You should select the following standard version of the class settings provided by Software AG • `USER_Standard` for the class setting `Person` • `USERG_Standard` for the class setting `UserGroup` These class settings can be assigned to other user profiles that are responsible for editing and creating user and user group data. In this case, the function `ADMIN_UsersOverview` should be assigned to the relevant user profile.
User profiles that provide access to the object class `Person`:	If the users accessing a user profile should have only limited or no edit permissions to user information, then you must explicitly define either the `USER_ReadOnly` class setting or the `USER_LimitedEditability` class setting. Otherwise, the default class setting `USER_Standard*` will apply. The following standard class settings are available for the object class `Person`: • `USER_Standard*`: This is the default class setting and should **only** be assigned to users with administrative user profiles. The `USER_Standard*` class setting grants users the ability to edit all user data associated with objects that they have access permissions to.

Type of User Profile to Configure:	Recommendation:
	• `USER_LimitedEditability`: This class setting allows users to edit only custom object class properties for the object class `Person` associated with objects that they have access permissions to. This class setting is to be used for user profiles with conventional Read/Write access permissions. This is the class setting that is typically used for the majority of view schemes. • `USER_ReadOnly`: This class setting is to be used for user profiles that have ReadOnly access permissions to the user data associated with objects that they have access permissions to.
User profiles that provide access to the object class `UserGroup`:	If the users accessing a user profile should have only limited or no edit permissions to user group information, then you must explicitly define the `USERG_ReadOnly` class setting. Otherwise, the default class setting `USERG_Standard*` will apply. The following standard class settings are available for the object class `UserGroup`: • `USERG_Standard*`: This is the default class setting and should **only** be assigned to user groups with administrative user profiles. The `USERG_Standard*` class setting grants users in the user group the ability to edit all user group data associated with objects that they have access permissions to. • `USERG_ReadOnly`: This class setting is to be used for user profiles that should have ReadOnly access permissions to the user group data associated with objects that they have access permissions to.
User profiles accessing the functionalities in the **Configuration** module. For on overview of these functionalities and the tasks that can be performed with them, see the reference manual *Configuring Evaluation and Reference Data in Alfabet*.	You should select the following standard versions of the class settings provided by Software AG. These class settings provide Read/Write access permissions to the reference data configured in the **Configuration** module. • `COSTCT_Standard` for the class setting `CostCentreType` • `COSTTYP_Standard` for the class setting `CostType` • `EVALTYP_Standard` for the class setting `EvaluationType` • `INCTYP_Standard` for the class setting `IncomeType` • `INDTYP_Standard` for the class setting `IndicatorType` • `IDCT_CR_Standard` for the class setting `IndicatorTypeComputationRule`

Type of User Profile to Configure:	Recommendation:
	• `ROLETYP_Standard` for the class setting `RoleType` • `SKL_Standard` for the class setting `Skill` Only a user administrator should assign Read/Write access permissions to user profiles accessing the **Configuration** module. For more information, see the section *Defining and Managing User Profiles* in the reference manual *User and Solution Administration*.
User profiles with **NO** administrative or configuration responsibilities	You should select the following ReadOnly versions of the class settings provided by Software AG. • `COSTCT_ReadOnly` for the class setting `CostCentreType` • `COSTTYP_ReadOnly` for the class setting `CostType` • `EVALTYP_ReadOnly` for the class setting `EvaluationType` • `INCTYP_ReadOnly` for the class setting `IncomeType` • `INDTYP_ReadOnly` for the class setting `IndicatorType` • `IDCT_CR_ReadOnly` for the class setting `IndicatorTypeComputationRule` • `ROLETYP_ReadOnly` for the class setting `RoleType` • `SKL_ReadOnly` for the class setting `Skill` • `USER_ReadOnly` for the class setting `Person` • `USRG_ReadOnly` for the class setting `UserGroup`
For user profiles accessing the **View As-Is and To-Be** (`View_AsIs_ToBe`) functionality.	You should select the following ReadOnly versions of the class settings provided by Software AG. • `ITMP_ReadOnly` for the class setting `MasterPlan` • `ITMPFLD_ReadOnly` for the class setting `MasterPlanPlan` • `ITMPM_ReadOnly` for the class setting `MasterPlanMap` • `ITS_ReadOnly` for the class setting `Strategy` • `ITSFLD_ReadOnly` for the class setting `ITStrategyFolder` • `ITSM_ReadOnly` for the class setting `ITStrategyMap`
User profiles containing **Search** functionalities (for example,	You must ensure that all object classes that are to be searchable in the **Search** functionalities have the attribute **Searchable** set to `True` for the class setting assigned to the view scheme. The

Type of User Profile to Configure:	Recommendation:
Simple Search, **Full-Text Search**, etc.)	**Searchable** attribute is set to `True` per default for the class setting <ObjectClass> `_Standard`. For an overview of all object classes that are searchable per default in the standard class settings, see the chapter *Overview of Configurable Features for Object Classes* in the reference manual *Configuring Alfabet with Alfabet Expand - Appendix*.

Creating a View Scheme and Assigning Class Settings

A view scheme is associated with a user profile and groups a set of class settings that describe the visibility of objects in the associated object classes. Only one class setting per object class may be assigned to a view scheme.

The view scheme also contains the definition about the functionalities available in the object views accessible via the view scheme. For each standard and configured object view available to the view scheme, workspaces, page views, and toolbar buttons that allow object data to be created, edited, and deleted, for example, can be hidden.

To create a view scheme and assign class settings to it:

1) Go to the **Presentation** tab and expand the **View Schemes** node.
2) To create the view scheme, do one of the following:

- Right-click the **View Schemes** folder and select **New View Scheme** to create a new view scheme from scratch, or
- Click a view scheme you want to copy and select **New View Scheme as Copy** to create a new view scheme based on an existing view scheme.

3) You will see the new view scheme  added to the **View Schemes** folder. In the attribute window, enter a name in the **Name** attribute.

A validation mechanism checks for correct syntax when defining a technical name. The technical name of a configuration object may not begin with an empty space nor include any of the following special characters: **\ / * ? " > < |':**

Furthermore, please note that names may not begin with an empty space nor include special characters. For a list of the special characters that are not allowed, see the section Defining Attributes for Configuration Objects in the chapter Getting Started with Alfabet Expand.

Furthermore, if the technical name of a configuration object is changed, the name will be correctly updated in other configuration objects referencing the changed object during design time. Please note that the name of a changed configuration object will not be updated in guide pages nor if the guide pages reference a configuration object listed in the **Show Usage** functionality. If you plan to change the name of a configuration object, the reference in the guide page should be changed prior to changing the configuration object name.

4) You should now systematically determine whether each object class/object class stereotype requires a custom class setting or whether the standard class setting suffices for your needs. To open the **View Scheme** editor for the selected view scheme, double-click the view scheme you are configuring. The **View Scheme** editor opens in the center pane.

5) The table labelled **Object Class Configuration** displays object classes/object class stereotypes on the first level. Click the + to expand the table below the object class or object class stereotype that you want to configure. When you expand the object class node, you will see all existing standard class settings and custom class settings configured by your enterprise for the selected object class. You can do the following in the **Object Class Configuration** table:

- To specify which class setting should be implemented in the selected view scheme, click in the **Use in View Scheme** column, set an X for the class setting to be implemented for the selected view scheme. Carry out this procedure for all object classes relevant to the view scheme.
- To create a new class setting for a view scheme, select the object class/object class stereotype in the **Object Class Configuration** table and click the **Create Class Settings** button in the toolbar above the table section. A new class setting will be added below the existing class settings with a default name. Click the class setting to open the property grid and define the attributes as described in the section Configuring Class Settings for Object Classes and Object Class Stereotypes.
- To create an XLS file displaying all class settings used in the selected view scheme, click the **Export to Excel** button in the toolbar above the **Object Class Configuration** table.

6) The table labelled **View Configuration** displays the configured object views, graphic views, and presentation objects implemented in the selected view scheme. Select an object view or presentation object that you want to remove from the view scheme and click the **Delete Selected Configuration** button. The selected configuration will be removed from the view scheme but will not be deleted from other view schemes that it might be assigned to. To create an XLS file displaying all object view and presentation object configurations used in the selected view scheme, click the **Export to Excel** button in the toolbar above the **View Configuration** table.

7) In the toolbar, click the **Save** button to save your changes. Once you have defined which class settings are relevant for the selected view scheme, you will be able to refine the visibility issues for the object views, editors, and page view functionalities for the view scheme. This is explained in the section Refining Visibility Issues in the View Scheme.

Assigning the View Scheme to a User Profile

In order to further refine visibility issues for the view scheme, you must access the view scheme in the Alfabet interface. Therefore, the view scheme must be assigned to a user profile in order to access Alfabet. Once Alfabet opens, you can access all object views associated with the class settings defined for the view scheme and configure the object views, editors, functionality, etc. available in the selected view scheme.

User profiles are typically created by a user administrator in your enterprise. User profiles can be created in Alfabet Expand as well as in the tool Alfabet Administrator or in the **User Profiles Administration** functionality that can be accessed via the `Admin` user profile.

Please note that changes made to user profiles via the **User Profiles Administration** functionality that can be accessed via the `Admin` user profile are not automatically updated to the user profile configuration in the configuration tool Alfabet Expand that is concurrently in use. The

solution designer working in Alfabet Expand must either use the **Rescan Tree** functionality or close and reopen the database to view the updated user profiles.

1) Go to the **Admin** tab, expand the **User Profiles** node, and select the user profile that you want to assign the view scheme to.
2) In the attribute window of the selected user profile, click the drop-down button in the **View Scheme** attribute to select the relevant view scheme.
3) In the toolbar, click the **Save** button to save your changes.

Once a view scheme has been assigned to a user profile, you can further refine visibility in the view scheme as well as review and test your configuration in the Alfabet interface. For more information, see Refining Visibility Issues in the View Scheme.

Refining Visibility Issues in the View Scheme

Two functionalities are available in the context menu of a user profile that allow you to view the solution configuration in a fully-functional Alfabet interface. The option **Run Application with Selected User Profile** opens Alfabet as it would be run for the end user and configuration is not possible. The option **Configure User Profile** opens Alfabet in configuration mode so that the solution designer can configure user profiles and refine visibility issues.

To access the Alfabet interface via the **Run Application with Selected User Profile** functionality or the **Configure User Profile** functionality, the solution designer must be assigned as a user to the user profile that is being used to access the Alfabet interface. The access permissions defined for the user profile (ReadOnly or Read/Write) are also applied when accessing Alfabet via the **Run Application with Selected User Profile** option.

Before you can access the Alfabet interface or further configure visibility issues for a view scheme, you must assign the relevant view scheme to a user profile. This is necessary to specify visibility issues in a view scheme as well as review/test your configuration of the Alfabet solution. For more information about assigning a view scheme to a user profile, see the section Assigning the View Scheme to a User Profile.

The configuration of class settings, view schemes, and user profiles play a role in what aspects of the configuration will be available to a user with a specified user profile. The following overview provides a guidline of which configuration object is relevant to specify visibility.

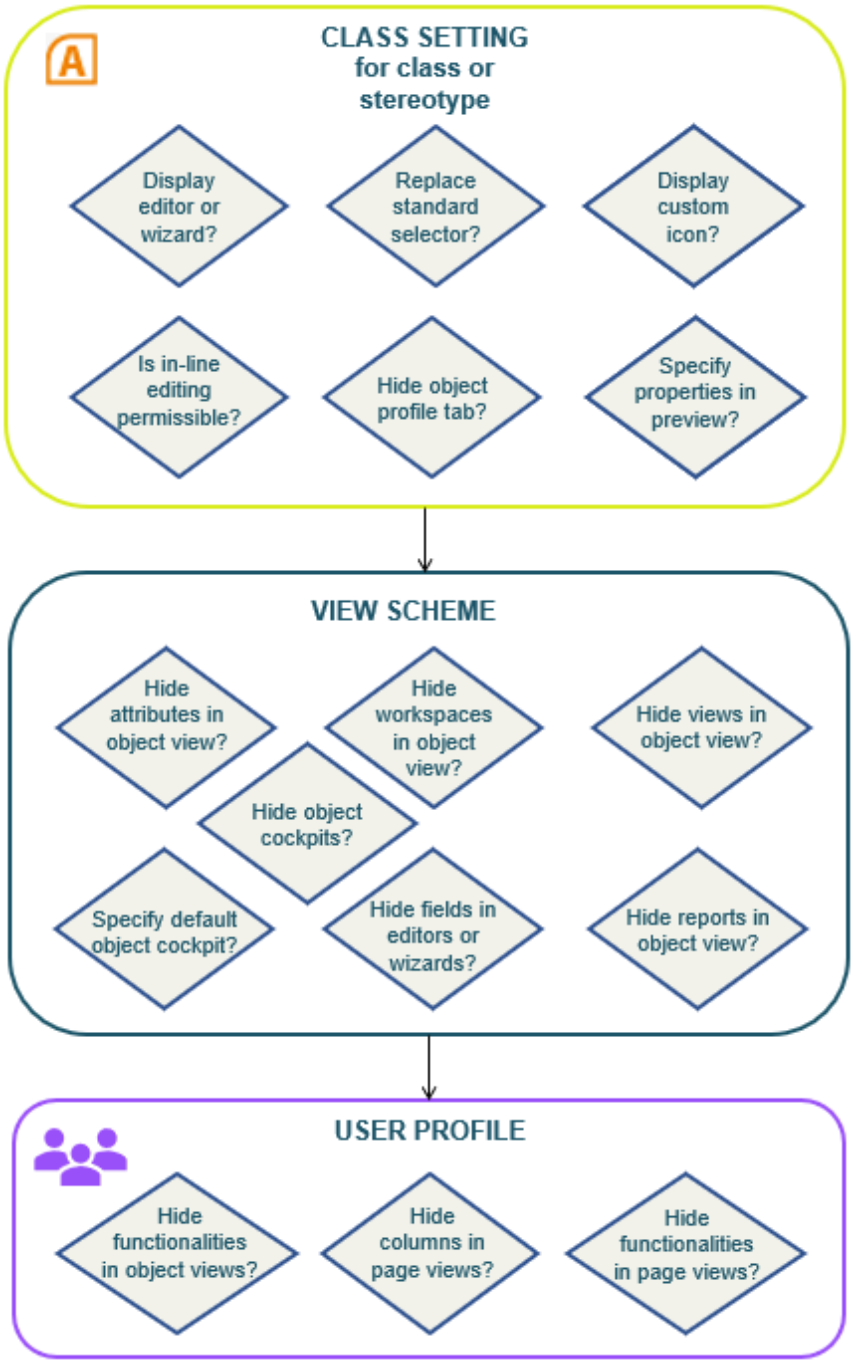

FIGURE: Configuration objects controlling visibility

Once a view scheme has been assigned to a user profile, you can access the Alfabet interface and refine the following for the view scheme:

- Visibility of standard and custom object class properties in standard editors, custom editors, and custom wizards
- Visibility of object class properties (in the **Attributes** section of the object profile), workspaces, page views and configured reports in standard and custom object views
- Visibility of standard and custom object class properties in page views and configured reports

- Functionality available via toolbar buttons in object views, object cockpits, page views, and configured reports (for example, **Create**..., **Copy**..., **Edit**..., **Navigate**..., etc.).

You can access the Alfabet interface from Alfabet Expand by right-clicking the user profile  that has the relevant view scheme assigned and select **Configure User Profile**. The Alfabet interface will open in a browser window.

After you have customized the view scheme (for example, by customizing a wizard or object view) in the Alfabet Web interface, you must reread the meta-model in order to update the changes to Alfabet Expand. Therefore, once the **Customization Editor** has been closed and you have returned to the Alfabet Expand interface, you must select **Meta-Model** > **Reread Meta-Model** to ensure that the customization is not overwritten.

The following information is available:

- Hiding Object Class Properties in Editors and Wizards
- Defining the Visibility of Object Class Properties, Workspaces, Page Views/Configured Reports, and Object Cockpits in an Object View
- Defining the Visibility of Page Views/Configured Reports Available at the Root Node of an Explorer
- Specifying the Visibility of Object Class Properties in Page Views
- Hiding Functionalities in an Object View
- Hiding Functionalities in a Page View or Configured Report

Hiding Object Class Properties in Editors and Wizards

You can hide standard or custom object class properties in standard or custom editors as well as the editors implemented in wizards. Please note the following about hiding object class properties in editors and wizards:

- Any object class properties that you hide in an editor cannot be defined or edited by users accessing Alfabet with the associated user profile.
- A red star in an editor indicates that the object class property is a mandatory property. It is possible to exclude a mandatory property in an editor or wizard as long as the mandatory property is not part of a class key definition. A class key definition specifies one or a combination of properties that must have unique values when the object is created. For more information about the configuration of class keys, see the section Configuring Class Keys for Object Classes in the chapter Configuring the Class Model.
- In conjunction with the task of hiding object class properties in editors, you can also specify a custom selector that is to be used in place of the standard object selector in editor fields that require a reference to an object to be defined. For more information about the configuration of a custom selector, see the section Configuring a Custom Selector for Search Functionalities.
- Properties that are hidden in an editor are ONLY excluded in the editor for the selected view scheme. If the object class properties should not be displayed at all in the Alfabet interface, then you must ensure that they are completely excluded from the view scheme and therefore not displayed in the **Attributes** section of a custom object view, page views, and configured reports.

- Properties that are hidden in an editor embedded in a wizard are excluded in that wizard for all user profiles that the wizard is assigned to.

  

  The configuration of a custom wizard will apply to all instances of the custom wizard in Alfabet. For example, if you hide object class properties or functionalities in a custom wizard, the object class properties or functionalities will be hidden for all instances of the custom wizard. In other words, a selected wizard cannot be differently configured in the context of different object class stereotypes. The wizard configuration will apply to each object class stereotype that the custom wizard is assigned to. If different configurations are required for a custom wizard, it is recommended that you create a new wizard via the copy functionality and modify the new wizard as needed. Once the wizard is configured, it can be selected in the **Wizard** attribute for the class setting that you create for the object class stereotype.

- If you are configuring a custom wizard, you will typically have wizard steps in which an editor, page view, or configured report is embedded. Follow the procedure described below to configure the embedded editor. You can also configure the page views and configured reports in the custom wizard, as described in the sections Specifying the Visibility of Object Class Properties in Page Views and Hiding Functionalities in a Page View or Configured Report. For a complete description of configuring visibility issues in a custom wizard, see the section Hiding Object Class Properties and Functionalities in the Wizard for a Specific User Profile in the chapter Configuring Wizards.
- If you are configuring the `DPL_Editor`, the `Stack` object class property may not be hidden otherwise an error may occur when deployments are created.
- System editors such as the **User Settings** (`ALFA_USER_SETTINGS_Editor`) editor or the **Personal Info** (`User_PersonalInfo_Editor`) editor are not configurable.

To hide object class properties in an editor:

1) Open the Alfabet interface by right-clicking the relevant user profile and selecting **Configure User Profile**.
2) Navigate to the editor or wizard that you want to configure. This could be the editor available via the **Edit**  button in an object view or via the relevant menu or button option in the toolbar of a page view.
3) In the upper right corner of the editor, click the **Configure View**  button. The **Customization Editor** opens and displays all protected and custom object class properties available for the object class.
4) Define the following as needed:

- **Select Configuration Object**: Displays the current configuration object that is being configured.
- **Select View Scheme**: Select the view scheme that the configuration is relevant for.
- **Select Hierarchy Level**. Select the hierarchy level for which the configuration is being defined. The levels are listed in the order of the hierarchy, starting with **All Classes**, followed by the object class and then the object class stereotypes.
- **Currently Applied Settings**: Displays the inherited configuration that is applied to the selected configuration object if the option **Inherited Settings from Parent Configuration Object** is selected in the **Choose One Settings Mode** menu. This field will be empty if settings have not been inherited.

- Select the relevant option in the **Choose One Settings Mode** menu in the toolbar of the dataset. The options available will depend on the configuration object that you are working with:
- **Explicit Settings from Selected Configuration Object**: Select to display a dataset that allows visibility to be explicitly specified for the relevant aspects of the selected configuration object displayed in the **Select Configuration Object** field.
- **Inherited Settings from Parent Configuration Object**: Select if the selected configuration object shall inherit the exclusion settings configured for the relevant parent configuration object. The **Currently Applied Settings** field will display the inherited configuration that is applied to the selected configuration object if the option **Inherited Settings from Parent Configuration Object** is selected in the **Choose One Settings Mode** menu.
- **No Explicit Settings from Configuration Object**: Select to display the current settings for the selected configuration object. This dataset allows no explicit settings to be configured. The **No Explicit Settings from Configuration Object** option is displayed instead of the **Inherited Settings from Parent Configuration Object** option if no settings can be inherited.

5) If **Explicit Settings from Selected Configuration Object** has been selected in the **Choose One Settings Mode** menu, you can configure the visibility of the tabs and object class properties in the editor as well as whether to use a custom selector instead of a standard object selector for relevant fields. The **View Configuration** editor displays the following columns for an editor:

- **Name**: Displays the technical name of a tab or object class property in a tab.
- **Caption**: Displays the caption defined for the tab or object class property in a tab.
- **Default Selector**: Displays the name of the default selector used to find objects if an object selector is required to define the object class property. This field will only by filled in if an object selector is actually implemented.
- **Excluded**: Click in the cell to set an X to specify that the respective element shall be hidden in the wizard. Click the X to clear the exclusion setting and make the element visible in the editor.
- **Custom Selector**: Select a custom selector to replace the default selector displayed in the **Default Selector** column. A drop-down menu will display all custom selectors configured for your solution. You must ensure that you select a custom selector relevant to the context for which it will be used. For more information about the configuration of a custom selector, see the section Configuring a Custom Selector for Search Functionalities.

6) Click the **OK** button to save the changes in the **Customization Editor** editor or click **Cancel** to exit without saving the changes.

Defining the Visibility of Object Class Properties, Workspaces, Page Views/Configured Reports, and Object Cockpits in an Object View

The visibility of object class properties, workspaces, page views, and configured reports can be specified for a standard object view or custom object view. Additionally, you can specify which object cockpits are visible for the user profile as well as which object cockpit is the default object cockpit that the user will navigate to the first time in the user session.

Please note that the first time that a user navigates to an object view for a specific object class, the object cockpit configured as the default cockpit will be displayed. If no object cockpit is specified as the default for the user profile, the user will automatically navigate to the first object

cockpit in the list of object cockpits in the **Default** field in the **View Configuration** editor available via a user profile. If no default object cockpit has been configured, the object profile will be displayed per default.

Please note that this configuration is done at the level of the individual object view. Each relevant object view must be explicitly configured. For each view scheme assigned to a user profile, the following should be configured:

- Hide standard or custom object class properties assigned to the **Attributes** section of the object profile
- Hide individual page views and configured reports.
- Hide an entire workspace. When you hide an entire workspace, all page views assigned to the workspace will also be hidden.
- Hide individual object cockpits
- Specify an object cockpit as the default object cockpit that is displayed when the user navigates to the object view. The user can switch to another cockpit, as needed.
- Specify which functionalities are available in the toolbar of the object view/object cockpit. This is described in the section Hiding Functionalities in an Object View.

To configure the visibility of object class properties, page views, configured reports, workspaces, and object cockpits in an object view:

1) Open the Alfabet interface by right-clicking the relevant user profile and selecting **Configure User Profile**.
2) Navigate to the object view that you want to configure and click the **Configure View**  button in the upper right corner of the view. The **Customization Editor** opens.
3) Define the following as needed:

- **Select Configuration Object**: Displays the current configuration object that is being configured.
- **Select View Scheme**: Select the view scheme that the configuration is relevant for.
- **Select Hierarchy Level**. Select the hierarchy level for which the configuration is being defined. The levels are listed in the order of the hierarchy, starting with **All Classes**, followed by the object class and then the object class stereotypes.
- **Currently Applied Settings**: Displays the inherited configuration that is applied to the selected configuration object if the option **Inherited Settings from Parent Configuration Object** is selected in the **Choose One Settings Mode** menu. This field will be empty if settings have not been inherited.
- Select the relevant option in the **Choose One Settings Mode** menu in the toolbar of the dataset. The options available will depend on the configuration object that you are working with:
- **Explicit Settings from Selected Configuration Object**: Select to display a dataset that allows visibility to be explicitly specified for the relevant aspects of the selected configuration object displayed in the **Select Configuration Object** field.
- **Inherited Settings from Parent Configuration Object**: Select if the selected configuration object shall inherit the exclusion settings configured for the relevant parent configuration object. The **Currently Applied Settings** field will display the inherited configuration that is applied to the selected

configuration object if the option **Inherited Settings from Parent Configuration Object** is selected in the **Choose One Settings Mode** menu.

- **No Explicit Settings from Configuration Object**: Select to display the current settings for the selected configuration object. This dataset allows no explicit settings to be configured. The **No Explicit Settings from Configuration Object** option is displayed instead of the **Inherited Settings from Parent Configuration Object** option if no settings can be inherited.

4) If **Explicit Settings from Selected Configuration Object** has been selected in the **Choose One Settings Mode** menu, you can configure the visibility of the **Attribute Section**, a section for each workspace, and a **Cockpits** section. Expand the section of the table in order to display the respective attributes, views, or cockpits that you want to configure by clicking the + symbol. If necessary, navigate to the next page in the **View Configuration** editor. The **View Configuration** editor displays the following columns:

- **Name**: Displays the name of the interface element in the object view (**Attribute** section, attributes, reports, workspaces, views, etc.) in the object view.
- **Caption**: Displays the caption defined for the interface element in the object view.
- **Type**: Displays the type of interface element in the object view (`Attribute`, `Report`, `Workspace`, `Cockpit`, etc.)
- **Excluded**: Click in the cell to set an X to specify that the respective interface element in the object view should be hidden. For example, to hide an object cockpit, scroll to the **Cockpits** section of the table and set an X in the **Excluded** column for the object cockpit that you want to hide for the selected view scheme.
- **Default Cockpit**: Click in the cell to set an X to specify that the object cockpit is the default view. The first time that a user navigates to an object view for a specific object class, the default object cockpit configured will be displayed. The user can switch to another object cockpit as needed. If no object cockpit is specified as the default for the user profile, the user will automatically navigate to the first object cockpit in the list of object cockpits in the **Default** field in the **View Configuration** editor of the user profile. If no object cockpits have been configured, the object profile will be displayed per default.
- **Usage Type**: Displays the specification of the user type that the view is intended for (`All`, `Viewer`, `Data Entry`, `Functional`, `Expert`).

5) Click the **OK** button to save the changes in the **Customization Editor** editor or click **Cancel** to exit without saving the changes.

To configure the visibility of object class properties, page views, configured reports, workspaces, and object cockpits in an object view:

1) Open the Alfabet interface by right-clicking the relevant user profile and selecting **Configure User Profile**.

2) Navigate to the object view that you want to configure and click the **Configure View**  button in the upper right corner of the view. The **Customization Editor** opens.

3) Define the following as needed:

- **Select Configuration Object**: Displays the current configuration object that is being configured.
- **Select View Scheme**: Select the view scheme that the configuration is relevant for.

- **Select Hierarchy Level**. Select the hierarchy level for which the configuration is being defined. The levels are listed in the order of the hierarchy, starting with **All Classes**, followed by the object class and then the object class stereotypes.
- **Currently Applied Settings**: Displays the inherited configuration that is applied to the selected configuration object if the option **Inherited Settings from Parent Configuration Object** is selected in the **Choose One Settings Mode** menu. This field will be empty if settings have not been inherited.
- Select the relevant option in the **Choose One Settings Mode** menu in the toolbar of the dataset. The options available will depend on the configuration object that you are working with:
- **Explicit Settings from Selected Configuration Object**: Select to display a dataset that allows visibility to be explicitly specified for the relevant aspects of the selected configuration object displayed in the **Select Configuration Object** field.
- **Inherited Settings from Parent Configuration Object**: Select if the selected configuration object shall inherit the exclusion settings configured for the relevant parent configuration object. The **Currently Applied Settings** field will display the inherited configuration that is applied to the selected configuration object if the option **Inherited Settings from Parent Configuration Object** is selected in the **Choose One Settings Mode** menu.
- **No Explicit Settings from Configuration Object**: Select to display the current settings for the selected configuration object. This dataset allows no explicit settings to be configured. The **No Explicit Settings from Configuration Object** option is displayed instead of the **Inherited Settings from Parent Configuration Object** option if no settings can be inherited.

4) If **Explicit Settings from Selected Configuration Object** has been selected in the **Choose One Settings Mode** menu, you can configure the visibility of the **Attribute Section**, a section for each workspace, and a **Cockpits** section. Expand the section of the table in order to display the respective attributes, views, or cockpits that you want to configure by clicking the + symbol. If necessary, navigate to the next page in the **View Configuration** editor. The **View Configuration** editor displays the following columns:

- **Name**: Displays the name of the interface element in the object view (**Attribute** section, attributes, reports, workspaces, views, etc.) in the object view.
- **Caption**: Displays the caption defined for the interface element in the object view.
- **Type**: Displays the type of interface element in the object view (`Attribute`, `Report`, `Workspace`, `Cockpit`, etc.)
- **Excluded**: Click in the cell to set an X to specify that the respective interface element in the object view should be hidden. For example, to hide an object cockpit, scroll to the **Cockpits** section of the table and set an X in the **Excluded** column for the object cockpit that you want to hide for the selected view scheme.
- **Default Cockpit**: Click in the cell to set an X to specify that the object cockpit is the default view. The first time that a user navigates to an object view for a specific object class, the default object cockpit configured will be displayed. The user can switch to another object cockpit as needed. If no object cockpit is specified as the default for the user profile, the user will automatically navigate to the first object cockpit in the list of object cockpits in the **Default** field in the **View Configuration** editor of the user profile. If no object cockpits have been configured, the object profile will be displayed per default.
- **Usage Type**: Displays the specification of the user type that the view is intended for (`All`, `Viewer`, `Data Entry`, `Functional`, `Expert`).

5) Click the **OK** button to save the changes in the **Customization Editor** editor or click **Cancel** to exit without saving the changes.

Defining the Visibility of Page Views/Configured Reports Available at the Root Node of an Explorer

The visibility of page views and configured reports available for the root node of an explorer can be specified. To configure the visibility of page views configured reports for the workspace associated with an explorer root node:

1) Open the Alfabet interface by right-clicking the relevant user profile and selecting **Configure User Profile**.
2) Navigate to the explorer that you want to configure and in the upper right corner of the workspace, click the **Configure View**  button. The **Customization Editor** opens.
3) Define the following as needed:

- **Select Configuration Object**: Displays the current configuration object that is being configured.
- **Select View Scheme**: Select the view scheme that the configuration is relevant for.
- **Select Hierarchy Level**. Select the hierarchy level for which the configuration is being defined. The levels are listed in the order of the hierarchy, starting with **All Classes**, followed by the object class and then the object class stereotypes.
- **Currently Applied Settings**: Displays the inherited configuration that is applied to the selected configuration object if the option **Inherited Settings from Parent Configuration Object** is selected in the **Choose One Settings Mode** menu. This field will be empty if settings have not been inherited.
- Select the relevant option in the **Choose One Settings Mode** menu in the toolbar of the dataset. The options available will depend on the configuration object that you are working with:
- **Explicit Settings from Selected Configuration Object**: Select to display a dataset that allows visibility to be explicitly specified for the relevant aspects of the selected configuration object displayed in the **Select Configuration Object** field.
- **Inherited Settings from Parent Configuration Object**: Select if the selected configuration object shall inherit the exclusion settings configured for the relevant parent configuration object. The **Currently Applied Settings** field will display the inherited configuration that is applied to the selected configuration object if the option **Inherited Settings from Parent Configuration Object** is selected in the **Choose One Settings Mode** menu.
- **No Explicit Settings from Configuration Object**: Select to display the current settings for the selected configuration object. This dataset allows no explicit settings to be configured. The **No Explicit Settings from Configuration Object** option is displayed instead of the **Inherited Settings from Parent Configuration Object** option if no settings can be inherited.

4) If **Explicit Settings from Selected Configuration Object** has been selected in the **Choose One Settings Mode** menu, you can configure the visibility of the page views available on the root node of the explorer. The **Customization Editor** editor displays the following columns:

- **Name**: Displays the name of the page views and configured reports.
- **Caption**: Displays the caption defined for the page views and configured reports.

- **Type**: Displays either `GraphicView` or `Report`.
- **Usage Type**: Displays the specification of the user type that the view is intended for (`All`, `Viewer`, `Data Entry`, `Functional`, `Expert`).
- **Excluded**: Click in the cell to set an X to specify that the respective interface element in the object view should be hidden.

5) Click the **OK** button to save the changes in the **Customization Editor** editor or click **Cancel** to exit without saving the changes.

Specifying the Visibility of Object Class Properties in Page Views

You can define a default layout for many of the tabular reports available in standard page views. Tabular reports are views that display a table with columns. Each column represents a standard or custom object class property. The values for the standard or custom object class property are displayed in the column cells.

Please note the following:

- If the same page view is reused in another object view, the configuration will be applied to all instances of the page view associated with the selected view scheme.
- Each Alfabet user may configure the layout of standard Alfabet views displaying a tabular datasets if the **Allow User Specific Configuration** parameter in the server alias is set to `True`. When set to `False`, configuration of the layout of tabular reports is restricted to a solution designer accessing the Alfabet solution via Alfabet Expand and t configuration is then implemented for all users.

Tabular configured reports are always configurable by the Alfabet user independent of the setting defined in the **Allow User Specific Configuration**. The user-specific configuration is activated per report. The layout can then be changed by the user and is stored independently of the user profile in the user context settings. The solution designer cannot define a layout valid for all users logged in with the same user profile, even if the **Allow User Specific Configuration** parameter in the server alias is set to `FALSE`.

For more information about the **Allow User Specific Configuration** attribute, see the section *Configuration Attributes for the Alfabet Components* in the reference manual *System Administration*.

- The following cannot be hidden in page views as it represents core functionality for the view:

- **Comments** column in the **Affected Architecture** page view (`PRJ_AffectedArchitectureElements`)
- **CRUDP** and **In/Out** columns in the **Business Data** page view (`COM_BusinessData`)
- **CRUDP** and **In/Out** columns in the **Business Objects** page view (`BFN_BusinessObjects`)
- Please note that custom object class properties that display URLs (**Property Type** = `URL`) cannot be displayed via columns in a page view/configured report and are not available in the **Presentation Object Configuration** editor.

To configure the visibility of object class properties (columns) in standard page views:

1) Open the Alfabet interface by right-clicking the relevant user profile and selecting **Configure User Profile**.

2) Navigate to the page view or configured report in the relevant object view.

3) In the toolbar, click the **Configure View**  button to open the **Presentation Object Configuration** editor. Set a checkmark in the **Visible** column for each custom object class property that should be visible as a column in the view. Clear a checkmark to hide a custom property in the view. You can use the **Select All** and **Clear All** buttons to select or clear the checkboxes in the **Visible** column.

   Please note that if object class properties have been defined as excluded for the associated class setting, they will not be displayed on the interface of the relevant editor. However, for technical reasons, they will continue to be listed as visible in the **Visible** column of the **Presentation Object Configuration** editor even though the object class property is not visible:

4) In the **Presentation Object Configuration** editor, specify the sequence of the columns in the view by selecting an object class property and clicking the **Up** and **Down** buttons. Repeat this step until all object class properties specified as visible are in the correct sequence.

5) To freeze columns so that they cannot be resized or resequenced in the view, select the number of columns that shall be frozen in the dataset in the **Number of Fixed Columns** field. The columns will be frozen starting with the first column on the left. The fixed columns cannot be manually resized or resequenced.

   If the **Number of Fixed Columns** s attribute is defined in the **Presentation Object Configuration** editor and a view is exported to PDF, the specification of the **Number of Fixed Columns** attribute might be ignored and the dataset will be exported as a normal table without fixed columns. Please note that the fixed column definition will only be dropped if the number of fixed columns makes paging of the table across multiple PDF pages impossible with a row header repetition logic. If this is undesired, the user is advised to select a different paper format and rerun the export.

6) Click the **OK** button to save the changes in the **Presentation Object Configuration** editor or click **Cancel** to exit without saving the changes.

Hiding Functionalities in an Object View

Object views typically feature a toolbar with menus and buttons that allow you to carry out tasks relevant to the object. For example, toolbar buttons are usually available that allows users to edit an object, trigger a workflow, access an audit history about the object, and publish the object's data to an Microsoft Word or a PDF file, etc. You can hide many toolbar buttons that provide functionality for a selected object view. In this case, the buttons will be greyed out and cannot be used. Please note the following about the configuration of the toolbar:

- Most functionalities can be disabled so that they are not displayed in the toolbar, thus preventing users from performing certain actions in the selected object view. These functionalities are displayed in the **Customization Editor**.

- Some functionalities are part of the standard configuration of Alfabet, and their visibility cannot be configured. Please note the following
- Standard functionalities that cannot be disabled will not be displayed in the **Customization Editor**.
- The **Workflow** button that is available for ALL object views, but it will be hidden automatically if the current object class is not referred to for a workflow template via the **Base Class** or **Source Class** attributes. The **Workflow** button may be hidden if needed.
- The **Add to Clipboard** button is available in the toolbar of object profiles for the classes **Application** (`App_Profile`), **Component** (`COM_Profile`), **Demand** (`DEM_Profile`), **Device** (`DEV_Profile`), **ICT Object** (`ICTO_Profile`), **Peripheral** (`PER_Profile`), **Project** (`PRJ_Profile`), **Organization** (`ORG_BSP_Profile`), **Standard Platform** (`SPL_Profile`), **Service Product** (`SRVPRD_Profile`), **Technology** (`TLG_Profile`), **Vendor** (`VDR_Profile`), **Vendor Product** (`VP_Profile`), and `Generic_Profile`).
- The **Audit Trail** button in the object view toolbar provides access to the **Object Audit** view (`Object_Audit`). Please note that the **Object Audit** view (`Object_Audit`) displays ALL information about the object regardless of the access permissions assigned to the user accessing the view. If this information should not be available to users accessing the object view, then it is recommended that you hide the standard **Audit Trail** button from the object view toolbar and create a configured report based on native SQL that the provides a customized display of audit information for users. For information about the structure of the database table for auditing and how to configure such a report, see the section Defining Audit Management Related Configured Reports in the chapter Configuring Reports. Once the report is configured, you must make it available in the relevant custom object view by configuring a custom button for the relevant custom object view. If the standard **Audit Trail** button should not be implemented in the custom object view, you must ensure that it is hidden in the relevant view scheme. For more information, see the section Configuring Custom Buttons for the Toolbar of a Custom Object View in the chapter Configuring Object Views.
- If a drop-down menu provides one or multiple options, you can hide one or more of these functionalities. Please note that if you hide all functionalities available for a menu, you must explicitly exclude the parent menu in order to ensure that it is hidden from the toolbar.
- You can also specify a custom selector to open in place of the standard selector for relevant toolbar options. The configuration of custom selectors and implementation in the Alfabet solution is described in detail in the section Configuring a Custom Selector for Search Functionalities.
- Please note that this configuration is done at the level of the individual object view. Each relevant object view must be explicitly configured.

To configure the toolbar for a selected object view:

1) Open the Alfabet interface by right-clicking the relevant user profile and selecting **Configure User Profile**.
2) Navigate to the object view of any object in the object class for which you want to define the visibility of object view functionalities and in the upper right corner of the workspace, click the **Configure View** button. The **Customization Editor** opens.
3) To specify the visibility of functionalities, select `Toolbar` in the **Select Configuration Object** field.

4) In the **Choose One Settings Mode** menu in the toolbar of the dataset, select **Explicit Settings from Selected Configuration Object** to display a dataset that allows visibility to be explicitly specified for the selected object view.

5) In the **Excluded** column, click in the cell to set an X to specify that the respective menu or action button is hidden in the view.

> If a button includes a drop-down menu providing one or multiple options, you can hide one or more of these functionalities. Please note that if you hide all functionalities available for a button, you must explicitly exclude the parent button in order to ensure that it is hidden from the toolbar.

6) Click the **OK** button to save the changes in the **Customization Editor** or click **Cancel** to exit without saving the changes.

Hiding Functionalities in a Page View or Configured Report

Alfabet standard page views feature a variety of functionalities in the toolbar. For example, toolbar buttons are typically available that allows users to create a new object, add an existing object, edit, delete or detach an object, or navigate to an object view. Most functionalities can be hidden so that they are not displayed in the toolbar, thus preventing users from performing certain actions in the selected page view. Please note the following about the configuration of the toolbar:

- **Please note that this configuration is done at the level of the page view. If the same page view is reused in another object view, the configuration will be applied to all instances of the page view associated with the selected view scheme.**
- Most functionalities can be hidden so that they are not displayed in the toolbar, thus preventing users from performing certain actions in the selected page view. These functionalities are displayed in the **Customization Editor**.

  > The **Export** button cannot be excluded from configured console reports although it is displayed in the **Customization Editor**.

- Some functionalities are part of the standard configuration of Alfabet. This is the case, for example, with the **Add to Clipboard** button or **Configure View** button. Standard functionalities cannot be hidden and are therefore NOT displayed in the **Customization Editor**.
- Functionalities in page views cannot be hidden in the context of a wizard. Wizards must be configured in the context of the **Configure Wizard** option available for the wizard.
- If a drop-down menu provides one or multiple options, you can hide one or more of these functionalities. Please note that if you hide all functionalities available for a menu, you must explicitly exclude the parent menu in order to ensure that it is hidden from the toolbar.
- If the class settings defined in the view scheme of the user profile allow context creation via the AlfaBot for an object class, at least one button marked as available for the AlfaBot should be included in the user profile configuration. Set a checkmark in the **Available for AlfaBot** column of the **Customization Editor** if a button shall be used by the AlfaBot to identify this page as relevant for context dependent creation of an object. For more information about the configuration of the AlfaBot, see the section Implementing the AlfaBot for Navigation via a Full-Text Command.

- You can also specify a custom selector to open in place of the standard selector for relevant toolbar options. The configuration of custom selectors and implementation in the Alfabet solution is described in detail in the section Configuring a Custom Selector for Search Functionalities.
- If you are configuring the **Responsibilities** page view, it is possible to exclude role types from the **Person** menu and **Organization** menu. For each relevant role type, click in the **Excluded** column for the corresponding row.
- If users should not have access to the Alfabet Diagram Designer, then the **Open Diagram** button available in diagram page views should be hidden in those page views. For an overview of all views in which the **Open Diagram** button is available, see the section *Page Views Providing Access to the Alfabet Diagram Designer* in the reference manual *Designing IT Landscape Diagrams in Alfabet*.
- Users may also explicitly specify a color for objects in object classes that have a ***Color*** property and that the user has access permissions to. This is carried out via the **Colors** button which is available in standard Alfabet views and configured reports with business graphics (for example, portfolios and bar charts) in the Alfabet user interface. Please note that if the user changes the color of an object, the selected color is used for the object in all views and reports for all Alfabet users. This capability is typically used for demonstration purposes, and it is highly recommended that the **Colors** button is hidden from Alfabet views and configured reports in order to prevent users from changing object colors across the user community. The **Colors** button may be globally hidden via the **Allow Edit Object Colors** attribute in the server alias or may be hidden on a per-view basis. For more information about globally hiding the **Colors** button via the server alias, see the section *Allowing Users to Change the Color Assigned to Objects in Business Graphics* in the reference manual *System Administration*.
- Several page views have two buttons or menu options with the same caption. These buttons/menu options typically open similar editors with some differences in functionality. Each button/menu option has a different tooltip describing the functionality of the editor that will open. If these views are implemented in the selected user profile, you should navigate to the following views and hide one of the buttons:

Technical Name of Page View	Caption of Page View	Duplicate Button/Menu Option
APP_CaptureApplications	**Capture Applications**	**Mass Update**
APP_CaptureApplications_Ex	**Capture Applications**	**Mass Update**
APP_Lifecycle	**Lifecycle**	**Edit Lifecycle**
APP_UserApplications	**Document Applications**	**Mass Update**
BusinessData	**Business Data**	**Edit Attributes**

Technical Name of Page View	Caption of Page View	Duplicate Button/Menu Option
CNTR_CaptureContracts	**Capture Contracts**	**Mass Update**
CNTR_CaptureContracts	**Capture Contracts**	**Mass Update**
COM_CaptureComponents	**Capture Components**	**Mass Update**
COM_CaptureComponents_Ex	**Capture Components**	**Mass Update**
COM_Lifecycle	**Lifecycle**	**Edit Lifecycle**
COM_UserComponents	**Document Components**	**Mass Update**
COM_InformationFlows	**Information Flows**	**Create New Incoming Information Flow.**
COM_InformationFlows	**Information Flows**	**Create New Outgoing Information Flow.**
COMCT_Lifecycle	**Lifecycle**	**Edit Lifecycle**
DEV_CaptureDevices	**Capture Devices**	**Mass Update**
DEV_CaptureDevices_Ex	**Capture Devices**	**Mass Update**
DEV_UserDevices	**Document Devices**	**Mass Update**
ENTRLS_TimeSchedule	**Enterprise Release Time Schedule**	**Show Enterprise Milestones**
ICTO_CaptureICTObjects	**Capture ICT Objects**	**Mass Update**
ICTO_CaptureICTObjects_Ex	**Capture ICT Objects**	**Mass Update**

Technical Name of Page View	Caption of Page View	Duplicate Button/Menu Option
ICTO_Lifecycle	**Lifecycle**	**Edit Lifecycle**
ICTO_UserICTObjects	**Document ICT Objects**	**Mass Update**
ITSM_StrategyCompliance-Report	**Strategic Migration Alignment Report**	**Edit**
ObjectAttachments	**Attachments**	**Add Document**
ObjectDeputies	**Deputies**	**Create Deputy**
Lifecycle	**Lifecycle**	**Edit Lifecycle**
PRF_CapturePeripherals	**Capture Peripherals**	**Mass Update**
PRF_CapturePeripherals_Ex	**Capture Peripherals**	**Mass Update**
PRF_UserPeripherals	**Document Peripherals**	**Mass Update**
PRJ_InputDemands	**Input Demands**	**Create**
SPL_CaptureStandardPlatforms	**Capture Standard Platforms**	**Mass Update**
SPL_CaptureStandardPlatforms_Ex	**Capture Standard Platforms**	**Mass Update**
SPL_Lifecycle	**Lifecycle**	**Edit Lifecycle**
SVRPD_Lifecycle	**Lifecycle**	**Edit Lifecycle**
VP_CaptureVendorProducts	**Capture Vendor Products**	**Mass Update**

Technical Name of Page View	Caption of Page View	Duplicate Button/Menu Option
VP_CaptureVendorProducts_Ex	**Capture Vendor Products**	**Mass Update**
VP_UserVendorProducts	**Document Vendor Products**	**Mass Update**

To hide functionalities in a selected page view:

1) Open the Alfabet interface by right-clicking the relevant user profile and selecting **Configure User Profile**.
2) Navigate to the page view of any object in the object class for which you want to define the visibility of page view functionalities and in the upper right corner of the workspace, click the **Configure View**  button. The **Customization Editor** opens.
3) Define the following as needed:

- **Select Configuration Object**: Displays the current configuration object that is being configured.
- **Select View Scheme**: Select the view scheme that the configuration is relevant for.
- **Select Hierarchy Level**. Select the hierarchy level for which the configuration is being defined. The levels are listed in the order of the hierarchy, starting with **All Classes**, followed by the object class and then the object class stereotypes.
- **Currently Applied Settings**: Displays the inherited configuration that is applied to the selected configuration object if the option **Inherited Settings from Parent Configuration Object** is selected in the **Choose One Settings Mode** menu. This field will be empty if settings have not been inherited.
- Select the relevant option in the **Choose One Settings Mode** menu in the toolbar of the dataset. The options available will depend on the configuration object that you are working with:
- **Explicit Settings from Selected Configuration Object**: Select to display a dataset that allows visibility to be explicitly specified for the relevant aspects of the selected configuration object displayed in the **Select Configuration Object** field.
- **Inherited Settings from Parent Configuration Object**: Select if the selected configuration object shall inherit the exclusion settings configured for the relevant parent configuration object. The **Currently Applied Settings** field will display the inherited configuration that is applied to the selected configuration object if the option **Inherited Settings from Parent Configuration Object** is selected in the **Choose One Settings Mode** menu.
- **No Explicit Settings from Configuration Object**: Select to display the current settings for the selected configuration object. This dataset allows no explicit settings to be configured. The **No Explicit Settings from Configuration Object** option is displayed instead of the **Inherited Settings from Parent Configuration Object** option if no settings can be inherited.

4) If **Explicit Settings from Selected Configuration Object** has been selected in the **Choose One Settings Mode** menu, you can configure the visibility of the functionalities in the page view or configured report. The **Customization Editor** displays the following columns:

- **Name**: Displays the name of the menu, menu option, or action button.
- **Caption**: Displays the caption defined for the menu or action button.
- **Type**: Displays the type of element.
- **Excluded**: Click in the cell to set an X to specify that the respective menu or action button is hidden in the view.

> If a button includes a drop-down menu providing one or multiple options, you can hide one or more of these functionalities. Please note that if you hide all functionalities available for a button, you must explicitly exclude the parent button in order to ensure that it is hidden from the toolbar.

- **Custom Selector**: Select a custom selector to replace the default selector, if necessary. A drop-down menu will display all custom selectors configured for your solution. You must ensure that you select a custom selector relevant to the context for which it will be used.
- **Default Selector**: Displays the name of the default selector used to find objects. This field will only by filled in if an object selector is implemented.

5) Click the **OK** button to save the changes in the **Customization Editor** or click **Cancel** to exit without saving the changes.

Reviewing the Solution Configuration in the Alfabet Interface

Two functionalities are available in the context menu of a user profile that allow you to view the solution configuration in a fully-functional Alfabet interface. The option **Run Application with Selected User Profile** opens Alfabet as it would be run for the end user and configuration is not possible. The option **Configure User Profile** opens Alfabet in configuration mode so that the solution designer can configure user profiles and refine visibility issues.

To access the Alfabet interface via the **Run Application with Selected User Profile** functionality or the **Configure User Profile** functionality, the solution designer must be assigned as a user to the user profile that is being used to access the Alfabet interface. The access permissions defined for the user profile (ReadOnly or Read/Write) are also applied when accessing Alfabet via the **Run Application with Selected User Profile** option.

Once you have accessed the Alfabet interface, you can further define or modify the visibility of various interface elements for the selected view scheme in the context of the user profile. For more information, see Refining Visibility Issues in the View Scheme.

To review and edit the solution configuration:

1) Go to the **Admin** tab, expand the **User Profiles** node, and right-click the user profile  that you want to validate and select **Run Application with Selected User Profile**. The Alfabet solution opens.
2) Navigate through Alfabet to review the configuration, as needed.

Reviewing the Usage of a User Profile

The **Show Usage** functionality allows you to understand the configuration objects in which a specific user profile is implemented. Additionally, you can review the number of users assigned to a specific user profile.

To access the **Show Usage** dialog, right-click the user profile  and select **Show Usage**. A matrix will show the number of users assigned to the selected user profile. Click **OK** to close the dialog. For more information, see the section Using the Show Usage Functionality in the chapter Getting Started with Alfabet Expand.

Configuring Barrier-Free User Profiles

Software AG provides a number of options to support accessibility to Alfabet functionality and content in conformance with established accessibility guidelines and requirements.

- **JAWS® for Windows® screen reader software**: Alfabet can be used in conjunction with JAWS® for Windows® software (v. 18) in order to support visually impaired users. Please note the following information about working with JAWS:

- The screen reader will read out the login information displayed in the Alfabet user interface about the current user, user profile, and mandates when the start page is in focus if Alfabet is rendered in Google Chrome® and Microsoft Internet Explorer.

- The screen reader will read out the text of the interface element that currently has the focus. This includes, for example, menus and menu options, data-entry fields, static texts, and buttons.

- The screen reader will read out the ARIA label, control type, and help-related content such as page view descriptions or editor and filter field descriptions. Additionally, relevant keyboard shortcuts will also be read out loud by the screen reader. For example, if the keyboard shortcut SHIFT + F7 is used to select a block of text to ease navigation via tabbing, the screen reader will read aloud the keyboard shortcut SHIFT + F7.

- The screen reader will read out if a field is a mandatory field.

- The texts for the interface elements will be read out in the language the user has selected in the Alfabet user interface if the same language has been selected in the JAWS® for Windows® software.

- **Tabbing navigation and keyboard shortcuts**: Users can use tabbing navigation to navigate through the interface. Keyboard shortcuts and key sequences allow the user to move the focus in the Alfabet interface and carry out tasks without using the mouse. Keyboard shortcuts are available in all functionalities in Alfabet and can be used to navigate via the menu bar of the Start page, explorers, object profiles, page views, editors, wizards, filters, and selectors.

For an overview of barrier-free accessibility in Alfabet as well as detailed information about the use of tabbing navigation and keyboard shortcuts in the user interface, see the section *Barrier-Free Accessibility in Alfabet* in the reference manual *Getting Started with Alfabet*.

Please note the following configuration requirements and recommendations to implement barrier-free accessibility:

- The implementation of JAWS® for Windows® software with Alfabet must be explicitly enabled for the relevant user profile. The **Use WAI-ARIA** attribute should be set to `True` for the relevant user profile in order to implement the WAI ARIA (Web Accessibility Initiative – Accessible Rich Internet

Applications) specification for barrier-free accessibility. If the **Use WAI-ARIA** attribute is set to `True` for a user profile, the following changes will be automatically implemented to support barrier-free accessibility:

- Conventional tabular datasets will be replaced by flat datasets with no hierarchical grouping in the table, no legend, and no cell coloring or icons in the cells. If a dataset is empty, the text " **No data provided** " will be read by the screen reader software. The **Export** > **MS File** and **MS PowerPoint** options will be available and the **Export** > **HTML** options removed. Please note that a special set of keyboard combinations are available for this dataset and are described in the section *Using Keyboard Shortcuts in Page Views* in the reference manual *Getting Started with Alfabet*.

  

  Please note that editable cells with JAWS® for Windows® software will only be read by the JAWS® for Windows® software if Alfabet is rendered in Google Chrome®. This functionality is not available if Alfabet is rendered in Microsoft Internet Explorer.

- The auto-complete functionality that is typically available for edit search fields or combo-boxes in editors and filter fields will be automatically disabled.
- The pop-up calendar that is typically available to select dates will be replaced by a simple data entry field for date fields.
- The slide-in toolbar, secondary windows, and AlfaBot will not be available in the Alfabet user interface.
- Placeholder texts displayed in editor fields and filter fields will be automatically disabled.
- It is recommended that high contrast mode is specified for the browsers used by visually impaired users. Please note that the default high-contrast mode used in Microsoft Windows may display the background as pure black and white without support for inverse colors, thus causing any specified background colors to be not visible. Therefore, it is highly recommended that users render the Alfabet interface with Google Chrome® or Mozilla® Firefox® with their add-on extensions for high-contrast mode.
- It is recommended that access to Alfabet functionalities is available via menus in the main toolbar rather than via guide pages. This will ease navigation through the interface considerably for users requiring barrier-free accessibility. For more information about considering accessibility via the Alfabet menu bar, see the section Defining Access to the Functionalities via the Menu Bar. If you do provide accessibility only through guide pages and guide views, please note the following:
- For all elements created in a guide page project including the search field, top menus, application links, internal links, external links, help links, and document links, the **Caption** attribute should be configured so that a caption can be read for the element and the **Hint** attribute should be configured so that information relevant to navigation can be read. In the case of guide views, the tab sequence should be explicitly defined via the **Tab Order** button in the toolbar of the guide view designer or the **Tab Index** attribute available for each interface control in the guide view.
- The configuration of the welcome panel should allow texts to be read aloud by the screen reader capability provided in conjunction with JAWS® for Windows® software. Please note that the attributes **Welcome Name Text**, **Welcome Name Description**, **Welcome Name Tooltip**, **Logo Image Alt**, and **Welcome Name Picture Alt** are available for this purpose.
- In order to support accessibility to the Alfabet interface for users that are required to use keyboard shortcuts, it is recommended that the visualization of the focus is configured according to the individual needs of the users via the ***AlfaGuiScheme*** definition. This will ease navigation through the interface considerably for users requiring barrier-free accessibility.

The ***AlfaGuiScheme*** definition allows you to specify the font type to display as well as the colors used for various aspects of the interface. Multiple GUI schemes can be created so that one or more ***AlfaGuiScheme*** objects can be created explicitly for the purposes of configuring barrier-free accessibility as well as styling requirements for different entities in a federated enterprise. The GUI scheme must be assigned to the relevant object profile in the **GUI Scheme** attribute available on the object profile. The ***AlfaGuiScheme*** definition will be applied to all aspects of the Alfabet interface including any configured guide pages. For more information about configuring ***AlfaGuiScheme*** objects, see the section Configuring GUI Scheme Definitions for the Alfabet Interface in the chapter Configuring the Visualization of the Alfabet Interface as well as examples of the definition of each attribute in the section *Overview of GUI Scheme Attributes* of the reference manual *Configuring Alfabet with Alfabet Expand - Appendix*.

Please note that the following attributes either specify the ways that focus is visualized, or the font is colored in the Alfabet interface. Please consider especially which attributes in the **Application** and **Data Rows Highlighting** grid sections should be specified for the user profile. The attributes you need to define will depend on the needs of the users working with the user profile. The following attributes in the **Application** grid section are particularly relevant to support users working with keyboard shortcuts.

- **Focus Background Color**
- **Focus Foreground Color**
- **Focus Outline Color**
- **Focus Outline Style**
- **Focus Outline Width**

- It is recommended that object profiles are available in the user profiles requiring accessibility to Alfabet functionality via keyboard shortcuts rather than via object cockpits. This will ease navigation through the interface considerably for users requiring barrier-free accessibility. For more information, see the chapter Configuring Object Views. Please note that if object cockpits based on a Table Layout Panel interface control are implemented in a barrier-free user profile, the tab sequence for the cells in the table will automatically be from left-to-right and top-to-bottom. The **Tab Index** attribute defined for the interface controls in each table cell will be ignored. This ensures a consistent navigation for user profiles configured for barrier-free accessibility.
- It is recommended that the **Enable Automated Assistant** attribute for the use profile definition is set to `False` for user profiles requiring barrier-free accessibility.
- Keyboard shortcuts are not supported in the context of the **Workflow Activities Explorer** view (`WFS_Explorer`). Therefore, one of the **Workflow Activities** views (`WF_Activities`,`WF_ActivitiesFiltered`, `WF_ActivitiesWithInitiation`,) must be implemented for user profiles requiring accessibility to workflow activities via keyboard shortcuts. For more information about the configuration of views for workflows, see the section Making the Workflow Capability Available to the User Community in the chapter Configuring Workflows.
- Keyboard shortcuts are not supported in the Alfabet Diagram Designer. Therefore, the **Open Diagram** button should be hidden in all views providing access to the Alfabet Diagram Designer for user profiles requiring the use of keyboard shortcuts. For an overview of all views that provide access to the Alfabet Diagram Designer, see the section *Getting Started with the Alfabet Diagram Designer* in the reference manual *Designing IT Landscape Diagrams in Alfabet*. For more information about hiding the **Open Diagram** button, see the section Hiding Functionalities in a Page View or Configured Report.
- Keyboard shortcuts are not supported in the standard **Lifecycle** editor (`ObjectLifecycleEditor`), which requires the dragging of interface elements to specify lifecycle phases. The standard

Lifecycle editor should be replaced with the alternative **Lifecycle** editor (`ObjectLifecycleEditor_TAB`), which displays a tabular dataset and allows the lifecycle phases to be defined by tabbing to rows representing lifecycles phases and defining individual date fields or the duration of the lifecycle phase as expressed in number of years, months, and days. The **Align** menu provides options to define the end dates based on the defined start dates or to define the start and end dates based on the defined durations.

If you implement `ObjectLifecycleEditor_TAB`, you should hide the **Edit Lifecycle** button that opens `ObjectLifecycleEditor` in all **Lifecycle** page views that the user profile will access. Likewise, you should ensure that the **Edit Lifecycle** button that opens `ObjectLifecycleEditor_TAB` should be visible. The following pages are relevant:

- `APP_Lifecycle` to define application lifecycles
- `COM_Lifecycle` to define component lifecycles
- `COMCT_Lifecycle` to define component catalog lifecycles
- `ICTO_Lifecycle` to define ICT object lifecycles
- `SPL_Lifecycle` to define standard platform lifecycles
- `SRVPRD_Lifecycle` to define service product lifecycles
- `ObjectTimeStatusPlan` to define lifecycles for all other object classes supporting lifecycle definition. For an overview of the object classes for which lifecycles can be defined, see the chapter *Overview of Configurable Features for Object Classes* in the *Configuring Alfabet with Alfabet Expand - Appendix*.
- For more information about how to hide/show the **Edit Lifecycle** buttons, see the section Hiding Functionalities in a Page View or Configured Report.

- The screen reader software reads all **Caption** attributes and **Hint** attributes available for the standard interface controls in the Alfabet user interface. If you have configured custom editors, custom selectors, configured reports, custom object profiles, etc., you must ensure that the **Caption** attribute should is specified. Further information about the content expected for the custom interface control as well as other user assistance can be specified via the **Hint** attribute.
- For configured reports, the `PictureAssignment` instruction has been amended with the option to define a text for the icon that can be read as the description for the icon. For more information, see the section Displaying Graphics for Cells Containing Specific Data.

Configuring User Profile Request or Assignment for the User Community

In an enterprise with a significant number of users, the task of fulfilling user requests to assign a new user profile to a user may be difficult to manage. Software AG provides a Self Administration capability that can be configured to allows users to request user profiles or to automatically assign themselves new user profiles. If the capability is implemented, a logged on user will see the option **Assign User Profile** in the < **AlfabetUserName** > menu available in the Alfabet interface. The drop-down menu will list the permissible user profiles that a user may assign to him/herself.

The solution designer should thus clarify the following for the user profiles implemented in the enterprise:

- Shall users be able to request a specified user profile through a managed approval process? If this capability is implemented, users requesting the permissible user profile via the **Assign User Profile** in the **User** menu will trigger a configured workflow that begins and manages a request and approval process.
- Shall users be able to automatically assign a specified user profile to themselves? If this capability is implemented, ALL named user will be able to automatically assign him/herself the permissible user profile via the **Assign User Profile** in the < **AlfabetUserName** > menu available in the Alfabet interface. This situation typically applies to ReadOnly user profiles or, for example, user profiles that allow a set of users to capture demands or requests for technology usage.

You must ensure that the XML attribute `ShowProfileSelfAdminMenu` in the XML object ***PlatformConfiguration*** is set to "`true`" in order to ensure that the **Assign User Profile** option is available in the < **AlfabetUserName** > menu available in the Alfabet interface. If this XML attribute is not set to "`true`", users will have no mechanism to trigger the self-administration or user profile request processes. For more information about configuring the XML object ***PlatformConfiguration***, see the section Configuring the Visibility of Tabs in Alfabet Expand.

The **Enable User Self-Administration** and **Workflow Template** attributes can also be defined for a user profile via the **User Profile Administration** functionality that can be accessed via an administrative user profile. For more information, see the reference manual *User and Solution Administration*.

Configuring a Managed User Profile Request Process

You can configure the user profile so that users can request a permissible user profile via the **Assign User Profile** in the < **AlfabetUserName** > menu available in the Alfabet interface. When a user selects the user profile in the menu, they will trigger a configured workflow that begins a managed request and approval process.

To implement the capability so that users may request a specified user profile through a managed approval process, you must carry out the following steps:

- First, via the **Workflows** tab in Alfabet Expand, configure the workflow template that you want to implement for the user profile request. Because a different workflow template can be configured for each user profile, the workflow can be tailored to the specific user profile initiating the request. The entire set of workflow functionality is available to the solution designer. For more information about the configuration of workflow templates, see the chapter Configuring Workflows.

- Next, select the configured workflow template in the **Workflow Template** attribute for the relevant user profile. The workflow template will be triggered when the user selects the user profile via the **Assign User Profile** in the < **AlfabetUserName** > menu available in the Alfabet interface.
- In the toolbar, click the **Save** button to save the user profile configuration.

Configuring the Automatic Assignment of a User Profile

You can configure the user profile so that users will be able to automatically assign a specified user profile to themselves via the **Assign User Profile** in the < **AlfabetUserName** > menu available in the Alfabet interface. This situation would typically apply to ReadOnly user profiles or user profiles that, for example, allow a set of users to capture demands or requests for technology usage.

Please note that if the **Enable User Self-Administration** attribute is set to `True`, all named users can assign a permissible user profile to themselves via the **Assign User Profile** option in the < **AlfabetUserName** > menu available in the Alfabet interface.

To implement the capability so that users may assign themselves a permissible user profile, you must carry out the following steps:

1) Go to the **Admin** tab, expand the **User Profiles** node, and click the user profile that you want to configure.
2) In the attribute window, set the **Enable User Self-Administration** attribute to `True`.

   Please note that if you are implementing the self-administration capability, any user may assign this user profile to him/herself. This may include users who access Alfabet as anonymous users. Therefore, you may decide that the self-administration function should only be implemented for user profiles of the type `ReadOnly`. It is recommended that you carefully consider which users may be assigning themselves a user profile via the self-administration capability. This is especially critical when configuring the `Admin` user profile, which grants `ReadWrite` access permissions to ALL objects in Alfabet!

3) In the toolbar, click the **Save** button to save the user profile configuration.

Chapter 12: Providing Custom Online Help to the User Community

A standard context-sensitive help is available in Alfabet that provides the user community with information to understand the standard views in the Alfabet user interface that they are currently working with. The standard online help available for your Alfabet product contains documentation for all functionalities in the software, including those that may not be part of the configuration of your Alfabet solution.

Because Alfabet is highly configurable, it may be that you require additional customized help for your solution configuration in order to provide relevant information to your user community.

Various mechanisms are available in Alfabet that allow you to provide information to your user community to help them understand how to perform their tasks using the standard functionalities provided by Alfabet as well as your enterprise's solution configuration:

- A standard context-sensitive help is available in Alfabet that provides the user community with information to understand the standard views in the Alfabet user interface that they are currently working with. The standard online help available for your Alfabet product contains documentation for all functionalities in the software, including those that may not be part of the configuration of your Alfabet solution
- A custom context-sensitive help can be made available as a URL for a standard business function/custom explorer, custom object profile and object cockpit, standard page view, or configured report included in the Alfabet user interface.
- A custom help link may be made available for a user profile, thus allowing information to be available to relevant users regardless of the view that they are currently looking at.
- An automated help assistant can be defined that opens a pop-up displaying information provided by your enterprise to help occasional users with their tasks in Alfabet. The automated help assistant can be made available for a specific user profile, guide view/guide page, standard business function/custom explorer, custom object profile and object cockpit, standard page view, or configured report.
- Custom tooltips can be defined for all custom properties as well as for protected properties.

The content for the custom context-sensitive help as well as the automated help assistant capability must be located in the same domain as the Alfabet Web Application. The installation of the standard context-sensitive help is part of the installation procedure described in the section *Installation* in the reference manual *User and Solution Administration*.

The following information is available:

- Specifying Custom Help for Editors and Wizards
- Specifying Custom Help for Guide Views and Guide Pages
- Providing Custom Tooltips for Custom and Protected Object Class Properties
- Configuring Server Variables for the Custom Help

Understanding the Context-Sensitive Help

A standard context-sensitive help is available in Alfabet that provides the user community with information to understand the standard views in the Alfabet user interface that they are currently working with. The standard context-sensitive help available for your Alfabet product contains documentation for all functionalities in the software, including those that may not be part of the configuration of your Alfabet solution.

In addition to the standard help, you can also provide a custom context-sensitive help for any standard business function/custom explorer, custom object profile and object cockpit, standard page view, or configured report included in the Alfabet user interface. Alfabet provides you with the possibility to decide per view whether the custom context-sensitive help should be displayed and whether the standard context-sensitive help should or should not be displayed. The custom context-sensitive help that you provide for your user community must be available via a URL or server variable(s) that targets a URL that can be viewed in a browser. Users can access the standard context-sensitive help and/or custom context-sensitive help for the current view that they are working with.

Additionally, a custom context-sensitive help link may be made available for a user profile, thus allowing information to be available to relevant users regardless of the view that they are currently looking at.

The standard context-sensitive help available for Alfabet is hierarchically structured and mapped to the technical structure of the interface. The display of the context-sensitive help links in the **Help Selector** mirrors this structure. Standard and custom context-sensitive help links that are specified to be visible will be displayed in the following sequence in the **Help Selector**:

- Solution Help
- Solution Help Search
- Custom Help on User Profile
- Standard Help on Business Function
- Custom Help on Business Function
- Standard Help on Explorer
- Custom Help on Explorer
- Standard Help on Object View
- Custom Help on Object View
- Custom Help on Object Cockpit
- Standard Help on Page View
- Custom Help on Page View/Configured Report

Users will be able to access the standard online help and/or custom online help for the current view that they are working with by clicking the **Help** button in the upper-right corner of the interface. The **Help Selector** will open providing the available help links listed according to the hierarchical structure of the interface. The user can click a link in the **Help Selector** to open the relevant help. The online help will open in a separate browser tab.

The custom context-sensitive online help cannot be defined for more than one culture. The URL defined in the **Custom Context-Sensitive Help URL** attribute will be displayed for the specified view, regardless of the current language of the user interface. The text **Custom Help on...** displayed in the **Help Selector** will be translated as well as the name of the linked view, providing that a translation is available for that view.

The content for the custom context-sensitive help must be located in the same domain as the Alfabet Web Application. The installation of the standard context-sensitive help is part of the installation procedure described in the section *Installation* in the reference manual *User and Solution Administration*.

Understanding the Automated Help Assistant

Training users how to process a specific use case or to carry out their tasks in Alfabet can be challenging. The automated help assistant capability supports the enterprise in training efforts as well as disseminating relevant information to occasional users about the Alfabet functionalities that they use. The automated help assistant capability allows the enterprise to provide a URL targeting an HTML document, video, animation, PowerPoint file, etc. with explanations about methodology, use cases, procedural instructions, and complex processes when working with wizards with many wizard steps, for example. The automated help assistant can be configured for any user profile and displayed on the Home page whether that is a guide view/guide page, splash screen, or storyboard. Automated help assistants can also be configured for a custom wizard, custom object profile and object cockpit, standard business function/custom explorer, standard page view, or configured report. If the standard page view or configured report is embedded in a wizard step, the automated help assistant will also be available for that wizard step.

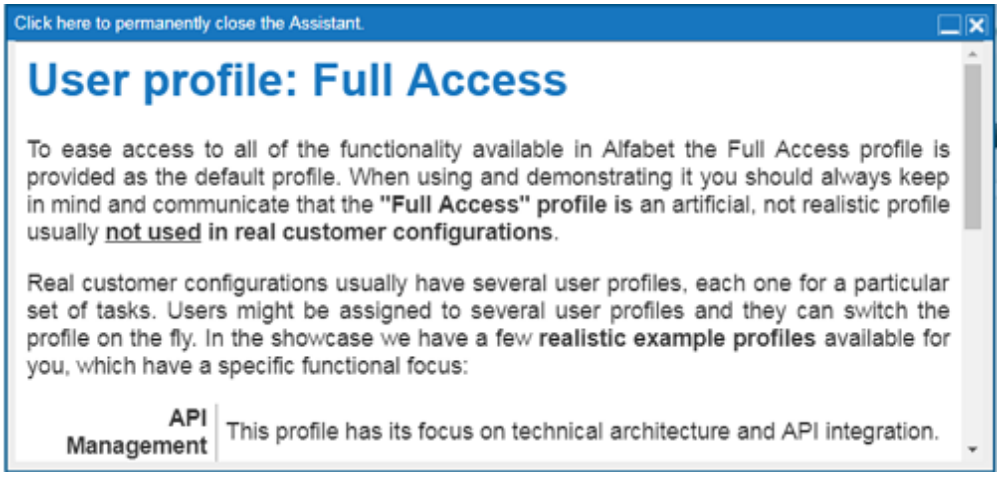

FIGURE: Automated hep assistant for a user profile

When a relevant guide view, wizard, etc. is opened for which an automated help assistant has been configured, a fly-in element will be displayed for a few seconds in the upper-right corner of the user interface below the main menu. Users can click the fly-in element to open the automated help assistant which will open

in a separate window. If the automated help assistant is not opened by the user, it will drop into the slide-in toolbar on the right of the screen in order to provide an unobstructed view of the current view. The automated help assistant for the current view can be opened at any time, as needed, by clicking the colored notch in the slide-in toolbar.

Please note the following:

- The automated help assistant will automatically be minimized if the user clicks in the Alfabet user interface.
- To close the automated help assistant, the user must click the close (**X**) button in the automated help assistant window.
- To reopen the automated help assistant for the current view, click the colored notch in the slide-in toolbar and click the automated help assistant icon to open the assistant.

Please note the following regarding the configuration of the automated help assistant capability:

- The automated help assistant capability must be activated for the user profile(s) that shall have access to the assistants. To enable the automated help assistant capability for a user profile, set the **Enable Automated Assistant** attribute for the user profile to `True`. It is recommended that the **Enable Automated Assistant** attribute is set to `False` for user profiles requiring barrier-free accessibility. Please note that an individual user may disable the automated help assistant capability via the **Enable Automated Help Assistant** attribute in the **User Settings** editor.

  

  In order to simplify the specification and management of automated assistants, the URLs for automated assistants may be imported or maintained via an Excel file. To export an XLSX file with all standard and custom configuration objects for which an automated help assistant may be specified, click **Help Manager** > **Export Automated Assistants**. An XLSX file will be generated with a column displaying the configuration object type (user profile, business function, editor, etc.), the name of the configuration object, a subordinate configuration object if relevant (for example, an object view may have a subordinate object cockpit), and a column in which the URL may be entered. To import the XLSX file, click **Help Manager** > **Import Automated Assistants** and select the XLSX file with the specified URLs to import.

- To make the automated help assistant available for a configuration object, the URL targeting the content must be specified in the **Automated Assistant URL** attribute available for the configuration object. To do so, go to the relevant user profile, custom wizard, standard business function/custom explorer, custom object profile, object cockpit, standard page view, or configured report assigned to a custom object view and enter the URL in the **Automated Assistant URL** attribute.
- The size of the automated help assistant, its position in the Alfabet user interface as well as the color of the header of the automated help assistant and its corresponding notch in the slide-in toolbar are configured for each configuration object type in the GUI scheme. For more information about defining GUI schemes, see the section Configuring GUI Scheme Definitions for the Alfabet Interface. For details about the individual GUI scheme attributes that are relevant for the automated help assistant, see the section *Overview of GUI Scheme Attributes* in the reference manual *Configuring Alfabet with Alfabet Expand - Appendix*.
- If your enterprise provides translations of the content of the automated help assistants, the translated content may be displayed when the user interface is rendered in a secondary language. Please note the following:

- The URL defined for the automated assistant should include a {CURRENT_LANGUAGE} parameter whereby {CURRENT_LANGUAGE} is replaced with the language of the user interface at the time of the

call. For example:
`http://autohelp.alfabet.com/\{CURRENT_LANGUAGE}/showcase/user_profile/Full_Access.html`

- The replacement value for the {CURRENT_LANGUAGE} parameter must be specified in the **Automated Assistant Parameter** attribute available for the culture. This could be, for example, DE or Deutsch or 1031 or DE-de. If no parameter is specified, the four-digit ISO code will be used (for example 1031). For more information about configuring cultures, see the section Specifying the Cultures Relevant to Your Enterprise.
- If the Alfabet Web Application is accessed via HTTPS protocol, then the URL targeting the automated help must also begin with HTTPS. Alternatively, if the Alfabet Web Application is accessed via HTTP protocol, then the URL targeting the automated help must also begin with HTTP.
- The content for the automated help assistant capability must be located in the same domain as the Alfabet Web Application. The installation of the help is part of the installation procedure described in the section *Installation* in the reference manual *User and Solution Administration*.

Assigning Custom Help and Automated Help Assistants to a User Profile

Except for the `Admin` user profile, all user profiles will typically be configured by your enterprise's user administrator and thus will have no standard help available. The `Admin` user profile, which is required to access the `Administration` module, is an exception and does provide a standard context-sensitive help that provides access to the documentation required to understand the functionalities available to the `Admin` user profile.

You can provide a link to custom context-sensitive help for any user profile configured by your solution designer as well as for the `Admin` user profile. You can specify only one custom context-sensitive help per user profile. The context-sensitive help entry will be displayed in the **Help Selector** with the syntax **Custom Help on <User Profile Name>**. The custom context-sensitive help link will be displayed in the **Help Selector** as long as the user is logged in with the user profile. For general information about the standard and custom context-sensitive help, see the section Understanding the Context-Sensitive Help.

Furthermore, you can specify content for the automated help assistant and make it available to the user profile. The automated help assistant will be displayed the first time each user with the user profile accesses Alfabet with the user profile. The automated help assistant can be minimized, closed for the user session, or disabled entirely as needed by each user. For general information about the automated help assistant capability, see the section Understanding the Automated Help Assistant.

Server variables can be used in the **Custom Context-Sensitive Help URL** attribute and the **Automated Assistant URL** attribute to specify the custom help links. Server variables allow you to define all or part of the URL definition in the alias server setting instead of directly defining it in the configuration in Alfabet Expand. Use of server variables is, for example, useful in order to change a Web server name defined in multiple URL definitions in Alfabet Expand. Instead of changing all URL definitions, only the variable value in the alias server setting must be updated. For more information about defining server variables for custom online help, see the section Configuring Server Variables for the Custom Help.

Please note that if the automated help assistant configured for a user profile is open or minimized and the page is reloaded via the F5 key, the user profile will not be reloaded but rather the

associated guide view/guide page will be reloaded. As a result, the automated help assistant content configured for the guide view/guide page will also be reloaded.

To specify custom help for a user profile:

1) Go to the **Admin** tab, expand the **User Profiles** explorer node and click the user profile  that you want to define a custom context-sensitive help link for.
2) Define the following attributes, as needed:

- **Automated Assistant Enabled**: Set to `True` if the automated help assistant capability should be enabled for the user profile. Set to `False` if all assistants available for the user profile shall be disabled. It is recommended that the **Enable Automated Assistant** attribute is set to `False` for users requiring barrier-free accessibility.
- **Automated Assistant URL**: Enter the URL or server variable that targets the content to display in the automated help assistant assigned to the user profile.

  The size of the automated help assistant, its header color and position in the Alfabet user interface, and the notch in the slide-in toolbar are configured for each configuration object type in the GUI scheme. For more information about defining GUI schemes, see the section Configuring GUI Scheme Definitions for the Alfabet Interface. For details about the individual GUI scheme attributes that are relevant for the automated help assistant, see the section *Overview of GUI Scheme Attributes* in the reference manual *Configuring Alfabet with Alfabet Expand - Appendix*.

- **Custom Context-Sensitive Help URL**: Enter the URL or server variable that targets the custom context-sensitive help for the user profile.
- **Standard Context-Sensitive Help Index**: Displays the HTML file that is available as the standard context-sensitive help for this user profile. A standard context-sensitive help is only available for the `Admin` user profile. The standard online help provides information about the user administration and solution administration functionalities available that can be accessed in the Alfabet user interface via the `Admin` user profile.
- **Standard Context-Sensitive Help Visible**: Select `True` to display both the standard and custom context-sensitive help file in the **Help Selector** Select `False` if the link to the standard context-sensitive help should not be available to the user profile and should not be displayed in the **Help Selector**.

3) In the toolbar, click the **Save**  button to save your changes.

Assigning Custom Help and Automated Help Assistants to Standard Business Functions and Custom Explorers

You can provide a link to custom help for any standard business function provided by Alfabet as well as any custom explorer configured by your solution designer. You can specify only one custom online help per standard business function or per custom explorer. Users will be able to access the online help for the standard business function or custom explorer that is currently displayed in the Alfabet user interface.

The custom help that you provide for your user community must be available via a URL that can be viewed in a browser. For each standard business function, you can decide whether custom online help should be

displayed and whether the standard online help should or should not be displayed. If you specify that both the standard online help and the custom online help are to be displayed, the link for the standard online help will be listed first in the **Help Selector**, followed by the custom help link. The online help entry will be displayed in the **Help Selector** with the syntax **Custom Help on <Business Function Caption>** or **Custom Help on <Custom Explorer Caption>**. For general information about the standard and custom context-sensitive help, see the section Understanding the Context-Sensitive Help.

Furthermore, you can specify content for the automated help assistant and make it available to a selected standard business function or custom explorer. The automated help assistant will be displayed in a fly-in element in the upper-right corner of the user interface when the user accesses the standard business function or custom explorer in the Alfabet user interface. The automated help assistant can be closed, whereby it will drop into the slide-in toolbar and can be opened for the current view at another time. For general information about the automated help assistant capability, see the section Understanding the Automated Help Assistant.

Server variables can be used in the **Custom Context-Sensitive Help URL** attribute and the **Automated Assistant URL** attribute to specify the custom help links. Server variables allow you to define all or part of the URL definition in the alias server setting instead of directly defining it in the configuration in Alfabet Expand. Use of server variables is, for example, useful in order to change a Web server name defined in multiple URL definitions in Alfabet Expand. Instead of changing all URL definitions, only the variable value in the alias server setting must be updated. For more information about defining server variables for custom online help, see the section Configuring Server Variables for the Custom Help.

To specify custom help for a standard business function or custom explorer:

1) Go to the **Functions** tab, expand the **Business Functions** explorer node and navigate either to the standard business function or the custom explorer that you want to define a custom help for.
2) Define the following attributes, as needed:

- **Automated Assistant URL**: Enter the URL or server variable that targets the content to display in the automated help assistant assigned to the business function or custom explorer.

  The size of the automated help assistant, its header color and position in the Alfabet user interface, and the notch in the slide-in toolbar are configured for each configuration object type in the GUI scheme. For more information about defining GUI schemes, see the section Configuring GUI Scheme Definitions for the Alfabet Interface. For details about the individual GUI scheme attributes that are relevant for the automated help assistant, see the section *Overview of GUI Scheme Attributes* in the reference manual *Configuring Alfabet with Alfabet Expand - Appendix*.

- **Custom Context-Sensitive Help URL**: Enter the URL or server variable that targets the custom context-sensitive help.
- **Standard Context-Sensitive Help Index**: Displays the HTML file that is available as the standard context-sensitive help for a standard business function. This field cannot be edited.
- **Standard Context-Sensitive Help Visible**: Select `True` to display both the standard and custom context-sensitive help file in the **Help Selector** Select `False` if the link to the standard context-sensitive help should not be available and should not be displayed in the **Help Selector**.

3) In the toolbar, click the **Save** button to save your changes.

Assigning Custom Help and Automated Help Assistants to Custom Object Views and Object Cockpits

You can provide custom context-sensitive help for any custom object view or object cockpit configured by your solution designer. You can specify only one custom context-sensitive help link per object view and only one custom context-sensitive help link per object cockpit. Users will be able to access the context-sensitive help for the object profile or object cockpit that is currently displayed in the Alfabet user interface.

The custom context-sensitive help that you provide for your user community must be available via a URL that can be viewed in a browser. For each custom object view, you can decide whether custom context-sensitive help should be displayed and whether the standard context-sensitive help should or should not be displayed. If you specify that both the standard context-sensitive help and the custom context-sensitive help are to be displayed, the link for the standard context-sensitive help will be listed first in the **Help Selector**, followed by the custom context-sensitive help link. The links will be displayed in the **Help Selector** with the syntax **Custom Help on<Object View Caption>** or **Custom Help on<Object Cockpit Caption>**. For general information about the standard and custom context-sensitive help, see the section Understanding the Context-Sensitive Help.

Furthermore, you can specify content for the automated help assistant and make it available to a selected object view and/or object cockpit. The automated help assistant will be displayed in a fly-in element in the upper-right corner of the user interface when the user accesses the object view or object cockpit in the Alfabet user interface. The automated help assistant can be closed, whereby it will drop into the slide-in toolbar and can be opened for the current view at another time. For general information about the automated help assistant capability, see the section Understanding the Automated Help Assistant.

Server variables can be used in the **Custom Context-Sensitive Help URL** attribute and the **Automated Assistant URL** attribute to specify the custom help links. Server variables allow you to define all or part of the URL definition in the alias server setting instead of directly defining it in the configuration in Alfabet Expand. Use of server variables is, for example, useful in order to change a Web server name defined in multiple URL definitions in Alfabet Expand. Instead of changing all URL definitions, only the variable value in the alias server setting must be updated. For more information about defining server variables for custom online help, see the section Configuring Server Variables for the Custom Help.

For more information about defining tooltips for the custom and protected properties that are displayed in the **Attributes** section of an object view, see the section Providing Custom Tooltips for Custom and Protected Object Class Properties.

To specify custom help for a custom object view or object cockpit:

1) Go to the **Presentation** tab, expand the **Object Views** explorer node and navigate either to the standard object vie w  or object cockpit  that you want to define a custom help for.
2) Define the following attributes, as needed.

- **Automated Assistant URL**: Enter the URL or server variable that targets the content to display in the automated help assistant assigned to the object view or object cockpit.

The size of the automated help assistant, its header color and position in the Alfabet user interface, and the notch in the slide-in toolbar are configured for each configuration object type in the GUI scheme. For more information about defining GUI schemes, see the section Configuring GUI Scheme Definitions for the Alfabet Interface. For details about the individual GUI scheme attributes that are relevant for the

automated help assistant, see the section *Overview of GUI Scheme Attributes* in the reference manual *Configuring Alfabet with Alfabet Expand - Appendix*.

- **Custom Context-Sensitive Help URL**: Enter the URL or server variable that targets the custom context-sensitive help.
- **Standard Context-Sensitive Help Index**: Displays the HTML file that is available as the standard context-sensitive help for the object view.

  The **Standard Context-Sensitive Help Index** attribute can be edited for a custom object view for purposes of backward compatibility. Prior to release 10.1, users specified the location of the external help file using the following syntax: `CUSTOM_HELP:<URL>` (For example: `CUSTOM_HELP:http://helphost/objectview1.html`). The link to the external help file will be displayed in the **Help Selector**. Server variables can be used in the help links. It is recommended that you specify your custom help by means of the **Custom Context-Sensitive Help URL** attribute.

- **Standard Context-Sensitive Help Visible**: Select `True` to display both the standard and custom context-sensitive help file in the **Help Selector** Select `False` if the link to the standard context-sensitive help should not be available and should not be displayed in the **Help Selector**.

3) In the toolbar, click the **Save** button to save your changes.

Assigning Custom Help and Automated Help Assistants to Standard Page Views

You can provide a link to custom help for any standard page view configured by your solution designer. You can specify only one custom online help per standard page view. Users will be able to access the online help for the standard page view that is currently displayed in the Alfabet user interface.

The custom help that you provide for your user community must be available via a URL that can be viewed in a browser. For each standard page view, you can decide whether custom online help should be displayed and whether the standard online help should or should not be displayed. If you specify that both the standard online help and the custom online help are to be displayed, the link for the standard online help will be listed first in the **Help Selector**, followed by the custom help link. The online help entry will be displayed in the **Help Selector** with the syntax **Custom Help on <Page View Caption>**. For general information about the standard and custom context-sensitive help, see the section Understanding the Context-Sensitive Help.

Furthermore, you can specify content for the automated help assistant and make it available to a selected standard page view. The automated help assistant will be displayed in a fly-in element in the upper-right corner of the user interface when the user accesses the standard page view in the Alfabet user interface. The automated help assistant can be closed, whereby it will drop into the slide-in toolbar and can be opened for the current view at another time. If an automated help assistant is specified for a standard page view and that page view is embedded in a wizard step, the automated help assistant will also be available for the wizard step. For general information about the automated help assistant capability, see the section Understanding the Automated Help Assistant.

The custom help that you assign to a page view will be available for every instance of that page view, regardless of the object view context that you define. For example, a custom help link

assigned to the **Assignments** page view in the context of a custom object view configured for the class `Application` will also be available in the **Assignments** page view in the context the object view for the class `Component`.

Server variables can be used in the **Custom Context-Sensitive Help URL** attribute and the **Automated Assistant URL** attribute to specify the custom help links. Server variables allow you to define all or part of the URL definition in the alias server setting instead of directly defining it in the configuration in Alfabet Expand. Use of server variables is, for example, useful in order to change a Web server name defined in multiple URL definitions in Alfabet Expand. Instead of changing all URL definitions, only the variable value in the alias server setting must be updated. For more information about defining server variables for custom online help, see the section Configuring Server Variables for the Custom Help.

To specify custom help for a standard page view:

1) Go to the **Presentation** tab, expand the **Object Views** explorer node, and navigate to the page view that you want to define a custom help for.
2) Define the following attributes, as needed:

- **Automated Assistant URL**: Enter the URL or server variable that targets the content to display in the automated help assistant assigned to the standard page view.

  The size of the automated help assistant, its header color and position in the Alfabet user interface, and the notch in the slide-in toolbar are configured for each configuration object type in the GUI scheme. For more information about defining GUI schemes, see the section Configuring GUI Scheme Definitions for the Alfabet Interface. For details about the individual GUI scheme attributes that are relevant for the automated help assistant, see the section *Overview of GUI Scheme Attributes* in the reference manual *Configuring Alfabet with Alfabet Expand - Appendix*.

- **Custom Context-Sensitive Help URL**: Enter the URL or server variable that targets the custom context-sensitive help.
- **Standard Context-Sensitive Help Index**: Displays the HTML file that is available as the standard context-sensitive help for the page view. This field cannot be edited.
- **Standard Context-Sensitive Help Visible**: Select `True` to display both the standard and custom context-sensitive help file in the **Help Selector** Select `False` if the link to the standard context-sensitive help should not be available and should not be displayed in the **Help Selector**.

3) In the toolbar, click the **Save** button to save your changes.

Assigning Custom Help and Automated Help Assistants to Configured Reports

You can provide a link to custom help for any configured report created by your solution designer. You can specify only one custom online help per configured report. Users will be able to access the online help for the configured report that is currently displayed in the Alfabet user interface.

The custom help that you provide for your user community must be available via a URL that can be viewed in a browser. For each configured report, you can decide whether custom online help should be displayed and whether the standard online help should or should not be displayed. If you specify that both the

standard online help and the custom online help are to be displayed, the link for the standard online help will be listed first in the **Help Selector**, followed by the custom help link. The online help entry will be displayed in the **Help Selector** with the syntax **Custom Help on<Configured Report Caption>**. For general information about the standard and custom context-sensitive help, see the section Understanding the Context-Sensitive Help.

Furthermore, you can specify content for the automated help assistant and make it available to a selected configured report. The automated help assistant will be displayed in a fly-in element in the upper-right corner of the user interface when the user accesses the configured report in the Alfabet user interface. The automated help assistant can be closed, whereby it will drop into the slide-in toolbar and can be opened for the current view at another time. For general information about the automated help assistant capability, see the section Understanding the Automated Help Assistant.

The custom help that you assign to a configured report will be available for every instance of that configured report. For example, a custom help link assigned to the configured report **Data Quality Checklist** in the context of a custom object view configured for the class `Application` will also be available in the configured report **Data Quality Checklist** in the context the object view for the class `Component`.

Server variables can be used in the **Custom Context-Sensitive Help URL** attribute and the **Automated Assistant URL** attribute to specify the custom help links. Server variables allow you to define all or part of the URL definition in the alias server setting instead of directly defining it in the configuration in Alfabet Expand. Use of server variables is, for example, useful in order to change a Web server name defined in multiple URL definitions in Alfabet Expand. Instead of changing all URL definitions, only the variable value in the alias server setting must be updated. For more information about defining server variables for custom online help, see the section Configuring Server Variables for the Custom Help.

To specify custom help for a configured report:

1) Go to the **Reports** tab and navigate to the configured report that you want to define a custom help for.
2) Ensure that the configured report has **Report State** set to **Plan**. To change the report state, right-click the configured report and select **Set Report State to 'Plan'**.
3) Click the report view node below the configured report to open the attribute grid. Define the following attributes, as needed:

- **Automated Assistant URL**: Enter the URL or server variable that targets the content to display in the automated help assistant assigned to the configured report.

  

  The size of the automated help assistant, its header color and position in the Alfabet user interface, and the notch in the slide-in toolbar are configured for each configuration object type in the GUI scheme. For more information about defining GUI schemes, see the section Configuring GUI Scheme Definitions for the Alfabet Interface. For details about the individual GUI scheme attributes that are relevant for the automated help assistant, see the section *Overview of GUI Scheme Attributes* in the reference manual *Configuring Alfabet with Alfabet Expand - Appendix*.

- **Custom Context-Sensitive Help URL**: Enter the URL or server variable that targets the custom context-sensitive help.
- **Standard Context-Sensitive Help Index**: This field will be empty for a configured report.

The **Standard Context-Sensitive Help Index** attribute on the configured report node (not the configured report view node) can be edited for purposes of backward compatibility. Prior to release 10.1, users specified the location of the external help file using the following syntax: `CUSTOM_HELP:<URL>` (For example: `CUSTOM_HELP:http://helphost/report1.html`). The link to the external help file will be displayed in the **Help Selector**. Server variables can be used in the help links. It is recommended that you specify your custom help by means of the **Custom Context-Sensitive Help URL** attribute on the report view node.

- **Standard Context-Sensitive Help Visible**: Select `True` to display both the standard and custom context-sensitive help file in the **Help Selector** Select `False` if the link to the standard context-sensitive help should not be available and should not be displayed in the **Help Selector**.

4) In the toolbar, click the **Save** button to save your changes.

Specifying Custom Help for Editors and Wizards

You can specify content for the automated help assistant and make it available to a selected custom editor or custom wizard. The automated help assistant will be displayed in a fly-in element in the upper-right corner of the user interface when the user accesses the custom editor or custom wizard in the Alfabet user interface. The automated help assistant can be closed, whereby it will drop into the slide-in toolbar and can be opened for the current view at another time. For general information about the automated help assistant capability, see the section Understanding the Automated Help Assistant.

To define a custom tooltip in a custom editor, you must explicitly define the **Hint** attribute for the interface control associated with the custom object class property in the custom editor. For more information about the specification of tooltips in custom editors, see the section Adding Help Text to Interface Controls in the Custom Editor in the chapter Configuring Custom Editors.

If an automated help assistant is specified for a standard page view and that page view is embedded in a wizard step, the automated help assistant will be displayed for the wizard step. For more information about defining an automated help assistant for a standard page view, see the section Assigning Custom Help and Automated Help Assistants to Standard Page Views.

1) Go to the **Presentation** tab, expand the **Custom Editors** explorer node and navigate to the custom editor that you want to define the automated help assistant capability for. In the case of a custom wizard, expand the **Wizards** explorer node and navigate to the custom wizard that you want to define the automated help assistant capability for.
2) In the **Automated Assistant URL** attribute, enter the URL or server variable that targets the content to display in the automated help assistant assigned to the custom editor.

   The size of the automated help assistant, its header color and position in the Alfabet user interface, and the notch in the slide-in toolbar are configured for each configuration object type in the GUI scheme. For more information about defining GUI schemes, see the section Configuring GUI Scheme Definitions for the Alfabet Interface. For details about the individual GUI scheme attributes that are relevant for the automated help assistant, see the section *Overview of GUI Scheme Attributes* in the reference manual *Configuring Alfabet with Alfabet Expand - Appendix*.

3) In the toolbar, click the **Save** button to save your changes.

Specifying Custom Help for Guide Views and Guide Pages

You can specify content for the automated help assistant and make it available to a selected guide view or guide page. The automated help assistant will be displayed in a fly-in element in the upper-right corner of the user interface when the user accesses the guide view or guide page in the Alfabet user interface. The automated help assistant can be closed, whereby it will drop into the slide-in toolbar and can be opened for the current view at another time. For general information about the automated help assistant capability, see the section Understanding the Automated Help Assistant.

1) In the toolbar, click **Managers** > **Guide Page Designer**. The Guide Pages Designer opens in a browser window.
2) Select the relevant guide page project in the **Select Guide Page Project** field.
3) Click the relevant guide view or guide page node that you want to define the automated help assistant capability for.
4) In the **Automated Assistant URL** attribute, enter the URL or server variable that targets the content to display in the automated help assistant assigned to the custom editor.

   The size of the automated help assistant, its header color and position in the Alfabet user interface, and the notch in the slide-in toolbar are configured for each configuration object type in the GUI scheme. For more information about defining GUI schemes, see the section Configuring GUI Scheme Definitions for the Alfabet Interface. For details about the individual GUI scheme attributes that are relevant for the automated help assistant, see the section *Overview of GUI Scheme Attributes* in the reference manual *Configuring Alfabet with Alfabet Expand - Appendix*.

5) In the toolbar, click the **Save** button to save your changes.

Providing Custom Tooltips for Custom and Protected Object Class Properties

Custom tooltips can be defined for all custom properties as well as for protected properties. Users can view the tooltip for the custom object class property in the **Attributes** section of the respective object view. This is defined via the **Hint** attribute defined for the custom/protected object class property. Please note that the **Hint** attribute defined for the custom object class property will not be displayed in a custom editor. For more information about defining the **Hint** attribute for the custom object class property, see the section Configuring Custom Properties for Protected or Public Object Classes in the chapter Configuring the Class Model.

To define a custom tooltip in a custom editor, you must explicitly define the **Hint** attribute for the interface control associated with the custom object class property in the custom editor. For more information about the specification of custom editors, see the section Adding Help Text to Interface Controls in the Custom Editor in the chapter Configuring Custom Editors.

Configuring Server Variables for the Custom Help

The definition of server variables allows information about the targeted links to be defined in the server alias configuration. Defining the information about the URL in the server alias configuration instead of directly defining it in the configured report definitions eases the propagation of changes. You can user server variables in the definition of **Custom Context-Sensitive Help URL** attribute as well as the **Standard Context-Sensitive Help Index** attribute available for custom object views and configured reports.

A variable is referenced as `$<server variable name>`. For example, a server variable called `MYHELPDIRECTORY` is referenced as `$MYHELPDIRECTORY`. In the definition of the **Custom Context-Sensitive Help URL** attribute, the variable definition can either substitute the whole connection string or only part of the connection string. It is also possible to build the URL from a number of concatenated server variables or server variables appended with a URL. For example: `$MYHELPDIRECTORY/CustomHelpPage.html`

Server variables are defined in the Alfabet Administrator:

1) In the Alfabet Administrator, click the **Alfabet Aliases** node in the **Administrator** explorer.
2) In the table on the right, select the server alias that you want to define a server variable for and click the **Edit**  button. The alias editor opens.
3) Go to the **Variables** tab and click the **New** button. A dialog box opens.
4) In the **Variable Name** field, enter a unique name for the server variable.

   

   The server variable name may only contain letters (English alphabet), numbers, and the underscore symbol.

5) In the **Variable Value** field, enter all or part of the URL that should be the target of the Web link.

   

   If the Web link contains a special character according to XML standards (for example: &, %, ;,<,>), these characters must be replaced by their XML conformant variant (for example: `&` for &)

6) Click **OK** to save your changes. The server variable definition appears in the list of server variables.

   

   To edit or delete the server variable, select the server variable in the table and click the **Edit** or **Delete** button below the table.

7) Click **OK** to save your changes and close the editor. The server variable definition is now available in the server alias configuration and can be used for the URL definition specified in Alfabet Expand.

Chapter 13: Configuring Workflows

Software AG supports your enterprise in defining and maintaining workflows in which you can track and coordinate the activities that should be performed by various persons in a particular sequence. For a general overview of the workflow capability, see the section *Executing Workflows and Participating in Workflow Steps* in the reference manual *Getting Started with Alfabet*.

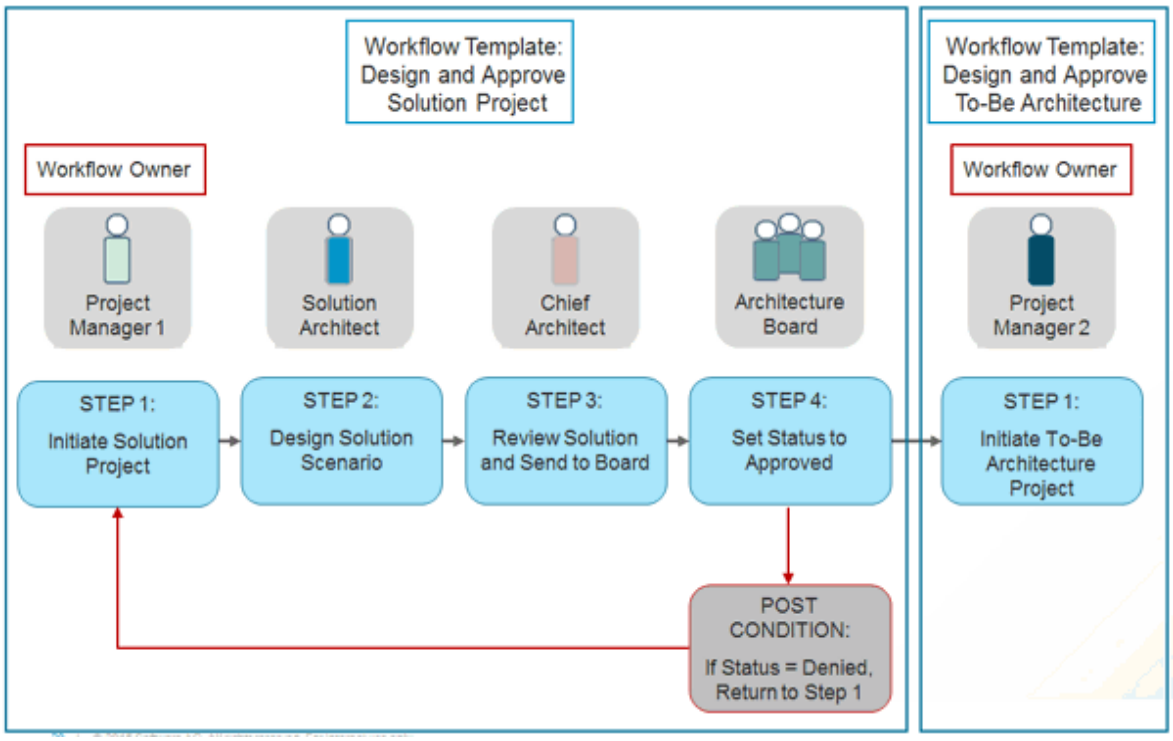

FIGURE: Example of an Alfabet workflow for project proposal and design

A workflow is a collaborative process made up of workflow steps that are typically carried out by one or more users. A workflow is based on a configured workflow template that determines the sequence of workflow steps that are to be performed on a specific object and its references by specified user(s). Workflow steps may have specific pre- and post-conditions that determine different paths to take in the workflow depending on whether the conditions are or are not met.

Typically, the workflow owner is the user who initiates and is responsible for maintaining the workflow. When a workflow is initiated by the workflow owner and when a workflow advances to the next workflow step, relevant users may be informed via automatically-generated emails of their impending responsibility for the workflow step. This functionality ensures that all relevant users are informed and reminded of their responsibilities in the collaborative workflow. The option to refuse, delegate, and pause workflow steps, remind users of an impending target date for a workflow step as well as redirect a workflow that has encountered an error enables workflow owners and workflow administrators to keep track, coordinate, and manage the completion of each workflow step and the workflow as a whole.

To implement workflows in your enterprise, you must first create a workflow template that serves as the basis for the workflow.

For an overview of the object classes for which workflows can be configured, see *Overview of Configurable Features for Object Classes*.

A workflow template is a customer-defined blueprint for one or more workflows. The template specifies what object class is the point-of-departure in the workflow, which user groups and/or user profiles may initiate and administrate the workflow, which workflow steps comprise the workflow as well as their sequence, any possible per- and post-conditions or update actions associated with a workflow step, and what kinds of workflow notifications should be sent to collaborating users in which contexts. The user who creates the workflow template is the workflow template owner.

A workflow template must have the attribute **Workflow State** attribute set to `Plan` to be configured and validated. Once the workflow template is completed and approved, the attribute **Workflow State** must be switched to `Active` in order to make it available to the user community. Once the workflow template is available in Alfabet, a permitted user may initiate a workflow based on the workflow template. Multiple workflows may be simultaneously initiated and running for a workflow template.

Once the workflow template is created, you must create the workflow steps that allow the tasks to be carried out in the workflow.

A workflow step is an activity or task in a workflow that must be performed. The workflow template may have as many workflow steps as needed to complete the relevant task. Standard and custom editors, wizards, page views, configured reports, and object profiles may be implemented in the workflow step so that users can complete the task. A workflow step may entail entering, modifying or reviewing data, or a workflow step may be configured to be automatically executed by the Alfabet system. If the workflow step is not automatically executed by the system, one or more users may be defined as responsible to perform the workflow step. A user may delegate a workflow step to another user or refuse a workflow step. Depending on the configuration of the workflow step, a user may be required to confirm a workflow step before the workflow can advance to the next workflow steps, or the confirmation of the workflow step may occur automatically. A workflow step may also have one or more associated workflow step actions which allow various operations to be performed when the workflow step is entered, exited, refused, or expired. Additionally, each workflow step may have one or more pre-conditions or post-conditions that must be fulfilled in order to enter or exit the workflow step.

If the name of a custom editor, class setting, or user profile is changed and that configuration object is implemented in a workflow template, the changed name will be correctly updated in the workflow templates where that configuration object is implemented. A warning message will be generated during the migration process if a configured report, wizard or text template that is used in a workflow template has been renamed. **The modified names of user profiles, configured reports, wizards, or text templates that are referenced in workflow templates must be explicitly retrofitted for running workflow instances by configuring an appropriate workflow migration definition.**

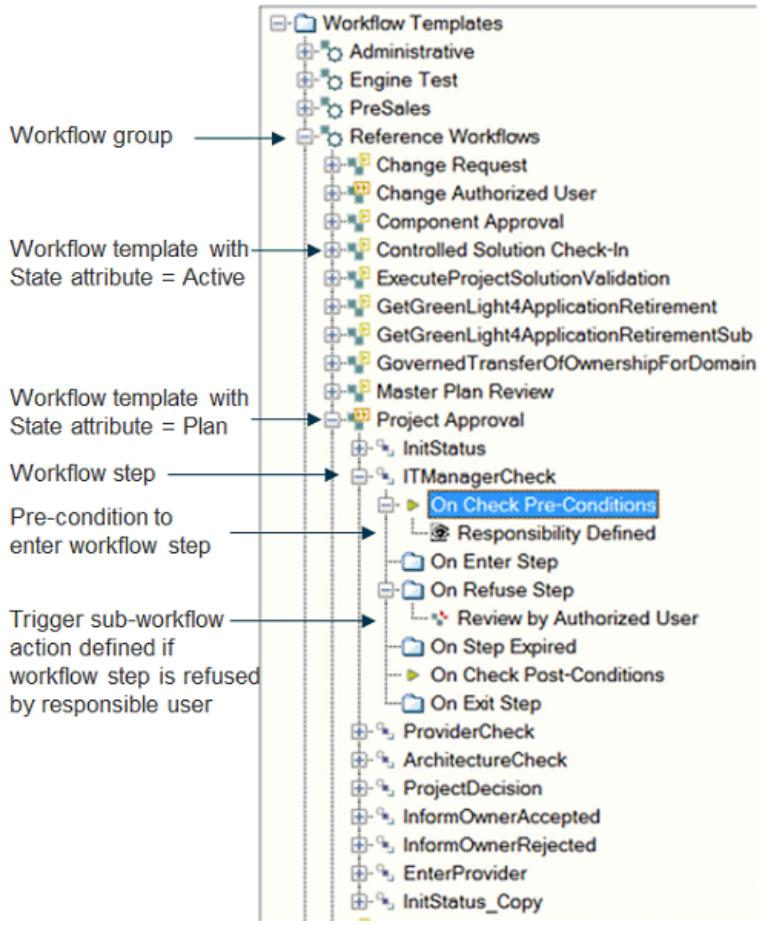

FIGURE: Workflow Templates explorer in the Workflows tab

Workflows are configured in the **Workflow Templates** explorer in the **Workflows** tab of Alfabet Expand. The **Workflow Templates** explorer displays workflow groups, their workflow templates which are listed alphabetically, the workflow steps defined for a workflow template as well as the workflow step actions that allow emails to be automatically sent, object class properties to be automatically updated, sub-workflows to be triggered, pre-conditions /post-conditions to be executed, etc when a workflow step is entered, exited, refused, or expired. Only workflow templates with the **Workflow State** attribute set to `Plan` can be configured and edited.

New workflow objects can be created in the explorer by right-clicking the relevant node and selected an option in the context menu. Click a node in the explorer to open the attribute window in the right pane of the explorer to further specify the nodes attributes.

Workflows can be started via a RESTful service call to the new workflow endpoint of the Alfabet RESTful services. The **Applicable for REST API** attribute is available for workflow templates. The attribute must be set to `True` to start a workflow based on the workflow template via the new endpoint workflow. Only workflow templates with the attribute **Automatic Start** set to `True` can be executed via RESTful service calls. Furthermore, a workflow step action can be configured to trigger an event when a workflow step is entered, refused, expired, or exited. For more information about the configuration required to implement the event capability, see the chapter Configuring Events.

In addition to the workflow capability, Software AG also provides a wizard capability that structures the data capture process for a user. For more information about configuring a wizard for structured data capture, see the chapter Configuring Wizards.

Overview of Individuals Involved in the Workflow Capability

The following individuals are typically involved in the configuration, execution, and management of a workflow:

- **Workflow Designer**: A workflow designer configures the workflow template in Alfabet Expand. It is his/her responsibility to set the workflow template's **Workflow State** attribute to `Active` once the workflow template is ready for implementation in the production environment. The workflow designer is the initial owner of the workflow template. The workflow template owner can be changed in the **Workflow Administration** functionality via the **Change Owner** button. For more information about changing the workflow template owner, see chapter *Tracking and Managing Workflows* in the reference manual *User and Solution Administration*.
- **Workflow Owner**: A workflow owner initiates a workflow in Alfabet based on the workflow template. This can be carried out manually in the **My Workflow Activities** functionalities (`WF_UserWorkflowActivities`, `WF_UserWorkflowActivitiesExt`, and `WF_UserWorkflowActivitiesCommon`) and/or the **Workflow Activities Explorer** (`WFS_Explorer`), in the **Workflow Administration** functionality, or via a batch process. The workflow owner also tracks the progress of any workflow that he/she is the owner of in the **Workflows** section of the **My Workflows** functionality. For more information, see the section *Executing Workflows and Participating in Workflow Steps* in the reference manual *Getting Started with Alfabet*. Further, the workflow owner may interrupt and reactivate a workflow that he/she owns. Additionally, he/she can delegate a workflow step to a different user, withdraw a current workflow step thus removing it from the **My Workflow Activities** functionalities/ **Workflow Activities Explorer** of all responsible users, or, if an error has occurred, redirect the workflow to a different workflow step. These tasks can be carried out in the object profile of the relevant workflow.

All users who may potentially be identified as someone who should initiate a workflow should have a user profile that provides access to the **My Workflows** or **Initiate Workflow** functionalities. Further, the workflow administrator may change the owner of a workflow or workflow template to a user that is not necessarily associated with the permitted user profiles or permitted user groups defined for the workflow template. These users must also be able to access Alfabet with a user profile that provides access to the **My Workflows** or **Initiate Workflow** functionalities. For more information about how access is made available to the workflow capability, see the section Making Functionalities Accessible to a User Profile in the chapter Configuring User Profiles for the User Community.

The owner of a workflow is determined as follows:

- If a workflow is started manually in the **My Workflows** functionality, the current user starting the workflow is the workflow owner.
- If a workflow is started automatically via the batch tool `AlfaWorkflowCommandPrompt.exe`, then the workflow owner is based on the owner of the workflow template. If no workflow template owner is defined, then the current user executing the batch job is the workflow owner.

- If a workflow is started in the **Workflow Administration** functionality via the **Start Automatically** button, the workflow owner is based on the owner of the workflow template. If no workflow template owner is defined, then the current user triggering the workflow in the **Workflow Administration** functionality is the workflow owner.

- **Workflow Step Responsibles**: One or more users that have been identified as responsible for a workflow step execute the task required for the workflow step and confirm the completion of the workflow step in the **My Workflow Activities** functionalities. Responsible users may refuse or delegate a workflow step, if the configuration of their workflow step includes the **Refuse** and/or **Delegate** button. All users who may potentially be identified as responsible users for a workflow step should have a user profile that provides access to the relevant **My Workflow Activities** functionalities (`WF_UserWorkflowActivities`, `WF_UserWorkflowActivitiesExt`, and `WF_UserWorkflowActivitiesCommon`) and/or the **Workflow Activities Explorer** (`WFS_Explorer`). For more information about how access is made available to the workflow capability, see the section Making Functionalities Accessible to a User Profile in the chapter Configuring User Profiles for the User Community.

- **Workflow Administrator**: A workflow administrator maintains all workflow templates configured for the enterprise and tracks the progress of all workflows. The workflow administrator can change the workflow state of any workflow template, assign a new workflow owner to any workflow or workflow template, check workflow deadlines, delete old workflows, and resolve any errors that have occurred in a workflow by, for example, redirecting a workflow to a different workflow step, closing out unconfirmed workflow steps, or releasing a lock on a workflow. These tasks are carried out in the **Workflow Administration** functionality. For more information, see the section *Tracking and Managing Workflows* in the reference manual *User and Solution Administration*.

- **System Administrator**: A system administrator regularly initiates a batch process to send the email notifications generated in a workflow and initiate any automated processes that have been configured for the workflow (for example, the automatic start of workflows and automatic delete of completed workflows). This task is carried out with the `AlfaWorkflowCommandPrompt.exe`. For more information, see the section *Batch Processes for Workflows with AlfaWorkflowCommandPrompt.exe* in the reference manual *System Administration*.

Best-Practice Procedure for Configuring Workflow Templates in the Test Environment

For security reasons, workflow templates cannot be altered during runtime of the Alfabet Server. Instead, workflow templates should be created, configured and tested in a test environment.

You should ensure that the Alfabet Server is configured to send all emails to an explicit test email account instead of using the email account defined for the user that is the recipient of the email. This allows testing to be performed without changing the email account configuration of the users. For more information, see the section *Re-Routing Emails to a Defined Address for Testing* in the reference manual. *System Administration*

The general configuration of workflow templates and workflow steps is described in detail in other sections of the workflow documentation. This section provides general information about the import of the configuration to the production environment. After completion of the workflow template configuration in the test

environment, you can use one of the following methods to import the report configuration to the production environment:

- The configuration of workflow templates can be saved to an AMM updater file either separately or in combination with other configurations specified in Alfabet Expand. The AMM updater file can then be used to replace or merge the configuration in the updater file with the configuration of a target database. Workflow migration can optionally be performed in the target database as part of the AMM configuration import mechanism. This method requires that you are using Alfabet Expand in stand-alone mode. It is part of the overall database update methods and described in the chapter Applying Configuration Changes to Other Databases.
- The configuration of all workflow templates or of a single workflow template can be saved to an XML file. This file can be merged with the workflow template configuration in a target database or replace the workflow template configuration in the target database. The method is available in stand-alone and remote mode. The procedure is described below.

  1) In the test environment, open Alfabet Expand with a server alias or remote alias.
  2) In the **Workflow** tab, right-click the folder **Workflow Templates** at the top of the explorer hierarchy and select **Save As**.
  3) In the explorer window that opens, select a location for the XML file and click **Save** to save the file.
  4) In the production environment, shut down the Alfabet Server.

     

     For information about the shutdown of Alfabet components, see the section *Planned Outages of the Alfabet Components* in the reference manual *System Administration*.

  5) In the production environment, open Alfabet Expand.
  6) In the **Workflow** tab, right-click the folder **Workflow Templates** and select either:

- **Replace from File** to overwrite the current configuration with the configuration in the XML file, or
- **Merge from File** to merge the current configuration with the configuration in the XML file.

  

  Please note the following:

  - **Replace from File** functionality: All objects in the configuration will overwrite corresponding objects in the database. Database objects that have no corresponding object in the configuration file will be deleted.
  - **Merge from File** functionality: All objects in the configuration will overwrite corresponding objects in the database. Database objects that have no corresponding object in the configuration file will remain unchanged. Objects that are only available in the configuration file will be added.

  7) In the explorer window that opens, select the XML file with your new workflow configuration.
  8) Confirm the warning message. The configuration in the production environment is changed.

After replacing or merging a configuration with the configuration in an XML file or AMM file and after upgrading to another Alfabet release, it is recommended to test whether changes in the meta-model require queries to be adapted to any changed workflow configurations. A test mechanism is provided that controls whether Alfabet queries in the customer configuration match the current meta-model. The test procedure is described in the section Testing Queries for Compliance with the Current Release in the chapter Defining Queries.

Conceptualizing the Workflow

For an overview of the object classes for which workflows can be configured, see *Overview of Configurable Features for Object Classes*.

The workflow designer should consider the following issues when defining a workflow template:

- Which object class will the workflow target? Will only one object be targeted throughout the workflow or will another object also be processed at some point during the workflow? For more information, see Specifying the Objects Targeted by the Workflows.
- Will the user need to define data for objects in other object classes as well? If object classes other than the base class are required, a query must be defined to determine the base object for each workflow step that deviates from the base object class. For more information, see Changing to a Different Base Object for a Workflow Step.
- Should an existing object be processed by the workflow or should a new object be created by initiating the workflow? For more information, see Defining the Start of Workflows Based on the Workflow Template.
- Should workflows be automatically generated via batch process for the workflow template or should users manually initiate the workflows? Who may initiate workflows for a specific workflow template?
- What tasks are to be completed for each workflow step in the workflow? Which view is required by the user to complete the task? A workflow step may consist of any of the following:

- a wizard
- a standard editor
- a custom editor
- a standard Alfabet page view
- an object view
- a tabular query-based configured report
- a query-based custom report displaying graphics (such as a tree-map or layered diagram report)
- triggered sub-workflows
- a system-generated action

For more information, see Defining the View Implemented for a Workflow Step.

- Which users should be responsible for each workflow step? Must all responsible users complete the workflow step or can the workflow step be completed if only one responsible user completes the workflow step? For more information, see Defining the Users Responsible for a Workflow Step.
- Should some workflow functionalities (for example, delegate, refuse, etc.) be disabled for a particular workflow step? If this is the case, you can customize the workflow capability to show only toolbar buttons relevant for the current workflow step. For more information, see Configuring the Action Buttons Available for a Workflow Step.

- Are pre-conditions necessary for a workflow step? By defining an Alfabet query or SQL query as a pre-condition, you can stipulate the criteria that must be fulfilled in order to enter a workflow step. For more information, see Configuring Pre- and Post-Conditions for a Workflow Step.
- Are post-conditions necessary to ensure that the data is complete before a workflow step can be exited?
- Should object class properties be automatically updated in the context of a workflow step? For example, should the object class property `Status` be automatically changed to another value once a workflow step is finished? For more information, see Configuring Automatic Property Updates for a Workflow Step.
- Should email notifications be automatically sent to relevant users when a workflow step is entered, refused, delegated, or exited? For more information, see Configuring Email Notifications for Workflows.
- Should sub-workflows be triggered as the consequence of specifying a specific object class property value or entering, completing, refusing, or delegating a workflow step? What should happen in the base workflow if triggered sub-workflows are cancelled? For more information, see Configuring a Workflow Step to Trigger a Subordinate Workflow.
- Should the workflow step have a deadline? If so, should email notifications be sent reminding users of the deadline? Should the workflow owner be informed if the workflow step surpasses its deadline? For more information, see Defining a Deadline and Reminders for a Workflow Step.
- Which workflow functionalities will users require for the workflow?
  - Should users work in one of the **My Workflow Activities** functionalities (`WF_UserWorkflowActivities`, `WF_UserWorkflowActivitiesExt`, and `WF_UserWorkflowActivitiesCommon`)? These are Alfabet's standard tabular views that allow only a minimal amount of customization:
  - Should users process their workflow steps in the **Workflow Activities Explorer** functionality (`WFS_Explorer`), which is a customized view based on a configured HTML template? The **Workflow Activities Explorer** functionality features a design and layout of data that is similar to established email management systems so that users can easily and efficiently accomplish their workflow tasks. Because the view is highly configurable, users can be provided with precisely the data they need in order to process the task-at-hand with a minimum number of clicks and navigation to other views. For more information, see Specifying the Customized Workflow Activities Explorer (WFS_Explorer) or a Custom Explorer.
  - Should any object class properties be hidden in the view implemented for a wizard step?

For more information, see Making the Workflow Capability Available to the User Community.

Creating a Workflow Template

Workflow templates cannot be created and edited during run-time of the Alfabet Server. Therefore, any modifications to workflow templates or testing of workflow templates must occur in a test environment. Once configuration and testing of the workflow template has been completed, you can export the workflow template as part of the Alfabet configuration to an XML file. This XML file can later be imported to the production environment in order to make the changed or new workflow template available to the users.

The mechanism to save the workflow configuration as an XML file as well as to read or merge the configuration are available in both Alfabet Expand and the Alfabet Administrator. For more information, see the section Best-Practice Procedure for Configuring Workflow Templates in the Test Environment.

A workflow template is a customer-defined blueprint for one or more workflows. The template specifies what object class is the point-of-departure in the workflow, which user groups and/or user profiles may initiate and administrate the workflow, which workflow steps comprise the workflow as well as their sequence, any possible per- and post-conditions or update actions associated with a workflow step, and what kinds of workflow notifications should be sent to collaborating users in which contexts. The user who creates the workflow template is the workflow template owner.

A workflow template must have the attribute **Workflow State** attribute set to `Plan` to be configured and validated. Once the workflow template is completed and approved, the attribute **Workflow State** must be switched to `Active` in order to make it available to the user community. Once the workflow template is available in Alfabet, a permitted user may initiate a workflow based on the workflow template. Multiple workflows may be simultaneously initiated and running for a workflow template.

The initial creation of a workflow template is done in two steps:

- First you must create the workflow template and define general attributes including the name.
- Second you must create the initial workflow step. Once the workflow step is created, you must specify the workflow step that the workflow is to begin with. If the workflow is to begin with an existing object, you must define the **Start Step for Existing Object** attribute. If the workflow is to begin by creating a new object, you must define the **Start Step for New Object** attribute. (A workflow template may be configured to begin with both new and existing objects.)

Once the first step has been created, you can then continue defining all other workflow steps including their pre- or post-conditions or updating actions as well as more general information about the workflow template such as email notifications, target date reminders, batch processing of workflows, etc.

If the workflow template that you are configuring should be triggered in the context of another workflow, please review the information in the section Configuring a Workflow Step to Trigger a Subordinate Workflow before configuring the workflow template.

Workflows can be started via a RESTful service call to the new workflow endpoint of the Alfabet RESTful services. The **Applicable for REST API** attribute is available for workflow templates. The attribute must be set to `True` to start a workflow based on the workflow template via the new endpoint workflow. Only workflow templates with the attribute **Automatic Start** set to `True` can be executed via RESTful service calls. For more information about the configuration required to implement the event capability, see the chapter Configuring Events.

To create a workflow template and define the first initial attributes:

1) In the **Workflow** tab, right-click the **Workflow Templates** icon at the top of the explorer and select **Create New Workflow Template**. The new workflow template  is displayed in the explorer.
2) Click the workflow template to open the attribute window and begin defining some of the attributes in the section of the attribute window labeled **Common**.
3) Ensure that the **Workflow State** attribute is set to `Plan`. The workflow template may only be configured in the `Plan` state. The **Workflow State** attribute of the workflow template is edited by right-clicking the workflow template and selecting the relevant value (for example, **Set Workflow**

State to Plan) The workflow template state is updated in the **State** attribute in the attribute window.

4) In the **Caption** attribute, enter a name to display in the Alfabet interface for the workflow template.

5) In the **Comment** attribute, enter an explanation about the workflow template. Users will see the comment in the **Description** attribute in the preview pane in the **My Workflows** and **Initiate Workflows** functionalities. Therefore, the comment should be specific enough so that users understand the intention and purpose of the workflow template.

6) To change the technical name of the workflow template, enter a name for the workflow template in the **Name** attribute. This name is not visible in the Alfabet software.

A validation mechanism checks for correct syntax when defining a technical name. The technical name of a configuration object may not begin with an empty space nor include any of the following special characters: **\ / * ? " > < |':**

Furthermore, please note that names may not begin with an empty space nor include special characters. For a list of the special characters that are not allowed, see the section Defining Attributes for Configuration Objects in the chapter Getting Started with Alfabet Expand.

Furthermore, if the technical name of a configuration object is changed, the name will be correctly updated in other configuration objects referencing the changed object during design time. Please note that the name of a changed configuration object will not be updated in guide pages nor if the guide pages reference a configuration object listed in the **Show Usage** functionality. If you plan to change the name of a configuration object, the reference in the guide page should be changed prior to changing the configuration object name.

The **Name** attribute of the workflow template should NOT be changed if it is already referenced as a sub-workflow (once it is selected in the **Workflow Template** attribute of a workflow step action of the **Type** `TriggerWorkflow`). If the workflow template name is changed, the sub-workflows may not be correctly triggered.

7) If you would like the workflows to be automatically deleted once they are completed, select `True` in the **Auto Delete** attribute. The automatic deletion of finished workflows requires a batch process that is executed by your system administrator. For more information about initiating a batch process for workflows, see the section *Batch Processes for Workflows with AlfaWorkflowCommandPrompt.exe* in the reference manual *System Administration*.

8) If you would like to allow multiple workflow steps that fulfill their pre-conditions to be executed at the same time in parallel to one another, select `True` in the **Allow Simultaneous Execution of Steps** attribute. If workflow steps may not be simultaneously executed, select `False` in the **Allow Simultaneous Execution of Steps** attribute.

If multiple workflow steps are defined in the **Next Steps** attribute for a workflow step and the pre-conditions are fulfilled for more than one of these workflow steps, the following scenarios are possible:

- If the **Allow Simultaneous Execution of Steps** attribute is set to `False`, an error message will occur. In other words, you must ensure that only one workflow step listed in the **Next Steps** attribute of each workflow step can have its pre-conditions fulfilled and be entered.

- If the **Allow Simultaneous Execution of Steps** attribute is set to `True`, then all workflow steps in the **Next Steps** attribute that fulfill their pre-conditions will be executed in parallel. The subsequent behavior of the workflow will depend on how the **Next Steps** attributes are defined for the parallel workflow steps. There are two alternatives for the configuration of the subsequent workflow steps:

  - All parallel running workflow steps will merge directly or indirectly into the same subsequent workflow step (defined in the **Next Steps** attribute of the merging workflow steps). In this case, the subsequent workflow step will only be entered when all preceding parallel-running steps have been completed.

  - Each parallel running workflow step forms its own independent branch with subsequent workflow steps. The branches do not merge into a common workflow step. The workflow will be completed only when ALL branches reach their last workflow step. **Please note that this workflow design is not recommended. Best practice recommendation for designing workflows with parallel branches is to merge all those branches back into a single lane of execution prior to ending the workflow.**

  Please note that if a workflow includes parallel workflow steps and one of the branches forms a cycle that returns to the workflow step where the branching occurred, the availability of that workflow step will be checked prior to recreating the workflow step. If the workflow step is still active, it will not be recreated.

9) If you would like to structure the workflow template in a workflow template folder, either enter the name of a new folder or select an existing folder in the **Group** attribute. Workflow folders are only for the purposes of organizing workflow templates in Alfabet Expand. They are not visible in the Alfabet interface.

10) Click the **Save**  button to save your definitions.

You must now create at least the first workflow step. If the workflow is to begin with an existing object, you must define the **Start Step for Existing Object** attribute. If the workflow is to begin by creating a new object, you must define the **Start Step for New Object** attribute. To carry out these procedures, see:

- Creating a Workflow Step
- Defining the Sequence of the Workflow Steps

Defining the Start of Workflows Based on the Workflow Template

When you configure the start definition for a workflow template, you determine whether workflows may be started manually by specific users in the Alfabet community, whether workflows may be started automatically via a batch process, or whether workflows may be started manually and automatically.

If the workflow template is to be manually started, permissible users may start the workflow in the **My Workflows** functionality, the **Initiate Workflows** functionality, or for a relevant object via the **Workflows** button available in the toolbar of the object profile.

Please note the following about the configuration of the workflow template:

- To configure the manual or automatic start of a workflow, you should first create the first step in the workflow. The workflow step does not need to be configured in detail at this point. However, it must exist and must have a name. For more information about defining a workflow step, see the section Creating a Workflow Step.
- Every workflow will begin with a base object that is the target of the workflow. The configuration of the objects targeted by workflows based on workflow templates configured to start manually or automatically is addressed in the section Specifying the Objects Targeted by the Workflows.
- In order for a workflow to be started manually or automatically, the **Workflow State** attribute of the workflow template must be set to `Active`. Workflows cannot be started for workflow templates that have the **Workflow State** attribute set to `Plan` or `Retired`. For more information about changing the **Workflow State** attribute, see the section Changing the Workflow State and Activating/Deactivating the Workflow Template.

The owner of a workflow is determined as follows:

- If a workflow is started manually in the **My Workflows** functionality, the current user starting the workflow is the workflow owner.
- If a workflow is started automatically via the batch tool `AlfaWorkflowCommandPrompt.exe`, then the workflow owner is based on the owner of the workflow template. If no workflow template owner is defined, then the current user executing the batch job is the workflow owner.
- If a workflow is started in the **Workflow Administration** functionality via the **Start Automatically** button, the workflow owner is based on the owner of the workflow template. If no workflow template owner is defined, then the current user triggering the workflow in the **Workflow Administration** functionality is the workflow owner.

The following information is available:

- Configuring the Manual Start of Workflows
- Configuring the Automatic Start of Workflows

Configuring the Manual Start of Workflows

You can configure the workflow template so that workflows can be started manually by permissible users. In this case, users with access permissions to the workflow template can start workflows for the workflow template in either the **My Workflows** functionality or the **Initiate Workflows** functionality. Only workflow templates with an active workflow state will be displayed in the **My Workflows** functionality and **Initiate Workflows** functionality.

The definition of permissible users is specified via the user group or user profile affiliation. The user who initiates the workflow is the original workflow owner and is responsible for maintaining the workflow as long as he/she remains the workflow owner.

To specify the manual start of workflows for a workflow template:

1) Click the workflow template  to open the attribute window.

2) Define the manual start of workflows for the workflow template. In the **Manual Start** attribute, select `True`.

3) Next, define the users who shall have permissions to initiate workflows for the selected workflow template. You can identify the users via user profiles and user groups. Define one or all of the following attributes:

- **Permitted User Profiles**: Select one or more user profiles that may initiate a workflow that is based on this workflow template.

  

  If the **Permitted User Profiles** attribute is not defined, then access will only be granted to

  the users that are member of the **Permitted User Groups** attribute.

- **Permitted User Groups**: Select one or more user groups that may initiate a workflow that is based on this workflow template.

  

  If you define one or more user profiles and one or more user groups, then only users belonging to at least one specified user profile OR at least one specified user group will be able to initiate a workflow based on the workflow template.

4) Next, you should specify the first step that will be used to start the workflow:

- If existing objects should be targeted in the first step of the workflow, specify the first workflow step in the **Start Step for Existing Object** attribute. Leave this attribute empty if existing objects are not targeted in the first workflow step.
- If new objects will be created during the initiation of the workflow, specify the first workflow step in the **Start Step for New Object** attribute. Leave this attribute empty if new objects are not targeted in the first workflow step.

  

  The workflow step must already be created. However, it does not need to be configured in detail at this point. However, it must exist and must have a name. For more information about defining a workflow step, see the section Creating a Workflow Step.

  Every workflow will begin with a base object that is the target of the workflow. To configure the objects targeted by a workflow template configured to be manually started, see the sections:

  - Configuring the Manual Start of Workflows
  - Configuring Automatically Started Workflows to Start with Existing Objects
  - Configuring Manually-Started Workflows to Start with New Objects
  - Changing to a Different Base Object for a Workflow Step

5) Next, you may define a caption for the initiation of the workflow template that will be displayed in the **My Workflows** functionality, **Initiate Workflows** functionality, and in the drop-down menu displayed via the **Workflows** button in the object profile. This allows you to define a caption that provides basic information to the user (for example, to indicate whether they will start the workflow with a new or existing object).

- If you have defined the **Start Step for Existing Object** attribute, enter a caption in the **Caption for Existing Object** attribute.
- If you have defined the **Start Step for New Object** attribute, enter a caption in the **Caption for New Object** attribute.

6) To provide additional direction for the workflow template in the **My Workflows** functionality and the **Initiate Workflows** functionality, enter a comment in the **Caption** attribute. This information will be displayed in the preview pane that opens when a user selects the workflow template in the table. If you do not define the **Caption for Existing Object** attribute or the **Caption for New Object** attribute, the text defined in the **Caption** attribute will be displayed in table and preview pane in the **My Workflows** functionality and the **Initiate Workflows** functionality.

7) Click the **Save** button to save your definitions.

Configuration Required to Start a Workflow in an Object Profile

A workflow may be manually started via the object profile of an object relevant for the workflow.

Typically, workflows may be manually started via the object profile for a base object in the object class specified in the **Start Base Class** attribute. If the **Source Base Class** attribute has also been specified for the workflow template, a workflow for the source object referencing the base object can also be started via the object profile. The workflow for the source object will be displayed along with the workflow for the base object in the drop-down menu for the **Workflow** button. For more information about the configuration of the **Start Base Class** attribute and the **Source Base Class** attribute, see the section Specifying the Objects Targeted by the Workflows.

If workflows may be started via the object profile, users will see the **Workflow** button in the toolbar of the relevant object profile of the object class specified in the **Start Base Class** attribute of the workflow template. In the case of object class stereotypes, the **Workflow** button will be displayed only in the custom object views configured for the object class stereotype.

To initiate a workflow, the user must click the **Workflow** button in the object profile and select the relevant workflow template listed in the in the drop-down menu. The workflow will be initiated for the selected object. A workflow based on a selected workflow template may only be initiated once for an object.

For users to be able to initiate a workflow for an object via the object profile, the following must be taken into consideration regarding the configuration of the workflow template:

- The workflow template must be configured to start manually. Ensure that the **Manual Start** attribute is set to `True`.
- The workflow template must be configured to start with an existing object. Therefore, the **Start Step for Existing Object** attribute must be defined. (Please note that this does not need to be defined for a source object.) For more information, see the section Specifying the Objects Targeted by the Workflows.
- If the workflow step specified in the **Start Step for Existing Object** attribute is a workflow step for which the **Type** attribute is set to `System`, an informational message can be configured in the

Message for Started Workflow attribute that lets the user know that a workflow has been started when he/she clicks the **Workflow** button. A workflow step for which the **Type** attribute is set to `System` is a system-generated action that does not require user input or user action. If no workflow message is defined, the workflow will begin, but it may not be apparent to the user initiating the workflow that the workflow has actually started.

Configuring the Automatic Start of Workflows

For each workflow template that is to be started automatically, a query must be defined in order to find or create the objects targeted by the workflow.

If the workflow template is to be started automatically, a batch process must be configured and executed by the system administrator in order to trigger the creation of the workflows. For more information about configuring and initiating a batch process for workflows, see the section *Batch Processes for Workflows with AlfaWorkflowCommandPrompt.exe* in the reference manual *System Administration*.

Typically, the system administrator will execute scheduled batch processes in the enterprise. If the workflow template is to be started via a batch process, a workflow administrator can also execute the batch initiation of workflows for a selected workflow template in the **Workflow Administration** functionality in the **Administration** application. For more information about how the workflow administrator can execute a batch process for a specific workflow template, see the chapter *Tracking and Managing Workflows* in the reference manual *User and Solution Administration*.

Workflows can be started via a RESTful service call to the new workflow endpoint of the Alfabet RESTful services. The **Applicable for REST API** attribute is available for workflow templates. The attribute must be set to `True` to start a workflow based on the workflow template via the new endpoint workflow. Only workflow templates with the attribute **Automatic Start** set to `True` can be executed via RESTful service calls. For more information about the configuration required to implement the event capability, see the chapter Configuring Events.

To specify the automatic start of a workflow via a configured batch process:

1) Click the workflow template to open the attribute window.
2) Ensure that `True` is selected in the **Automatic Start** attribute.
3) Next, you should specify the first step that will be used to start the workflow:

- If existing objects should be targeted in the first step of the workflow, specify the first workflow step in the **Start Step for Existing Object** attribute.
- If new objects will be created in the first step of the workflow, specify the first workflow step in the **Start Step for New Object** attribute.

The workflow step must already be created. However, it does not need to be configured in detail at this point. However, it must exist and must have a name. For more information about defining a workflow step, see the section Creating a Workflow Step.

For each workflow template that is to be started automatically, a query must be defined in order to find or create the objects targeted by the workflow. If the workflow template

is configured to automatically start for objects already existing in the database, a workflow will be started for each object found by the query.

To configure the objects targeted by a workflow templates configured to be automatically started, see the sections:

- Configuring Automatically Started Workflows to Start with Existing Objects
- Changing to a Different Base Object for a Workflow Step

4) Click the **Save** button to save your definitions.

Specifying the Objects Targeted by the Workflows

This section focuses on the configuration of the objects for which workflows are to be started. The documentation is relevant for both conventional workflow templates as well as workflow templates that have been configured to trigger sub-workflows via the `TriggerWorkflow` option in the **Type** attribute defined for a workflow step action.

Whether you specify the target objects via the attributes **Start Base Class** or **Source Base Class** will depend on the scenario that you plan to implement to start the workflow template.

- Should workflows be initiated for objects that already exist in the database?
- Should new objects be created as part of the workflow start?
- Should new objects be created for an object found in a base object class. For example, for each application, a corresponding risk object should be created.
- Should new objects be created via an automatically-started workflow. For example, a set of new applications should be created with specified data already defined.
- Should new objects be created that must be approved before they can be added to the Alfabet database. For example, a set of new applications must go through an approval process before they can be added to the Alfabet inventory.

- You must ensure that the object class specified in the **Start Base Class**, **Base Object Query**, and the **Source Object Query** attributes has a `Name` attribute and an `ID` attribute defined. If the object class has no **Name** attribute or **ID** attribute, then you must configure a custom object class property for the `Name` attribute and `ID` attribute. For more information about the configuration of custom object class properties, see the section Configuring Custom Properties for Protected or Public Object Classes.
- If you are creating a workflow template for the object class `ITMapView`, you must configure the workflow template to start with existing objects because a map view is dependent on the object class `ITMasterPlanMap`. A new map view cannot be created in the context of a workflow.

The following information is available:

- Configuring Manually Started Workflows to Start with Existing Objects
- Configuring Automatically Started Workflows to Start with Existing Objects

- Configuring Manually-Started Workflows to Start with New Objects
- Configuring Workflows to Create New Target Objects via the Source Base Class Attribute
- Changing to a Different Base Object for a Workflow Step

Configuring Manually Started Workflows to Start with Existing Objects

If the manually-started workflow is to begin with existing objects, you must define the **Start Base Class** attribute to specify the base object class of the workflow.

Users with permissions to the workflow template will be able to select the object that they want to start a workflow for by means of a configured standard or custom selector. The object that is targeted by the workflow is considered the base object of the workflow. The first workflow step as well as all subsequent workflow steps will target the base object unless a workflow step is explicitly configured to work with an object other than the base object.

To specify existing objects as the targets of manually-started workflows:

1) Click the workflow template  to open the attribute window.
2) Ensure that the **Manual Start** attribute is set to `True`.
3) Define the base object class for the workflow template. This is the object class that the workflow begins with when the first workflow step is performed. In the **Start Base Class** attribute, select the base object class for the workflow template.

   

   If you select an object class stereotype (`<ObjectClass:ObjectClassStereotype>`) in the **Start Base Class** attribute:

   - The standard object selector that will open will display all objects for all stereotypes configured for the object class. The user starting the workflow must ensure that he/she selects an object of the correct stereotype in the object selector. To avoid this, you can specify a custom selector configured specifically for the object class stereotype. For more information about the configuration of custom selectors, see section Configuring a Custom Selector for Search Functionalities.
   - The **Workflow**  button will be displayed only in the custom object views configured for the object class stereotype.

   For an overview of the object classes for which workflows can be configured, see *Overview of Configurable Features for Object Classes* in the reference manual *Configuring Alfabet with Alfabet Expand - Appendix*.

4) Ensure that the **Start Step for Existing Object** attribute is specified with the first workflow step. When the user clicks the **New Workflow** button in the **My Workflows** functionality or the **Initiate Workflows** functionality, the workflow will begin and the relevant view defined for the first workflow step will open (with the exception of a workflow step action where the **Type** attribute is set to `System`).

The workflow step must already be created. However, it does not need to be configured in detail at this point. However, it must exist and must have a name. For more information about defining a workflow step, see the section Creating a Workflow Step.

5) In the **Define Base or Source Artifact Selector** attribute, specify the standard or custom selector that should be implemented for users to find the relevant object.

- If no selector is defined in the **Define Base or Source Artifact Selector** attribute, then the standard or custom selector defined in the **Selector Definition** attribute of the relevant class setting will be implemented. For more information about defining class settings, see the section Configuring Class Settings for Object Classes and Object Class Stereotypes in the chapter Configuring User Profiles for the User Community.
- If a custom selector is defined in the **Define Base or Source Artifact Selector** attribute, then the custom selector specification will override the class setting definition. For more information about the configuration of custom selectors, see the section Configuring a Custom Selector for Search Functionalities.

6) In the **Object Permission** attribute, select `AllUsers` if any user with Read/Write access permissions to the workflow template may start the workflow template, regardless of the access permissions defined for the object that is targeted by the workflow template. Select `AuthorizedUsersOnly` if only users with Read/Write access permissions to the object that is targeted by the workflow template may start the workflow.

For an overview of the access permission concept in Alfabet, see the section Overview of Access Permissions for Objects.

7) In the **Allow Multiple Workflows for Same Object** attribute, select `True` if multiple workflows can be created for the same object in the base object class. Select `False` if only one workflow can be created per object for the base object class. To avoid multiple users simultaneously entering conflicting data, it is recommended that this attribute be set to `False`.

8) Click the **Save** button to save your definitions.

Configuring Automatically Started Workflows to Start with Existing Objects

If the automatically-started workflow is to begin with existing objects, you must define the **Start Base Class** attribute to specify the base object class of the workflow. Additionally, you must specify a query in the **Base Objects by Query** attribute that specifies the objects for which workflows should be started.

A workflow will be automatically started for each object found by the query. The first workflow step will be entered once the workflow is started. Depending on the configuration of the workflow step, responsible users may see and thus perform the first workflow step in the **My Workflow Activities** functionalities (`WF_UserWorkflowActivities`, `WF_UserWorkflowActivitiesExt`, and `WF_UserWorkflowActivitiesCommon`) and/or the **Workflow Activities Explorer** (`WFS_Explorer`).

The object that is targeted by the workflow is considered the base object of the workflow. The first workflow step as well as all subsequent workflow steps will target the base object unless a workflow step is explicitly configured to work with an object other than the base object.

If the workflow template is to be started automatically, a batch process must be configured and executed by the system administrator in order to trigger the creation of the workflows. For more information about configuring and initiating a batch process for workflows, see the section *Batch Processes for Workflows with AlfaWorkflowCommandPrompt.exe* in the reference manual *System Administration*.

Typically, the system administrator will execute scheduled batch processes in the enterprise. If the workflow template is to be started via a batch process, a workflow administrator can also execute the batch initiation of workflows for a selected workflow template in the **Workflow Administration** functionality in the **Administration** application. For more information about how the workflow administrator can execute a batch process for a specific workflow template, see the chapter *Tracking and Managing Workflows* in the reference manual *User and Solution Administration*.

To specify existing objects as the targets of automatically-started workflows:

1) Click the workflow template  to open the attribute window.
2) Ensure that `True` is selected in the **Automatic Start** attribute.
3) Define the base object class for the workflow template. This is the object class that the workflow begins with when the first workflow step is performed. In the **Start Base Class** attribute, select the base object class for the workflow template.

   If you select an object class stereotype (`<ObjectClass:ObjectClassStereotype>`) in the **Start Base Class** attribute:

   - The standard object selector that will open will display all objects for all stereotypes configured for the object class. The user starting the workflow must ensure that he/she selects an object of the correct stereotype in the object selector. To avoid this, you can specify a custom selector configured specifically for the object class stereotype. For more information about the configuration of custom selectors, see section Configuring a Custom Selector for Search Functionalities.
   - The **Workflow**  button will be displayed only in the custom object views configured for the object class stereotype.

   For an overview of the object classes for which workflows can be configured, see *Overview of Configurable Features for Object Classes* in the reference manual *Configuring Alfabet with Alfabet Expand - Appendix*.

4) Ensure that the **Start Step for Existing Object** attribute is specified with the first workflow step. When the user clicks the **New Workflow** button in the **My Workflows** functionality or the **Initiate Workflows** functionality, the workflow will begin and the relevant view defined for the first workflow step will open (with the exception of a workflow step action where the **Type** attribute is set to `System`).

   The workflow step must already be created. However, it does not need to be configured in detail at this point. However, it must exist and must have a name. For more information about defining a workflow step, see the section Creating a Workflow Step.

5) In the **Base Objects via Query** attribute, define a query to find the objects for which a workflow should start.

The following Alfabet query is an example of a query defined to find existing applications via the role definition:

```
ALFABET_QUERY_500

FIND

Application

    InnerJoin Role AS RMrole ON RMrole.Object =
    Application.REFSTR

    InnerJoin RoleType AS RMroletype ON RMroletype.REFSTR =
    RMrole.RoleType

    InnerJoin Role AS RErole ON RErole.Object =
    Application.REFSTR

    InnerJoin RoleType AS REroletype ON REroletype.REFSTR =
    RErole.RoleType

WHERE

    (AND

       RMroletype.Name ='Risk Manager'

       REroletype.Name ='Risk Evaluator'

    )
```

For general information about defining an Alfabet query or an SQL query, see the chapter Defining Queries.

6) In the **Allow Multiple Workflows for Same Object** attribute, select `True` if multiple workflows can be created for the same object in the base object class. Select `False` if only one workflow can be created per object for the base object class. To avoid multiple users simultaneously entering conflicting data, it is recommended that this attribute be set to `False`.

7) Click the **Save** button to save your definitions.

Configuring Manually-Started Workflows to Start with New Objects

If the manually-started workflow is to begin with new objects, you must define the **Start Base Class** attribute to specify the base object class of the workflow.

Users with permissions to the workflow template will be able to start a workflow for the workflow template. The editor or wizard configured for the first workflow step will open and the user can enter the required basic data to create the object.

The object that is created via the workflow is considered the base object of the workflow. All subsequent workflow steps will target the base object unless a workflow step is explicitly configured to work with an object other than the base object.

To specify the creation of new objects for manually-started workflows:

1) Click the workflow template to open the attribute window.
2) Ensure that the **Manual Start** attribute is set to `True`.

3) Define the base object class for the workflow template. This is the object class that the workflow begins with when the first workflow step is performed. In the **Start Base Class** attribute, select the base object class for the workflow template.

   If you select an object class stereotype (`<ObjectClass:ObjectClassStereotype>`) in the **Start Base Class** attribute:

   - The standard object selector that will open will display all objects for all stereotypes configured for the object class. The user starting the workflow must ensure that he/she selects an object of the correct stereotype in the object selector. To avoid this, you can specify a custom selector configured specifically for the object class stereotype. For more information about the configuration of custom selectors, see section Configuring a Custom Selector for Search Functionalities.
   - The **Workflow** button will be displayed only in the custom object views configured for the object class stereotype.

   For an overview of the object classes for which workflows can be configured, see *Overview of Configurable Features for Object Classes* in the reference manual *Configuring Alfabet with Alfabet Expand - Appendix*.

4) Ensure that the **Start Step for New Object** attribute is specified with the first workflow step. When the user clicks the **New Workflow** button in the **My Workflows** functionality or the **Initiate Workflows** functionality, the workflow will begin and the relevant editor or wizard defined for the first workflow step will open.

   The workflow step must already be created. However, it does not need to be configured in detail at this point. However, it must exist and must have a name. For more information about defining a workflow step, see the section Creating a Workflow Step.

5) Click the **Save** button to save your definitions.

Configuring Workflows to Create New Target Objects via the Source Base Class Attribute

Software AG provides the possibility of configuring more complex workflow scenarios in terms of creating or finding target objects for workflows. Such configurations require the specification of the **Start Base Class** attribute and the **Source Base Class** attribute as well as associated queries. This configuration is more involved than the previously described scenarios.

The following scenarios can be addressed for both manually and automatically started workflows via the configuration of the **Start Base Class** attribute and the **Source Base Class** attribute:

- New objects should be created for each found object in a base object class. For example, for each application, a corresponding risk object should be created.
- New objects should be created via an automatically-started workflow. For example, a set of new applications should be created with specified data already defined. In this case, you must configure a query that specifies how many objects to create as well as the initial values that should be automatically written to the object class properties.

A query must be configured via the **Source Objects via Query** attribute to create the objects for which workflows must be started. In this case, you must initially specify which object class properties are automatically filled for the new objects (such as `Name`). This must be specified by configuring an **Action on Entered Step** action for the first workflow step.

Typically, workflows may be manually started via the object profile for a base object in the object class specified in the **Start Base Class** attribute. If the **Source Base Class** attribute has also been specified for the workflow template, a workflow for the source object referencing the base object can also be started via the object profile. The workflow for the source object will be displayed along with the workflow for the base object in the drop-down menu for the **Workflow** button. For more information about the configuration of the **Start Base Class** attribute and the **Source Base Class** attribute, see the section Specifying the Objects Targeted by the Workflows.

A workflow will be started for each object created via a query. The first workflow step will be entered once the workflow is started. The object that is created by the workflow is considered the base object of the workflow. The first workflow step as well as all subsequent workflow steps will target the base object unless a workflow step is explicitly configured to work with an object other than the base object.

If the workflow template is to be started automatically, a batch process must be configured and executed by the system administrator in order to trigger the creation of the workflows. For more information about configuring and initiating a batch process for workflows, see the section *Batch Processes for Workflows with AlfaWorkflowCommandPrompt.exe* in the reference manual *System Administration*.

Typically, the system administrator will execute scheduled batch processes in the enterprise. If the workflow template is to be started via a batch process, a workflow administrator can also execute the batch initiation of workflows for a selected workflow template in the **Workflow Administration** functionality in the **Administration** application. For more information about how the workflow administrator can execute a batch process for a specific workflow template, see the chapter *Tracking and Managing Workflows* in the reference manual *User and Solution Administration*.

To specify the creation of new target objects via the **Source Base Class** attribute:

1) Click the workflow template to open the attribute window. The **Automatic Start** attribute and the **Manual Start** attribute may be set `True`.
2) Next define the start base object class for the workflow template. This is either the custom object class or another Alfabet object class that the workflow will begin with when the first workflow step is performed. Objects will be initially created for this object class. In the **Start Base Class** attribute, select the start base object class for the workflow template.
3) Next, define the source base object class for the workflow template. This is the referenced object class containing objects in the Alfabet inventory for which workflows will be started. In the **Source Base Class** attribute, select the source base object class for the workflow template.

   If relevant workflow step actions have been configured, the data for the source base objects will be copied to the transient objects (based on the start base object class) when the workflows are created.

4) If the **Automatic Start** attribute is set to ***True***: In the **Source Objects via Query** attribute, define a query to create the objects for which workflows should be started.

For example, the workflow template is targeted at the creation of workflows for applications that are not yet allocated domains in the enterprise. The **Start Base Class** attribute of the workflow template specifies a custom class that has been created specifically for this workflow template. The **Source Base Class** is Application. The following Alfabet query searches for existing active applications in the inventory that have no domain assignment.

```
ALFABET_QUERY_500
FIND Application
WHERE (AND Application.Domain IS NULL
    Application.ResponsibleUser IS NOT NULL
    Application.ObjectState ='Active')
```

For general information about defining an Alfabet query or SQL query, see the chapter Defining Queries.

5) Next, define an action of the **Type** `Script` for the **Action On Entered Step** defined for the first workflow step. In the **Statements** attribute, you should specify the object class properties that should be automatically written to the transient objects.

For example.

```
Set(WORKFLOWBASE.BASEOBJECT,SOURCE.REFSTR);
Set(WORKFLOWBASE.ID,SOURCE.ID);
Set(WORKFLOWBASE.Name,SOURCE.Name);
```

For more configuration of a property update of the type `Script`, see the section Configuring Automatic Property Updates for a Workflow Step.

6) Configure the remaining workflow steps for the workflow template, as needed.

7) If the **Manual Start** attribute is set to ***True***: In the **Object Permission** attribute, select `AllUsers` if any user with access permissions to the workflow template may start the workflow template, regardless of the access permissions defined for the object that is targeted by the workflow template. Select `AuthorizedUsersOnly` if only users with access permissions to the object that is targeted by the workflow template may start the workflow.

8) Click the **Save**  button to save your definitions.

Changing to a Different Base Object for a Workflow Step

Typically, a workflow will process a single object in the base object class defined for the workflow template. However, it may be necessary during the workflow to change to a different object for a workflow step. This could be necessary, for example, in order to allow objects related to the base object to be defined.

For example, a wizard has been configured in order to capture application data. The enterprise requires that the ICT object that the application is assigned also be defined at the time that the application data is captured. In this case, you can configure a query to find the object in object class ICT object that should be defined in the context of the wizard

In order to change to a different object from the same base object class or a different base object class as that defined in **Start Base Class** attribute for the workflow template, you must configure a query for each workflow step that targets an object that is not the original base object. The query will be executed when the workflow step is entered.

The object found by the query will only be applied to the current workflow step. The subsequent workflow step will return to the original target object found in the **Start Base Class** attribute. If the subsequent workflow step should not return to the original target object, you must enter the same query or a different query for the subsequent workflow step. In other words, if you change from the base object to another object and this new object is the target of 3 workflow steps, the query to find the target object must be specified in all three workflow steps.

To configure the workflow to change to a different object than the original base object.

1) Click the workflow step that should target a different object than the original base object.
2) You can define either an Alfabet query or an SQL query. Define one of the following:

- In the **Base Object via Query** attribute, click the **Browse** button to open the **Alfabet Query Builder** and define the query. For information about defining an Alfabet query or SQL query, see the chapter Defining Queries.
- In the **Base Object via Query as Text** attribute, paste in an Alfabet query or SQL query that you have defined in a text editor.

The following example displays an Alfabet query that searches for the ICT object that the application is assigned to:

```
ALFABET_QUERY_500
FIND
ICTObject
  InnerJoin Application
        ON Application.ICTObject = ICTObject.REFSTR

WHERE
Application.REFSTR CONTAINS  :BASE
```

3) Once you have defined the base object query for the selected workflow step, you can proceed to define the workflow step as described in the section Creating a Workflow Step.

Keep the following in mind when configuring the base object query for a workflow step:

- The object class identified in **Base Object Query** attribute must have an object class property `ID` defined. If the object class has no object class property `ID` defined, then you must configure a custom object class property for the `ID`. For more information about the configuration of custom object class properties, see the section Configuring Custom Properties for Protected or Public Object Classes.
- The query to find the base object for the workflow step is evaluated before the evaluation of queries associated with the workflow step (for example, queries for pre-conditions, post-conditions, or other workflow step actions). Therefore, when using the parameter `BASE` in queries related to a workflow step, `BASE` returns the `REFSTR` of the base object of the workflow step. To refer to the initial base object of the workflow, use the parameter `WORKFLOWBASE`.

- The result of the query entered in the **Base Object Query** attribute should have the `REFSTR` of the object which should be used as Base Object in the first column. Therefore, the `REFSTR` of the object must be defined as the first `SELECT` property in native SQL queries. For Alfabet queries, `SHOW` properties do not need to be defined. The `REFSTR` of the object found by the query is selected automatically as the query result.
- Please note that you must ensure that only one object is found in the query you specify. An error will occur if more than one object is found by the query or if no object is found by the query. If an error occurs, the workflow administrator or workflow owner will need to intervene and redirect the workflow.

4) Click the **Save**  button to save your definitions.

Creating a Workflow Step

A workflow step is an activity or task in a workflow that must be performed. The workflow template may have as many workflow steps as needed to complete the relevant task. Standard and custom editors, wizards, page views, configured reports, and object profiles may be implemented in the workflow step so that users can complete the task. A workflow step may entail entering, modifying or reviewing data, or a workflow step may be configured to be automatically executed by the Alfabet system. If the workflow step is not automatically executed by the system, one or more users may be defined as responsible to perform the workflow step. A user may delegate a workflow step to another user or refuse a workflow step. Depending on the configuration of the workflow step, a user may be required to confirm a workflow step before the workflow can advance to the next workflow steps, or the confirmation of the workflow step may occur automatically. A workflow step may also have one or more associated workflow step actions which allow various operations to be performed when the workflow step is entered, exited, refused, or expired. Additionally, each workflow step may have one or more pre-conditions or post-conditions that must be fulfilled in order to enter or exit the workflow step.

When all workflow steps have been created, they should be sequenced. This is explained in the section Defining the Sequence of the Workflow Steps.

To create a workflow step:

1) In the **Workflow** tab, right-click the workflow template  and select **Add New Workflow Step**. The new workflow step  is displayed in the explorer.

   

   A workflow step can also be created based on a copy of an existing workflow step. To do so, create a new workflow step without defining any attributes. Select the workflow step you want to copy and right click and select **Copy**. Click the new workflow step and select **Paste**. The attributes are filled as defined and can be modified, as needed.

2) Click the + symbol next to the workflow step to expand the node.

   Below the workflow step you will see workflow step actions. The nodes are labeled **Pre-Conditions**, **Post-Conditions**, **Action on Entered Step**, **Action on Refused Step**, **Action on Expired Step**, and **Action on Exited Step**.

   

   These nodes will later allow you to define automatic property updates, triggered workflows (sub-workflows), and email notifications that should occur when a workflow step is entered, refused, expired, or exited as well as any pre-conditions or post-conditions that must be fulfilled in order for the workflow step to be entered or exited. These configuration aspects are described in the following sections.

   - Configuring Pre- and Post-Conditions for a Workflow Step
   - Configuring Automatic Property Updates for a Workflow Step
   - Configuring Events to Be Triggered for a Workflow Step
   - Configuring a Workflow Step to Trigger a Subordinate Workflow
   - Configuring Email Notifications for Workflows

3) Click the workflow step  to open the attribute window and begin defining some of the basic attributes.

4) To change the technical name of the workflow step, enter a name for the workflow step in the **Name** attribute. The name will be displayed in the Alfabet interface.

   A validation mechanism checks for correct syntax when defining a technical name. The technical name of a configuration object may not begin with an empty space nor include any of the following special characters: **\ / * ? " > < |':**

   Furthermore, please note that names may not begin with an empty space nor include special characters. For a list of the special characters that are not allowed, see the section Defining Attributes for Configuration Objects in the chapter Getting Started with Alfabet Expand.

   Furthermore, if the technical name of a configuration object is changed, the name will be correctly updated in other configuration objects referencing the changed object during design time. Please note that the name of a changed configuration object will not be updated in guide pages nor if the guide pages reference a configuration object listed in the **Show Usage** functionality. If you plan to change the name of a configuration object, the reference in the guide page should be changed prior to changing the configuration object name.

5) In the **Caption** attribute, enter a caption for the workflow step. The caption will be displayed in the Alfabet interface.

6) In the **Comment** attribute, enter an explanation about the workflow step. The comment will be displayed as a workflow step description in the Alfabet interface.

7) Click the **Save** button to save your definitions.

The following information is available:

- Specifying a Dynamically-Generated View for the Workflow Step
- Specifying a System-Generated Action for the Workflow Step
- Defining the Users Responsible for a Workflow Step
- Defining a Deadline and Reminders for a Workflow Step
- Configuring the Action Buttons Available for a Workflow Step
- Specifying the Confirmation of a Workflow Step of the Type Wizard or Editor
- Automatic Confirmation of a Workflow Step (Types Wizard and Editor)
- Confirmation via the Workflow Step Completion Editor (Types Wizard and Editor)
- One-Click Confirmation via the Confirm Button (Types Wizard and Editor)

Defining the View Implemented for a Workflow Step

A workflow step may constitute a wide variety of tasks or actions that are either executed by a single user or a groups of users, or by the system itself. The following types of views can be implemented for a workflow step:

- Standard and/or custom editor
- Standard or custom wizard
- Standard Alfabet page view (technically called a `graphic view`)
- Object view
- Configured report created by your enterprise

If you are defining the first workflow step of the workflow, you must select either `Editor` or `Wizard` in the **Type** attribute for the workflow step. The first workflow step is specified for the workflow in either the **Start Step for Existing Object** attribute or the **Start Step for New Object** for the workflow template. For more information about specifying the first workflow step, see the section Defining the Sequence of the Workflow Steps.

Depending on the task that is to be executed in the workflow step, you can configure the workflow step so that users may be required to enter data for an object or to review data for the object. Thus, if a user is expected to only review and confirm data that has been defined, you can specify the workflow step to be ReadOnly.

Additionally, you can refine the visibility of data or functionalities in the views assigned to a workflow step. For editors, for example, you can hide tabbed pages, and for object views, graphic views, and configured reports, you can hide toolbar functionalities, thereby ensuring that users do not execute an unwanted action.

The following information is available:

One or more post-conditions can later be defined to ensure that the correct data has been completed by a user for a workflow step. For more information about the configuration of post-conditions, see the section Configuring Pre- and Post-Conditions for a Workflow Step.

The following information is available:

- Specifying a Wizard for the Workflow Step
- Specifying an Editor for the Workflow Step
- Specifying a Standard Alfabet Page View for the Workflow Step
- Specifying a Configured Report for the Workflow Step
- Specifying an Object View for the Workflow Step
- Specifying a Dynamically-Generated View for the Workflow Step
- Specifying a System-Generated Action for the Workflow Step

Specifying a Wizard for the Workflow Step

A wizard can be implemented in the workflow capability to capture the initial data required for a new object or to provide a structured process for the definition of references, cost data, project planning, etc. A wizard that is to be implemented in the workflow capability must first be configured in the **Wizards** node. Once the wizard has been configured and tested, it can be assigned to the relevant workflow step.

A wizard cannot be configured in the context of the workflow step and therefore the **Configure View** option will not be available when right-clicking the workflow step. Therefore, the wizard should be configured in the context of the wizard configuration capability before the workflow is configured. The wizard should be designed specifically for the workflow step and should require no further modifications once it is assigned to the workflow step. For detailed information about how to configure a wizard, see the chapter Configuring Wizards.

To specify that a wizard is to be implemented in a workflow:

1) Click the workflow step to open the attribute window.
2) In the **Type** attribute, select `Wizard` in order to implement a wizard for the selected workflow step.
3) In the **View** attribute, select the relevant wizard that should open so that users can carry out the selected step.
4) Click the **Save** button to save the workflow step definition.

Specifying an Editor for the Workflow Step

You can define a standard editor to be displayed for the workflow step. You can also specify a custom editor to be displayed with the standard editor. In this case, you must specify both the standard editor and custom editor to implement.

It is possible to hide interface controls (such as Edit fields) of the editor that are not relevant for the workflow step. By hiding tabbed pages or other interface controls in either the standard or custom editor, you can ensure that the user only sees the interface controls that are necessary for the task at hand. For example, if only the custom editor is relevant for the workflows step, the tabbed pages in the standard editor can be completely hidden from the user in the context of the workflow step.

Any custom editor you plan to implement for a workflow step must be configured before you configure the workflow step. For detailed information about how to configure a custom editor, see the chapter Configuring Custom Editors.

To specify that a standard or custom wizard is to be implemented in a workflow:

1) Click the workflow step to open the attribute window.
2) In the **Type** attribute, select `Editor` in order to implement a standard or custom editor for the selected workflow step.
3) In the **View** attribute, select the relevant standard editor for the workflow step. You must select a standard editor, even if you only want a custom editor to be displayed for the workflow step.
4) If you want to include a custom editor in the workflow step, select the relevant custom editor in the **Custom Editor** attribute.

5) If the data in the editor should only be reviewed and not edited, you can remove Read/Write access permissions to the editor. To do so, select `True` in the **Is Read-Only** attribute.

6) To hide tabbed pages or other interface controls in the standard or custom editor, right-click the workflow step in the explorer and select **Configure View**. The **View Configuration** editor opens. The **Select Object** attribute displays the name of the editor that is being configured in the context of the workflow step and the **Select View Scheme** attribute displays the name of the selected workflow step.

7) All tabs in the standard editor and, if defined, custom editor are displayed in the table. For each tabbed page or interface control that should be hidden in the context of the workflow step, click the relevant cell in the **Excluded** attribute. An X indicates that the interface control will be hidden. To make the interface control visible in the editor, remove the X in the **Excluded** attribute.

8) If a custom selector should replace the standard selector displayed in the **Default Selector** attribute, select the custom selector in the **Custom Selector** attribute.

9) Click **OK** to save the visibility definition and close the editor.

10) Click the **Save** button to save the workflow step configuration.

Specifying a Standard Alfabet Page View for the Workflow Step

You can define a standard Alfabet view to be displayed for the workflow step. You can hide any functionalities available in the toolbar buttons of the page view that are not relevant to the selected workflow step.

For an overview of the meaning of the technical page views listed in the **View** attribute, see *Page Views Assigned to Explorer Root Nodes* in the reference manual *Configuring Alfabet with Alfabet Expand - Appendix*.

To specify that a standard Alfabet page view is to be implemented in a workflow:

1) Click the workflow step to open the attribute window.

2) In the **Type** attribute, select `Graphic View` to select a standard Alfabet page view for the workflow step.

3) In the **View** attribute, select the relevant view that should open so that users can carry out the selected step. You must ensure that the page view you select is a relevant view for the object being processed.

4) If the data in the view should only be reviewed and not edited, you can remove Read/Write access permissions for the view. To do so, select `True` in the **Is ReadOnly** attribute.

5) To hide toolbar buttons in the standard Alfabet interface, right-click the workflow step in the explorer and select **Configure View**.

6) All functionalities in the view are displayed. In the upper right corner of the editor, click the **Configure** button to open the editor that allows you to hide functionalities in the view.

   The **Current View Scheme** attribute in the **View Configuration** editor displays the name of the selected workflow step.

7) For each tabbed page or interface control that should be hidden in the context of the workflow step, click the relevant cell in the **Excluded** attribute. An X indicates that the interface element will be hidden. To make the element visible in the editor, remove the X in the **Excluded** attribute.

8) If a custom selector should replace the standard selector displayed in the **Default Selector** attribute, select the custom selector in the **Custom Selector** attribute.

9) Click **OK** to save the visibility definition and close the editor.

Specifying a Configured Report for the Workflow Step

Reports of the type `Query` or `Custom` can be included in a workflow step. You can hide any functionalities available in the report's toolbar buttons that are not relevant to the selected workflow step.

It is highly recommended for reasons of interface compatibility, that you do not embed the configured report directly in the workflow step as described below. Instead, you should place the report in a wizard and assign the wizard to the workflow step. When the user clicks the **Perform** button, the wizard will open and display the report. The user can close the report via the wizard buttons. For more information about assigning a configured report to a wizard step, see the section Configuring a Wizard Step to Display a Configured Report in the chapter *Configuring Wizards*. For more information about embedding the wizard in a workflow step, see the section Specifying a Wizard for the Workflow Step.

To specify that a configured report is to be implemented in a workflow:

1) Click the workflow step  to open the attribute window.

2) In the **Type** attribute, select `Report` to select a configured report for the workflow step.

3) In the **View** attribute, select the relevant report that should open so that users can carry out the selected step.

4) To hide toolbar buttons in the report, right-click the workflow step  in the explorer and select **Configure View**.

5) All functionalities in the report are displayed. In the upper right corner of the editor, click the **Configure**  button to open the editor that allows you to hide functionalities in the report.

The **Current View Scheme** attribute in the **View Configuration** editor displays the name of the selected workflow step.

6) For each tabbed page or interface control that should be hidden in the context of the workflow step, click the relevant cell in the **Excluded** attribute. An X indicates that the interface element will be hidden. To make the element visible in the editor, remove the X in the **Excluded** attribute.

7) If a custom selector should replace the standard selector displayed in the **Default Selector** attribute, select the custom selector in the **Custom Selector** attribute.

8) Click **OK** to save the visibility definition and close the editor.

Specifying an Object View for the Workflow Step

Per default, users who navigate to a standard or custom object view in the context of a workflow step will have Read/Write access permissions to the object view. However, you can specify if ReadOnly access permissions should be implemented for the workflow step. You can hide any workspaces, views, and functionalities that are not relevant to the selected workflow step.

Any custom object views you plan to implement for a workflow step must be configured before you configure the workflow step. For detailed information about how to configure a custom object view, see the chapter Configuring Object Views.

To specify that a standard or custom object view is to be implemented in a workflow:

1) Click the workflow step to open the attribute window.
2) In the **Type** attribute select `Navigate` to open an editable standard or custom object view for the object being processed in the workflow step.
3) In the **View** attribute, select the relevant standard object view or custom object view for the workflow step.
4) If a user should have ReadOnly access permissions when navigating to an object profile in a workflow step, select `True` in the **ReadOnly** attribute.
5) To hide entire workspaces or individual views in the object view, right-click the workflow step in the explorer and select **Configure View**.
6) All workspaces and views are displayed. In the upper-right corner of the editor, click the **Configure** button to open the editor that allows you to hide workspaces and views in the object view.

   The **Current View Scheme** attribute in the **View Configuration** editor displays the name of the selected workflow step.

7) For each tabbed page or interface control that should be hidden in the context of the workflow step, click the relevant cell in the **Excluded** field. An X indicates that the interface element will be hidden. To make the element visible in the editor, remove the X in the **Excluded** field.
8) If a custom selector should replace the standard selector displayed in the **Default Selector** field, select the custom selector in the **Custom Selector** field. Click **OK** to save the configuration.
9) Click the **Save** button to save the workflow step configuration.

Specifying a Dynamically-Generated View for the Workflow Step

The workflow step type `Dynamic` is available to dynamically compute the views, editors, wizards, object profiles, and configured reports to be used in a workflow step based on a query that defines a rule. The workflow designer can define a query to dynamically compute the view in either the **View Query** attribute or the **View Query as Text** attribute. Please note that the first workflow step of the workflow cannot be of the type `Dynamic`.

To specify that the view is dynamically generated:

1) Click the workflow step to open the attribute window.
2) In the **Type** attribute, select `Dynamic`.
3) In the **View Query** attribute, select the relevant object class that should be queried and define the query as needed. The query must return a string representing a combination of a workflow step type appended by a colon and the name of the view to be used. The query returning the string should return a dummy value as the first column or the `RefString` and the required string as the second column. For example: Editor:<editor name> or Wizard:<wizard name>, or Navigate:<object view name>, etc. The query may use any of the following parameters:

- @BASE
- @WORKFLOWBASE
- @CURRENT_STEP
- @PREVIOUS_STEP
- @WORKFLOW
- @CURRENT_USER
- @CURRENT_MANDATE
- @CURRENT_PROFILE.

4) Click the **Save** button to save the workflow step configuration.

Specifying a System-Generated Action for the Workflow Step

A system-generated action can be configured for a workflow step. Prior to the Alfabet release 6.0, this definition was made via the **Type** attribute for the workflow step. For reasons of backward compatibility, the **Type** attribute continues to display the value `System`. However, it is highly recommended that the implementation of a system-generated action is defined via the workflow step actions available for each workflow For more information, see the section Configuring the Action Buttons Available for a Workflow Step.

Defining the Users Responsible for a Workflow Step

For each workflow step configured for the workflow template (other than steps of the type `System`), you must identify one or more users who are potentially responsible for the workflow step. You can configure one single user or a set of users to be responsible for the workflow step. A user may edit an object in the context of a workflow even though he/she may not otherwise have access permissions to the object. However, additional access permissions are not granted for the object outside of the workflow step.

The users who are identified via your configuration as responsible for performing the workflow step will automatically see the workflow step in the **My Workflow Activities** functionalities (`WF_UserWorkflowActivities`, `WF_UserWorkflowActivitiesExt`, and `WF_UserWorkflowActivitiesCommon`)

and/or the **Workflow Activities Explorer** (`WFS_Explorer`). Depending on the configuration of the workflow step, the responsible users may also receive an email notification when the workflow has advanced to the workflow step they are responsible for.

When you configure the workflow step, you must specify who the users are that are responsible to perform the workflow step. For example, the responsible user could be the authorized user of the object targeted by the workflow or users with a specified role (such as the role Architect). You can configure the responsible users to be found via any one or a combination of the following:

- The responsible user affiliation. In this case, the user is the authorized user of the object targeted by the workflow step.
- The role affiliation. In this case, users associated with one or more roles defined for the object can be specified. You can configure that only one user or all users with a role specified for the object targeted by the workflow step must carry out the workflow step.
- A set of users find by a query with the base object class `Person` or `User Group`. For example, a query could be defined to find the workflow owner or workflow initiator as the responsible user, or a query could be defined to find the authorized user of an object referenced by the base object (for example, the authorized user of an ICT owning the application that is the target of the workflow step)
- The user group affiliation.
- Users assigned to a user group. Multiple user groups can be specified. In this case, users associated with one or more users groups defined as authorized user groups for an object are responsible. You can configure that only one member of a user group, all members in a user group, or only one member in each user group must carry out the workflow step.
- Users in a user group found via a query based on the object class `UserGroup`.

Finally, you can specify whether the user currently working with an object via a currently active workflow step has exclusive edit rights to the object. This ensures that other users not involved in the current workflow step do not edit the data of the object that is being currently processed in the workflow step. Depending on the configuration of the users responsible for the workflow step, you may be removing the implicit access permissions that an authorized user has to the object targeted by this workflow step.

Please note the following regarding the configuration of the first workflow step:

- For a first workflow step initiated manually for new and existing objects in the **My Workflows** or **Initiate Workflows** functionalities or for a new object via the **Workflow** button in an object profile, the initiator of the workflow will be the responsible user initiating the first workflow step. (With the exception of a workflow step of the type `System`.) The attributes for the first workflow step defined in the **Responsibility** section of the attribute window (**Responsible User**, **Responsibles by Query**, etc.). are not relevant for workflows that are manually started.
- For a first workflow step that is automatically initiated for new and existing objects via the **Workflow Administration** functionality as well as new and existing objects initiated via a triggered sub-workflow or a batch process, the responsible user for the workflow step will be the responsible user(s) defined via the attributes available in the **Responsibility** section of the attribute window (**Responsible User**, **Responsibles by Query**, etc.).

Mandates are ignored in the context of workflows. Regardless of the mandate assignments to the user and the object managed in a workflow step, the user assigned responsibility for a workflow step has all access permissions required to execute the workflow step within the context of the **My Workflow Activities** functionalities (`WF_UserWorkflowActivities`, `WF_UserWorkflowActivitiesExt`, and `WF_UserWorkflowActivitiesCommon`) and/or the **Workflow Activities Explorer** (`WFS_Explorer`).

Therefore, if only users with a specific mandate should be permitted to perform a workflow step, the workflow designer must ensure that mandate assignment is taken into consideration via a query configured for the workflow step.

Once the user responsible for the workflow step has been configured, the following configurations can be specified:

- The automatic dispatch of email notifications informing each user that he/she is responsible for a current workflow step. For more information about the configuration of email notifications, see the section Configuring Email Notifications for Workflows.
- The configuration of the activities permissible for the workflow step. For example, should a user be able to refuse or delegate the workflow step? Is the user required to manually confirm a workflow step when has been executed? Are comments required by a user when performing or confirming a workflow step? Must the workflow step be specified by the user as completed in order to move to the next workflow step? For more information about the configuration of the actions allowed or required for the workflow step, see the section Configuring the Action Buttons Available for a Workflow Step.

To define the users responsible to perform a workflow step:

1) Click the workflow step to open the attribute window.
2) To explicitly define the responsible persons for the workflow step, define one or more of the following:

- **The authorized user of the object targeted by the workflow step**: Set the **Responsible User** attribute to `True` if the responsible user of the object addressed in this workflow step is the user that is responsible for performing the workflow step. Set to `False` if the responsible user of the object is not responsible to perform the workflow step.
- **Users assigned one or more specified roles**: In the **Responsibles by Roles** attribute, click the **Browse** button and select one or more role types to identify the responsible user(s) of the object targeted by this workflow step.
- **One or more users found via a query defined for the base object class** `Person`: If you want to specify that either the workflow owner, workflow initiator, or other set of persons are responsible for performing the workflow step, you can define a query based on the object class `Person` to find the user(s) who are responsible for performing the workflow step. Click the **Browse** button in the **Responsibles by Query** attribute to open the **Alfabet Query Builder** in order to define an Alfabet query or enter an SQL query in the **Responsibles by Query as Text** attribute.

  - The query must return the `REFSTR` property of one or multiple objects of the object class `Person` or the object class `UserGroup`. If you are defining an Alfabet query, no `SHOW` properties must be defined. The `REFSTR` of the object found by the Alfabet query is automatically returned as Alfabet query result. For native SQL queries, the `REFSTR` must be defined as the first property in

the SELECT statement. For information about defining Alfabet queries and native SQL queries in the context of Alfabet configurations, see the chapter Defining Queries.

- If you want to define the workflow owner or the workflow initiator as workflow step responsible, you must refer to the current workflow with the parameter WORKFLOW in the query. Each workflow corresponds to an object Workflow in the Alfabet database. The class Workflow has the object class property Initiator, which specifies the workflow initiator, and the object class property Owner, which specifies the workflow owner. Both object class properties reference the object class Person. To refer to the current workflow in the query, the parameter WORKFLOW can be used to return the REFSTR object class property of the current workflow. For example, the following Alfabet query finds the initiator of the workflow:

```
ALFABET_QUERY_500
FIND
Person
InnerJoin Workflow ON Workflow.Initiator =
Person.REFSTR
WHERE
Workflow.REFSTR CONTAINS:WORKFLOW
```

If no responsible user is found via the configured query, the workflow step will escalate and must then be dealt with by either the workflow owner or the workflow administrator in the **Workflows Administration** functionality.

3) To implicitly find users via their user group affiliation:

- **Users assigned one or more specified user groups**: In the **Responsibles by User Groups** attribute, click the **Browse** button and select one or more user groups to identify the responsible user(s) of the object addressed in this workflow step.
- **Users found for one or more user groups found via a query defined for the base object class User Group**: If you want to specify that users are found via a user group affiliation that cannot be defined via **Responsibles by User Groups** attribute, you can define a query based on the object class UserGroup to find the user(s) who are responsible for performing the workflow step. Click the **Browse** button in the **Responsibles by Query** attribute to open the **Alfabet Query Builder** in order to define an Alfabet query. Or enter an SQL query in the **Responsibles by Query as Text** attribute.

The query must return the REFSTR property of one or multiple objects of the object class Person or the object class UserGroup. If you are defining an Alfabet query, no SHOW properties must be defined. The REFSTR of the object found by the Alfabet query is automatically returned as Alfabet query result. For native SQL queries, the REFSTR must be defined as the first property in the SELECT statement. For information about defining an Alfabet query or native SQL query, see the chapter Defining Queries.

4) To specify that the user currently working with an object via a currently active workflow step has exclusive edit rights to the object, select True in the **Has Exclusive Edit Rights** attribute. This ensures that other users not involved in the current workflow step do not edit the data of the

object that is being currently processed in the workflow step. Depending on the configuration of the users responsible for the workflow step, you may be removing the implicit access permissions that an authorized user has to the object subject to this workflow step.

5) Click the **Save** button to save your definitions.

Defining a Deadline and Reminders for a Workflow Step

You can define due dates and reminders for each workflow step. If a workflow step's target due date is approaching, an email may be sent to the responsible user(s) of the workflow step if a corresponding batch process has been configured.

You can specify the number of days that a user has to complete the workflow step, the number of days before the deadline when the first reminder notification should be sent, and at which frequency the user should be reminded of the impending deadline.

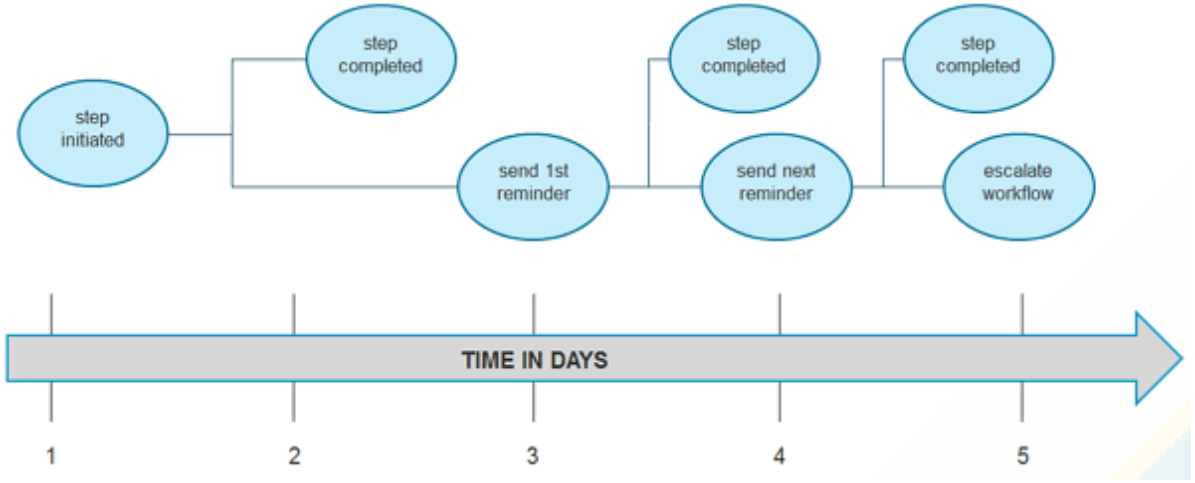

FIGURE: Example of the configuration and execution of a performance duration definition.

If the deadline has passed and an expired workflow step has been configured for the selected workflow step, then an expired workflow step will automatically advance to the configured step.

If this is the case, this series of events will be documented in the **Workflow Event Trace** page view for the selected workflow. If no subsequent step has been configured, the workflow step will be escalated (status: `Expired`) and must be manually redirected to a subsequent workflow step via the **Go To** button in the **Workflow Event Trace** page view

Workflow activities that are finished, expired, cancelled, etc. will remain visible in the **My Workflow Activities** explorers and in the respective sub-folder in the **Workflow Explorer** functionality for 30 days after they have been completed, etc. Thereafter, they will be automatically removed from the views.

If the **Performance Duration** attribute is defined for the workflow template, the batch job `WorkflowCommandPrompt.exe` must be executed in order to check the deadline of the workflow step and change the event type to `StepExpired`. It is recommended that reminder emails are sent every day. Therefore, the batch job `WorkflowCommandPrompt.exe` should be executed on daily basis because the reminders are sent when the specified reminder start, and frequency is matched based on the day that the workflow activity was created. For more information about

configuring a batch job to check workflow deadlines, see the section *Batch Processes for Workflows with AlfaWorkflowCommandPrompt.exe* in the reference manual *System Administration*.

Depending on the extent that workflows are implemented in your enterprise, some users may receive an extraordinary amount of reminder email notifications informing about impending workflow step deadlines. Therefore, you may want to consider concatenating all reminder emails generated for a user into one single email. This can be done by your system administrator via the parameter `SendWorkflowReminderWithOneEmail` in the server alias configuration. If the parameter is set to `True`, all reminder emails will be concatenate into one email for all users when the batch job `WorkflowCommandPrompt.exe` is executed. For more information about configuring the concatenation of reminder email notifications, see the section *Batch Processes for Workflows with AlfaWorkflowCommandPrompt.exe* in the reference manual *System Administration*.

To define a deadline for the workflow step as well as the timing of the reminder notifications to be sent to responsible users that a deadline is approaching or passed:

1) Click a workflow step to open its attribute window.
2) In the **Performance Duration** attribute, define the number of days that the workflow step may require to be completed.

   The integer entered for the **Performance Duration** attribute must be greater than 0 if the **Check Performance Duration** option should be enabled in the **Workflow Administration** functionality. Please note that a workflow step that has its performance duration set to 1 will not expire one day after it was started but the day after that.

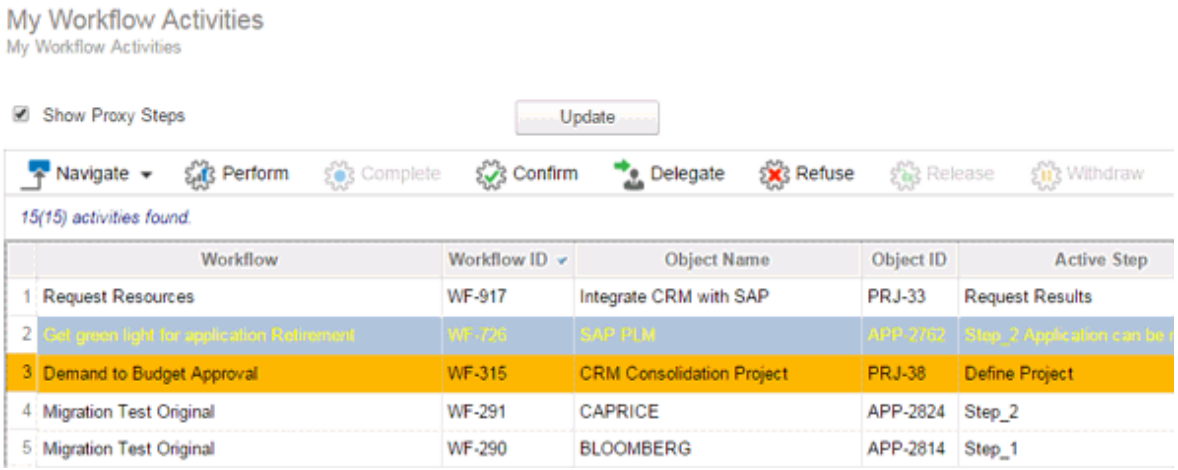
   If you do not change the default value of 0, the responsible user will have an unlimited amount of time to complete the workflow step. If the **Performance Duration** attribute for a workflow step is set to 0 so that the workflow step never expires, reminder email notifications will be sent out based on specifications of the **Performance Reminder Start** and **Performance Reminder Frequency** attributes. For more information, see the section *Checking a Workflow Step's Deadline* in the reference manual *User and Solution Administration*.

3) In the **Performance Reminder Start** attribute, define a number indicating on which day during the duration of the workflow step (day 1 = start of workflow step) the first reminder should be generated and sent to the responsible users. In the **Performance Reminder Frequency** attribute, enter a number indicating in which intervals (number of days) an email notification should be generated and sent to the responsible users reminding them that the workflow step must be completed.
4) In the **Expiration Step** attribute, you can optionally define the workflow step that should be the subsequent workflow step if the selected step is not completed by a user in the timeframe defined in the **Performance Duration** attribute. You may only define one workflow step for this attribute. If you do not define an expired workflow step, the workflow administrator will be required to manually redirect the workflow to a subsequent step if the workflow step has expired.
5) Click the **Save** button to save your definitions.

Configuring the Action Buttons Available for a Workflow Step

For each workflows step, you can specify which options are possible for a user to carry out for a workflow step by making the relevant toolbar buttons available in the toolbar. The accessibility of toolbar buttons must be specified for each workflow step where the **Type** attribute is not set to `System`. Buttons that are not made available for the workflow step will be disabled in the toolbar.

The configuration of the buttons can be made on the level of the workflow template and/or workflow step. If the button attributes are defined for the workflow template, the button definition will be applied to all workflow steps unless a button definition is explicitly made for a workflow step, in which case the workflow step definition will take precedence over the workflow template definition. If a workflow step is to inherit the button configuration from the workflow template, you should ensure that the value `Inherited` is selected for the **Visibility** attribute in the respective attribute (**Complete Button**, **Confirm Button**, **Delegate Button**, **Perform Button**, and **Refuse Button**).



The following buttons are available for configuration in the **My Workflow Activities** functionalities (`WF_UserWorkflowActivities`, `WF_UserWorkflowActivitiesExt`, and `WF_UserWorkflowActivitiesCommon`) as well as the **Workflow Activities Explorer** (`WFS_Explorer`).

- **Perform** button: This button opens the configured editor, wizard, view, etc. needed to process the workflow step. A **Perform** button should be available for ALL workflow steps except those workflow steps where the **Type** attribute is set to `System`.
- **Confirm** button: This button allows an explicit confirmation of the workflow step to be made via one-click without requiring a comment to be entered. In this case, the workflow step will immediately advance to the next workflow step if all post-conditions are satisfied. If the workflow step is based on an object view, graphic view, or custom report, the user must have either the **Confirm** or **Complete** button available
- **Complete** button: This button allows an explicit confirmation, refusal, or continuation of the workflow step to be made via the **Workflow Step Completion** editor. The configuration of the **Complete** button makes the **Confirm** button and **Refuse** button superfluous. Furthermore, a **Comment** attribute is available that may be specified as optional or mandatory. If the workflow step is based on an object view, graphic view, or custom report, the user must have either the **Confirm** or **Complete** button available. The option to refuse the workflow step may be removed from the **Workflow Step Completion** editor.

- **Refuse** button: This button allows a workflow step to be refused by a user. The refusal of a workflow step by a single user results in the overall refusal of the workflow step for all responsible users. Once a workflow step has been refused by one user, the workflow step will be removed from the **My Workflow Activities** functionalities and/or the **Workflow Activities Explorer** or all other responsible users.
- **Delegate** button: This button opens the **Delegate Step** editor in which the responsible user or workflow owner delegating the workflow step must provide an explanation about the delegation. When the user delegates a workflow step, he/she can choose to delegate only his/her responsibility for the workflow step or remove the responsibility from all users identified as responsible users. The step will be removed accordingly from the **My Workflow Activities** functionalities and/or the **Workflow Activities Explorer** for all other responsible users

The following issues should be clarified for each workflow step before configuring the button options and confirmation details:

- Once the workflow step task is performed by a user, will the workflow step be automatically confirmed or must the user explicitly confirm the workflow step?
- If the workflow step is to be automatically confirmed, is a comment required by the user before the automatic confirmation can be triggered?
- If the workflow step must be explicitly confirmed, should the confirmation occur via the one-time click of the **Confirm** button in the toolbar or by selecting an option in the **Workflow Step Completion** editor. By configuring the confirmation via the **Confirm** button, the user can click the button and if all post-conditions are satisfied, the workflow will advance to the next workflow step. By configuring the confirmation via the **Workflow Step Completion** editor, the user has the option in the editor to either confirm the workflow step, refuse the workflow step, continue working on the workflow step, and provide a mandatory or optional comment about the workflow step.
- May the user refuse the workflow step?
- May the user delegate the workflow step to another user? All workflow steps in which a responsible user may delegate the workflow step require the **Delegate** button to be visible in the toolbar. An additional query can be defined for the workflow template that specifies the set of users to whom a workflow step may be delegated.
- Who must confirm the workflow step in order for the workflow to advance to the next workflow step? If more than one user is responsible for the workflow step, is it required that only one user, all users, or, if relevant, one user per responsible user group must confirm the workflow step to advance the workflow?
- Which functionalities will be implemented for the user to process the workflow step. If the user will be working in the **My Workflow Activities** functionalities (`WF_UserWorkflowActivities`, `WF_UserWorkflowActivitiesExt`, and `WF_UserWorkflowActivitiesCommon`), then only the visibility of the buttons can be configured (in other words, whether or not the buttons are displayed in the toolbar). If the users are processing the workflow step in the **Workflow Activities Explorer** (`WFS_Explorer`), the captions on the buttons as well as the icon can be customized. This allows the task at hand to be made more explicit for the user. (For example, the **Perform** button may be captioned **Enter Data**, **Review Data**, or **Approve Project**, depending on the task at hand.)

The following information is available:

- Specifying the Confirmation of a Workflow Step of the Type Wizard or Editor
- Automatic Confirmation of a Workflow Step (Types Wizard and Editor)

- Confirmation via the Workflow Step Completion Editor (Types Wizard and Editor)
- One-Click Confirmation via the Confirm Button (Types Wizard and Editor)
- Specifying the Explicit Confirmation of a Workflow Step of the Types Navigate, GraphicView, and Report
- Confirmation via the Workflow Step Completion Editor (Types Navigation, GraphicView, Report)
- One-Click Confirmation via the Confirm Button (Types Navigation, GraphicView, Report)
- Specifying the Users Required to Confirm a Workflow Step
- Confirmation for Authorized Users, Role Responsibles, and Users Found via Queries of Class Person
- Confirmation for User Group Responsibles and Users Found via Queries of Class User Group
- Removing the Option to Refuse a Workflow Step
- Making the Refuse Capability Available for a Workflow Step
- Making the Delegate Capability Available for the Workflow Step
- Defining Permissible Users That a Workflow Step May Be Delegated To
- Ensuring the Automatic Closure of Performed Workflow Steps
- Configuring the Visualization of the Buttons in the Workflow Activities Explorer

Specifying the Confirmation of a Workflow Step of the Type Wizard or Editor

There are many ways to specify the automatic confirmation of a workflow step. The following information is available:

- Automatic Confirmation of a Workflow Step (Types Wizard and Editor)
- Confirmation via the Workflow Step Completion Editor (Types Wizard and Editor)
- One-Click Confirmation via the Confirm Button (Types Wizard and Editor)

Automatic Confirmation of a Workflow Step (Types Wizard and Editor)

If the **Type** attribute for a workflow step is set to `Wizard` or `Editor`, it is possible to configure the workflow step so that it will be automatically confirmed once the workflow step has been performed.

In this case, the user would perform the required task and when the user clicks the **OK** button (in the editor) or the **Finish** button (in the wizard), the workflow step will be automatically confirmed. If all post-conditions are satisfied, the workflow will advance to the next workflow step. Thus, users are not explicitly required to confirm the workflow step via the **Confirm** button or via a selection in the **Workflow Step Completion** editor.

To configure the automatic confirmation of a workflow step:

1) Click the workflow step  to open the attribute window. Expand the **Visualization** section of the grid by clicking the arrow.

2) Expand the **Perform Button** attribute and ensure that the **Visibility** attribute is set to `Visible` so that the user can perform the relevant workflow task.

3) To activate the automatic confirmation capability, select `AutoConfirm` in the **Completion Type** attribute.

The **Visibility** attribute of the **Complete Button** and **Confirm Button** attributes are typically set to `False` in this case.

4) To specify whether a mandatory comment is required before the workflow step can be automatically confirmed, define the **Completion Comment Required** attribute:

- If a mandatory comment should be provided by the user in the **Workflow Step Completion** editor after the workflow step has been performed, select `True` in the **Completion Comment Required** attribute. Only the **Comment** attribute will be editable in the **Workflow Step Completion** editor. The comments will be displayed in the **Active Workflow Steps** view for the workflow.
- If no comment is required after the workflow step has been performed, select `False` in the **Completion Comment Required** attribute. In this case, the workflow will immediately advance to the next workflow step once the editor/wizard is closed and all post-conditions have been satisfied.

5) Additionally, a post-condition can be defined to ensure that the relevant data has been provided before the workflow step can be automatically confirmed. For more information about the configuration of a post-condition for a workflow step, see the section Configuring Post-Conditions for a Workflow Step.

6) Click the **Save**  button to save your definitions.

Confirmation via the Workflow Step Completion Editor (Types Wizard and Editor)

If the **Type** attribute for a workflow step is set to `Wizard` or `Editor`, it is possible to configure the workflow step so that the **Workflow Step Completion** editor automatically opens after the workflow step is performed. In this case, the user would perform the required task and when the user clicks the **OK** button in the wizard or editor, the **Workflow Step Completion** editor will open and the user can either confirm that the workflow step is complete (whereby the workflow will advance to the next workflow step), continue to perform the workflow step, or refuse the workflow step. If the user continues working on the workflow step, he/she would then subsequently click the **Complete** button to reopen the **Workflow Step Completion** editor and confirm the workflow step and, if all post-conditions are satisfied, advance the workflow to the next workflow step.

To configure the refuse capability so that it is disabled in the toolbar and in the **Workflow Step Completion** editor, see the section Removing the Option to Refuse a Workflow Step.

The **Workflow Step Completion** editor cannot be customized.

To configure the explicit confirmation of a workflow step via the **Workflow Step Completion** editor:

1) Click the workflow step  to open the attribute window. Expand the **Visualization** section of the grid by clicking the arrow.

2) Expand the **Perform Button** attribute and ensure that the **Visibility** attribute is set to `Visible` so that the user can perform the relevant workflow task.

3) Expand the **Complete Button** attribute and ensure that the **Visibility** attribute is set to `Visible` so that the user can continue the confirmation process if he/she interrupts it.

The **Visibility** attribute of the **Confirm Button** attribute is typically set to `Hidden` in this case.

4) To activate the confirmation capability, select `ConfirmPrompt` in the **Completion Type** attribute.

5) To specify whether a mandatory comment is required as part of the confirmation process, define the **Completion Comment Required** attribute:

- If a mandatory comment should be provided by the user in the **Workflow Step Completion** editor after the workflow step has been performed, select `True` in the **Completion Comment Required** attribute. Comments will be displayed in the **Active Workflow Steps** view for the workflow.
- If no comment is required after the workflow step has been performed, select False in the **Completion Comment Required** attribute.

6) Click the **Save**  button to save your definitions.

One-Click Confirmation via the Confirm Button (Types Wizard and Editor)

To configure the explicit confirmation of a workflow step via the **Confirm** button:

1) Click the workflow step  to open the attribute window. Expand the **Visualization** section of the grid by clicking the arrow.

2) Expand the **Perform Button** attribute and ensure that the **Visibility** attribute is set to `Visible` so that the user can perform the relevant workflow task.

3) Expand the **Confirm Button** attribute and ensure that the **Visibility** attribute is set to `Visible` in order to allow the user to advance directly to the next workflow step.

Typically, either only the **Confirm Button** button or the **Complete Button** should be available in the toolbar. Therefore, in this case, the **Visibility** attribute of the **Complete Button** should be set to `Hidden`.

4) To specify the confirmation capability, select `NotSpecified` for the **Completion Type** attribute.

5) To ensure that the **Workflow Step Completion** editor is NOT displayed to the user, select `False` for the **Completion Comment Required** attribute.

If the **Completion Comment Required** attribute is set to `True`, the dialog will be displayed upon clicking the **Confirm** button, whereby the option to refuse the workflow step will be displayed. Thus, the user can provide a comment for his confirmation.

6) Click the **Save**  button to save your definitions.

Specifying the Explicit Confirmation of a Workflow Step of the Types Navigate, GraphicView, and Report

It is possible to configure the explicit confirmation of a workflow step of the type `Navigate`, `GraphicView`, and `Report`. If the workflow step is based on an object view, graphic view, or custom report, the user must have either the **Confirm** or **Complete** button available in the **My Workflow Activities** functionalities and/or the **Workflow Activities Explorer** in order to be able to indicate that the workflow step has been performed and is completed. Please consider the following:

- If the user should be able to simply confirm the workflow step and NOT be required to enter a comment, it is recommended that the workflow step is to be confirmed via the **Confirm** button and that the **Workflow Step Completion** editor is not implemented for the workflow step. In this case, the workflow step will immediately advance to the next workflow step if all post-conditions are satisfied.
- If the user should be able to confirm the workflow step and also is required to enter a comment, it is recommended that the workflow step is to be confirmed via the **Complete** button. In this case, the **Workflow Step Completion** editor will open and the user can either confirm that the workflow step is complete (whereby the workflow will advance to the next workflow step), continue to perform the workflow step, or, if permissible for the workflow step, refuse the workflow step.

The following options are available to configure the explicit confirmation of a workflow step in which an object view, graphic view, or custom report is implemented:

- Confirmation via the Workflow Step Completion Editor (Types Navigation, GraphicView, Report)
- One-Click Confirmation via the Confirm Button (Types Navigation, GraphicView, Report)

Confirmation via the Workflow Step Completion Editor (Types Navigation, GraphicView, Report)

To configure the explicit confirmation of a workflow step via the **Workflow Step Completion** editor:

To configure the refuse capability so that it is disabled in the toolbar and the **Workflow Step Completion** editor, see the section Removing the Option to Refuse a Workflow Step.

The **Workflow Step Completion** editor cannot be customized.

1) Click the workflow step  to open the attribute window. Expand the **Visualization** section of the grid by clicking the arrow.
2) Expand the **Perform Button** attribute and ensure that the **Visibility** attribute is set to `Visible` so that the user can perform the relevant workflow task.
3) Expand the **Complete Button** attribute and ensure that the **Visibility** attribute is set to `Visible` so that the user can confirm the workflow step via the **Workflow Step Completion** editor.

   Typically, either only the **Confirm** button or the **Complete** button should be available in the toolbar. Therefore, in this case, the **Visibility** attribute for the **Confirm Button** attribute should be set to `Hidden`.

4) To activate the confirmation capability, select `ConfirmPrompt` in the **Completion Type** attribute.

5) To specify whether a mandatory comment is required as part of the confirmation process, define the **Completion Comment Required** attribute:

- If a mandatory comment should be provided by the user in the **Workflow Step Completion** editor after the workflow step has been performed, select `True` in the **Completion Comment Required** attribute. Comments are displayed in the **Workflow Event Trace** view for the workflow as well as the views available in the **Step-Related Activities** workspace in the object profile for a workflow step.
- If no comment is required after the workflow step has been performed, select `False` in the **Completion Comment Required** attribute.

6) Click the **Save** button to save your definitions.

One-Click Confirmation via the Confirm Button (Types Navigation, GraphicView, Report)

To configure the explicit confirmation of a workflow step via the **Confirm** button:

1) Click the workflow step to open the attribute window. Expand the **Visualization** section of the grid by clicking the arrow.
2) Expand the **Perform Button** attribute and ensure that the **Visibility** attribute is set to `Visible` so that the user can perform the relevant workflow task.
3) Expand the **Confirm Button** attribute and ensure that the **Visibility** attribute is set to `Visible` in order to allow the user to advance directly to the next workflow step.

   Typically, either only the **Confirm Button** button or the **Complete Button** should be available in the toolbar. Therefore, in this case, the **Visibility** attribute of the **Complete Button** should be set to `Hidden`.

4) To specify the confirmation capability, select `NotSpecified` for the **Completion Type** attribute.
5) To ensure that the **Workflow Step Completion** editor is NOT displayed to the user, select `False` for the **Completion Comment Required** attribute.

   If the **Completion Comment Required** attribute is set to `True`, the dialog will be displayed upon clicking the **Confirm** button, whereby the option to refuse the workflow step will be displayed. Thus, the user can provide a comment for his confirmation.

6) Click the **Save** button to save your definitions.

Specifying the Users Required to Confirm a Workflow Step

Depending on the configuration of the users responsible for a workflow step, the set of responsible users may be quite large. In some cases, it may be necessary that all users actually perform and confirm the workflow step whereas in other cases, it may suffice if one single user performs and confirms the workflow step.

If the responsible users are found via their affiliation to a user group, you can stipulate that one user in each user group must perform and confirm the workflow step. In this case, the workflow step will not be

complete until a user in every responsible user groups have confirmed the workflow step. If a user confirms the workflow step and that user is a member of multiple responsible user groups, the confirmation will fulfill the required confirmation for each user group that the user is a member of.

The following information is available:

- Confirmation for Authorized Users, Role Responsibles, and Users Found via Queries of Class Person
- Confirmation for User Group Responsibles and Users Found via Queries of Class User Group

Confirmation for Authorized Users, Role Responsibles, and Users Found via Queries of Class Person

If you have defined the user responsible definition via either the **Responsible User** attribute, **Responsibles by Roles** attribute, or a query based on the object class `Person`, define one of the following to determine who is responsible for confirming the workflow step in order for it to be completed:

- If only one of the users identified to perform this workflow step must confirm the workflow step to complete it, select `SingleUser` for the attribute **Confirmation Type**. The first user who confirms the workflow step completes the workflow step. If all post-conditions are fulfilled for the workflow step, the workflow step will be removed from the **My Workflow Activities** functionalities and/or the **Workflow Activities Explorer** for all responsible users and the workflow will subsequently advance to the next workflow step.
- If all users identified to perform this workflow step must confirm the workflow step to complete it, select `AllUsers` for the attribute **Confirmation Type**. In this case, the workflow step will only be completed once all responsible users have confirmed the workflow step.

Click the **Save**  button to save your definitions.

Confirmation for User Group Responsibles and Users Found via Queries of Class User Group

If you have defined the user responsible definition via either the **Responsibles by User Groups** attribute or a query based on the object class `User Group`, define one of the following to determine who is responsible for confirming the workflow step in order for it to be completed

- If only one member in each user group selected in the **Responsibles by User Groups** attribute must confirm the workflow step to complete, select `SingleUserOfEachUserGroup` for the **Confirmation Type** attribute. In this case, the workflow step will not be complete until a user in all user groups responsible for the workflow step have confirmed the workflow step. If a user confirms the workflow step and that user is a member of multiple responsible user groups, the confirmation will fulfill the required confirmation for each user group that the user is a member of.
- If only one of the users identified to perform this workflow step must confirm the workflow step to complete it, select `SingleUser` for the **Confirmation Type** attribute. The first user who confirms the workflow step completes the workflow step. If all post-conditions are fulfilled for the workflow step, the workflow step will be removed from the **My Workflow Activities** functionalities and/or the **Workflow Activities Explorer** for all responsible users and the workflow will subsequently advance to the next workflow step.

- If all users identified to perform this workflow step must confirm the workflow step to complete it, select `AllUsers` for the **Confirmation Type** attribute. In this case, the workflow step will only be completed once all responsible users have confirmed the workflow step.

Click the **Save** button to save your definitions.

Removing the Option to Refuse a Workflow Step

In some cases, it may be that a responsible user may NOT refuse a workflow step and instead is required to perform the workflow step. In this case, you can configure the refuse capability so that it is unavailable in the toolbar of the **My Workflow Activities** functionalities (`WF_UserWorkflowActivities`, `WF_UserWorkflowActivitiesExt`, and `WF_UserWorkflowActivitiesCommon`) and/or the **Workflow Activities Explorer** as well as in the **Workflow Step Completion** editor.

To ensure that users may not refuse the workflow step:

1) Click the workflow step to open the attribute window.
2) Select `NotSpecified` for the **Completion Type** attribute.
3) Expand the **Visualization** section of the grid by clicking the arrow. Expand the **Refuse Button** attribute and ensure that the **Visibility** attribute is set to `Hidden` to ensure that the refuse capability is not available in the toolbar.
4) Click the **Save** button to save your definitions.

Making the Refuse Capability Available for a Workflow Step

The refusal of a workflow step by a single user results in the overall refusal of the workflow step for all responsible users. Once a workflow step has been refused by one user, the workflow step will be removed from the **My Workflow Activities** functionalities (`WF_UserWorkflowActivities`, `WF_UserWorkflowActivitiesExt`, and `WF_UserWorkflowActivitiesCommon`) and/or the **Workflow Activities Explorer** for all other responsible users.

Please keep the following in mind when configuring the refusal capability:

- If the **Workflow Step Completion** editor is implemented for the workflow step, the refusal capability will be automatically displayed in the editor. The **Refuse** button can nevertheless be configured to be displayed in the toolbar as an additional means to refuse the workflow step.
- If the **Confirm** button or the automatic confirmation capability is implemented in the workflow step, then the **Refuse** button must be made available in the toolbar if users may refuse the workflow step.

Any user refusing a workflow step must provide an explanation in either the **Workflow Step Completion** editor or the **Refuse Step** editor that opens when he/she clicks the **Refuse** button. Comments are displayed in the **Active Workflow Steps** view for the workflow.

1) Click the workflow step to open the attribute window. Expand the **Visualization** section of the grid by clicking the arrow.

2) Expand the **Refuse Button** attribute and ensure that the **Visibility** attribute is set to `Visible` to display the **Refuse** button in the toolbar of the **My Workflow Activities** functionalities and/or the **Workflow Activities Explorer** as well as in the **Workflow Step Completion** editor. The **Refuse** button allows users to refuse a workflow step that they are responsible for. Select `Hidden` if the user should not have the option to refuse the workflow step.

3) In the **Refuse Step** attribute for the selected workflow step, define the workflow step that the workflow should advance to if the selected workflow step is refused. For more information, see the section Defining the Sequence of the Workflow Steps.

4) Click the **Save** button to save your definitions.

If the configuration of the workflow step allows users to refuse a workflow step, you may specify a property update, email notification, or workflow trigger for an **Action on Refused Step** for the workflow step. For more information, see the following sections:

- Configuring Automatic Property Updates for a Workflow Step
- Configuring Email Notifications for Workflows
- Configuring a Workflow Step to Trigger a Subordinate Workflow

Making the Delegate Capability Available for the Workflow Step

In some cases, you may decide that the responsible users or workflow owner may delegate their workflow step to another user whom they consider more appropriate. For this purpose, the **Delegate** button must be displayed in the toolbar of the **My Workflow Activities** functionalities (`WF_UserWorkflowActivities`, `WF_UserWorkflowActivitiesExt`, and `WF_UserWorkflowActivitiesCommon`) and/or the **Workflow Activities Explorer** in order to enable the user or workflow owner to delegate a workflow step to another user.

A responsible user or workflow owner delegating a workflow step must provide an explanation in the **Delegate Step** editor that opens when he/she clicks the **Delegate** button. When the user delegates a workflow step, he/she can choose to delegate only his/her responsibility for the workflow step or remove the responsibility from all users identified as responsible users. The step will be removed accordingly from the **My Workflow Activities** functionalities and/or the **Workflow Activities Explorer** for all other responsible users.

If the **Delegate** button is not implemented for the workflow step, then the workflow owner and responsible users will not be able to delegate the workflow step to another user.

Please note that if the workflow administrator must have access to the **Delegate** button, he/she must be specified as one of the responsible users for the workflow step. Regardless of whether the workflow administrator has access to the **Delegate** button or not, he/she will still be able to reassign workflows and workflow steps for users that have left the organization in the **Workflow Administration** functionality.

Typically, when the user clicks the **Delegate** button, the standard person selector opens displaying all named users in Alfabet. In order to limit the set of users displayed in the person selector, you can define a query for the associated workflow template in the **Step Delegate Rule** attribute of the workflow template. This option is described below in the section Defining Permissible Users That a Workflow Step May Be Delegated To.

Please note that only users that are qualified named users in Alfabet may be delegated workflow steps. If an external source selector (for example, LDAP) is configured as the selector for the object class `Person`, the configuration will be ignored and the standard person selector will be implemented.

1) Click the workflow step to open the attribute window. Expand the **Visualization** section of the grid by clicking the arrow.
2) Expand the **Delegate Button** attribute and ensure that the **Visibility** attribute is set to `Visible` to display the **Delegate** button in the toolbar of the **My Workflow Activities** functionalities and/or the **Workflow Activities Explorer** as well as the **Active Workflow Steps** view of the relevant workflow. Select `Hidden` if the button should not be disabled in these views.

   Typically, when the user clicks the **Delegate** button, the standard person selector opens displaying all named users in Alfabet. In order to limit the set of users displayed in the person selector, you can define a query for the associated workflow template in the **Step Delegate Rule** attribute of the workflow template. For more information, see the section Defining Permissible Users That a Workflow Step May Be Delegated To.

3) Click the **Save** button to save your definitions.

Defining Permissible Users That a Workflow Step May Be Delegated To

Typically, when the responsible user or workflow owner delegates a workflow step, the standard person selector opens displaying all named users in Alfabet. In order to limit the set of users displayed in the person selector, you can define a query for the workflow template that the workflow step belongs to.

The rule you define applies to all relevant workflow steps generated in the context of the selected workflow template. When a user clicks the **Delegate** button in the **My Workflow Activities** functionalities (`WF_UserWorkflowActivities`, `WF_UserWorkflowActivitiesExt`, and `WF_UserWorkflowActivitiesCommon`) and/or the **Workflow Activities Explorer**, for example, a person selector will open displaying the names of all users found by the query.

For example, to configure a query find only users for which the custom object class property `CustomType` is set to `Workflow`:

```
Person.CustomType="Workflow"
```

All users found via the `WHERE` clause of the query are permissible to be the recipient of a workflow step delegation and will be displayed in the person selector.

For general information about defining an Alfabet query or SQL query, see the chapter Defining Queries.

To define a set of users to whom a workflow step generated in the context of the selected workflow template can be delegated to:

1) Click the workflow template to open the attribute window.
2) In the **Step Delegation Rule** attribute, enter an Alfabet query or an SQL query. The query should be defined like a `WHERE` clause.

3) Click the **Save** button to save your definitions.

Ensuring the Automatic Closure of Performed Workflow Steps

It is possible to specify that a configured batch process should automatically close any workflow steps that are unconfirmed but for which all post-conditions have been satisfied.

In this case, a batch job must be configured by the system administrator. The batch job `alfaWorkflowCommandPrompt.exe` must include the runtime option `StepClosure`. For more information about the configuration of the batch job, see the section *Batch Processes for Workflows with AlfaWorkflowCommandPrompt.exe* in the reference manual *System Administration*.

1) Click the workflow step to open the attribute window.
2) In the **Allow Automatic Closure** attribute, select `True`. Any unconfirmed workflow steps will be checked when the batch process is triggered, and any workflow steps whose post-conditions are fulfilled will automatically be closed and the workflow will advance to the next workflow step.
3) Click the **Save** button to save your definitions.

Configuring the Visualization of the Buttons in the Workflow Activities Explorer

To specify which button should be displayed (and thus which actions are possible for a workflow step) in the **My Workflow Activities** functionalities (`WF_UserWorkflowActivities`, `WF_UserWorkflowActivitiesExt`, and `WF_UserWorkflowActivitiesCommon`), you must define the attributes **Complete Button**, **Confirm Button**, **Delegate Button**, **Perform Button**, and **Refuse Button** in the **Visualization** section of the attribute window.

If these attributes are defined for the workflow template, the button definition will be applied to all workflow steps unless a button definition is explicitly made for a workflow step, in which case the workflow step definition will take precedence over the workflow template definition. For each button, a further table section can be opened displaying the attributes **Visibility**, **Caption**, and **Icon**.

Define as explained below for the attributes **Complete Button**, **Confirm Button**, **Delegate Button**, **Perform Button**, and **Refuse Button**.

1) Click the workflow step to open the attribute window. Expand the **Visualization** section of the grid by clicking the arrow.
2) Expand the grid for the relevant button by clicking the arrow.
3) In the **Visibility** attribute:

- Select `False` if the button should not be available for the respective workflow step (or workflow template).
- Select `True` if the button should be available for the respective workflow step (or workflow template).
- If you select `True` for the **Visibility** attribute, define the following attributes:
- **Caption**: Enter a caption to display on the button

- **Icon**: Select an image from a preconfigured button library to display on the button.

4) Click the **Save**  button to save your definitions.

Configuring Pre- and Post-Conditions for a Workflow Step

For each workflow step, you may define one or more pre-conditions and post-conditions that must be fulfilled before the workflow can enter or exit the workflow step. A workflow step's pre-conditions should define the minimum conditions that should apply for the workflow step to be entered and a workflow step's post-conditions should define the minimum conditions that should apply for the workflow step to be exited.

- The following example describes a scenario for a pre-condition:

A workflow step A requires a proposed project's cost to be estimated. The next workflow steps of workflow step A are workflow step B and C.

Workflow step B has a precondition that all project proposals must be over € 25k to advance to workflow step B. Workflow step C has a pre-condition that all project proposals must be under or equal to € 25k to advance to workflow step C. Therefore, if the estimated cost is over € 25k, the next workflow step will be workflow step B, but if the estimated cost is under or equal to € 25k, the next workflow step will be workflow step C.

- The following example describes a scenario for a post-condition:

A workflow step A requires that a proposed project is reviewed and that specific data is entered. A post-condition requires that the release status of the project proposal is set to Scope Reviewed. The release status must therefore be set to Scope Reviewed by a responsible user of the workflow step (via an editor or wizard) before workflow step A can be confirmed and workflow step B may begin.

The definition of pre-conditions and post-conditions is generally handled in the same way. Both types of conditions require an Alfabet query or SQL query to be defined that checks whether the condition has been fulfilled.

The following information is available:

- Configuring Pre-Conditions for a Workflow Step
- Configuring Post-Conditions for a Workflow Step

Configuring Pre-Conditions for a Workflow Step

A pre-condition is based on an Alfabet query or an SQL query that checks whether a workflow step may or may not be executed. Each workflow step may have multiple pre-conditions defined. All pre-conditions must be fulfilled before the workflow step may be started. Pre-conditions are required, for example, when a workflow step has multiple next workflow steps defined. Each next workflow step must have one or more pre-conditions defined in order to determine which of the potential next workflow steps should be the subsequent next workflow step.

Pre-conditions configured for workflow steps will be evaluated prior to the base object query.

A pre-condition can be created based on a copy of an existing pre-condition. To do so, create a new pre-condition without defining any attributes. Select the pre-condition you want to copy and right click and select **Copy**. Click the new pre-condition and select **Paste**. The attributes are filled as defined and can be modified, as needed.

To define a pre-condition for the selected workflow step:

1) Click the + next to the workflow step  to expand the workflow step node.
2) Right-click **Pre-Conditions** and select **Add New Pre-Condition** to create a pre-condition.
3) Click the pre-condition  to display the attribute window.
4) **If you are defining pre-conditions for the first workflow step**: Define the **Message** attribute explaining what must be done to fulfill the pre-condition. If the pre-condition is not fulfilled and an error occurs during the initialization of the workflow, the message text will be displayed in an error dialog and should provide users with an explanation about how the pre-condition must be fulfilled in order to complete the initialization. The error message will be displayed as follows:

   An error has occurred during the initialization of the workflow'<`WorkflowTemplate.Caption`>'. Reason: <`WorkflowStep.PreCondition.Message`>.
5) The error message will display the following text:
6) Define the query that determines the check that is executed to ascertain whether the pre-condition has been fulfilled. To define an Alfabet query, click the **Browse**  button in the **Query** attribute to open the **Alfabet Query Builder** or paste an SQL query in the **Query as Text** attribute. For information about defining an Alfabet query, see the chapter Defining Queries.

   You must ensure that the pre-conditions are defined so that only one workflow step fulfills the criteria to become the next workflow step. If multiple workflow steps fulfill the criteria, an error will occur in the workflow.
7) In the **Result Type** attribute, select either `Positive` or `Negative` to define what constitutes a fulfilled condition.

- `Positive` means that the condition is fulfilled if the Alfabet query has delivered a result (at least one row.)
- `Negative` means that the condition is fulfilled if the Alfabet query doesn't deliver any results.

8) Click the **Save**  button to save your definitions.
9) To specify the sequence that the pre-conditions should be executed for the workflow step, click the relevant workflow step and order the conditions in the **Pre-Conditions** attribute. Click the **Save**  button.

Configuring Post-Conditions for a Workflow Step

A post-condition is based on a query that checks whether a workflow step has been completed. Each workflow step may have multiple post-conditions defined. All post-conditions must be fulfilled in order to confirm and complete a workflow step and advance to the subsequent workflow step.

A post-condition can be created based on a copy of an existing post-condition. To do so, create a new post-condition without defining any attributes. Select the post-condition you want to copy and right click and select **Copy**. Click the new post-condition and select **Paste**. The attributes are filled as defined and can be modified, as needed.

1) Click the + next to the workflow step to expand the workflow step node.
2) Right-click **Post-Conditions** and select **Add New Post- Condition** to create a post-condition.
3) Click the post-condition to display the attribute window.
4) Define the **Message** attribute explaining what must be done to fulfill the post-condition. The message text will be displayed in an error dialog and should provide users with an explanation about how the post-condition must be fulfilled in order to complete the workflow step.
5) Define the query that determines the check that is executed to ascertain whether the post-condition has been fulfilled. To define an Alfabet query, click the **Browse** button to the **Query** attribute open the **Alfabet Query Builder** or paste an SQL query in the **Query as Text** attribute. For information about defining an Alfabet query or SQL query, see the chapter Defining Queries.
6) In the **Result Type** attribute, select either `Positive` or `Negative` to define what constitutes a fulfilled condition.

- `Positive` means that the condition is fulfilled if the Alfabet query has delivered a result (at least one row.)
- `Negative` means that the condition is fulfilled if the Alfabet query doesn't deliver any results.

7) If the workflow step should be automatically closed once all post-conditions have been satisfied, click the workflow step to open its attribute window. In the **Allow Automatic Closure** attribute, `True` if the workflow step should be automatically closed and advance to the next workflow step via a batch process if all post-conditions have been satisfied. The user responsible for the workflow step does not need to manually confirm the workflow step in this case. Select `False` if the workflow step must be manually confirmed by the responsible user.

- The **Allow Automatic Closure** attribute must be set to `True` if the **Check Post Conditions and Close Activity** option should be enabled in the **Workflow Administration** functionality. If the **Allow Automatic Closure** attribute is set to `False`, the workflow administrator will not be able to check post-conditions and close a workflow step. For more information, see the section *Checking a Workflow Step's Post-Conditions and Closing the Workflow Step* in the reference manual *User and Solution Administration*.
- If the **Allow Automatic Closure** attribute is set to `True`, the batch job `alfaWorkflowCommandPrompt.exe` must include the runtime option `StepClosure`. For form information about the configuration of the batch job, see the section *Batch Processes for Workflows with AlfaWorkflowCommandPrompt.exe* in the reference manual *System Administration*.

8) Click the **Save** button to save your definitions.

9) To specify the sequence that the post-conditions should be executed for the workflow step, click the relevant workflow step and order the conditions in the **Post-Conditions** attribute. Click the **Save**  button.

Configuring Automatic Property Updates for a Workflow Step

You can configure various mechanisms to update property values when a workflow step is entered, exited, refused, or expired. The update to a property value can be configured for the object that is targeted by the workflow step as well as an object referenced by it.

The following workflow step actions targeting the update of a scalar property can be configured when a workflow step is entered, exited, refused, or expired:

- A workflow step action of the type `Script` can be created and statements using the commands `SET`, `CLEAR`, `ADDRELATIONS`, and `REMOVERELATIONS` can be defined.
- One or more values can be removed from a object class property. For example, you could configure that a specified object class property is cleared if a workflow step expires.
- One or more values can be entered for a object class property. For example, you could configure that a status value is automatically set when a workflow step is entered.
- a combination of multiple set and clear workflow step actions is possible.
- A workflow step action of the type `SQL` can be created and the commands `UPDATE` and `INSERT` can be defined.

The following information is available:

- Define a Workflow Step Action of the Type Script
- Defining a Workflow Step Action of the Type SQL

Define a Workflow Step Action of the Type Script

A workflow step action of the type `Script` can be created and statements using the commands `SET`, `CLEAR`, `ADDRELATIONS`, and `REMOVERELATIONS` can be defined. Please note the following regarding the syntax of the statements:

- Scalar properties and reference properties may be updated. An object class property can be defined via multiple relationships.
- Enter one statement for each updating workflow step action. If multiple statements are required, a separate workflow step action must be created for each statement.
- Each statement should begin with the command for the workflow step action. Permissible commands are `SET`, `CLEAR`, `ADDRELATIONS`, and `REMOVERELATIONS`. The correct syntax for a statement is: `INSTRUCTION(<Parameter>);`
- The notation for the base object of the workflow is `@WORKFLFOWBASE` and the notation for the object targeted by a workflow step is `@BASE`.

- The following parameters may be used in the statement:
- To specify the target object class property to be set: `@BASE`, `@WORKFLOW`, `@WORKFLOWBASE`, `@CURRENT_STEP`, `@PREVIOUS_STEP`, `@SOURCE`, `@CURRENT_USER`
- To specify the source object class property: `@BASE`, `@WORKFLOW`, `@WORKFLOWBASE`, `@CURRENT_STEP`, `@PREVIOUS_STEP`, `@SOURCE`, `@CURRENT_USER`, `@CURRENT_MANDATE`, `@CURRENT_PROFILE`, `@TODAY`.
- Dot notation may be implemented to concatenate multiple references in one statement. For example: `<Base.Ref1.Ref2....Target>`.
- Each statement must be terminated by a semi-colon.
- There is no mechanism to verify the syntax of the statement. If an error occurs, it will be written to the **Workflow Event Trace** page view for the workflow in Alfabet.
- There is no mechanism to verify the correctness of the command. If an error occurs (for example, because the source or target reference cannot be found for the `Set` command), the error will be written to the **Workflow Event Trace** page view for the workflow in Alfabet. For more information, see the section *Suspending, Resuming, or Withdrawing the Workflow* in the reference manual *Configuring Alfabet with Alfabet Expand*.

For example:

If the name of the base object of the workflow is to be set via the name of the component that the base object references, the statement would be:

```
SET(@WORKFLOWBASE.Name,@WORKFLOWBASE.Component.Name);
```

If the responsible user of the base object of the workflow is to be set via the responsible user of the component that the base object references, the statement would be:

```
SET(@WORKFLOWBASE.ResponsibleUser,@WORKFLOWBASE.Component.Responsible
User);
```

If the name of the object targeted by the workflow step is to be set to a specified value, the statement would be:

```
SET(@BASE.Name,"SpecifiedValue");
```

If the responsible user of the object targeted by the workflow step is to be removed, the statement would be:

```
CLEAR(@CURRENT_STEP.ResponsibleUser);
```

If a newly created application that is the base object of the workflow should be added to an application group that is the base object of the current workflow step, the statement would be:

```
ADDRELATIONS(@BASE.Applications,@WORKFLOWBASE);
```

To define a property update for a workflow step:

1) Depending on when the property update should occur, right-click one of the following workflow step actions:

- Right-click **Action On Entered Step** and select **Add New Action On Entered Step** in order to configure a property update that should occur when the workflow step is entered.

Please note the following if an **Action On Entered Step** workflow step action is configured for the first workflow step in a workflow template:

The **Action On Entered Step** workflow step action will be executed before the configured editor/wizard opens for the first workflow step. Therefore, if an **Action On Entered Step** workflow step action for the first workflow step is executed at workflow initiation and the workflow is then cancelled, the **Action On Entered Step** workflow step action will have already been executed. The updating workflow step action will not be automatically reversed with the cancellation of the workflow.

- Right-click **Action On Refused Step** and select **New Action on Refused Step** in order to configure a property update that should occur when the workflow step is refused.
- Right-click **Action On Expired Step** and select **New Action on Expired Step** in order to configure a property update that should occur when the workflow step is expired.
- Right-click **Action On Exited Step** and select **New Action on Exited Step** in order to configure a property update that should occur when the workflow step is exited.

2) Click the action to open the attribute window.
3) In the **Technical Name** attribute, enter a name for the workflow step action. This name is not displayed in the Alfabet interface.
4) In the **Type** attribute, select `Script`.
5) In the **Statements** attribute, click the **Browse** button to open the **Statements** editor. Enter one or more statements for the updating workflow step action.
6) Click the **Save** button to save your definitions.

Defining a Workflow Step Action of the Type SQL

A property update via a native SQL statement allows an `UPDATE` or `INSERT` statement to be specified. The SQL statement may be configured for the nodes **Action On Entered Step**, **Action On Expired Step**, **Action On Refused Step**, and **Action On Exited Step**.

Please note that the `INSERT` statement is only allowed to insert new relation entries in the `RELATIONS` table. If you attempt to insert new relation entries in class tables, an error will occur because the `GUID` and `REFSTR` are not automatically created and result in a `NULL` value.

To define a workflow step action of the type `SQL`:

1) Expand the relevant workflow step to display the workflow step actions.
2) Right-click the relevant workflow step action and select either **Action On Entered Step**, **Action On Expired Step**, **Action On Refused Step**, and **Action On Exited Step**.
3) Click the action to open the attribute window.
4) In the **Technical Name** attribute, enter a name for the workflow step action. This name is not displayed in the Alfabet interface.
5) In the **Type** attribute, select `SQL`.

6) In the **Statements** attribute, click the **Browse** button to open the **Statements** editor. Enter one or more statements for the updating workflow step action.

The following examples display the correct syntax to use for statements in this context:

```
UPDATE ICTOBJECT
SET DESCRIPTION='ICTO Description' WHERE ICTOBJECT.REFSTR
=@BASE
```

7) Click the **Save** button to save your definitions.

Configuring Events to Be Triggered for a Workflow Step

You can configure that an event is triggered when a workflow step is entered, exited, refused, or expired. Events allow for real-time automated updates to external systems as well as to data in Alfabet. Events allow, for example, a configured action to be triggered when a user closes the workflow window in the middle of the workflow process. As an alternative to batch jobs which may typically be initiated daily, events can be configured for workflow steps if a specified event occurs in the workflow step, a configured ADIF scheme will be triggered to process the data.

Additional configuration is required in order to trigger events. For more information about the configuration required to implement the event capability, see the chapter Configuring Events.

To configure the workflow step to trigger an event:

1) In Alfabet Expand, navigate to the workflow step that you want the event to be triggered from.
2) Go to the **Presentations** tab, expand the custom workflow and expand the relevant workflow step.
3) Right-click the node of the relevant workflow step action that shall trigger the event and select **Action On Entered Step**, **Action On Expired Step**, **Action On Refused Step**, and **Action On Exited Step**.
4) Click the action to open the attribute window and define the following attributes:

- **Technical Name**. Enter a name for the workflow step action. This name is not displayed in the Alfabet interface.
- **Action Type**: Select `TriggerEvent`.
- **Technical Comment**: Enter any relevant information about the workflow step action.
- **Event Template**: Select the relevant event template from the drop-down list.

5) Click the **Save** button to save your definitions.

Configuring a Workflow Step to Trigger a Subordinate Workflow

Some workflow template configurations will require that sub-workflows are triggered when a particular event occurs (for example, a workflow step is refused) or as the result of data input (for example, a specified value is defined for an object).

In this case, it is possible to configure a workflow step on the base workflow template so that the workflow step references a second workflow template. Depending on the circumstance that will trigger the sub-workflows, a workflow step action of the type `TriggerWorkflow` must be defined on the relevant workflow step action (**Action On Entered Step**, **Action On Expired Step**, **Action On Refused Step**, and **Action On Exited Step**). The following are examples of typical scenarios where triggered sub-workflows might be implemented.

- Sub-workflows can be triggered based on a workflow step action. For example, it may be necessary to trigger sub-workflows if a workflow step is refused by a responsible user. In this case, the `TriggerWorkflow` option must be configured for the workflow step action **Action On Refused Step**. The `TriggerWorkflow` option allows you to stipulate the workflow template that should be triggered to generate sub-workflows if the workflow step is refused.
- Sub-workflows can also be triggered based on whether pre-conditions or post-conditions configured for a workflow step action are/are not fulfilled. If the pre-condition specifies, for example, that the target object of the workflow step must have a specified status, then the workflow template would be triggered if the pre-condition is fulfilled. If the pre-condition is not fulfilled, the workflow step would not be entered and the workflow template would not be triggered. In this case, the workflow would advance to the next workflow step for which the pre-conditions are fulfilled.

A query must be configured to find the objects for which workflows must be generated. If multiple objects are found, a sub-workflow will be triggered for each workflow. The workflow owner of the workflows generated for the triggered workflow template will be the same as the owner of the base workflow template that the triggered workflow template is assigned to.

As part of the configuration, you must also decide how to proceed to the next workflow step of the base workflow template after the sub-workflows are triggered and running. Should the next workflow step of the workflow be entered when all sub-workflows are complete or does it suffice that only one sub-workflow must be complete before the next workflow step can be entered.

Finally, you need to consider what should happen if a sub-workflow must be stopped for some reason. If sub-workflows have been triggered for a workflow step of the base workflow, it may be necessary to specify that the sub-workflows can be stopped under certain circumstances. For example, if multiple sub-workflows initiate an approval process that is carried out by various individuals, and during the course of one of the sub-workflows a user determines that circumstances have changed drastically and the object targeted by the approval process warrants no further consideration, then one or all sub-workflows should be stopped.

The following information is available:

- Defining a Sub-Workflow To Be Triggered
- Defining the Re-Evaluation of Active Workflow Steps in Sub-Workflows
- Defining the Cancellation of Triggered Sub-Workflows
- Understanding Where Sub-Workflows are Implemented

Defining a Sub-Workflow To Be Triggered

The following should be completed before you configure a workflow step action of the type `TriggerWorkflow`:

For the parent workflow template:

- Create and configure the selected workflow step and the subsequent workflow step.
- If pre- or post-conditions are required to determine whether sub-workflows should be triggered, configure the pre-condition or post-condition for the selected workflow step. A query must be configured for each condition. For more information about the configuration of conditions, see the section Configuring Pre- and Post-Conditions for a Workflow Step.
- A query must be configured for the workflow step action when the **Type** attribute is set to `TriggerWorkflow` in order to find the objects for which workflows must be generated. If multiple objects are found, a sub-workflow will be triggered for each object.
- If the query is configured to find multiple objects so that multiple sub-workflows will be triggered, consider what conditions must be fulfilled before the subsequent workflow step can begin. Must all sub-workflows be complete before the next workflow step may begin? Or must only one sub-workflow be complete before the next workflow step may begin? The information is defined in the **Synchronize Triggered Workflows** attribute on the workflow step.

For the sub-workflow template: Create and configure the entire workflow template. Sub-workflows will be generated for the base object class identified in the **Start Base Class** attribute of the sub-workflow template. If the **Source Base Class** attribute is configured for the sub-workflow template, the sub-workflows will be generated for the source object class. The workflow template for sub-workflows is configured as for a conventional workflow template. For more information about configuring the objects targeted by a workflow template, see the section Specifying the Objects Targeted by the Workflows.

To define a workflow step action of the type `TriggerWorkflow`:

1) On the relevant workflow step of the base workflow template, right-click one of the following workflow step actions based on when the workflow trigger should occur:

- Right-click **Action On Entered Step** and select **New Action On Entered Step** in order to specify a workflow that should be triggered when the workflow step is entered.
- Right-click **Action On Refused Step** and select **New Action On Refused Step** in order to specify a workflow that should be triggered when the workflow step is refused.
- Right-click **Action On Expired Step** and select **New Action On Expired Step** in order to specify a workflow that should be triggered when the workflow step is expired.
- Right-click **Action On Exited Step** and select **New Action On Exited Step** in order to specify a workflow that should be triggered when the workflow step is exited.

2) Click the action  to open the attribute window.

3) In the **Technical Name** attribute, enter a name for the workflow step action. This name is not displayed in the Alfabet interface.

4) In the **Type** attribute, select `TriggerWokflow`.

5) In the **Workflow Template** attribute, select the workflow template that should be triggered for the action.

The **Name** attribute of the workflow template should NOT be changed if it is already referenced as a sub-workflow (once it is selected in the **Workflow Template** attribute of a workflow step action of the **Type** `TriggerWorkflow`). If the workflow template name is changed, the sub-workflows may not be correctly triggered.

6) You must now configure an Alfabet query or SQL query that finds the objects for which workflows should be generated when the workflow template is initialized. Enter either an SQL query or Alfabet query in the **Query as Text** attribute, or click the **Browse** button in the **Query** attribute, to open the **Alfabet Query Builder**.

If the **Source Base Class** attribute is defined, the source object class will be automatically be specified in the Alfabet query. For information about defining Alfabet queries and SQL queries, see the chapter Defining Queries.

7) Next, you must specify what conditions must be fulfilled before the subsequent workflow step can begin. In the **Synchronize Triggered Workflows** attribute on the workflow step of the base workflow template, select one of the following:

- Select `NoWait` if the next workflow step can be entered as soon as the workflow step is finished. This essentially represents a "fire & forget" scenario. The sub-workflows are triggered and are executed independent of the parent workflow triggering them. This is most applicable in situations where the parent process is merely used to determine which objects a sub-process should be triggered for.
- Select `WaitForFirstFinished` if the next workflow step can be entered as soon as the first sub-workflow is finished. This essentially represents a "winner takes all" scenario where the parent workflow triggers a number of sub-workflows and will resume activity as soon as the first of the sub-workflows has finished. The first response will be used to determine how to proceed in the parent workflow. This approach is best used in a situation where it is important to take a decision quickly rather than waiting indefinitely for a good decision.
- Select `WaitForAllCompleted` if the next workflow step can only be entered once all sub-workflows are finished. This essentially represents a "quorum" scenario where the parent workflow will wait for all opinions to be returned and derive the decision to proceed with the workflow based on all the results received. This approach is best suited for any type of majority vote or proportional vote decision-making scenario that is typically the case when deciding about introducing new technologies, launching new services, or introducing new policies that need to be endorsed by a number of decision bodies.

8) Click the **Save** button to save your definitions.

Defining the Re-Evaluation of Active Workflow Steps in Sub-Workflows

In some cases, it may be necessary to trigger a re-evaluation of active workflow steps for sub-workflows if, for example, they are only valid while a specified workflow step of the parent workflow is active.

In this case, a workflow step action of the **Type** `AutoClosureSubworkflowSteps` may be defined for the relevant workflow step of the parent workflow. If the workflow step of the parent workflow is confirmed, the re-evaluation of all active workflow steps of all sub-workflows will be triggered. If the **Allow Automatic Closure** attribute has been set to `True` for an active workflow step of a sub-workflow and all post-conditions have been met for that workflow step, the active workflow step will be completed and the sub-workflow will proceed to the next workflow step.

Defining the Cancellation of Triggered Sub-Workflows

If sub-workflows have been triggered for a workflow step of the base workflow, it may be necessary to specify that the sub-workflows can be stopped under certain circumstances.

Typically, the first workflow step in the triggered workflow template will have a pre-condition specifying that if a condition is met (for example, a specific value is defined for a object class property), then the workflow will proceed to a next workflow step that serves to cancel the workflow. In this case, you must create a workflow step that will stop the sub-workflow.

Furthermore, you must specify how the parent workflow template should respond if a sub-workflow is stopped. Should the stopped sub-workflow be ignored so that the other active sub-workflows continue to run their course until completion? Or should all running sub-workflows be immediately stopped?

Finally, what should then occur in the base workflow template after sub-workflows have been stopped. This must be configured in a next workflow step defined to follow the workflow step that triggered the sub-workflows.

To define the cancellation of triggered sub-workflows:

1) On the workflow template specifying the workflow steps of the triggered sub-workflows, create a new workflow step.
2) Right-click **Action On Entered Step** and select **Add Action On Entered Step** in order to specify a workflow step to stop the sub-workflow.
3) Click the action  to open the attribute window.
4) In the **Technical Name** attribute, enter a name for the workflow step action. This name is not displayed in the Alfabet interface.
5) In the **Technical Comment** attribute, enter an explanation for the abortion.
6) In the **Type** attribute, select `StopWorkflow`.
7) On the workflow step of the base workflow template configured to trigger the sub-workflows, specify what should occur to the running sub-workflows. In the **Sub-Workflow Stop Propagation** attribute on the workflow step, select one of the following:

- Select `NoStop` if no running sub-workflows should be aborted.
- Select `StopAll` if all running sub-workflows should be aborted if one parallel sub-workflow is aborted.

For more in formation about the configuration of sub-workflows, see the section Configuring a Workflow Step to Trigger a Subordinate Workflow.

8) Click the **Save**  button to save your definitions.

Understanding Where Sub-Workflows are Implemented

To understand which workflow template has implemented a selected workflow template, right-click the workflow template and select **Show Usage**. The **Objects Usage** dialog opens. All workflow templates in which the selected workflow template is implemented as a sub-workflow are displayed in the **Using Path** column. Click **Close** to close the dialog.

Defining the Sequence of the Workflow Steps

Once some of the workflow steps have been created, you can begin to define the sequence of the workflow steps. When you define the sequence of workflow steps for the workflow, you must define all possible subsequent workflow steps for each workflow step.

Furthermore, you should specify which workflow steps are to follow a workflow step that is refused by a user or a workflow step that has not been completed by its configured deadline.

The possible next workflow steps will depend on whether pre-conditions that have been defined for any subsequent workflow step are fulfilled for the object that is the target of the workflow step. Therefore, you may opt to define pre-conditions for each workflow step before you define the sequence of workflow steps. For more information, see Configuring Pre- and Post-Conditions for a Workflow Step.

The **Next Steps** attribute should remain empty for the last workflow step(s) in the workflow.

You can define the order of how the workflow steps should be structured below the workflow template node via the **Steps** attribute on the workflow template. This is only a visual structuring of the workflow steps. The actual sequence of workflow steps as they should occur in a running workflow is described below.

To define the sequence of the workflow steps:

1) Click a workflow template  to open its attribute window.

2) First, you must specify which workflow step is the first workflow step for the workflow template:

- If the workflow template has been configured to target existing objects when workflows are started, select the first workflow step in the **Start Step for Existing Object** attribute for the workflow template.
- If the workflow template has been configured to target new objects when workflows are started, select the first workflow step in the **Start Step for New Object** attribute for the workflow template.

If you have not already done so, you may define a caption for the initiation of the workflow template that will be displayed in the **My Workflows** functionality and the **Initiate Workflows** functionality. This allows you to define basic instruction to the user (for example, to indicate whether they will start the workflow with a new or existing object). If you do not define a caption for the initiation, the caption of the workflow template defined in the **Caption** attribute will be displayed in the **My Workflows** functionality and the **Initiate Workflows** functionality.

- If you have defined the **Start Step for Existing Object** attribute, enter a caption in the **Caption for Existing Object** attribute.
- If you have defined the **Start Step for New Object** attribute, enter a caption in the **Caption for New Object** attribute.

Next, you must define the sequencing of workflow steps for all workflows. For each workflow step, carry out the following.

3) Select the workflow step  to open its attribute window. In the **Next Step** s attribute, click in the cell and select all potential workflow steps that may follow the initial step.

4) If you have defined multiple workflow steps in the **Next Steps** attribute and would like to allow multiple workflow steps that fulfill their pre-conditions to be executed at the same time in parallel to one another, you must ensure that `True` is selected in the **Allow Simultaneous Execution of Steps** attribute of the workflow template. If workflow steps may not be simultaneously executed, you must ensure that `False` is selected in the **Allow Simultaneous Execution of Steps** attribute of the workflow template.

If multiple workflow steps are defined in the **Next Steps** attribute for a workflow step and the pre-conditions are fulfilled for more than one of these workflow steps, the following scenarios are possible:

- If the **Allow Simultaneous Execution of Steps** attribute is set to `False`, an error message will occur. In other words, you must ensure that only one workflow step listed in the **Next Steps** attribute of each workflow step can have its pre-conditions fulfilled and be entered.
- If the **Allow Simultaneous Execution of Steps** attribute is set to `True`, then all workflow steps in the **Next Steps** attribute that fulfill their pre-conditions will be executed in parallel. The subsequent behavior of the workflow will depend on how the **Next Steps** attributes are defined for the parallel workflow steps. There are two alternatives for the configuration of the subsequent workflow steps:
  - All parallel running workflow steps will merge directly or indirectly into the same subsequent workflow step (defined in the **Next Steps** attribute of the merging workflow steps). In this case, the subsequent workflow step will only be entered when all preceding parallel-running steps have been completed.
  - Each parallel running workflow step forms its own independent branch with subsequent workflow steps. The branches do not merge into a common workflow step. The workflow will be completed only when ALL branches reach their last workflow step. **Please note that this workflow design is not recommended. Best practice recommendation for designing workflows with parallel branches is to merge all those branches back into a single lane of execution prior to ending the workflow.**

Please note that if a workflow includes parallel workflow steps and one of the branches forms a cycle that returns to the workflow step where the branching occurred, the availability of that workflow step will be checked prior to recreating the workflow step. If the workflow step is still active, it will not be recreated.

In Alfabet, the workflow step status `Entering` indicates that a workflow step has several parallel workflow steps proceeding it. If one of the parallel branches has been completed, the workflow step that the branches merge into will acquire the status `Entering`. Once all relevant parallel branches have been completed, the workflow step where the branches merge will acquire the status `Pending`. Email notifications will then be sent, if relevant, and the workflow step can be performed by the responsible users.

5) For each workflow step  (including the first workflow step), you may optionally define the **Expiration Step** attribute in order to specify that a specific workflow step should follow the selected step if it surpasses its deadline. In the **Expiration Step** attribute, define the workflow step that should be the next workflow step if the selected step is not completed by a user in the timeframe defined in the **Performance Duration** attribute. You may only define one workflow step for this attribute.

If no workflow step is defined and the workflow step expires, an error will occur in the workflow ad a workflow administrator or workflow owner will have to intervene and re-direct the workflow.

Alternatively, you can configure another workflow to be triggered if a workflow step is expired. In this case, you must define an action for the **On Step Expired** action of the selected workflow step. The action must be of the type `TriggerWorkflow`. The **Expiration Step** attribute should be left empty in this case. For more information about configuring a workflow to follow an expired workflow step, see the section Configuring a Workflow Step to Trigger a Subordinate Workflow.

For more information about defining the **Performance Duration** attribute, see the section Defining a Deadline and Reminders for a Workflow Step.

6) For each workflow step (including the first workflow step), you may optionally define the **Refuse Step** attribute. In the **Refuse Step** attribute for each workflow step, define the workflow step that should be the next workflow step if the selected step is refused by a user. You may only define one workflow step for this attribute.

If no workflow step is defined and the workflow step is refused, an error will occur in the workflow and a workflow administrator or workflow owner will have to intervene and re-direct the workflow.

Alternatively, you can configure another workflow to be triggered if a workflow step is refused. In this case, you must define an action for the **On Refuse Step** action of the selected workflow step. The action must be of the type `TriggerWorkflow`. The **Refuse Step** attribute should be left empty in this case. For more information about configuring a workflow to follow a refused workflow step, see the section Configuring a Workflow Step to Trigger a Subordinate Workflow.

Regardless of the setting defined in the **Confirmation Type** attribute, the refusal of a workflow step by a single user results in the overall refusal of the workflow step. Once a workflow step has been refused by a responsible user, all other responsible users will no longer be required to confirm the workflow step. For more information about defining configuring the refusal capability, see the section Configuring the Action Buttons Available for a Workflow Step.

7) Click the **Save**  button to save your definitions.

Configuring Email Notifications for Workflows

The workflow capability in Alfabet allows for the configuration of automatically-generated email notifications for a wide variety of events that could occur in a workflow. Email notifications can be automatically generated and sent to the relevant users for the following workflow actions:

- a workflow step has been entered (with the exception of the first workflow step)
- a workflow step has been refused
- a workflow step has been completed
- a workflow step has been delegated
- the targeted deadline for a workflow step is approaching
- the targeted deadline for a workflow step has expired
- an error has occurred in the workflow
- a workflow has been suspended
- a suspended workflow has been resumed
- the workflow owner has been changed
- a workflow has been completed

As the workflow designer, you can either enable the email functionality for all workflows generated for a workflow template or completely disable the email functionality for the workflow template. If you disable the email functionality, no email notifications will be generated in the context of the workflow. Please note that once a workflow step has been confirmed and thus completed, the workflow step can no longer be opened via the link in the email notification.

All email notifications sent in the context of a workflow are based on text templates that specify the text in the email as well as information about and hyperlinks to the workflow step triggering the notification and, if relevant, the object targeted by the workflow step in which the email is being generated. Software AG provides standard text templates for all contexts in which emails are generated. The standard text templates may be modified or new custom text templates can be created based on a standard text template.

The sender of the email notification will be determined based on the following, in the order given below:

1) Email address configured in the **System Mail Account** attribute in the server alias configuration.
2) Email address configured in the **Notification Sender Address** attribute for the workflow template.
3) Email address of the workflow owner.
4) Email address of the workflow template owner.

The following configuration requirements must be completed by the system administrator in the tool Alfabet Administrator:

- All Alfabet functionalities for which the email capability is to be implemented require the setup of a connection to an SMTP server for outgoing email. For more information, see the

section *Activating the Dispatch of Email Notifications in Alfabet* in the reference manual *System Administration*.

- The user profile used to open the Alfabet views targeted by hyperlinks in the email is, by default, the user profile that the sender was logged in with when the view was sent/triggered. However, your system administrator may configure that Alfabet views in email notifications are to be opened using the recipient's user profile. For more information, see the section *Configuring the Setup To Open the Alfabet Interface via Links in Email Notifications* in the reference manual *System Administration*.

For email notifications triggered via batch processes (such as reminder notifications or automatically-started workflows), a batch process must be configured by your system administration in the tool Alfabet Administrator. For more information about configuring a batch job for workflows, see the section *Batch Processes for Workflows with AlfaWorkflowCommandPrompt.exe* in the reference manual *System Administration*.

The following steps are required in order to configure and implement email notifications for a workflow template:

- Activate the email capability for the workflow template via the **Use Email Notification** attribute.
- Specify whether to concatenate messages per user via the **Notification Type** and, if necessary, **Notification Subject** attributes.
- Review and edit protected text templates available for workflows or create customized public text templates, as needed.
- Assign the relevant protected or public text template to each workflow step or relevant workflow step action.

The following information is available:

- Implementing the Email Notification Functionality for a Workflow Template
- Configuring Email Notifications When a Workflow Step Is Entered
- Configuring Email Notifications When a Workflow Step Is Refused
- Configuring Email Notifications When a Workflow Step Is Expired
- Configuring Email Notifications When a Workflow Step Is Exited
- Configuring Reminder Email Notifications About Approaching Deadlines
- Configuring Email Notifications About Delegated Workflow Steps
- Configuring Email Notifications About Changes in Workflow Ownership
- Configuring Email Notifications About Errors Occurring in a Workflow
- Configuring Email Notifications When a Workflow Is Paused and Resumed
- Configuring Email Notifications When a Workflow Is Completed

Implementing the Email Notification Functionality for a Workflow Template

The following steps are required in order to configure the implementation of email notifications for a workflow template:

1) Select `True` in the **Use Email Notification** attribute for the workflow template. If this attribute is set to `False`, no emails will be generated, regardless of any further configuration of email notification.

2) In the **Notification Type** attribute, specify if multiple emails should be concatenated for notifications generated via batch processes. Select one of the following:

Please note that if email notifications are consolidated for workflow templates and the **Is HTML** attribute is set to `True` for the associated text template, the consolidated email will also have HTML formatting. For information about configuring text templates, see the section Configuring Text Templates for Email Notifications.

- `NoConsolidation`: Select if an email should be generated for each message associated with an event triggering the notification. This is the default value.
- `ConsolidateAllMessages`: Select if all messages generated for a workflow template for a user should be concatenated in one email.
- `ConsolidateMessagesByStep`: Select if all messages generated for a workflow step for a user should be concatenated in one email.
- `ConsolidateMessagesByTemplate`: Select if all messages generated based on a text template in the context of a workflow for a user should be concatenated in one email. If this value is selected, the user will reserve all messages based on a specific type of activity, regardless of the workflow step in which they were generated.

3) If `ConsolidateAllMessages` or `ConsolidateMessagesByStep` is selected in the **Notification Type** attribute, the subject line of the email notification can be customized in the **Notification Subject** attribute.

4) In the **Executing User Profiles** attribute for the workflow template, define which user profile should be used when a user accesses the **My Workflow Activities** functionalities (`WF_UserWorkflowActivities`, `WF_UserWorkflowActivitiesExt`, and `WF_UserWorkflowActivitiesCommon`) and/or the **Workflow Activities Explorer** via the hyperlink in an email notification.

5) In the toolbar, click the **Save**  button to save your changes.

6) Define the text that should be displayed in the email notifications. Software AG provides a predefined default text template for each context in which a notification can be triggered. These text templates can be used as-is, modified, or used as a basis to create new text templates. This is done on the **Text Templates** node in the **Presentation** tab of Alfabet Expand. For general information about defining text templates, see the section Configuring Text Templates for Email Notifications in the chapter Configuring Alfabet Functionalities Implemented in the Solution Environment.

Configuring Email Notifications When a Workflow Step Is Entered

Email notifications may be configured and automatically generated when a workflow step has been entered.

Please note however that this is not possible for the first workflow step. The **Type** attribute may not be set to `Notification` for a workflow step action of the type **Action On Entered Step**.

You can configure each workflow step so that email notifications will be sent to the users specified in the associated query.

```
Dear {Person:Name} {Person:FirstName},

You are responsible for the workflow
step: {WorkflowStep:Name} '{WorkflowStep:Caption}'.

The object targeted by the workflow step is: '{Object:RefImage}'.
The workflow was created by the user: {Sender:Name} {Sender:FirstName}.

Please follow this link
        {Link:ObjectView}
to access the My Workflow Activities functionality.
```

FIGURE: Example of the standard text template WorkflowActivityNew

You can use the standard text template ***WorkflowActivityNew*** or a custom text template that you create for your enterprise. For more information about the standard text template ***WorkflowActivityNew*** and the permissible variables for the text template, see the section *Text Templates for Workflows* in the chapter *Overview of Preconfigured Text Templates and Their Variables* in the reference manual *Configuring Alfabet with Alfabet Expand - Appendix*.

To configure email notifications to be sent when a workflow step is entered:

1) Expand the relevant workflow step node  to display its subordinate workflow step actions.
2) Right-click the workflow step action **Action On Entered Step** and select **New Action On Entered Step**.

   If you define an action of the type `Notification` for the workflow step action **Action On Entered Step**, then the **Email Template by Enter Step** or **Email Template by Enter Step from Refuse** attributes for the workflow step may not be defined. Otherwise an error will occur.

3) Click the action  to open the attribute window and select `Notification` in the **Type** attribute.
4) In the **Technical Name** attribute, enter a name for the notification action.
5) In the **Text Template** attribute, select the standard text template ***WorkflowActivityNew*** or a customized text template that should be sent when the workflow step is entered.
6) In the **Query as Text** attribute, enter an Alfabet query or native SQL query returning the recipient email addresses to which email notifications shall be sent. The email addresses are entered in the relevant **To:** field, **CC:** field, **BCC:** field.:

   Emails can be sent to any email addresses stored in custom object class properties of the property type `Email` or the standard property `Email` of the object class `Person`. There are two ways to specify the recipient emails

- Define a query finding the relevant objects only. Emails will be sent to all email addresses stored in any object class property of the property type `Email` defined for the returned objects. The query can be either a native SQL query or an Alfabet query.

  For example to send emails to any email addresses defined for Alfabet users, you must at least define:

  ```
  Select REFSTR from PERSON
  ```

  or

  ```
  ALFABET_QUERY_500
  FIND PERSON
  ```

- If an object class has multiple properties of the property type `Email` and you would like emails to be send to the email addresses stored in one of these object class properties only, you must specify an Alfabet Query. The Alfabet query must return the email addresses in the **Show Properties** definition. The `FIND` class is not relevant.

  For example, the following query triggers sending of emails to the email addresses stored in a custom property of the type `Email` defined for the object class `Application`, although `Application` is not the `FIND` class. The information about the relevant object class and object class property are read from the **Show Properties**:

  ```
  ALFABET_QUERY_500
  FIND Person
  InnerJoin Application ON Person.REFSTR =
  Application.ResponsibleUser
  WHERE
  Application.MyEmailProp IS NOT NULL
  QUERY_XML
  <QueryDef>
  <ShowProperty Type="Property" ClassName="Application"
  Name="MyEmailProp">
  </QueryDef>
  ```

  Please note that the Alfabet Query Builder and the native SQL specific editor are not available in this attribute. If you would like to define the query in one of the specific editors, you can define and test the query in a configured report of the type `Query` or `NativeSQL` and past it into this attribute afterwards.

7) In the **CC Query as Text** attribute, enter an Alfabet query or SQL query to find the users who should be in the CC list of the email.
8) In the **BCC Query as Text** attribute, enter an Alfabet query or SQL query to find the users who should be in the BCC list of the email.
9) Click the **Save**  button to save your definitions.

Configuring Email Notifications When a Workflow Step Is Refused

You can configure each workflow step so that email notifications will be sent to the users specified in the associated query.

```
Dear {Person:Name} {Person:FirstName},

{Sender:Name} {Sender:FirstName} has refused the workflow
step: {WorkflowStep:Name} '{WorkflowStep:Caption}'

The object targeted by the workflow step is:  '{Object:RefImage}'

The following message provides explanation: {Message:Text}.
```

FIGURE: Example of the standard text template WorkflowStepRefused

You can use the standard text template ***WorkflowStepRefused*** or a custom text template that you create for your enterprise. For more information about the standard text template ***WorkflowStepRefused*** and the permissible variables for the text template, see the section *Text Templates for Workflows* in the chapter *Overview of Preconfigured Text Templates and Their Variables* in the reference manual *Configuring Alfabet with Alfabet Expand - Appendix*.

The refusal of the workflow step by one user results in the refusal of the workflow step for all responsible users. If a workflow step is refused, the workflow would advance to the workflow step defined in the **Refuse Step** attribute for the refused workflow step. If email notification is configured for the workflow step defined in the **Refuse Step** attribute, then the users responsible for that workflow step would receive email notification when that workflow step is entered.

To configure email notifications to be sent when a workflow step is refused:

1) Expand the relevant workflow step node  to display its subordinate workflow step actions.
2) Right-click the workflow step action **Action On Refused Step** and select **New Action On Refused Step**.
3) Click the action  to open the attribute window and select `Notification` in the **Type** attribute.
4) In the **Technical Name** attribute, enter a name for the notification action.
5) In the **Text Template** attribute, select the standard text template ***WorkflowStepRefused*** or a customized text template that should be sent when the workflow step is refused.
6) In the **Query as Text** attribute, enter an Alfabet query or native SQL query returning the recipient email addresses to which email notifications shall be sent. The email addresses are entered in the relevant **To:** field, **CC:** field, **BCC:** field.:

   Emails can be sent to any email addresses stored in custom object class properties of the property type `Email` or the standard property `Email` of the object class `Person`. There are two ways to specify the recipient emails

- Define a query finding the relevant objects only. Emails will be sent to all email addresses stored in any object class property of the property type `Email` defined for the returned objects. The query can be either a native SQL query or an Alfabet query.

For example to send emails to any email addresses defined for Alfabet users, you must at least define:

```
Select REFSTR from PERSON
```

or

```
ALFABET_QUERY_500
FIND PERSON
```

- If an object class has multiple properties of the property type `Email` and you would like emails to be send to the email addresses stored in one of these object class properties only, you must specify an Alfabet Query. The Alfabet query must return the email addresses in the **Show Properties** definition. The `FIND` class is not relevant.

For example the following query triggers sending of emails to the email addresses stored in a custom property of the type `Email` defined for the object class `Application`, although `Application` is not the `FIND` class. The information about the relevant object class and object class property are read from the **Show Properties**:

```
ALFABET_QUERY_500
FIND Person
InnerJoin Application ON Person.REFSTR =
Application.ResponsibleUser
WHERE
Application.MyEmailProp IS NOT NULL
QUERY_XML
<QueryDef>
<ShowProperty Type="Property" ClassName="Application"
Name="MyEmailProp">
</QueryDef>
```

Please note that the Alfabet Query Builder and the native SQL specific editor are not available in this attribute. If you would like to define the query in one of the specific editors, you can define and test the query in a configured report of the type `Query` or `NativeSQL` and past it into this attribute afterwards.

7) In the **CC Query as Text** attribute, enter an Alfabet query or SQL query to find the users who should be in the CC list of the email.

8) In the **BCC Query as Text** attribute, enter an Alfabet query or SQL query to find the users who should be in the BCC list of the email.

9) Click the **Save**  button to save your definitions.

Configuring Email Notifications When a Workflow Step Is Expired

You can configure each workflow step so that email notifications will be sent to the users specified in the associated query.

```
Dear {Person:Name} {Person:FirstName},

The workflow step: {WorkflowStep:Name} '{WorkflowStep:Caption}'

has escalated for the object targeted by the workflow
step: '{Object:RefImage}'

The following message provides explanation: {Message:Text}.
```

FIGURE: Example of the standard text template WorkflowStepEscalated

You can use the standard text template ***WorkflowStepEscalated*** or a custom text template that you create for your enterprise. For more information about the standard text template ***WorkflowStepEscalated*** and the permissible variables for the text template, see the section *Text Templates for Workflows* in the chapter *Overview of Preconfigured Text Templates and Their Variables* in the reference manual *Configuring Alfabet with Alfabet Expand - Appendix*.

If the current step is not performed in the number of days defined in the **Performance Duration** attribute starting with the day the workflow step is entered, the email notifications will be triggered. Please note however that either batch process must be executed by the system administrator in order for the deadline check to be executed. Alternatively, the workflow administer can trigger the **Check Performance Duration** functionality for a selected workflow in the **Workflow Administration** view.

For more information about configuring a batch job to check workflow deadlines, see the section *Batch Processes for Workflows with AlfaWorkflowCommandPrompt.exe* in the reference manual *System Administration*.

To configure email notifications to be sent when a workflow step has escalated due to, for example, a surpassed deadline:

1) Expand the relevant workflow step node  to display its subordinate workflow step actions.
2) Right-click the workflow step action **Action On Expired Step** and select **New Action On Expired Step**.
3) Click the action  to open the attribute window and select `Notification` in the **Type** attribute.
4) In the **Technical Name** attribute, enter a name for the notification action.
5) In the **Text Template** attribute, select the standard text template ***WorkflowStepEscalated*** or a custom text template that should be sent when the workflow step surpasses its deadline.
6) In the **Query as Text** attribute, enter an Alfabet query or native SQL query returning the recipient email addresses to which email notifications shall be sent. The email addresses are entered in the relevant **To:** field, **CC:** field, **BCC:** field.:

   Emails can be sent to any email addresses stored in custom object class properties of the property type `Email` or the standard property `Email` of the object class `Person`. There are two ways to specify the recipient emails

- Define a query finding the relevant objects only. Emails will be sent to all email addresses stored in any object class property of the property type `Email` defined for the returned objects. The query can be either a native SQL query or an Alfabet query.

  For example, to send emails to any email addresses defined for Alfabet users, you must at least define:

  ```
  Select REFSTR from PERSON
  ```

  or

  ```
  ALFABET_QUERY_500
  FIND PERSON
  ```

- If an object class has multiple properties of the property type `Email` and you would like emails to be send to the email addresses stored in one of these object class properties only, you must specify an Alfabet Query. The Alfabet query must return the email addresses in the **Show Properties** definition. The `FIND` class is not relevant.

  For example, the following query triggers sending of emails to the email addresses stored in a custom property of the type `Email` defined for the object class `Application`, although `Application` is not the `FIND` class. The information about the relevant object class and object class property are read from the **Show Properties**:

  ```
  ALFABET_QUERY_500
  FIND Person
  InnerJoin Application ON Person.REFSTR =
  Application.ResponsibleUser
  WHERE
  Application.MyEmailProp IS NOT NULL
  QUERY_XML
  <QueryDef>
  <ShowProperty Type="Property" ClassName="Application"
  Name="MyEmailProp">
  </QueryDef>
  ```

  Please note that the Alfabet Query Builder and the native SQL specific editor are not available in this attribute. If you would like to define the query in one of the specific editors, you can define and test the query in a configured report of the type `Query` or `NativeSQL` and past it into this attribute afterwards.

7) In the **CC Query as Text** attribute, enter an Alfabet query or SQL query to find the users who should be in the CC list of the email.
8) In the **BCC Query as Text** attribute, enter an Alfabet query or SQL query to find the users who should be in the BCC list of the email.
9) Click the **Save**  button to save your definitions.

Configuring Email Notifications When a Workflow Step Is Exited

You can configure email notifications to be sent to the users specified in the associated query when the workflow step has been completed.

You can create a custom text template for your enterprise. For more information about the standard text templates and their variables, see the section *Text Templates for Workflows* in the chapter *Overview of Pre-configured Text Templates and Their Variables* in the reference manual *Configuring Alfabet with Alfabet Expand - Appendix*.

To configure email notifications to be sent when a workflow step has been completed:

1) Expand the relevant workflow step node to display its subordinate workflow step actions.
2) Right-click the workflow step action **Action On Exited Step** and select **New Action On Exited Step**.
3) Click the action to open the attribute window and select `Notification` in the **Type** attribute.
4) In the **Technical Name** attribute, enter a name for the notification action.
5) In the **Text Template** attribute, select the email template that should be sent to the workflow owner when the workflow step is exited.
6) In the **Query as Text** attribute, enter an Alfabet query or native SQL query returning the recipient email addresses to which email notifications shall be sent. The email addresses are entered in the relevant **To:** field, **CC:** field, **BCC:** field.:

   Emails can be sent to any email addresses stored in custom object class properties of the property type `Email` or the standard property `Email` of the object class `Person`. There are two ways to specify the recipient emails

- Define a query finding the relevant objects only. Emails will be sent to all email addresses stored in any object class property of the property type `Email` defined for the returned objects. The query can be either a native SQL query or an Alfabet query.

  For example to send emails to any email addresses defined for Alfabet users, you must at least define:

  ```
  Select REFSTR from PERSON
  ```

  or

  ```
  ALFABET_QUERY_500
  FIND PERSON
  ```

- If an object class has multiple properties of the property type `Email` and you would like emails to be send to the email addresses stored in one of these object class properties only, you must specify an Alfabet Query. The Alfabet query must return the email addresses in the **Show Properties** definition. The `FIND` class is not relevant.

  For example, the following query triggers sending of emails to the email addresses stored in a custom property of the type `Email` defined for the object class `Application`, although `Application` is not the `FIND` class. The information about the relevant object class and object class property are read from the **Show Properties**:

```
ALFABET_QUERY_500

FIND Person

InnerJoin Application ON Person.REFSTR =
Application.ResponsibleUser

WHERE

Application.MyEmailProp IS NOT NULL

QUERY_XML

<QueryDef>

<ShowProperty Type="Property" ClassName="Application"
Name="MyEmailProp">

</QueryDef>
```

Please note that the Alfabet Query Builder and the native SQL specific editor are not available in this attribute. If you would like to define the query in one of the specific editors, you can define and test the query in a configured report of the type `Query` or `NativeSQL` and past it into this attribute afterwards.

7) In the **CC Query as Text** attribute, enter an Alfabet query or SQL query to find the users who should be in the CC list of the email.

8) In the **BCC Query as Text** attribute, enter an Alfabet query or SQL query to find the users who should be in the BCC list of the email.

9) Click the **Save**  button to save your definitions.

Configuring Reminder Email Notifications About Approaching Deadlines

If a workflow step's target due date is approaching, an email may be sent to the responsible user(s) of the workflow step. You can define email notifications for both the responsible users informing them of the pending deadline as well as the workflow owner informing him/her that reminders have been sent to the responsible users. This configuration can be made on the level of the workflow template as well as the workflow step.

The definitions made for the workflow step will have precedence over the definition defined for the workflow template.

```
Person: {Person:Name} {Person:FirstName}
Sender: {Sender:Name} {Sender:FirstName}

Dear {Person:Name} {Person:FirstName},

Workflow Activity: {WorkflowStep:Name} '{WorkflowStep:Caption}'

The object targeted by the workflow step is: '{Object:RefImage}'.

Please follow this link
        {Link:ObjectView}
to access the My Workflow Activities functionality.
```

FIGURE: Example of the standard text template WorkflowReminder

You can use the standard text template ***WorkflowReminder*** or a custom text template that you create for your enterprise. For more information about the standard text template ***WorkflowReminder*** and the permissible variables for the text template, see the section *Text Templates for Workflows* in the chapter *Overview of Preconfigured Text Templates and Their Variables* in the reference manual *Configuring Alfabet with Alfabet Expand - Appendix*.

The workflow step deadline is configured via the **Performance Duration** attribute and includes the number of days that a user has to complete the workflow step, the number of days before the deadline when the first reminder notification should be sent, and the how often the frequency that the user should be reminded of the impending deadline. Reminder frequency is defined on the level of an individual workflow step. For more information, see Defining a Deadline and Reminders for a Workflow Step.

If the **Performance Duration** attribute is defined for the workflow template, it is recommended that reminder emails are sent every day. Therefore, the batch job `WorkflowCommandPrompt.exe` should be executed on daily basis because the reminders are sent when the specified reminder start and frequency is matched based on the day that the workflow activity was created. For more information about configuring a batch job to check workflow deadlines, see the section *Batch Processes for Workflows with AlfaWorkflowCommandPrompt.exe* in the reference manual *System Administration*.

To configure the reminder emails that should be sent out to inform users about impending deadlines:

1) To define reminder notifications for the workflow template as a whole, click the workflow step  or workflow template  to display the attribute window.
2) In the **Email Template by Reminder** attribute, select the standard text template ***WorkflowReminder*** or a customized text template that should be sent as a reminder of the workflow step's impending target date.

   If an email template has been defined in the **Email Template by Reminder** or **Email Template by Reminder Alert** attributes for a workflow step, then the template defined for a workflow step will be used instead of the one defined for the workflow template. Reminder frequency is defined on the level of an individual workflow step. For more information, see Defining a Deadline and Reminders for a Workflow Step.

3) In the **Email Template by Reminder Alert** attribute, select the email template that should be sent to the workflow owner and initiator of the workflow if a reminder email is sent to the users responsible for the current workflow step. If an email template is not selected, the workflow owner and initiator will not be informed about impending target dates
4) Click the **Save**  button to save your definitions.

Configuring Email Notifications About Delegated Workflow Steps

You can configure the workflow template so that email notifications will be sent to the workflow owner and the user to whom the workflow step is being delegated.

```
Dear {Person:Name} {Person:FirstName},

{Sender:Name} {Sender:FirstName}

has delegated the following workflow step to you.

The workflow step is: {WorkflowStep:Name} '{WorkflowStep:Caption}'

The object targeted by the workflow step is: '{Object:RefImage}'.

The following message provides explanation: {Message:Text}.

Please follow this link
        {Link:ObjectView}
to access the My Workflow Activities functionality.
```

FIGURE: Example of the standard text template WorkflowStepDelegated

You can use the standard text template ***WorkflowStepDelegated*** or a custom text template that you create for your enterprise. For more information about the standard text template ***WorkflowStepDelegated*** and the permissible variables for the text template, see the section *Text Templates for Workflows* in the chapter *Overview of Preconfigured Text Templates and Their Variables* in the reference manual *Configuring Alfabet with Alfabet Expand - Appendix*.

To configure email notifications to be sent when a workflow is delegated:

1) Click the workflow template  to display the attribute window.
2) In the **Email Template by Delegate** attribute, select standard text template ***WorkflowStepDelegated*** or a custom text template that should be sent to the workflow owner and the user to whom the workflow step is being delegated.
3) Click the **Save**  button to save your definitions.

Configuring Email Notifications About Changes in Workflow Ownership

The owner of a workflow is typically the user that has created the workflow based on the workflow template. If necessary, the workflow administrator can change the owner of the workflow to another user that has access to the **My Workflows** or **Initiate Workflows** functionality via his/her user profile.

You can configure the workflow template so that email notifications will be sent to the original workflow owner and the new workflow owner when the workflow administrator has changed the ownership of a workflow

```
Dear {Person:Name} {Person:FirstName},

{Sender:Name} {Sender:FirstName}
has changed the workflow owner.

The following message provides explanation: {Message:Text}.

Please follow this link
        {Link:ObjectView}
to access the My Workflows functionality.
```

FIGURE: Example of the standard text template WorkflowChangeOwner

You can use the standard text template ***WorkflowChangeOwner*** or a custom text template that you create for your enterprise. For more information about the standard text template ***WorkflowChangeOwner*** and the permissible variables for the text template, see the section *Text Templates for Workflows* in the chapter *Overview of Preconfigured Text Templates and Their Variables* in the reference manual *Configuring Alfabet with Alfabet Expand - Appendix*.

For more information about changing the ownership of a workflow, see the section *Changing the Owner of a Workflow Template or Workflow* in the reference manual *User and Solution Administration*.

To configure email notifications to be sent when the workflow owner is changed:

1) Click the workflow template  to display the attribute window.
2) In the **Email Template by Change Owner** attribute, select the standard text template ***WorkflowChangeOwner*** or a custom text template that should be sent to the new and original workflow owners when the ownership of a workflow has been changed by the system administrator.
3) Click the **Save**  button to save your definitions.

Configuring Email Notifications About Errors Occurring in a Workflow

Errors can occur in a workflow that prevent the workflow from advancing to a next workflow step. For example, if a workflow step's target date has expired, the workflow step may escalate (`EscalateByTime`), or if no responsible user is assigned to a workflow step or found via a predefined Alfabet query, the workflow step will escalate (`EsclatedByError`). The errors must then be dealt with and resolved by either the workflow owner or the workflow administrator.

You can configure the workflow template so that email notifications will be sent to the workflow owner when an error has occurred and the state of the workflow has escalated.

```
Dear {Person:Name} {Person:FirstName},

The workflow step: {WorkflowStep:Name} '{WorkflowStep:Caption}'

has escalated for the object targeted by the workflow
step: '{Object:RefImage}'

The following message provides explanation: {Message:Text}.
```

FIGURE: Example of the standard text template WorkflowStepEscalated

You can use the standard text template ***WorkflowStepEscalated*** or a custom text template that you create for your enterprise. For more information about the standard text template ***WorkflowStepEscalated*** and the permissible variables for the text template, see the section *Text Templates for Workflows* in the chapter *Overview of Preconfigured Text Templates and Their Variables* in the reference manual *Configuring Alfabet with Alfabet Expand - Appendix*.

For more information about error resolution, see the section *Fixing a Workflow with an Error State* in the reference manual *User and Solution Administration*.

To configure email notifications to be sent when an error has occurred in the workflow:

1) Click the workflow template to display the attribute window.
2) In the **Email Template by Escalate** attribute, select the email template that should be sent to the workflow owner and workflow administrator when a workflow step is escalated.
3) Click the **Save** button to save your definitions.

Configuring Email Notifications When a Workflow Is Paused and Resumed

You can configure the workflow template so that email notifications will be sent to the responsible users of the workflow step that is impacted when the workflow owner or workflow administrator suspends or resumes a workflow.

For more information about the standard text templates and their variables, see the section *Text Templates for Workflows* in the chapter *Overview of Preconfigured Text Templates and Their Variables* in the reference manual *Configuring Alfabet with Alfabet Expand - Appendix*.

For more information about how a workflow can be suspended or continued, see the section *Suspending, Resuming, or Withdrawing the Workflow* in the reference manual *User and Solution Administration*.

To configure email notifications to be sent when a workflow is suspended and continued:

1) Click the workflow template to display the attribute window.
2) In the **Email Template by Pause** attribute, select the standard text template ***WorkflowPaused*** or a custom text template that should be sent to the responsible user(s) when the workflow is suspended by the workflow owner or workflow administrator.

3) In the **Email Template by Resume** attribute, select the email template that should be sent to the responsible user(s) when the workflow is resumed by the workflow owner or workflow administrator.

4) Click the **Save**  button to save your definitions.

Configuring Email Notifications When a Workflow Is Completed

You can configure the workflow template so that email notifications will be sent to the workflow owner whenever his/her workflow based on the workflow template reaches the state `Finished`.

For more information about the standard text templates and their variables, see the section *Text Templates for Workflows* in the chapter *Overview of Preconfigured Text Templates and Their Variables* in the reference manual *Configuring Alfabet with Alfabet Expand - Appendix*.

To configure email notifications to be sent when a workflow is completed:

1) Click the workflow template  to display the attribute window.
2) In the **E-Mail Template by Finish** attribute, select the standard text template ***WorkflowResumed*** or a custom text template that should sent to workflow owners when workflows based on the selected workflow template reaches the state `Finished`.

3) Click the **Save**  button to save your definitions.

Specifying the Customized Workflow Activities Explorer (WFS_Explorer) or a Custom Explorer

Software AG provides several options to implement an explorer for users to process their workflow activities.

1) Implement the standard datasets for workflow activities. The **My Workflow Activities** functionalities (`WF_UserWorkflowActivities`, `WF_UserWorkflowActivitiesExt`, and `WF_UserWorkflowActivitiesCommon`) are standard tabular datasets that may be made available to the users who will be responsible for performing the workflow steps. These views are preconfigured and cannot be modified. For more information about these standard functionalities, see the section *Performing and Tracking Your Workflow Steps in the My Workflow Activities Functionality* in the reference manual *Getting Started with Alfabet*. The implementation of the standard functionalities is described in the section Making the Workflow Capability Available to the User Community.

2) Implement the **Workflow Activities Explorer** (`WFS_Explorer`). The **Workflow Activities Explorer** functionality (`WFS_Explorer`) is a standard explorer available to support users in processing their workflow activities. The **Workflow Activities Explorer** functionality features a design and layout of data in Alfabet similar to established email management systems so that users can more easily and efficiently accomplish their workflow tasks. The explorer structure is preconfigured and cannot be changed for the **Workflow Activities Explorer** (`WFS_Explorer`) but the data displayed in the right pane when a workflow activity is selected in the explorer is configurable and users can be provided with precisely the data they need in order to process the task-at-hand with a minimum number of clicks and navigation to other views. The **Workflow Activities Explorer** functionality (`WFS_Explorer`) includes the following:

- The **Workflow Activities Explorer** is displayed in the left pane. It has a root node **My Workflow Activities** followed by the **Start New Workflow** node, which when clicked displays the **My Workflows** (`WF_UserWorkflows`) dataset in which a new workflow can be started. Below the **Start New Workflow** node, the subordinate nodes **Open Activities**, **Finished Activities**, **Refused Activities**, **Cancelled Activities**, and **Withdrawn Activities** and **Expired Activities** are available. Please note the following about the explorer:
- The nodes will only be displayed if the user has relevant activities. For example, the explorer node **Expired Activities** will only be displayed in the explorer if the user has workflow activities that have not been completed by the deadline.
- The workflow activities that the user is responsible for are displayed below the respective node. For each workflow activity, the name of the workflow activity is displayed followed by the name of the object targeted by the workflow activity. The captions for the objects targeted by the workflow are based on the **Image Properties** attribute for the relevant class setting.
- Standard symbols indicate the respective completion status of each workflow activity.
- Once the workflow activity is completed, it will automatically be removed from the **Open Activities** node.
- Completed activities will be displayed below the **Finished Activities** node for 30 days after they have been completed.
- Users can click the + symbol to expand a list and click the - symbol to collapse a node.

- The explorer search functionality is available and supports the user in finding a specific workflow activity in the explorer. For more information about using the explorer search functionality, see the section *Working with Explorers* in the reference manual *Getting Started with Alfabet*.
- Users can click a workflow activity in the explorer to display detailed information about the task in the reading pane. Please note the following:
- The toolbar above the reading pane displays only the action buttons relevant for the selected workflow activity. Users can click a button in the toolbar to perform the relevant action. The captions and symbols on the buttons are configurable and thus may vary among workflow activities. The display of buttons is determined by the definition of the attributes in the **Visualization** section of the workflow step's attribute grid as described in the section Configuring the Action Buttons Available for a Workflow Step.
- The content in the right pane is configured via an HTML template which specifies the content, navigation, and layout of the data. An HTML template may be configured for each individual workflow step defined for a workflow template if necessary. A HTML template may be reused for multiple workflow steps or assigned to the workflow template and used for all workflow steps. The configuration of the HTML template is described in the section Configuring HTML Templates for the Workflow Activities Explorer. Please note the following:
    - The header of the reading pane can be configured in the HTML template. For example, you could configure to display the name of the workflow activity and targeted object as well as the description configured for the workflow step.
    - You can specify one or more groups of information in the reading pane. For example, one section could display task-related information about the workflow activity including, for example, the status and target date of the workflow activity, other users responsible for the workflow activity, the name of the previous or next workflow activity as well as information about the workflow and user who triggered the workflow. Another section could display details about the object targeted by the workflow activity such as the name, release status, object state, start and end dates or other data relevant to the workflow activity.
    - The information displayed may be hyperlinked so that users can navigate to additional information in, for example, another object view, page view, or configured report.
    - The data may display a list of items (for example, responsible users). The view can be configured so that the list is abbreviated if the number of items exceeds a specified limit. Only the specified number of users will be displayed in the reading pane followed by the line**... + <number> more...**.

3) Implement a custom explorer. In order to implement a custom explorer for workflows, you must specify the content of the explorer tree as well as the content, layout, and navigation for the reading pane of the view. Unlike the **Workflow Activities Explorer** (`WFS_Explorer`), which only includes workflow activities, you can configure a custom explorer to display nodes with workflows as well nodes with workflow activities. By implementing a custom explorer instead of the standard **Workflow Activities Explorer** (`WFS_Explorer`), you can configure the content of the explorer tree as well as the information available in the reading pane described above. The custom explorer may consist of a single node and display one type of workflow activity such as all workflow activities that have been confirmed. Or the custom explorer may have multiple nodes, each of which shows a different type of workflow activity such as workflow activities past their deadline, workflow activities due in a week, workflow activities due in a month, and workflow activities that are not urgent.

The following information is available:

Configuring the Workflow Activities Explorer (WFS_Explorer)

In order to implement the **Workflow Activities Explorer** (`WFS_Explorer`), you must specify the content, layout, and navigation for the reading pane of the view as well as make the **Workflow Activities Explorer** (`WFS_Explorer`) available to the user community via a user profile or guide page/guide view. The visualization of the data in the reading pane of the **Workflow Activities Explorer** (`WFS_Explorer`) can be customized for each workflow step, if needed. Users will only see the workflow activities that they are responsible for in the **Workflow Activities Explorer** (`WFS_Explorer`).

The configuration of guide views and guide pages may contain a hyperlinked text or button displaying the number of workflow steps that the user is responsible for and that when clicked opens the **Workflow Activities Explorer**. Instead of displaying the default **Workflow Activities Explorer**, a custom explorer can be configured to open instead. The custom explorer must be specified in the **Custom Workflow Activities Explorer** attribute of the relevant user profile. For more information about configuring custom explorers, see the chapter Configuring Standard Business Functions and Custom Explorers.

The following must be completed in order to implement the **Workflow Activities Explorer** (`WFS_Explorer`):

1) Configure the workflow template and workflow steps as outlined in this chapter on workflow configuration. All configurations described for workflow templates and workflow steps should be completed before you begin specifying the implementation of the **Workflow Activities Explorer** (`WFS_Explorer`). Please note that the following:

- The **Perform**, **Confirm**, **Delegate**, etc. are specified either for the workflow template or for the workflow step via the options (**Perform** button, **Confirm** button, **Delegate** button, etc.) in the **Visualization** section of the attribute grid for the workflow template and/or workflow step. Please note that the workflow step definition will have precedence over the workflow template definition.
- The toolbar buttons specified for the workflow step/workflow template will be displayed above the reading pane in the **Workflow Activities Explorer** functionality.

2) Configure the HTML template to display the content, navigation, and layout of the data for the workflow steps. The HTML must be XML-conform HTML, compliant with HTML 5, and use standard HTML tags. For more information about how to specify the HTML template as well as the proprietary HTML elements available for the HTML template, see the section Guidelines for HTML Template Syntax in Workflows.

3) The HTML template must be assigned to the workflow template (if relevant for all or some of the workflow steps) or to the relevant workflow step via the **HTML Template for Step** attribute of either the workflow template or relevant workflow step.

If the **HTML Template for Step** attribute is defined for the workflow template, the HTML template will be applied to all workflow steps unless an HTML template is explicitly defined for a workflow step, in which case the workflow step definition will take precedence over the workflow template definition. All HTML templates listed below the **Visualization Items** node are displayed in the drop-down list for the **HTML Template for Step** attribute.

4) A CSS file must be configured to specify the styles for the HTML template. A reference to the CSS file must be included in the specification of the HTML template. The CSS file that you reference in the HTML template must be stored in the **Internal Document Selector**. For more information about configuring the CSS file, see the section Guidelines for the CSS File.

5) The **Workflow Activities Explorer** (`WFS_Explorer`) must be assigned as a business function to the user profile or implemented in a guide view to make it accessible to the user community.

6) You can specify whether the **Workflow Activities Explorer** functionality (`WFS_Explorer`) opens per default when the **Workflow Activities** link defined in a navigation page is clicked and the **Open Workflow Activities** link in an object profile is clicked. This is specified in the XML attribute `WFGuiVersion` in the XML object ***UserPersonalSettings***. Users can later specify their individual setting in the **User Settings** editor in the Alfabet interface. For more information, see the section Configuring Default User Settings for the User Community in the chapter Executing Administrative Tasks in Alfabet Expand.

7) In the XML object **SolutionOptions**, specify the maximum number of days that finished, refused, and expired workflow activities shall be displayed in the **Workflow Activities Explorer** functionality. This ensures that obsolete workflows are no longer cluttering the **My Workflow Activities** explorer.

The following information is available:

- Configuring HTML Templates for the Workflow Activities Explorer
- Guidelines for HTML Template Syntax in Workflows
- Guidelines for the CSS File
- Configuring the Maximum Days to Display Finished Workflow Activities

Configuring HTML Templates for the Workflow Activities Explorer

HTML templates contain basic elements to capture information about the workflow step as well as the object targeted by the workflow step, provide navigation to relevant object views, and specify the layout and visualization of the data. HTML templates can be implemented the **Workflow Activities Explorer** functionality (`WFS_Explorer`) as well as custom explorers configured for workflow activities.

The **Workflow Activities Explorer** in the `Showcase` database displays an example of an HTML template configuration. In this example, the caption of the workflow step is configured to provide navigation to the object profile of the workflow step. The header also displays the caption of the object that is targeted by the workflow step including relevant object class properties and navigation to the object profile of the targeted object. In the reading pane, two boxes grouping data are displayed side-by-side. The first box is captioned **Task-Related Details** and display information about the workflow step including the workflow

step's description, status, deadline, responsible users as well as information about the previous step and it's responsible users, and the workflow owner. The second box is captioned **<Object>-Related Details** and displays information about the object targeted by the workflow step, including relevant data such as the start and end date of the object, release status, contact persons, etc.

In the `Showcase` database provided by Software AG, the node **Visualization Items** contains preconfigured HTML templates that can be used as-is for workflow steps targeting applications, components, demands, and projects. The preconfigured HTML template `Generic_Standard`, a generic template that is not tailored to a specific object class, can also be used as a basis for configuring a custom HTML template. You can copy the HTML template `Generic_Standard` and paste it to a new HTML template and refine the definition in the **XML Def** attribute of the new HTML template, as needed.

An HTML template must first be configured in the **Visualization Items** node in the **Presentation** tab and then assigned to a workflow template or to one or more workflow steps. The HTML templates are based on XHTML using HTML 5 standards. HTML templates implement standard HTML elements as well as proprietary HTML elements (`AlfaHtmlElement` and `AlfaHtmlEvent`). The HTML can be defined in a standard XHTML editor and pasted into the HTML template. The placeholders for the proprietary HTML elements will then be replaced at run-time in Alfabet with the proper content. The syntax for the HTML template is described in detail in the section Guidelines for HTML Template Syntax in Workflows.

Please note the following:

- The HTML must be XML-conform HTML, compliant with HTML 5, and use standard HTML tags.
- We strongly recommend that JavaScript is not used in HTML templates since JavaScript code is not always compatible with all browsers supported for Alfabet. Using JavaScript in HTML templates may lead to errors in the display of HTML pages.

If an HTML template is assigned to a workflow template, it will be used for all relevant workflow steps defined for the workflow template. However, an HTML template can also be explicitly assigned to one or more workflow steps. In this case, the HTML template assigned to the workflow step has precedence over the HTML template assigned to the workflow template. Thus, HTML templates can be reused and assigned to multiple workflow steps and can even be assigned to other workflow templates.

To create and define an HTML template:

1) Go to the **Presentation** tab and expand the **Visualization Items** folder by clicking the + symbol. You will see the preconfigured templates `APP_Standard`, `COM_Standard`, `DEM_Standard`, `PRJ_Standard` and `Generic_Standard` (a class-independent template). You can copy a preconfigured HTML template as a basis for a custom HTML template or you can create a new HTML template from scratch.
2) Right-click the **Visualization Items** node and select **New HTML Template**. A new HTML template  is added to the **Visualization Items** folder.
3) Click the new HTML template to open the attribute window. In the attribute window, define the following attributes:

- **Name**: Enter a name.
- **Description**: Enter a description of the HTML template.
- **Sub-Type**: Select `Workflow`.

- **Group**: If the HTML template should be structured in a folder, enter the name of the folder. You can create a new HTML group this way or move the HTML template to an existing folder.

4) To use an existing HTML template as the basis for a new HTML template, right-click the template you want to use and select **Copy**. Right-click the new HTML template and click **Paste**.

5) To edit the HTML template, right-click it and select **Edit HTML Template**: The editor in the center pane opens. You can edit the HTML text directly in the editor or work in a standard HTML editor and copy the HTML text into the HTML template. The HTML must be XML-conform HTML, compliant with HTML 5, and use standard HTML tags. For details about the permissible syntax in the HTML template, see the section Guidelines for HTML Template Syntax in Workflows.

6) Click the **Save** button to save the HTML template.

7) To assign the HTML template to the relevant workflow template or workflow step, navigate to the relevant workflow template or workflow step node in the Workflows tab. Click the node to open the attribute window. In the **Visualizations** section of the table, select the HTML template in the **HTML Template for Step** attribute.

> If the **HTML Template for Step** attribute is defined for the workflow template, the HTML template will be applied to all workflow steps unless an HTML template is explicitly defined for a workflow step, in which case the workflow step definition will take precedence over the workflow template definition. All HTML templates listed below the **Visualization Items** node are displayed in the drop-down list for the **HTML Template for Step** attribute.

8) To specify which button should be displayed (and thus which actions are possible for a workflow step) in the **Workflow Activities Explorer** functionality (`WFS_Explorer`), you must define the attributes **Complete Button**, **Confirm Button**, **Delegate Button**, **Perform Button**, and **Refuse Button** in the **Visualization** section of the attribute window. If these attributes are defined for the workflow template, the button definition will be applied to all workflow steps unless a button definition is explicitly made for a workflow step, in which case the workflow step definition will take precedence over the workflow template definition. For each button, a further table section can be opened displaying the attributes **Visibility**, **Caption**, and **Icon**.

- Select `False` in the **Visibility** attribute for all toolbar buttons that should not be available for the respective workflow step (or workflow template).
- Select `True` in the **Visibility** attribute for all toolbar buttons that should be available for the respective workflow step (or workflow template). Define the following attributes:
- **Caption**: Enter a caption to display on the button
- **Icon**: Select an image from a preconfigured button library to display on the button.

> For a detailed description about the configuration of buttons for workflow steps including such issues as the users required to confirm a workflow step, the permissibility of the refusal or delegation of a workflow step, the automatic closure of a workflow step, etc., see the section Configuring the Action Buttons Available for a Workflow Step.

9) Click the **Save** button to save the changes made to the workflow template or workflow step.

Guidelines for HTML Template Syntax in Workflows

HTML templates are configured in the **Visualization Items** node in the **Presentation** tab. The HTML templates that you implement in your enterprise can be designed as needed. The HTML templates allow you to specify the information to display about the workflow step as well as the object targeted by the workflow step, provide navigation to relevant object views, page views, or configured reports, and specify the layout and visualization of the data. The preconfigured templates include a wrapper item displayed above the reading pane that displays a title for the workflow activity.

In the `Showcase` database provided by Software AG, the node **Visualization Items** contains preconfigured HTML templates that can be used as-is for workflow steps targeting applications, components, demands, and projects. The preconfigured HTML template `Generic_Standard`, a generic template that is not tailored to a specific object class, can also be used as a basis for configuring a custom HTML template. You can copy the HTML template `Generic_Standard` and paste it to a new HTML template and refine the definition in the **XML Def** attribute of the new HTML template, as needed.

We strongly recommend that JavaScript is not used in HTML templates since JavaScript code is not always compatible with all browsers supported for Alfabet. Using JavaScript in HTML templates may lead to errors in the display of HTML pages.

Please note the following about specifying the HTML template:

- The HTML templates are based on XHTML using HTML 5 standards. The HTML must be compliant with XHTML The HTML must be XML-conform HTML, compliant with XHTML and HTML 5, and use standard HTML tags. The HTML templates implement standard HTML elements as well as proprietary XML elements. All HTML and proprietary XML elements must be closed. For example, if you include an image, the element `<img>` must be written with a closing slash like for example: `<img src="image.gif"/>`.
- Each HTML template must begin with document type definition: `<!DOCTYPE HTML>`
- The root element of the HTML document must be `<xhtml>`.
- Standard HTML elements must be written in lower-case letters in order to be correctly parsed: `<xhtml>`, `<html>`, `<body>`, and `<culture_>`
- In the header of the XML document, an element `script` must be specified with the attributes as defined in the example:

```
<xhtml>
    <html>
        <head>
            <meta http-equiv="content-type" content="text/html;charset=utf-
            8" />
            <script language="javascript"
            src="alfaembeddedhtml.js"></script>
            <link type="text/css" rel="stylesheet"
            href="IDOC:\CSS\my_style_file.css"></link>
        </head>
        ...
    </html>
</xhtml>
```

- In the header of the XML document, an element `link` must reference the stylesheet to be used by the HTML template. The CSS file is stored in the **Internal Document Selector** available in the **Internal Documents** functionality in Alfabet. Details about the configuration of the CSS file is described in the section Guidelines for the CSS File. For example:

```
<xhtml>
    <html>
        <head>
            <meta http-equiv="content-type" content="text/html;charset=utf-
            8" />
            <script language="javascript"
            src="alfaembeddedhtml.js"></script>
            <link type="text/css" rel="stylesheet"
            href="IDOC:\CSS\my_style_file.css"></link>
        </head>
        ...
    </html>
</xhtml>
```

- Two proprietary elements are available to retrieve data from the Alfabet database. The XML element `<AlfaHtmlElement>` and the function `AlfaHtmlEvent()`.

- Each XML `<AlfaHtmlElement>` should be added as a child element to a standard HTML element such as `<td>`, `<span>`, `<div>`, etc. in order to retrieve data from the Alfabet. The following can be included in the XML element `<AlfaHtmlElement>`:

- The XML attributes `ApplyTo`, `ShowProps`, `PropName`, and `FormatString` can be used to retrieve and display data. For example, to display the comments of the current workflow step, you would specify the current workflow step in the XML attribute `ApplyTo` and the object class property `Comment` in the XML attribute `ShowProps`.

```
<span><AlfaHtmlElement ApplyTo="@CURRENT_STEP"
ShowProps="Comment"/></span>
```

To display previous workflow step of the current workflow step, you would specify the name of the referenced object class property in the XML attribute `PropName`, and the object class property `Caption` in the XML attribute `ShowProps`:

```
<span><AlfaHtmlElement ApplyTo="@CURRENT_STEP"
PropName="PreviousStep" ShowProps="Caption"/></span>
```

- The following Alfabet query language parameters can be used in the XML attribute `ApplyTo` to define the object whose data is to be displayed:
    - `@BASE`: to retrieve data about the object that the workflow step references
    - `@CURRENT_STEP`: to retrieve data about the current workflow step
    - `@PREVIOUS_STEP`: to retrieve data about the previous workflow step
    - `@WORKFLOW`: to retrieve data about the current workflow

- The XML attribute `SqlText` allows you to include an Alfabet query or native SQL query to retrieve data. Please note that if the XML attribute `SqlText` is included in the XML element `<AlfaHtmlElement>`, the XML attribute `ShowProps` will be ignored. In the example below, multiple users will be returned for

the query. The XML attribute `MaxCount` allows you to limit the number of rows (results) displayed. If the number of results is greater than the value in the XML attribute `MaxCount`, an additional line **+{X} more** will be displayed whereby X is determined by the number of results minus the value in the XML attribute `MaxCount`. For example:

```
<AlfaHtmlElementMaxCount ="5"
ApplyTo="@CURRENT_STEP,@CURRENT_USER"
onclick="AlfaHtmlEvent(this,'Navigate_OpenObjectView','@REF',
null);">
    <SqlText> <![CDATA[
        SELECT per.REFSTR, per.TECH_NAME,'(' + per.PHONE +')'
        FROM RELATIONS rel, PERSON per
        WHERE rel.FROMREF = @CURRENT_STEP
            AND rel.PROPERTY ='SignOnUsers'
            AND rel.TOREF = per.REFSTR
            AND per.REFSTR != @CURRENT_USER
        ORDER BY per.TECH_NAME
        ]]>
    </SqlText>
</AlfaHtmlElement>
```
